2.1.4 WEISS

To achieve the targeted 2 MW_e production capacity, WEISS and Scan American presented their standard 500 kW_e unit modular form. This size supported the RFQ requirements and aligned with the concept design change to only 500 kWe capacity.

2.1.4.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.3 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section.

2.1.4.2 Vendor Response

A copy of Weiss' response to the RFQ is included in Appendix C for reference as received.

2x 500 kW_e Plant Model

2.1.5 Proton Power

The system provided by Proton Power, in response to the RFQ, utilizes the CHyP (Cellulose to Hydrogen Power) product built by Proton Power Inc. to produce up to 2.0 MW_e of electricity using woody biomass as the fuel source. Each CHyP unit that makes up the system is an electrical resistance, multi-zone reactor system specifically designed for the continuous reaction of cellulosic feed materials to a maximum operation temperature of 1200 °C in a non-oxidizing atmosphere. The quotation includes preassembly, mounting, test operation and customer operational witness inspection of all supplied system components and controls prior to shipment to the installation site.

The 250 kW_e system will consist of the following unit operations:

- Automatic biomass processing and feed hoppers.
- CHyP reactor to produce high content hydrogen syngas.
- Automatic solids removal station to collect biochar for packaging, burial or resale.
- Gas cooling and gas cleanup stages.
- Gas composition monitoring for process control.

2.1.5.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.4 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section.

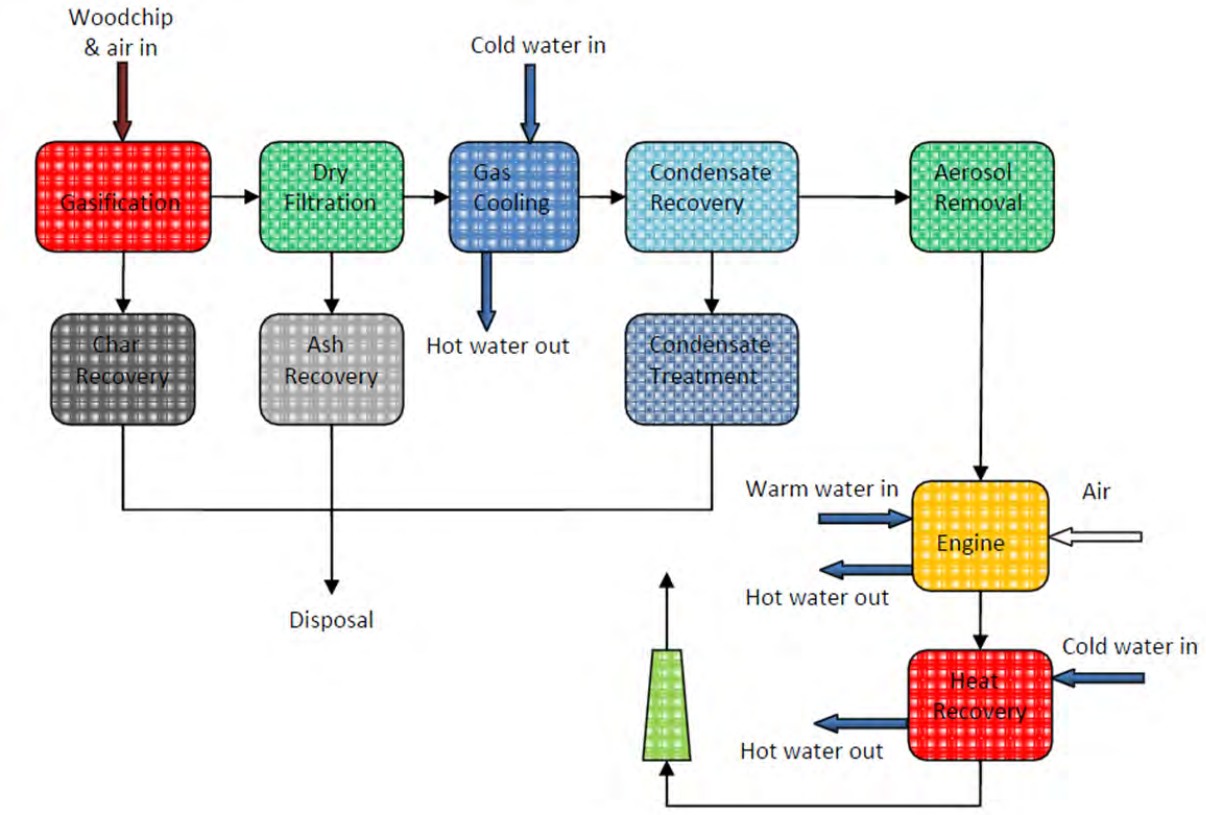
2.1.6 Biomass Engineering Ltd.

In response to our RFQ, Biomass UK responded with a proposal comprising the technical specifications and a budgetary estimate of the design, supply, delivery, installation, testing and commissioning of a 500 kW gasification plant.

Biomass Engineering Ltd. was established over 10 years ago and since that time has specialized in the design, development and supply of advanced gasification systems and the necessary ancillary equipment. Biomass Engineering specializes in the design, manufacture, installation and commissioning of compact gasification plants and equipment for converting the energy stored in wood into electricity and heat. The Biomass Engineering gasifier is designed to convert wood fuel into a steady stream of syngas, seen below:



2.1.6.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.5 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section. Beyond the system price, many detailed on the system operation were omitted.

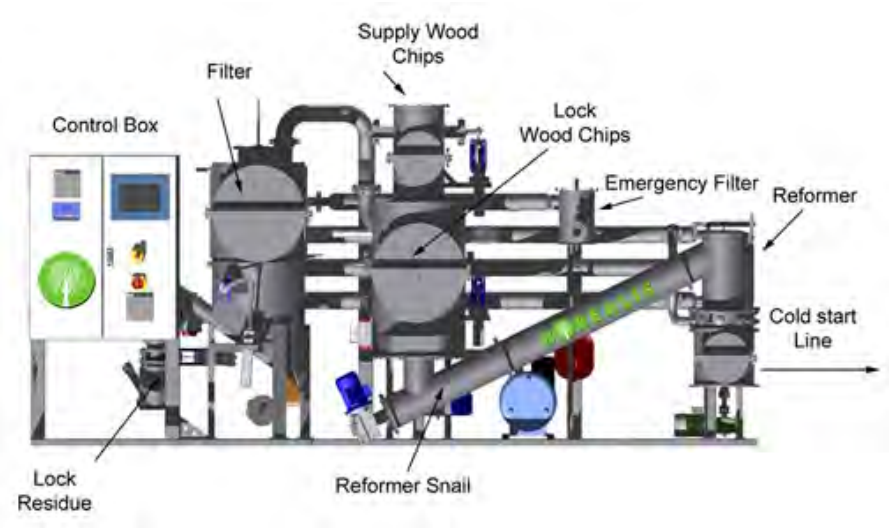
2.1.7 Borealis Wood Power Corporation (Spanner Re2 GmbH)

Technology Background

Borealis Wood Power Corporation is a Canadian company established in 2012, dedicated to marketing the Borealis CHP wood-plant system in Canada. Its focus is on both the market development and technical support for this system developed by Spanner Re2 GmbH of Germany and licensed to Borealis Wood Power Corporation. The system is marketed under the Borealis name and customized to the needs of the Canadian marketplace.



The reactor supports changing the wood chip fuel into wood gas. At the pyrolysis zone, the wood decomposes and begins reducing from its visible wood state. The fuel is then converted to a coal-like hydrocarbon and transported to the oxidation zone where part of the carbon is burned with injected air at approximately 800°C. As the gases move over the hot ember bed (oxidation zone) the tar and hydrocarbons are separated from the gas, resulting in a gas with very low tar.

2.1.7.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.6 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section.

Table 2.6 Borealis Wood Power Corporation (Spanner) Summary

2.1.8 E-Rational (ORC –Technology)

After re-assessing the amount of heat that can be utilized, it was found that a very high percentage would go unused during the summer months. It was therefore determined that the implementation of an Organic Rankine Cycle (ORC) might be beneficial by converting the remaining heat into electricity. E-Rational was selected as the most appropriate technology provider as it has the ability to utilize hot water, although only at 8-10% efficiency.

2.2 VENDOR COMPARISON

The Table 2.7 summarizes various parameters as they relate to each of the selected vendors (with little information available from Nexterra, it was excluded from this comparison). An initial assessment of the table information reveals several obvious omissions, denoted as “N/A”. In many circumstances, this lack of data can be accredited to the specific vendor, whereby much of this information could only be provided following a definitive order or down payment, or with vendors stating that more investigation would be required on their part into many project aspects before more accurate information could be provided. Therefore, vendor comparisons could not be adequately made across all fields, however much of the information provided gives a good general impression of the technology capabilities as a whole.

2.3 FACILITY SITING ASSESSMENT

In order to progress preliminary engineering it was necessary to select a site for the biomass plant. In parallel to the Stantec FEED study, Clean Technology Community Gateway (CTCG) was conducting an Evaluation of Waste Heat Potential study (CTCG, 2013). The results of the study were provided in mid-December and indicated that of all the potential waste heat uses, building heat would be the recommend usage (in particular heating only the school if a 500 kW_{th} plant was used). Further to their recommendation, CTCG referred Stantec to a previous Morrison-Hershfield (MH) district heating study for the village as a basis for potential building connection.

Using the results of the CTCG and MH study, Stantec developed a map using our in-house GIS capabilities to outline potential areas to locate the biomass plant. The map excerpt presented in Figure 2.4 shows 400 m buffer zones around buildings that could use the biomass plants waste heat. The buffer zone was established based on viable distance from heat loads determined by CTCG.

Based on the results of the waste heat study and the map areas indicated in Figure 2.4, Stantec recommended proceeding with a location near the school (see Figure 2.5) to capture the school heating load. This location had several advantages associated with it, including

- Being located near the existing diesel generator site.
- Close to the school but off school property – there is a tree line and road between the school and the plant.
- The district heating pipeline from the plant can run down the existing road to the school.
- Future expansion of the line further south would allow the plant to pick up the other buildings identified by CTCG/MH.
- If a greenhouse was of interest now (or becomes of interest in the future), it can be located on school property and fed from the network.
- Truck traffic would be kept to main traffic arteries (out of residential neighborhoods) – potential to receive fuel from the Alaska Highway entrance to the existing diesel site or new entrance.
- Tie in to the grid would be less complicated as the unit would be right next to the switchyard.
- Allows for the possibility of supplying syngas to the existing diesel generators – something CPC has indicated is a possibility.
- Potential exists to tie into the cultural centre to the North.

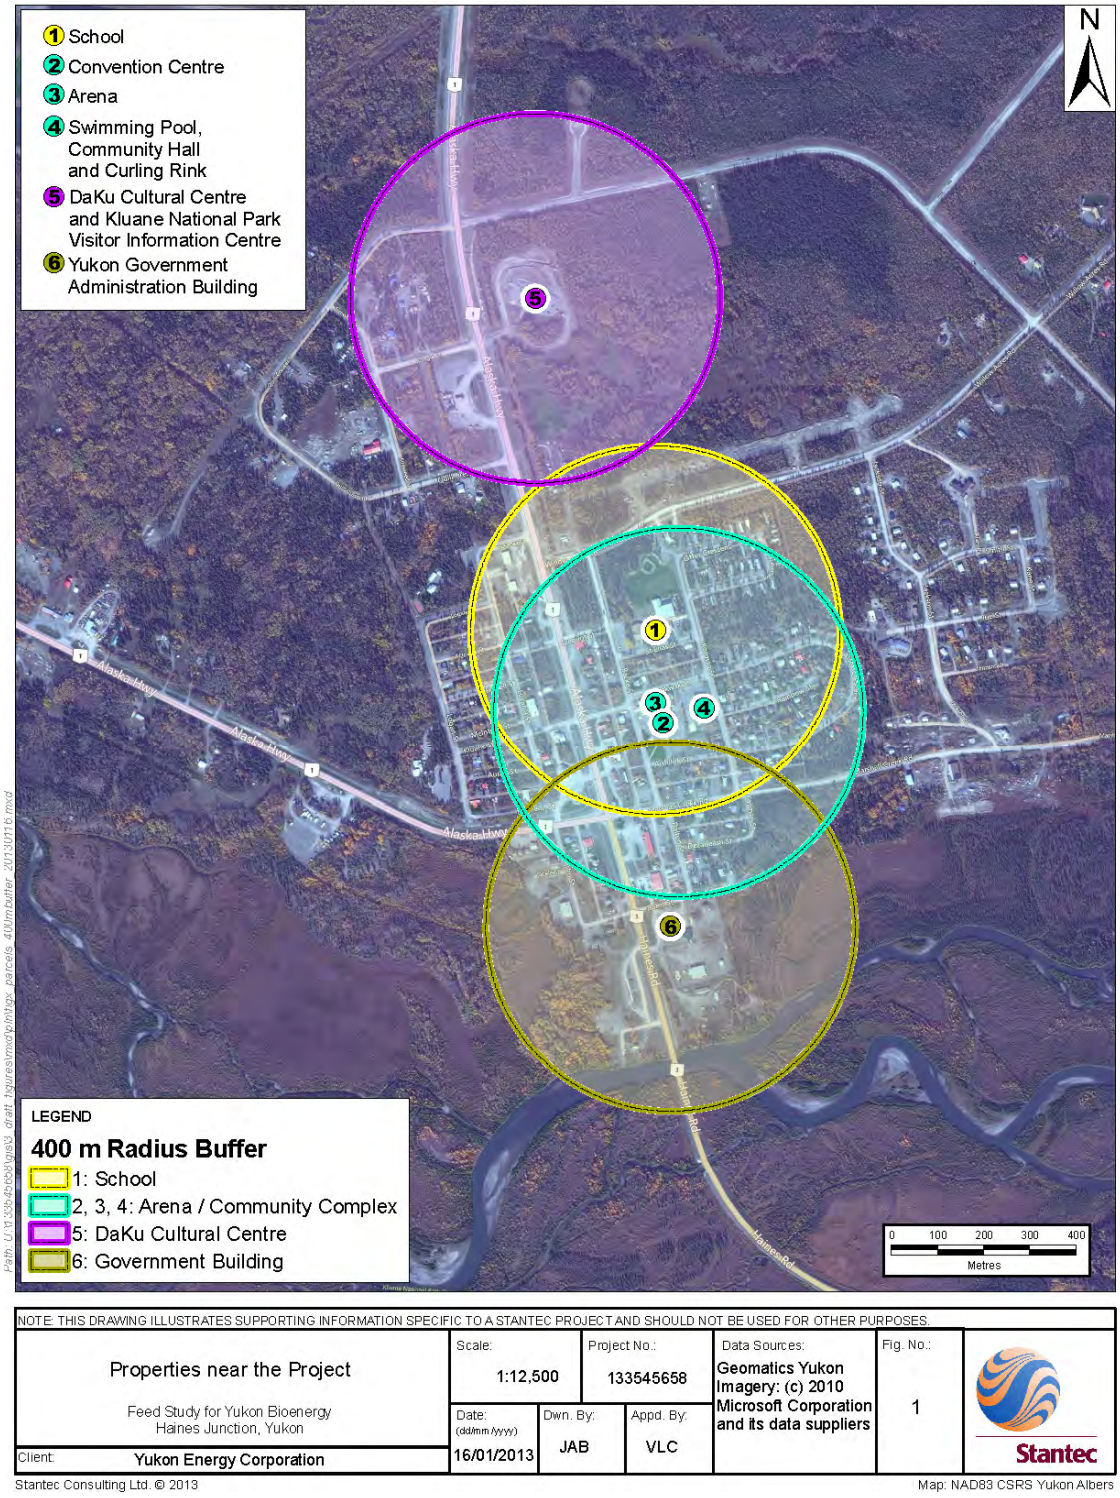

Figure 2.1 Building Heating Locations with 400 m Buffers

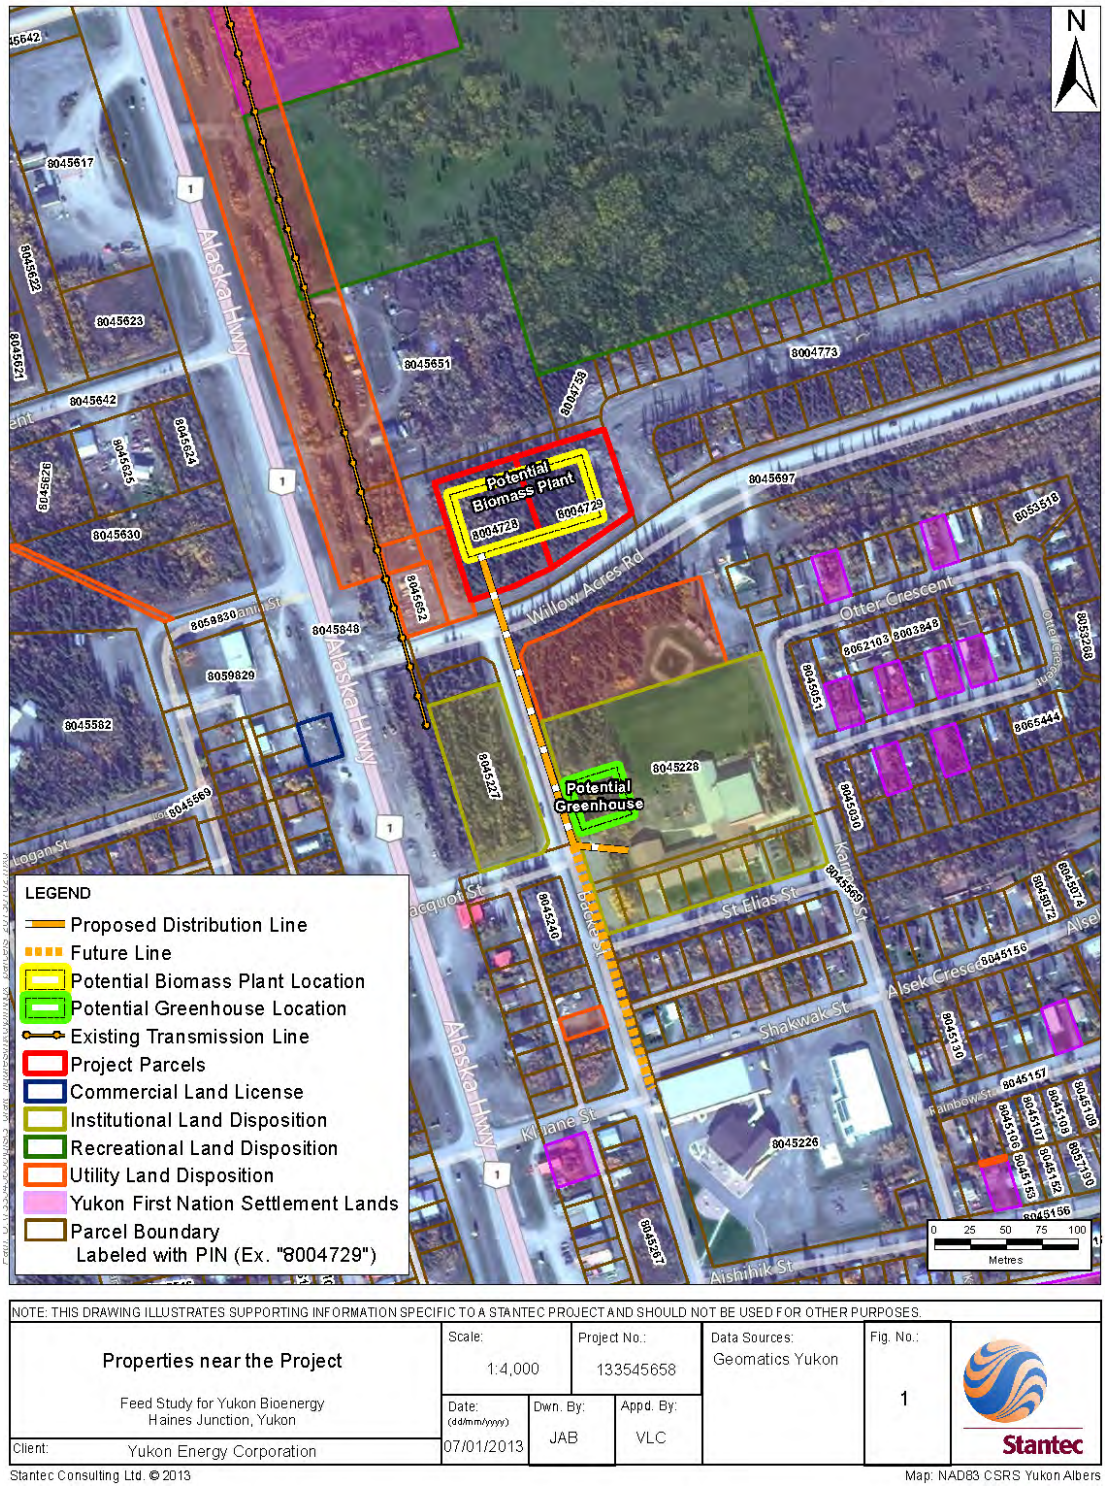

Figure 2.2 Biomass Potential Plant Location

2.4 PRELIMINARY DESIGN AND CAPITAL COST

As mentioned previously, the overall intent of the project is to demonstrate the viability of biomass power generation in the Yukon. For the purposes of the FEED design, it was assumed that the demonstration plant would start as a 500 kW_e power plant, and expand in the future once its operation and financial viability are confirmed. Using this approach, three (3) options to initiate the project were considered: Option #1 includes enclosing the entire plant in the power plant building, Option #2 provides a more aesthetically pleasing building enclosure (architecturally designed), and Option #3 reduces the enclosure to only include the fuel storage facility, locating the gasification plant outside in shipping containers.

Option #4 is presented to highlight the ability of the design to facilitate future expansion to 1.0 MW_e (500 kW_e addition) and 2.0 MW_e. This approach can also be used when the project starts off, if a larger capacity plant is desired. Please refer to Appendix D, E, F, & G for information regarding the design and opinion of capital cost for the biomass plant options described in the following sub-sections.

2.4.1 Option #1 – Full Building Enclosure – 500 kW_e

To support the development of the business case, and based on the preliminary design described herein, Stantec has prepared a Class IV Opinion of Probable Construction Cost (OoPCC) to install 2 x 250 kW_e wood gasification units supplied by Community Power Corporation (CPC) in Haines Junction. Option 1 OoPCC is based on preliminary planning in a new building in Haines Junction near the existing stand-by diesel substation

2.4.1.1 Scope Summary

The scope of work would include:

- Construction of new 37.4 m x 36.4 m pre-engineered building.
- Construction of new service roads.
- Installation of 2 X 250 kVA wood gasification generators.
- Installation of electrical power equipment, including step-up transformer and switchgear, to connect generator output to the existing 25 kV distribution system.

2.4.1.2 Detailed Project Scope Definition

CIVIL / STRUCTURAL

The civil/structural scope includes:

- Site Work. Clearing and grubbing, site grading, road and parking, building foundation preparation, buried water and sewer services.
- Concrete Work. Building foundations, building slab, door aprons, transformer pad, and elevated slab.
- Pre-Engineered Building (37.4 m x 36.4 m = 1360 m^2). Building steel, insulated walls, insulated roof, doors, openings for louvers and vents.
- Building Internals. Interior rooms (with storage above), chip bin areas, divider wall between chip handling and gasification/generation.

MECHANICAL

The mechanical scope includes:

- A 500 kW_e modular wood biomass CHP system.
- Radiant in-floor heating for entire building using boiler thermal energy as heat source with electric circulation heater backup.
- Combination of wall fans and roof gravity ventilators to provide necessary building minimum ventilation airflow as required by applicable standards for occupancy, oxygen levels, and airborne contaminants such as CO and combustion gases.
- Pressurization air units for the electrical and mechanical rooms.

- Split heat pump system covering the office / meeting room and the lunchroom.
- Small humidifier.
- Plumbing of one washroom and one kitchen sink.
- Fire protection provisions including dry sprinkler, standpipe, fire extinguishers, and pull stations for the entire building. Provision for a manual deluge fire suppression line is also included for each biomass conveyor.

ELECTRICAL

The electrical scope includes:

- Utility power for the building services loads and backup power source for the generator auxiliaries. This includes transformer, fused disconnect, and customer metering. Connections and material up to the meter assumed to be supplied by the utility but an allowance has been made in the estimate to cover the costs associated with this work.
- A 480 V / 400 A power distribution panel (complete with main breaker) feeding utility power to building services loads and aux power to the generators when required.
- Transfer switches at each generator allowing choice of auxiliary power source from either the online generators or the utility feed.
- 480 V switchgear to parallel the outputs of the generators.
- An oil filled 600 kVA step up transformer 480 V / 25 kV to connect generator outputs to the utility line. An oil containment system allowance has been carried.
- Allowance for the utility to connect the generator output from the step-up transformer to the line including fused disconnect.
- Allowance for utility to install revenue metering on the secondary of the step-up transformer.
- Allowance for grounding the building and equipment.
- Building services including low voltage distribution panels, lighting, fire alarms, receptacles, communications, etc.
- Allowance for a contractor to make electrical connection between the shipping splits of Vendor supplied equipment.

- A PLC based control system for miscellaneous building services and heating loop indicators and alarms.
- Communication connections between the Vendor's supplied equipment, the PLC controller, and a main network switch. This will allow remote monitoring of building and equipment alarms and allow remote configuration and monitoring of the CPC supplied units.
- All power, control, and communications wiring and raceway required to service the units and the surrounding infrastructure.

2.4.1.3 Detailed Basis of Estimate

ENGINEERING

The preliminary engineering allowance is 3.0% of capital, which would include a Class III estimate for project appropriations.

The detailed engineering allowance is 10% of capital for the purposes of this capital estimate. Should the project move forward and Yukon Energy solicit a proposal for further engineering by Stantec, an Opinion of Probable Engineering Costs (OoPEC) would be prepared and included in that proposal. This allows for typical engineering costs for the purposes of budget appropriations.

PROCUREMENT

Major equipment is assumed to be purchased by Yukon Energy and supplied to the installation contractor on site. In this particular study, that would include the switchgear, the step-up transformer, transfer switches, and Vendor supplied generators. This approach is advantageous in that:

- It ensures adherence to the utility standards for equipment where many options and additions are commonly available.
- It does not delegate away the responsibility of expediting these items to site. By maintaining responsibility, the Owner can exercise greater control of delivery on these critical items.
- It avoids the standard contractor markup of ~10% being added to large value line items.

All other items, including cable, cable tray, and all other commodity items required for the installation shall be supplied by the contractor as part of their lump sum installation pricing. This eliminates the need for utility engineers, managers, or consultants to be responsible or concerned with inventory levels of items that are extremely hard to track on a busy construction site.

PRODUCTIVITY FACTORS

Labour factor adjustments have been applied to this estimate based on the following:

- Distance from Whitehorse as it applies to accessing supplies.
- Distance from Whitehorse as it applies to accessing skilled labour.
- Estimated inventory levels at local supply houses.
- Working outdoors or in non-serviced building.

CONSTRUCTION

This OoPCC is based on the following sources of data for labour and materials:

- In-house databases built from historical or manufacturer’s listed prices.
- Direct contact with vendor for switchgear.
- NECA (National Electrical Contractor’s Association) Manual of Labour Units 2011-2012 for specific items covered by that publication.

- Historical labour costs for other items not specifically listed or requiring special consideration.

DIRECT CONSTRUCTION AND INSTALLATION COSTS

Civil / Structural

Site Work

Site work includes clearing and grubbing, site grading for the initial two unit arrangement, preparation of roadway and parking areas by replacement of 1 m of material with compacted pit run gravel, building foundation excavation and backfill, underground water and sewer services, and a fire water loop with two hydrants. For the purpose of this estimate, it has been assumed that water and sewer services exist under the adjacent streets with sufficient supply pressure for building fire protection.

Quantities were calculated and cost opinions were developed using costs from other jobs, with reference to the RS Means cost database, and with partial input from Jon Schmidt of JTS Cost Consulting, Whitehorse.

Concrete Work

Concrete work includes reinforced cast-in-place concrete for building foundations, grade and elevated slabs, door aprons, and transformer pad. Preliminary design has the building on spread footings founded below frost, with a full perimeter wall that extends 2500 mm above grade in the chip handling area to act as chip bins. Grade slab is 200 mm thick both for truck traffic and to support the gasification/generation equipment.

Stantec provided partial quantities and preliminary building layouts to JTS Cost Consulting who developed the cost opinion raw data.

Pre-Engineered Building

The 1360 m^2 building includes a structural steel frame with girts and purlins, wall panels insulated to R30, roof panels insulated to R50, man doors, overhead doors, and openings for louvers and vents. The roof is symmetrically peaked with a 1:12 slope. The east gable end structure has been designed to allow future expansion of the building in this direction.

Quantities and cost opinion for the building was provided by a pre-engineered building supplier (Varco Pruden Buildings).

Building Internals

Building internals include interior rooms for electrical, mechanical, storage, lunchroom, washroom, and administration. As presently proposed, the rooms would be masonry with a concrete roof slab on metal deck to create a storage area above. A wall aligned with the building peak would provide working separation between the chip storage area and the gasification/generation equipment.

Stantec provided partial quantities and preliminary building layouts to JTS Cost Consulting who developed the cost opinion raw data.

General Conditions

JTS Cost Consulting has provided a cost opinion for General Condition items, including:

- Bond, insurance, and permits.
- Temporary office, power, heat, phone, data, fencing, and toilets.
- Safety.
- Layout.
- Clean-up, snow clearing, and waste management.
- Freight and deliveries, materials handling and protection.
- Vehicles and fuel (vehicle and equipment).
- Hoisting, zoom boom, sky reach, and scaffolding.
- Tools.
- Supervision, project management, and foreman surcharge.
- Room and board, including travel.
- Mobilization, and demobilization.
- Close out, as-builts, and manuals.
- Winter works premium.

These items have been included in the civil-structural estimate although they apply to the entire construction activity and sequence.

Mechanical

The mechanical scope for Option 1 includes:

Wood Biomass CHP System

The assumed CHP system size is 500 kW_e nominal electrical and 644 kW_{th} thermal generation capacity.

Equipment cost based on scaling up base budget proposal from CPC for a 100 kW_e system by a factor of four. Efficiencies of scale are gained to achieve the additional output adding up to 500 kW_e total electrical generation capacity.

This system is installed by assembling 14 container type modules which include feedstock handling end, dryer module, gasifier module, genset module, filter module, and controls module.

HVAC

Radiant In-Floor Heating

Allowances cover the entire building concrete floor slab, including ancillary rooms. The primary source of heat for the in-floor heating will be provided by tapping into some of the thermal energy available from the boiler flow supplying the district heating system output from the plant. The fluid will be circulated to the various areas of the building by two circulation pumps (one backup). Control valves will distribute the flow as necessary to maintain the demand requirements of each temperature zone. The design intent is currently to maintain a floor temperature of 1 °C for the fuel delivery and storage building section, 10 °C for the generator house building section, electrical room, mechanical room, and storage room, and 21 °C for the lunchroom, office/meeting room, and washroom.

An allowance for a pair of electric circulation heaters was provided as a source of backup building heat when the boilers are not in operation.

Welded wire mesh for attaching tubing, vapour barrier, and insulation costs carried under civil estimate.

Radiant concrete slab heating cost estimate includes (2) slab temperature sensors for each temperature zone.

Ventilation

The design approach for ventilation of the areas of the building other than the ancillary rooms is to utilize wall mounted ventilation fans with insulated motorized dampers in conjunction with roof mounted low profile gravity ridge natural ventilators with manual chain operators. Those systems would provide necessary building minimum ventilation airflow as required by applicable standards for occupancy, oxygen levels, and airborne contaminants such as CO and combustion gases.

Roof curbs and flashing for the roof gravity ventilators included as part of the civil estimate.

An allowance has been made for the mechanical room and electrical room to have their own pressurization ventilation unit.

An allowance has been made for a small humidifier.

An allowance was made for rental of equipment required to install the HVAC components.

An allowance was made for HVAC related floor / piping penetrations.

An allowance has been made for a ductless split heat pump system covering the office / meeting room and the lunchroom.

Plumbing

A plumbing allowance has been made for a washroom sink, water closet, kitchen sink, water heater, heating system fill line, floor drain in mechanical room, and sewer line inside building.

Potable water supply assumed to be coming from the street.

Sewer piping from building to street covered in the civil estimate.

Fire Protection

For the purposes of determining fire protection requirements for the building, a cursory review of applicable 2010 NBC (National Building Code of Canada) requirements was conducted:

Preliminary building classification per 2010 NBC is high hazard industrial occupancy F-1 for the fuel delivery and storage building section and generator house building sections.

The generator house section is classified as high hazard F-1, as opposed to F-3 normally allowed by code, to avoid the need for a 2 hour rated fire separation, which would normally be required between the fuel delivery and storage section and generator house section as per NBC Section 3.1.3.1.

The reason to classify the entire building as a Type F-1 occupancy is that it is not practical to maintain a 2 hour fire separation at the biomass conveyor penetrations at the wall. The F-1 building falls under Group F Division 1 up to two storeys, under NBC Section 3.2.2.70 which requires sprinklers throughout.

A standpipe system is also required for the F-1 building since its classification does not fall under the exceptions listed under NBC Section 3.2.5.8.

The building requires stations and fire extinguishers.

Fire detection and alarm covered under electrical section.

In addition to specific NBC requirements, conveyors systems handling this amount of combustible material normally require a few manual deluge connections to provide local suppression from a risk mitigation standpoint. The insurer for the plant typically drives this requirement.

Electrical

General Methodology

The power distribution transformer and associated power system components and cabling have been sized for 250 kW_e output from each unit with a worst-case power factor of 0.85. The CPC supplied equipment is shipped to site in several shipping splits. Although the units are prewired by CPC, the installation contractor will make final connection between shipping splits as per CPC instructions.

General Description of Major Products

All new cable tray installed will be aluminum, B-Line series 25, and industrial cable tray. Typical tray grounding and supports are included.

All new power cables up to the low voltage side of the power distribution step-up transformer are 1 kV rated, Teck cable. Allowances have been made to allow the utility to make the 25 kV connections.

Transfer switches are manual type switches with make before break contacts when moving from utility to generator power after the generator has synchronized to the line.

Switchgear is based on GE LV switchgear with one main breaker and two unit breakers. Allocation has been made for two prepared spaces for future expansion.

The power distribution transformer used to connect the generator output to the grid is a liquid filled type installed outside with a containment system.

Electrical Installation Costs

Service Entrance

Allowances have been made for the utility to supply and install a pole mounted transformer and fused disconnect. Allowances have been made for a metered entrance and it is assumed that the utility preforms all work up to the line side of the meter.

A 400 A, 480 V, 3 phase power distribution panel complete with a main breaker will be installed inside the electrical room to supply building services and unit startup power.

Transfer Switches

Transfer switches will be installed to transfer generator auxiliary loads to the utility power feed for start-up. When the generators are online, the auxiliary loads would be switched back to the unit internal power.

Grounding

Allowance has been made to allow typical grounding of the service entrance, the generators, and the building itself.

Building Services

Power Distribution

Allowances have been made for lighting and miscellaneous power requirements for the building. This includes transformers, panels, and wiring for all building services loads.

Heating and Ventilation

Allowances have been made to connect heating and ventilation equipment.

Lighting

Allowances have been made for lighting in all areas of the building. Allowance has been made for the installation of roadway lighting along the service road.

Communications Including Remote Monitoring and Configuration Links

Combination data and telephone outlets are to be in the office area and several telephone outlets throughout the rest of the facility. Everything will be wired back to an incoming line within the electrical room. The CPC system will also be connected to allow remote monitoring, alarming, and configuration from CPC facilities.

Equipment will be installed to allow remote monitoring of indicators and alarms for major equipment in the building. This includes allowance for a small programmable logic controller and network switch. In addition, this connectivity will serve the CPC supplied equipment to allow for monitoring and configuration from their headquarters.

Fire Alarm

A fire alarm system has been included with smoke detectors, thermal detectors, heat detectors and manual pull stations to provide initiating protection. Horn strobes provide audio and visual

signaling. There is an allowance for several flow and tamper switches for a sprinkler system. Control relays were also considered with the fire alarm system for equipment shut downs.

Generator Output

The owner-supplied switchgear will be installed by the electrical contractor. Switchgear pricing is based on information received from GE for budgeting purposes. The switchgear includes a main breaker, two unit breakers and two prepared spaces in the pricing. All cabling, including raceway, required from the units to the switchgear have been included.

The electrical contractor will install the step-up transformer on a concrete pad outside the building. Pad to be provided by the civil contractor. Transformer pricing is based on review of pricing of similar transformers normalized to a value per kVA and scaled to 600 kVA.

Allowance has been made for the utility to make all connections beyond the secondary of the step-up transformer including a pole mounted fused disconnect and revenue-metering unit.

Instrumentation and Control

Allowances have been made for several poisonous gas detectors to be installed. Alarms will be relayed through the fire alarm panel.

Connections of the Vendor Supplied Equipment

There is an allowance of two men for one week for each unit intended to cover the interconnection of vendor supplied shipping splits. All material for this work is assumed to be supplied by the vendor.

MISCELLANEOUS CONSTRUCTION DIRECTS

Most construction directs have been accounted for in a blended labour rate. This would include small tools and consumables.

Allowances for required equipment rentals used as part of a normal installation are included in the blended labour rate.

Supervision, crew trailer, and personal PPE are also included.

Freight is included in the material / equipment pricing.

INDIRECT CONSTRUCTION COSTS

Construction Staff & Consultants

An allowance of 2.5% of capital has been carried for an onsite construction manager. An allowance of 1% of capital has been carried for site engineering services to support construction.

Owner's Staff Costs

No allowance has been made for Owner's personnel to support this work.

Commissioning Costs

Commissioning costs are carried as 1.5% of capital. This includes allowances to bring vendor representatives to site.

Escalation Costs

An escalation allowance of 5% has been allowed based on lead-time required before construction begins.

Capital Spares

A capital spares allowance of 5% of the equipment cost has been included.

Indirects Specifically Not Included

The indirect costs associated with the following have not been considered and are assumed to be supplied by Owner. No costs have been assigned to these services that will be associated with this project unless specifically noted in the OoPCC.

- Security.
- Lock-out tag-out (LOTO) coordination.
- Waste removal.
- Snow removal.
- Warehousing and utilities including temporary power supply.
- Temporary lighting.
- Taxes.

- Interest charges during construction.
- Owner's administration costs, including:
  - Legal fees.
  - Insurance.
  - Salaries of Owner's project staff.
  - Allowance for operators hours during training, commissioning, and start up.

Special costs to dispose from site construction waste.

2.4.1.4 Opinion of Probable Capital Cost

The Opinion of Probable Capital Cost for this option is $12.7 M. Table 2.7 provides a breakdown of the probable cost with a detailed line item list included in Appendix C.

Table 2.8 Option #1 Opinion of Probble Capital Cost

Line	Description	Labour Cost	Material Commodity Cost	Equipment Cost	Sub-Contractor Cost	Total Cost
1	**PROJECT TOTAL, BASE SCOPE**					**$12,727,154**
2	Civil - Structural	$562,428	$1,001,238	$195,250	$1,235,200	$3,528,066
3	Mechanical & HVAC	$168,520	$199,500	$5,205,000	$192,476	$5,816,052
4	Electrical	$371,089	$172,531	$238,465	$74,197	$948,827
5	**Sub Total**	**$1,102,037**	**$1,373,269**	**$5,638,715**	**$1,501,873**	**$10,292,945**

7	Detail Engineering @ 10% Direct Construction Cost					$508,824
8	Construction Management @ 2.5% Direct Construction Cost					$127,206
9	Site Construction Support by Engineering @ 1% Direct Construction Cost					$50,882
10	Commissioning Costs @ 1.5%					$76,324
11	Escalation Allowance @ 5%					$254,412
12	Capital Spares - 5% of CPC equipment cost					$250,000
13	**Sub Total**					**$11,570,140**
14	Contingency @ 10%					$1,157,014

Capital Cost Risk Analysis

No detailed risk analysis has been made on this Class IV OoPCC. A contingency of 10% has been allocated. As per AACE guidelines, a Class IV OoPCC is accurate to a range between -20% and +40%.

2.4.2 Option #2 – Full Architectural Enclosure – 500 kW_e

Option #2 retains the technical and operational characteristics of Option #1, while providing a superior aesthetic presence to the biomass facility to be located in the village.

2.4.2.1 Architectural Details

Accessed from the Alaska Highway the proposed biomass facility forms bold and angular shapes, establishing a powerful icon against the distant mountains. Elevated roof segments and strong, vertical glazing will serve to provide natural daylight and become a 'beacon' at night for travellers along the highway.

Backing on to boreal forest the building is designed to work with the natural surroundings and take advantage of the environmental conditions.

Sustainability and energy efficiency is modeled within LEED criteria and include:

- Use of natural and recyclable materials.

- Energy efficient building systems.
- Abundance of natural day lighting to reduce energy consumption and provision of a pleasant work environment.
- Use of low VOC materials and adhesives.
- Occupancy sensors to control electrical light fixtures operation.
- Rainwater will be diverted back into the soils.
- Combination wood and steel structure for recycling purposes.

Working within close proximity to the Alaska Highway the roadway entry leads into the clearly defined Main Entry for office personnel. As one approaches the building the single sloped roof, in concert with the 'V'-shaped structure, provides an intriguing form juxtaposed against the dominant, large biomass structure behind. Cladding materials will be a combination of smooth, cementitious, panels and corrugated metal cladding.

The facility is designed to support both the biomass plant function and administrative / office staff in one modern facility that is energy efficient and pleasant to work in. Programmatically the two-storey turbine plant is tucked in behind the one-storey offices and administration spaces. The soaring ceiling, in concert with natural materials, select bright colours and abundance of day lighting provides staff with a strong connection to the natural surroundings. Additionally, the project is designed to allow for future expansion of both specific programs.

Technically the spaces are supported by a thermally superior building envelope complete with coincident air/vapour barrier and polyisocyanurate insulation in the construction assemblies that exceed minimum thermal insulation code requirements.

2.4.2.2 Opinion of Probable Capital Cost

The Opinion of Probable Capital Cost for this option is $13.5 M. Table 2.8 provides a breakdown of the probable cost with a detailed line item list included in Appendix D.

Table 2.9 Option #2 Opinion of Probble Capital Cost

Line	Description	Labour Cost	Material Commodity Cost	Equipment Cost	Sub-Contractor Cost	Total Cost
1	**PROJECT TOTAL, BASE SCOPE**					**$13,494,160**
2	Civil - Structural	$617,073	$1,094,838	$203,150	$1,631,800	$3,528,066

9	Site Construction Support by Engineering @ 1% Direct Construction Cost					$56,551
10	Commissioning Costs @ 1.5%					$84,827
11	Escalation Allowance @ 5%					$282,757
12	Capital Spares - 5% of CPC equipment cost					$250,000
13	**Sub Total**					**$12,267,418**
14	Contingency @ 10%					$1,226,742

Capital Cost Risk Analysis

No detailed risk analysis has been made on this Class IV OoPCC. A contingency of 10% has been allocated. As per AACE guidelines, a Class IV OoPCC is accurate to a range between -20% and +40%.

2.4.3 Option #3 – Fuel Handling Enclosed – 500 kW_e

Option #3 retains the technical and operational characteristics of Option #1, but attempts to reduce costs by only enclosing the fuel handling area. This option would only be available for the CPC and Proton Power units as they are self-contained in standard shipping containers (CPC units depicted in the rendering).

2.4.3.1 Opinion of Probable Capital Cost

The Opinion of Probable Capital Cost for this option is $11.4 M. Table 2.9 provides a breakdown of the probable cost with a detailed line item list included in Appendix E.

Table 2.10 Option #3 Opinion of Probble Capital Cost

Line	Description	Labour Cost	Material Commodity Cost	Equipment Cost	Sub-Contractor Cost	Total Cost
1	**PROJECT TOTAL, BASE SCOPE**					**$11,402,782**
2	Civil - Structural	$399,213	$714,346	$167,750	$846,626	$3,528,066
3	Mechanical & HVAC	$205,634	$117,600	$5,204,000	$84,301	$5,816,052

9	Site Construction Support by Engineering @ 1% Direct Construction Cost					$40,944
10	Commissioning Costs @ 1.5%					$61,416
11	Escalation Allowance @ 5%					$204,719
12	Capital Spares - 5% of CPC equipment cost					$250,000
13	**Sub Total**					**$10,366,165**
14	Contingency @ 10%					$1,036,617

Capital Cost Risk Analysis

No detailed risk analysis has been made on this Class IV OoPCC. A contingency of 10% has been allocated. As per AACE guidelines, a Class IV OoPCC is accurate to a range between -20% and +40%.

2.4.4 Option #4 – Options for Expansion – 500 kW_e, 1000 kW_e, & 2000 kW_e

A potential path forward for the project is to first install a 500 kW_e plant as a proof-of-concept demonstration for the North, and then expand the facility in the near future. The design described for Option #1 facilitates the expansion of the power plant by an additional 500 kW_e without the need for added auxiliary services (i.e., sufficient space mechanically and electrically have been left to support the expansion). Beyond the 1.0 MW_e capacity, additional building services will be required. From a cost perspective, the first incremental 500 kW_e expansion will see cost savings compared to the initial installation, whereas achieving a 2.0 MWe would be equivalent to double the cost of the 1.0 MW_e plant. This is depicted in Figure 2.3.

To expand the plant in 500 kW_e blocks without incurring increased costs (i.e., each expansion costs the same) is possible, but would require a higher upfront capital cost to ensure the auxiliary services could support three future expansions. The owner needs to weigh the benefit of having the added infrastructure installed upfront for an expansion that may not take place.

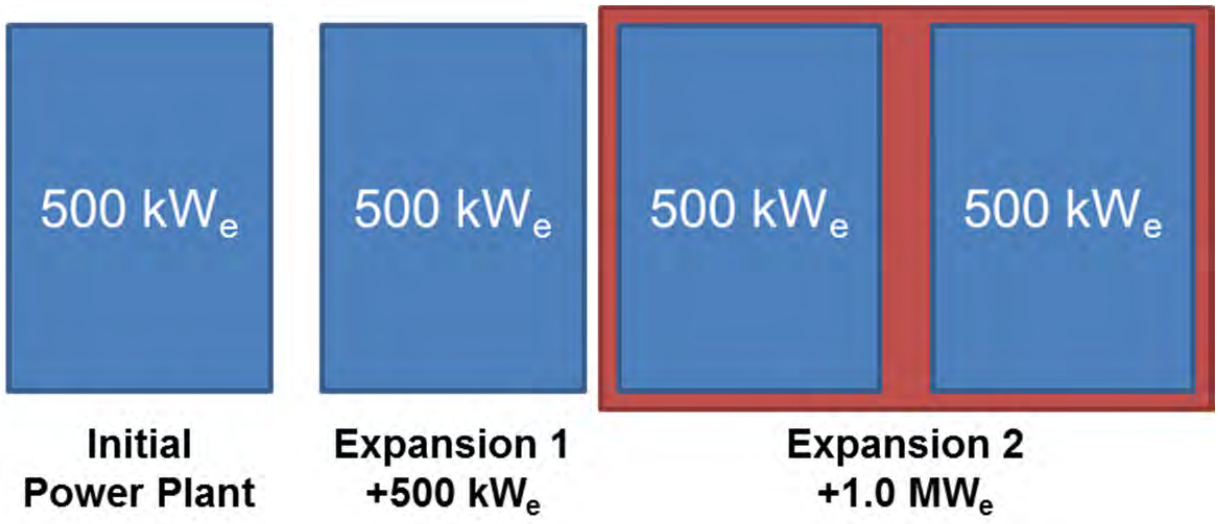

Figure 2.3 Expansion Incremental Costing

2.4.4.1 Opinion of Probable Capital Cost

The Opinion of Probable Capital Cost for this option is an additional $9.8 M on top of the base plant cost to achieve a total 1.0 MW_e capacity, or $22.5 M if 1.0 MW_e is installed initially. To achieve a 2.0 MW_e capacity, the combined figure would double to $45.0 M. Based on equipment costing for the gasification systems, to start the plant with a 2.0 MW_e capacity would be approximately the same budget, $45.0 M.

Table 2.10 provides a breakdown of the probable cost with a detailed line item list included in Appendix G.

Table 2.11 Option #4 Opinion of Probble Capital Cost

Line	Description	Labour Cost	Material Commodity Cost	Equipment Cost	Sub-Contractor Cost	Total Cost
1	**PROJECT TOTAL, BASE SCOPE**					**$22,484,173**
2	Civil - Structural	$648,841	$1,226,438	$229,250	$1,390,000	$3,528,066
3	Mechanical & HVAC	$408,694	$376,500	$10,210,000	$302,428	$5,816,052
4	Electrical	$658,369	$283,829	$320,748	$101,033	$948,827
5	**Sub Total**	**$1,715,905**	**$1,886,767**	**$10,759,998**	**$1,793,461**	**$10,292,945**
6	Preliminary Engineering @ 3% (Class III Estimate)					$368,538.46
7	Detail Engineering @ 10% Direct Construction Cost					$1,228,461.54
8	Construction Management @ 2.5% Direct Construction Cost					$307,115.39
9	Site Construction Support by Engineering @ 1% Direct Construction Cost					$122,846.15
10	Commissioning Costs @ 1.5%					$184,269.23
11	Escalation Allowance @ 5%					$614,230.77
12	Capital Spares - 5% of CPC equipment cost					$250,000
13	**Sub Total**					**$20,440,157**
14	Contingency @ 10%					$2,044,016

Capital Cost Risk Analysis

No detailed risk analysis has been made on this Class IV OoPCC. A contingency of 10% has been allocated. As per AACE guidelines, a Class IV OoPCC is accurate in a range between -20% and +40%.

2.5 OPERATING COST

The operation and maintenance estimated cost is based on the use of an outside Operation & Maintenance (O&M) contractor. Operations and maintenance costs for the biomass plant consists of several components:

- Labor.
- Maintenance and materials.
- Major Equipment Repair reserve fund.
- Annual Environmental Testing.
- Consumables and chemicals.

- Miscellaneous supplies.

The items included in each category are explained below:

- **Labor** - The labor component, excluding fuel cost and renewal fund, is the largest cost in an O&M budget. It consists of the salaries and benefits for the operators and admin staff. The size of the staff can vary significantly depending on the size and complexity of the plant. For a 0.5 MW_e biomass plant, the operation will consist of five (5) full-time operators. Staff will have one plant manager and four (4) operators. The staffing compliment could be lower if based on CPC's operator requirements of two (2) trained operators.

- **Maintenance and Materials** - The cost for maintenance and materials reflects normal daily, weekly, monthly costs for regular plant maintenance.

- **Major Equipment Repair Reserve Fund** - The major equipment in a biomass power plant needs to be overhauled and repaired on a regular basis in accordance with the vendor's recommended procedures. This fund is primarily associated with the gasifier and engine but also includes other major pieces of equipment, particularly rotating equipment and heat exchangers. A reserve fund is established so that money is available to cover the significant costs of the equipment overhaul several years in the future. This cost is carried separately in the business case as the Capital Renewal Annual Rate, see Table 4.14.

  In lieu of planning and reserving for major equipment overhauls and inspections, owners sometimes establish a Long Term Service Agreement (LTSA) with the vendor. The LTSA provides annual performance guarantees from the suppliers as well as responsibility for all repairs and overhauls for a fee. The term of the LTSA can vary from 10 to 15 years. Note this approach was not taken for this O&M estimate.

- **Environmental Testing** - Most environmental operating permits require annual testing for any air, water or wastewater discharges from a plant to verify compliance with the permit conditions.

- **Consumables and Chemicals** - The cost of lubricants, oils, chemicals and misc. consumables used during normal plant operation is included in this line item.

- **Misc. Supplies** - This item covers the general administrative cost of running the power plant. It includes phones, office supplies, computers, etc.

2.5.1 Opinion of Probable O&M Costs

The following table, Table 2.11, is a summary of estimated O&M costs for the two biomass plants:

Table 2.12 Opinion of Probable Conventional Biomass O&M Costs

Description	0.5 MW	2 MW
Labor	$200,000	$350,000
Maintenance & Materials	$50,000	$200,000
Environmental Testing	$15,000	$25,000
Consumables & Chemicals	$15,000	$45,000
Misc. Supplies	$5,000	$10,000
Total O&M Estimated Cost	**$285,000**	**$630,000**

The estimate cost for O&M reflects the estimated average annual cost. It does not include cost normally incurred by the owner. These costs include fuel; insurance; property taxes or asset management fees.

2.6 FEEDSTOCK CHARACTERIZATION (AGFOR)

In order to develop an understanding of the potential for local feedstock for the plant at any capacity, several aspects need to be considered. Of primary interest is the current level of harvesting around Haines Junction, Yukon. Second is the industry the current harvest is serving, and potential synergies with the proposed biomass facility. Finally an assessment of the available fuel characteristics (moisture content, heating value), quantities available/required by the plant, and preliminary costing are provided.

2.6.1 Harvesting and Existing Industries

Overall harvest activity is low with little economy of scale; most equipment is bought used to keep costs down. Harvesting is regulated by permit based on experience and capacity.

New personal use entrants with no harvesting track record are issued permit volumes up to 25 m^3 within specified location in a common area; successive permits can be issued upon successful

completion of a permit. Harvesting is by chainsaw and a variety of small scale forwarding equipment from manual, ATV, and snowmobile to pick-up truck.

Commercial harvesting activities listed in the Wood Allocation Strategy for Haines Junction are presented in four (4) tiers as follows and depicted in Figure 2.6 on the following page.

Tier 1 – New entrants with no recent Yukon harvest experience (in the past three years) are issued permit volumes from 25 m^3 to 200 m^3. This Tier is for operators who aspire to a Tier 2 permit. Successive permits can be issued. Ten Tier 1 opportunities are made available for a given time period. Harvesting is by chainsaw and a variety of small scale forwarding equipment such as ATVs, snowmobiles, farm tractors and skidders.

Tier 2 – Operators with recent Yukon harvest experience are provided with two years wood supply permits up to 999 m^3 per year within a three-year license period; successive permits can be issued upon successful completion of the current permit. Operators are encouraged to participate in the license design and YESAB screenings. Harvesting is mainly is by chainsaw and a variety of small scale forwarding equipment such as farm equipment and skidders.

Tier 3 – Existing operators with recent Yukon harvesting history (in the past three years) are provided with 1,000 m^3 to 10,000 m^3 per year permits for a maximum of a four-year supply within a five-year period. Operators are required to complete the license design and YESAB screenings. Harvesting is by mechanical felling and bunching, forwarding is by grapple skidder, delimbing ranges from operational limbing (breakage and chainsaw) to cut-to-length processor to produce delimbed logs at the landing ready for loading; alternatively, this is done with chainsaws and or a firewood processor.

Tier 4 – Initiatives requiring significant investment are usually issued a harvest volume greater than 10,000 m^3 per year linked to a capital investment. A five to 10-year term may be considered, depending on availability and the annual allowable cut (AAC). The operator would be responsible to prepare the Timber Harvest Plans (THPs), license area design assessment and YESAB screening and follow the entire process to completion of harvest. Harvesting is by mechanical felling and bunching, forwarding is by grapple skidder, delimbing ranges from operational limbing (breakage and chainsaw) to cut-to-length processor to produce delimbed logs at the landing ready for loading; alternatively, this is done with chainsaws.

New Entrants	**<25 m^3**			
		ATV, snowmobile	**Logs, firewood**	Tier 1 Entrants	**25 m^3 to 200 m^3**			
			**Chainsaw at landing**	Tier 2 Existing	**< 999 m^3**	**Tree-length**		
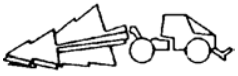
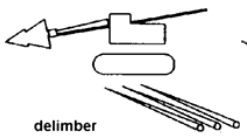
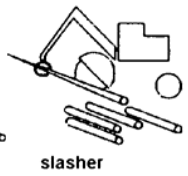
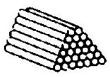
			**Chainsaw at landing**	Tier 2 Existing	**< 999 m^3**	**Whole-tree**		
				Tier 3 Existing 1,000–10,000 m^3	**Tier 4 New > 10,000 m^3**			
				








Source: AGFOR Inc.

Figure 2.4 Harvesting Tiers

During the course of the FEED, in addition to desktop level assessments, AGFOR spent eleven (11) days (during two separate trips) in the Yukon meeting with key individuals in the Yukon forestry sector including harvesters, sawmill operator, other forest professionals, and Forestry Management Branch staff.

Initially AGFOR met with the three principal harvesting operators in the region. For each operation, AGFOR sought to gain an appreciation of the following:

- Harvest volume of shipped product (firewood, sawlogs) in the recent year – all tenures considered.
- The quantity of wood left standing after harvest excluding regulatory requirements, expressed as percentage of volume of product shipped - as a precautionary measure, AGFOR reduced the volume left standing by 50% to ensure that the requirement to leave 25% of the original standing volume is not compromised.
- The quantity of wood left lying in the harvest block – all species, expressed as percentage of volume of product shipped.
- The quantity of wood left at the landing after product has been shipped – all species expressed as percentage of volume of product shipped.

The same questions were asked of the forestry professionals familiar with the harvesting practices in the Haines Junction area; responses were consistent with those of the operators. For the most part, their answers were comparable with responses in other jurisdictions (AGFOR in-house).

In the Yukon, there are two principle uses of biomass feedstock: firewood and two small sawmills (one in Dawson and one near Haines Junction). The Haines Junction firewood and sawmill industries are serviced by three principal harvesters who collectively harvest and deliver approximately 25,000 m^3 per year, all tenures considered (>90% of the Haines Junction harvest).

For the sawmill, it was important to estimate bark, sawdust, and shavings left after sawing merchantable lumber, and the mill's current recovery factor (m^3 of logs per thousand board feet – MFBM). Subtracting the sawn lumber volume from the gross log volume delivered to the sawmill allowed for an approximation of the sawmill recovery and residuals

Estimated residues, in green metric tonnes (GMT), for each of the above assessment (i.e., sawmill residues, biomass left standing, left lying in block, and left lying at the landing) are summarized in Table 2.12; these are the forest harvesting residuals after product is shipped and the sawmill residuals from producing lumber – they reflect local practices and conditions.

Table 2.13 Opinion of Probable Harvest and Sawmill Residues (GMT)

Known Sources :	Tonnes/year
Sawmill residues	2,000
Left at landing (slash)	1,450
Left in block (slash)	1,750
Left Standing (- Reduced by 50%)	2,400
Total	**7,600**

2.6.2 From the Forest

With estimates of the potential residues and standing residuals from the three larger forest harvesters in the region and the sawmill totaling approximately 7,600 tonnes/year, it should be possible to supply the biomass to a generating facility capacity of approximately 1 MW_e. The business case for the three larger harvesters should be explored to ensure the validity and longevity of any commitment. The business case for other smaller harvesters and possible new entrants should also be explored to provide forest residuals adding a layer of security of capacity and of supply.

As the biomass plant capacity begins to exceed this level of existing supply (>1 MW_e), it becomes important to appreciate the availability of the required feedstock in relation to the forest resource. A plant capacity larger than 1 MW_e will require green stands to be harvested.

Some of the forest characteristics provide a first indication of the resource:

- Age class distribution and stage of development: Age class distribution is the area of the forest for each age class (10, 20, 30 age classes). This is a gross portrait of the forest landscape and its age. Approximately 40% of the Forest Resource Management Zone (Green Zone) is between 100 and 200 years of age (source: Forest Management Branch data).
- The gross volume (cubic meters of wood per hectare) of timber typically available at each age class is found on a yield curve.
- A significant portion of the forest is mature. Forest stand maturity shifts to over-maturity at just over 200 years when the stand volume begins to decrease. The January 17, 2013 flight over the Haines Junction area suggested that there are no great areas of significant stand volume decrease. The preliminary conclusion is there is mature standing timber.

- A focus on forest stands in the Forest Management Zone (Green Zone) that have more than 75 m^3 per hectare (the lower end of economic operability for many operators) provide the known operable standing volume. This where the requirement should be met. A new forest inventory will provide a better idea of the harvest potential and its geographical distribution.

The first three bullets provide an indication that the overall forest should support the harvest of a small volume of forest biomass. While the final bullet provides an idea of the operable inventory and its location, it should be noted that the current harvest levels with the additional biomass would be below the 2006 temporary salvage harvest. The salvage annual allowable cut ends in 2016. The new Timber Supply Review should identify new areas of potential supply

2.6.3 Moisture Content

Moisture content is a weight-based value; wood from operations is typically quantified on the volume basis, usually by the cord. That means that costs are constant for a given volume regardless of the moisture content. The lower the moisture content, the less wood needs to be harvested. This is operationally significant and contributes to maintaining the overall landscape.

AGFOR heard anecdotal comments of low moisture contents, especially in standing dead trees; a moisture meter reading at the sawmill in October 2012 seemed to confirm that. Reports from other jurisdictions also suggested low moisture contents.

AGFOR undertook to have the moisture contents of wood samples from both freshly harvested live and dead trees. The samples were taken on January 17, 2013. The Yukon Research Centre did the moisture content determinations in their laboratories. The results, shown in Table 2.13 for the dead trees were consistent with expectations, although the results for the live trees were higher than expected.

Table 2.14 Feedstock Moisture Content

Attribute	Moisture Content
Dead spruce	14.8%
Live spruce	47.0%

Chipping to size and moisture content are two key components. The challenge will be the green moisture content and the availability of standing dead (dry) trees. There are indications that the inventory and salvage of standing dead trees will begin to drop with time - when the supply of dead standing spruce becomes unattractive to the firewood business, a move to standing green trees with higher average moisture content is necessary. Moisture content (MC) of 35% is used for standing green trees. When this change occurs during the life of the plant more green wood will enter the feedstock and other pre-processing techniques and measures should be considered. Calculations are based on AGFOR's original assumptions, which are 15% for residues and 35% for standing green wood.

Several factors could affect moisture content at the time of harvest and sampling. Regular moisture content sampling of harvested dead and green trees over a year on different site conditions could provide a better appreciation of the variability.

Measures to reduce moisture content should be explored during the detailed feedstock study following the FEED study; as such, measures could offset the apparent higher than expected moisture content of a limited sample from a few sites. Based on the unit performance outlined previously and 15% moisture content of the immediate feedstock, the feedstock requirements at the bookend capacities are presented in Table 2.14

Table 2.15 Summary of Feedstock Requirement

Scenarios:	0.5 MW_e	2 MW_e
Oven dry tonnes	3,000	15,900
With15% moisture	3,789	20,081
Cubic meters (m^3)	7,293	38,652
Cords	3,241	17,178
Cords per week	62	330
Truck loads/week	2-3 /week	11-15/week

The cubic meter is a solid measure that excludes air spaces and is equivalent to a solid volume of wood one meter wide, one meter high and one meter long

The cord is an apparent volume of stacked bolts of wood including the air spaces between bolts, hence apparent volume. A cord is 128 cubic feet, often described as a pile of wood measuring four feet wide, four feet high and eight feet long or some variation that equals 128 cubic feet.

2.6.4 Feedstock Cost

Feedstock costs are based on the local operating conditions and products that form the operator's business case.

Harvesting Cost

From each operator, AGFOR obtained an indication of their charge-out rate for each function/piece of equipment. This is the cost of harvesting equipment including labour, profit and overhead. In the absence of a charge out rate, AGFOR obtained the roadside selling price of firewood at the forest-roadside landing. From that, the current applicable stumpage and fees are deducted to arrive at a value that approximates their equipment costs with labour, profit and

overhead. These are values used on local operations. They were compared to earlier reference studies and to AGFOR in-house studies and cost models.

Transportation and Handling

Where possible AGFOR obtained local rates and found that they were similar to other sources. They were compared to earlier reference studies and to AGFOR in-house studies. Distances where adjusted to reflect average haul distances over time at 50 km for the sawmill residues and 70 km for the forest harvesting residues and dedicated feedstock harvest. The new forest inventory will provide a better idea of the harvest potential and geographical distribution.

Loading and handling costs rely on in-house data with some adjustment to reflect the small scale of the project. These would need to be validated once the siting and feedstock delivery logistics begin to firm-up during the detailed feedstock analysis.

Chipping costs need to be confirmed. There are approaches, such as roadside (landing) storage and chipping, which could provide value to the plant. These would need to be validated once the amount of feedstock, siting and delivery logistics are finalized.

The costs are competitive by many standards. The extent to which these might be considered will occur in a detailed feedstock procurement exercise.

It is anticipated for either scenario (0.5 MW_e or 2 MW_e), that 50% of the winter harvest would be put into inventory for approximately six months at a storage yard eight kilometers away and then reclaimed for consumption. Interest charges would have to be added to that half of the feedstock. Alternatively, the feedstock could be chipped at roadside and delivered directly to the plant.

Several measures should be explored during the final site selection and feedstock procurement to mitigate the extra handling and inventory costs of an off-site intermediate off-site log yard:

- Explore the possibility of a summer harvest to reduce inventory, and provide work for the harvest crew during the summer – this would need the CAFN/Forest Management Branch's approval and any roads would trigger a review process.
- Store wood at the harvest landing and only reclaim it during the summer for immediate processing and consumption – this would need CAFN/Forest Management Branch's approval and any roads would trigger a review process. We would expect the wood to dry while in storage.
- Using a mobile chipper at the harvest landing and chipping whole trees has significant advantages:
    - Logging cost will be reduced because no limbing or limited limbing would be involved; if chainsaws and skidders are used there is a significant reduction in the risk of injury.

- While the trees are in storage, the moisture content should reduce, and possibly offset the extra handling and storage costs.
- There is a gain in volume/weight by not topping the tree.

Both chipping and whole tree chipping (or with intermediate limbing) at the landing would require the CAFN/Forest Management Branch's approval and likely require regulatory approval.

SCENARIO 1 - 0.5 MW_e

Scenario 1 produces 0.5 MW_e and requires approximately 3,789 GMT at 15% moisture content (green basis). The sources are sawmill residues, logging debris at the landing (slash) and debris left in the harvest block. Little or no standing live trees are anticipated in this scenario. Should dead standing spruce no longer be available at a future date, a shift to standing live trees would occur. Note that residues make up the majority of the Scenario 1 feedstock which are at 15% MC, which aligned with the assumed moisture content required for use of the CPC system (denoted as 'as fired').

Scenario 1 - 0.5 MW_e	
GMT 'as fired'	**GMT @ 15% MC**
3,000	3,789

The following are the combined delivered and chipped costs of sawmill residues, harvest residues at the landing, and in the harvest block.

Scenario 1 costs as fired (bin)		
	$ GMT as fired	**GMT @ 15%**
(a) Direct to plant	Omitted	Omitted
(b) With secondary yard	Omitted	Omitted

Scenario 1(a), 0.5 MW_e, has an expected direct delivery wood cost of ($ Omitted) per GMT at 15% MC as fired (in the bin) without transitioning through an off-site log yard.

Scenario 1(b), 0.5 MW_e has an expected wood cost via an off-site storage yard eight kilometers away of ($ Omitted) per GMT at 15% MC as fired (in the bin).

SCENARIO 2 – 2.0 MW_e

Scenario 2 produces 2 MW_e and requires approximately 20,081 GMT at 15% MC (green basis). The sources are sawmill residues, logging debris at the landing (slash) and debris left in the harvest block and the harvest of standing live trees in this scenario. Should dead standing spruce no longer be available, the harvest of standing live trees would increase to possibly 78%

of the feedstock; this percentage is used in the Scenario 2 cost estimate with wood at 35% MC. This level of harvest would likely require regulatory approval.

Scenario 1 – 2.0 MW_e	
GMT 'as fired' @ 35% MC	**GMT @ 15% MC**
24,610	20,081

The following are the combined delivered and chipped costs of sawmill residues, harvest residues at the landing and in the harvest block, the harvest of standing residuals and the harvest of live trees for feedstock.

Scenario 2 costs as fired (bin)		
	$ GMT as fired	**GMT @ 15%**
(a) Direct to plant	Omitted	Omitted
(b) With secondary yard	Omitted	Omitted

Scenario 2(a), 2 MW_e, has an expected direct delivery wood cost of ($ Omitted) per GMT at 15% MC and ($ Omitted) per GMT as fired (in the bin) without transitioning through a log yard eight kilometers away.

Scenario 2(b), 2 MW_e, has an expected delivered wood cost via a storage yard of ($ Omitted) per GMT at 15% MC and ($ Omitted) per GMT as fired (in the bin).

2.6.5 Pre-Processing Implications of Biomass Properties

Costs (harvesting, handling, transport and chipping) are essentially constant regardless of moisture content as harvesters are paid on a volume basis. The facility operates in green metric tonnes (GMT) and benefits from any reduction in moisture content. The use of sawmill and harvest residues of dead wood is currently an advantage for all of Scenario 1 feedstock requirements and a portion of the Scenario 2 feedstock requirement. The remainder of the Scenario 2 feedstock will rely mostly on live trees (green). Opportunities to reduce the moisture content of live trees needs to be explored and integrated into the procurement practices.

It is anticipated that 50% of the winter harvest would be put into inventory for approximately six months at a storage yard eight kilometers away (assuming the experimental farm is used) and then reclaimed for consumption. Yard inventories of drier dead spruce and the green live spruce should be kept apart and dated for inventory control. The green live spruce should be reclaimed on a first in first out basis to capitalize on any moisture content reduction. Interest charges would have to be added.

Two off-site storage (inventory) opportunities should be explored:

- Leave the wood decked at the roadside landing in the woods that is accessible to a truck year-round, especially in the summer months, and remove for consumption as needed. This would need to be developed in the next phase (during the detailed feedstock analysis) and would likely require regulatory approval.
- Transport wood to an intermediate off-site yard and then reclaim for processing and consumption. This is the current Scenario 1b and 2b.

The first opportunity involves less handling and is less costly than the second.

A minimum operating feedstock inventory equivalent to two or three weeks supply should be sought. Off-site storage is needed for weekly deliveries of wood during the regular season and in the off-season months. The storage area needs to accommodate basic site access infrastructure and right-of way access for trucks and equipment to and from the piles all year including during the spring break-up. The site should have good drainage to support the traffic all year.

The approximate area required is presented below:

Scenario	Storage Capacity (m^3 - cords)	Area (hectares - acres)
1b	3,122 m^3 (1,388 cords)	0.9 hectares (2.1 acres)
2b	18,302 m^3 (13,700 cords)	5.2 hectares (13 acres)

Harvest of Green Trees (Scenario 2)

Harvest and delivery costs (as-fired) of green trees currently left standing and as a dedicated harvest including harvest, transport to plant and chipping are presented below (rounding differences occur).

In Scenario 2(a) direct delivery (no intermediate storage yard) to the plant for Live Trees - are as follows:

$ / m^3 @ 35% MC	GMT @ 35%	$/GMT @ 35%	Factor to 0%	$ /ODT
Omitted	0.639	Omitted	1.76	Omitted

In Scenario 2(b) indirect delivery via an off-site yard for Live Trees - are as follows:

$ / m^3 @ 35% MC	GMT @ 35%	$/GMT @ 35%	Factor to 0%	$ /ODT
Omitted	0.639	Omitted	1.76	Omitted

Potential Employment

Looking at the potential impact to existing employment, either scenario will require an increase both harvesting by local contractors and new employment to support the plant. Based on the fuel quantities expected, the breakdown for added employment is outlined in Table 2.15. This high-level assessment shows the need for increased activity by the local harvesters (Contractor) and the biomass facility (New Corporation (NEWCO)).

Table 2.16 Employment Impacts from Biomass Plant

Employment / Scenario	Scenario 1a	Scenario 1b	Scenario 2a	Scenario 2b
Person Days	265	343	1464	1612
Person Years Total	1.20	1.56	6.65	7.33
Contractor* Person Yrs	0.70	0.70	4.57	4.57
NEWCO Person Yrs + yard-site maintenance	0.50	0.86	2.08	2.76

*Scenario 2 includes part-time conventional chainsaw and skidder volume

3.0 Environmental Assessment and Permitting

3.1 REGULATORY APPROVALS STRATEGY

A draft Environmental and Socio-economic Impact Assessment (IA) has been prepared based on information currently available on the Project and existing conditions in the area. This report includes an overview of the effects assessment and regulatory regimes associated with permitting the Project, scoping of the assessment to include relevant Valued Components (VC), summaries of baseline conditions for each VC and expected effects and proposed mitigation. Determination of significance has been based on residual effects after implementation of mitigation. Adaptive management and monitoring activities are also outlined where deemed applicable. The environmental and socio-economic impact assessment report draft completed to date is attached as Appendix F.

As the plant site has not yet been confirmed, collection of data to provide an understanding of baseline conditions associated with the plant site has been done at a high level for Haines Junction and the surrounding area. Data available at a desktop level indicate that there are no major environmental constraints on the preliminary site (used in the FEED study). Field studies are required to confirm findings once the site has been selected and are suggested to include (but may not be limited to) heritage resource assessment, vegetation and wildlife surveys and an existing sound pressure level survey. Targeted meetings or interviews with CAFN members and the public should also be held to confirm the plant site should not cause any significant effects on traditional and current land use and culture.

The Project team has drafted the effects assessment thus far with the intent to meet the requirements of an Executive Committee level screening. This route was chosen as the full scope of the Project is not yet confirmed, and thus the volumes of harvesting required are not known. These depend on the plant size and the outcome of the preliminary feedstock harvesting study (now complete). The client has also indicated it is likely that an Executive Committee submission is required based on initial consultation with YESAB. At this time, it is important to note that the level of submission required under Yukon Environmental and Socio-economic Assessment Act (YESAA) has not been confirmed with YESAB. The YESAA trigger for Executive Committee assessment of this Project is based on harvesting of 20,000 m^3 or more of standing or fallen trees. If a plant size of 500 kW_e is chosen it is estimated to consume 10,500 m^3 per year with existing harvesting areas having the potential to supply all of this volume (6,000 m^3 in logging residues from current harvesting operations and 4,500 m^3 (2,200 GMT) of sawmill residues not currently being used). Therefore, this size of plant could potentially be permitted through a Designated Office (DO) level submission (assuming DO level proposals are submitted separately by existing operators for ongoing harvesting). This would reduce the level of detail required in the assessment and importantly the potential timelines for approval. These potential timelines for approval (to receive a Decision Document) of an

Executive Committee proposal are 1 to 2.5 years, whereas the DO process timeline is less than 1 year. Note that on occasion, regulators may require an assessment for a project that is otherwise exempted (although this mechanism has never been applied). There is also a possibility that a Project requiring a DO level submission (as per the requirements of YESAA) could be referred to the Executive Committee at either the onset or following initial review of the DO submission. This referral would primarily be based on the potential for adverse effects even with proposed mitigation as well as stakeholder concerns or use of unknown technologies. Therefore, consultation with YESAB is required to confirm the Project's stream and scope of assessment. This strategy is further discussed in Section 4.3.

3.2 DESKTOP FEEDSTOCK HARVESTING ANALYSIS

Key potential environmental and socio-economic issues associated with using beetle kill and potentially green feedstock in the Yukon have been described in the draft IA (Appendix F). Mitigation options have been identified based on the preliminary information available. The feedstock harvesting environmental analysis included consideration of:

- Long-term sustainability of supply (discussion of the overall sustainability of supply for expansion of biomass use).
- Responsible treatment of ecosystem and environment.
- Legislative and regulatory requirements for the timber resources.
- Fire Management.
- Respect of other uses and users of forests.

Some consideration for Traditional Activities and Culture as well as social, recreational, and commercial use has been included however, this is recommended as an area for further study, now that volumes of required harvest are better understood. For the smaller plant, these are not critical considerations in the event that existing harvesting activities are contracted to supply the Project. Very limited documentation exists to support this type of socio-economic assessment at a desktop level and the social aspect requires consultation to ensure current values and uses are considered.

Supply for a 500 kW_e plant has been determined to be sustainable with no change over existing harvest areas expected. The additional requirement for a 2 MW_e plant is also a low percentage of the overall resource; in consideration of the Green zones as denoted in the Integrated Landscape Plan, the current use and the Timber Harvest Level for the Champagne and Aishihik Traditional Territory (2006). Both the availability of supply and the harvest level are subjects for review as part of the new forest inventory of dead and live forests.

Key guiding documents and plans are highlighted as follows:

2004 – Strategic Forest Management Plan for the Champagne and Aishihik Traditional Territory (CATT) provides direction to the planning process presenting the values and objectives for the CATT necessary to ensure sustainability in the broadest terms and reflecting the traditional and non-traditional values and objectives of the community. It provides the indicators and the processes for involvement of the community in the planning process. It addresses the entire land base in the study area.

2006 - The Timber Harvest Level for the Champagne and Aishihik Traditional Territory spells out the harvest level determination of spruce bark beetle affected forest stands and timber harvesting opportunities. This agreement set a harvest ceiling of 1,000,000 m^3 annually for the spruce beetle affected forest over a ten-year period. The harvest level is being updated with the in progress forest inventory.

2007 – Integrated Landscape Plan for the Champagne and Aishihik Traditional Territory (CATT) originally made available publically in March 2006. It is a subordinate plant to the 2004 Strategic Forest Management Plan (SFMP) and introduces land use Zones and availability for forest harvesting. These zones include both CAFN Settlement Lands and non-Settlement Land. Three Zones are presented:

- Forest Management Zone shown in green (aka the Green zone – 93,700 ha) is the zone currently considered for Timber Harvest Project Planning. Most of the wood harvesting would be in this zone with accommodation for site-specific wildlife and habitat.
- Provisional Forest Management Zone (aka the Yellow Zone – 70,000 ha) is not currently targeted in Timber Harvest Project Planning.
- Conservation Forest Management Zone (aka the Orange Zone – 83,150 ha) in which no commercial harvesting is currently allowed. Significant amendments to the SFMP and the ILP would be required to allow harvesting in this zone.

These documents provide the forest planners with the scope for planning and wood supply analysis, their rules of engagement and are referenced in the *Forest Resources Act* 2008 (FRA) which came into effect in 2011 along with the regulations. The FRA applies to non-Settlement Land where as CAFN Settlement Land falls under the authority of CAFN and is regulated via the *Traditional Activities and Protection Act*.

During this time, inventory estimates were developed to allow a level of forest harvesting activity to occur in the Green Zone. The background data used in this timber supply analysis stemmed from earlier photo interpretation to provide a rough and broad estimate of standing timber. The Timber Harvest Level for the Champagne and Aishihik Traditional Territory is a binding

agreement on the allowable salvage harvest that was established in 2006 based on this analysis.

Spruce Bark Beetle, Yukon Forest Health – Forest Insect and Disease Bulletin 19 provides a recent history of the spruce bark beetle infestations and its dynamics - The most recent outbreak began in 1990 caused significant yet unquantified mortality. Large tracts of dead and dying mature white spruce were observable while the infestation was in progress. The harvest/salvage of this wood was made possible with a time limited salvage harvest (10-year period from 2006 to 2016). The extent that this salvage will continue to be available is now a key question as the standing dead trees are beginning to fall.

A Timber Supply Review or new forest inventory is in progress based on recent aerial photo interpretation at a finer resolution. This will provide better data on the volumes, distribution and condition of both dead and live trees.

2009 – Forest Health Report, Yukon Energy Mines and Resources uses a risk based approach to forest health; 2009 is the first year of publication. It provides an expanded history of various forest health issues. The spruce bark beetle is the most damaging forest pest targeting mature spruce in the Yukon. The Yukon outbreak began in 1990 and is (at the time of the report) still underway “It is by far the largest and longest lasting spruce beetle outbreak ever recorded in Canada.” “The intensity and duration of the current infestation are related directly to climatic stress …by the significant increase in temperature during the late 1980s and into the 1990s.

2012 Champagne and Aishihik - Yukon Forest Management Implementation Agreement “reaffirms the provisions included in the Strategic Forest Management Plan for the Champagne and Aishihik Traditional Territory and the Integrated Landscape Plan for the Champagne and Aishihik Traditional Territory (CATT) confirming guidance to the new Timber Supply Review.

The new Timber Supply Review will provide useful information on both dead and live trees and will be the object of public engagements before a revised final annual allowable cut (AAC) is set. The AAC will then be apportioned according to the types of use and license categories in accordance with the objectives of the Forest Management Implementation Agreement. Public consultation would also be conducted before allocations are made.

Current interim allowable harvest volume estimates are based on the earlier inventory and the salvage of dead white spruce. The allocations on non-Settlement Lands follow the process outlined in the **Wood Allocation Strategy (see Operational Policy Procedure June 2012 – Wood Allocation Strategy for Haines Junction):**

- A License is issued and provides the rights to a volume in the licensed area.

- A Timber Harvest Plan (THP) is prepared in accordance with the Act and is approved by Forest Management Branch.
- A Timber Cutting Permit is issued in accordance with the Act.
- YESAA applies to areas over 1,000 m^3 and is engaged.
- A site plan is prepared in accordance with the above and in accordance with the Act.
- A Cutting Permit is issued with the terms and conditions specifying time frames, stumpage and fees and reporting and completion requirements.
- A post assessment conducted by the Compliance Branch provides Closure to the license.

On Settlement Lands, the *Traditional Activities and Protection Act, The Timber Harvest Level for the Champagne and Aishihik Traditional Territory, the Forestry Implementation Agreement* as well as the SFMP and ILP provide some framework and legislation for harvesting activities. CAFN is currently in the process of developing additional forest policy framework, scheduled to be in place by 2015. This was one of the key objectives of the 2012 Forestry Implementation Agreement. (Per. Comm. Roger Brown CAFN 2013).

3.3 RISK MANAGEMENT STRATEGY FOR ENVIRONMENTAL/SOCIO-ECONOMIC AND REGULATORY APPROVALS

This risk management strategy for environmental and socio-economic regulatory approvals builds on the preliminary work undertaken as part of the environmental assessment and permitting phase. The objective is to define environmental and regulatory approval risks to the project. A summary of gaps and uncertainties and recommendations for further study and potential approvals schedules are provided.

Based on our preliminary work, we consider the overall risk to the Project to be low in relation to attainment of environmental/socio-economic regulatory permitting requirements.

3.3.1 Gaps and Uncertainties

Although some information from the FEED Study has been made available to the environmental team prior to release of the draft study, the effects assessment completed to date (January 31) does not incorporate the information provided in the draft FEED Study or the findings of the preliminary feedstock assessment as these activities were conducted and finalized concurrently. As these studies have been conducted concurrently, some updates to the effects assessment are required to reflect the conclusions of these studies (such as the plant site area, construction periods and activities, volumes of waste generated, water consumed). Further updates are likely

to be required depending on the decision of the steering committee on whether to proceed with the Project and at what size or scale.

At this stage (as directed by the Project team), no directed consultation with the Yukon Environmental and Socio-economic Assessment Board (YESAB) has been conducted. It is recommended that potential strategies and timelines be reviewed with YESAB prior to financial and board decisions to move forward so that their input can be considered.

Assessment of cumulative effects has not been completed in detail, as the Project will not be registered with YESAA until a decision to move forward is made by the steering committee and those providing financial support to the Project. Additional activities or projects could be initiated prior to that time. Based on preliminary review, no other activities or projects currently exist that would combine with this Project to cause a significant adverse environmental or socio-economic effect. Further study in relation to socio-economic effects on existing forest harvesting and traditional and current land use, activities and culture may be warranted, depending on the magnitude of harvesting proposed.

Further study of noise/sound quality effects from chipping should be completed once this activity's location and equipment/technology are defined. A set back from the nearest residence or other sensitive receptor (such as the school) of 500 m to 1,000 m is expected to be required to avoid annoyance from noise due to this operation. The preliminary air quality assessment indicates that the Project should comply with regulatory requirements, however this will need to be confirmed based on the emissions profile of the Project from the selected vendor.

3.3.2 Feedstock Harvesting

With regards to moisture content of green trees, limited samples were taken during a one-day field visit on January 17, 2013. The preliminary moisture contents of the green wood determined based on this sampling were higher than expected; these findings should be considered preliminary in nature. More volume of harvest would be needed to supply the feedstock using green wood; this has been partially adjusted in calculations presented in this report by assigning a 35% moisture content to all standing trees left in a block (to be harvested to meet the 2.0 MW_e feedstock needs). Further in-season moisture content analysis should provide a better indication of variability. Moisture content reduction strategies have also been identified for further study.

This is considered a concern as fewer large areas of standing dead wood (beetle kill) may be economically available over time than previously suspected. The new forest inventory of dead and live forests is intended to address that issue. In the event that current harvesters agree to supply the required feedstock for a 500 kW_e facility, minimal planning on the part of the Proponent would be required in harvesting operations. While harvesting for a 500 kW_e facility requires detailed planning of wood harvesting, storage and chipping location and activities to ensure compliance with procedures and continuous feedstock availability, the contracted harvesters could be expected to manage the majority of this planning. Depending on the

methods for hauling, storage and chipping, the effects assessment would be revised accordingly.

Harvesting feedstock for a plant larger than 500 kW_e would require an increase in harvesting, beyond current levels. Further study should be undertaken to define the activities and timelines for this harvesting (*e.g.*, types of equipment, blocks required annually and planned field studies, seasonality of harvesting required, wood storage and chipping locations). Once the activities and areas are defined, the additional scope of assessment of socio-economic and environmental effects will be modified.

The assumption that existing fuel wood harvesting will continue to operate as per the status quo and thus could supply the Project as part of this activity presents some risk. The risk to this assumption is that current harvesters could leave the Haines Junction area once the dead wood is depleted. Risk to supply may also increase as the dead wood is depleted, as the economic efficiency of using greenwood volumes is known to be less due to the requirement for drying. This has been accounted for in calculations by assigning a 35% moisture content to all standing trees left in a block and trees to be harvested to meet the 2.0 MW_e feedstock needs. A review of the harvester's business case and of operational moisture content reducing strategies are noted for further study.

3.3.3 Next Steps

The following steps are provided under the assumption that a decision to go forward with the Project is made. No environmental constraints have been identified in the desktop review. Preliminary consultation has indicated that there is community interest and support for the Project.

In consideration of the plant site itself, no environmental constraints are expected for the range considered (500 kW_e to 2.0 MW_e) that would result in denial of approval of the Project for environmental or socio-economic reasons. When the feedstock harvesting activities are combined with the plant operation, there is more uncertainty with the larger plant size in terms of scope of assessment and timeline for completion. However, as the requirements are still a small fraction of the previously estimated forest resource and when combined with current harvest levels, are well within the 2006 Timber Harvest Level for the Champagne and Aishihik Traditional Territory, the inclusion of the forest harvesting activities in the overall assessment is not expected to result in significant adverse environmental effects that cannot be mitigated (for the sizes of plant being considered).

It is recommended that the plant size be selected in consideration of FEED results (economics and technical constraints) and input from consultation with First Nations and the public as well as the expected timelines for permitting of the facility under different scenario (500 kW_e to 2.0 MW_e). Field studies should be defined for this site, as required, in order to finalize the impact assessment in relation to the plant.

Confirmation of the emissions profile and dispersion modeling should be completed during the vendor selection process. Modeling may need to be redone if emissions are higher than those estimated based on Community Power Corporation's (CPC) proposal or stack parameters are substantively different (much lower stack or lower velocity would result in worse ambient air quality predictions).

A strategy for regulatory permitting, which should allow for more timely consumption of beetle-killed wood, is to proceed with permitting of a 500 kW_e facility with minimal additional analysis of environmental issues associated with feedstock harvesting (assuming existing forest harvesting operations can provide the required feedstock and YESAB agrees to a DO level proposal for the plant). This may be justifiable and agreeable to YESAB and the public for the following reasons:

- In accordance with the CAFN strategic plan, CAFN is interested in pursuing regional economic development within its Traditional Territory by exploring opportunities in all economic sectors. CAFN has been actively investigating Biomass potential for 18-months prior to this FEED study.
- The Public and First Nations have not communicated any concerns that cannot be resolved and mitigated through planning.
- Some members of the community and CAFN leadership have expressed their desire to use the beetle killed wood before a catastrophic forest fire occurs or the resource loses its usefulness due to rot (although it is understood that not all members of the community may align with this view).
- Based on the FEED study, the feedstock supply for a 500 kW_e plant should be attainable through existing harvesters without increasing annual harvest area (by using waste from sawmill operations, slash being left in the blocks and at the landing).
- CAFN and the Yukon Government have developed a Strategic Forest Management Plan and Integrated Landscape Management Plan, which is applicable to Settlement and non-Settlement Lands. These plans as well as the Yukon *Forest Resources Act* and the Haines Junction Wood Allocation Strategy Operational Policy and Procedures (non-Settlement Lands) would be followed in harvesting for the Project.
- CAFN does not consider current regulatory/legislative tools to be sufficient to adequately manage forest resources on Settlement Lands and is thus in the process of developing a forest policy framework, scheduled to be in place by 2015. This was one of the key objectives of the 2012 Forestry Implementation Agreement. (pers. Comm. Roger Brown CAFN 2013).

As explained in the FEED study, modular designs are available for the plant. Following the installation and operation of the 500 kW_e plant, sufficient time would be allowed to monitor operational issues related to the plant and/or feedstock acquisition (either operational or environmental/socio-economic). Subsequent to this, a proposal could be submitted to the DO

for expansion. Assuming operation of the initial 500 kW_e plant is shown to cause no significant effects, permitting of an expansion may be relatively straightforward.
Additional studies surrounding feedstock-harvesting activities should be defined in consultation with the Forest Management Branch, Environment Yukon, The Alsek Renewable Resource Council (ARRC), CAFN and YESAB. Based on our work to date, we suggest the following may be warranted:

- Review of Heritage Resource Assessment process currently being undertaken in association with forest management.
- Development of a Heritage Resource Assessment plan for the life of the Project.
- Focused public, stakeholder and Aboriginal and First Nations consultation to discuss existing land use, traditional activities and culture, and local knowledge of the areas in terms of ecological and heritage resources (in relation to potentially harvestable areas).
- Bird surveys should be designed in consultation with Canadian Wildlife Service, Environment Canada, Environment Yukon, and ARRC. Multiple surveys may be required to target various bird species (e.g., Common Nighthawk, owls, early surveys for woodpeckers, breeding bird surveys).
- Rare plant surveys should be designed in consultation with Environment Yukon, multiple surveys may be required to ensure that early ephemeral species are captured as part of the survey.
- Additional wildlife surveys may be required depending on consultation with Environment Yukon. Surveys targeting bats and/or small mammals may be required.
- Fish and fish habitat surveys may be required depending on the location of the feedstock sites. Design of the survey would be conducted in association with input from regulatory agencies.

3.3.4 Preliminary Field Study and Permitting Schedule

Consultation with YESAB is recommended prior to a go decision on size of plant. This will help to ensure that any input from the regulators on required scope of assessment can be considered in the decision process. The schedule from that point is dependent on the required permitting path. Consultation with CAFN and the community of Haines Junction to confirm plant siting should be completed prior to finalizing the site. Site field surveys for wildlife and vegetation should be completed in 2013. Certain species (such as Woodpecker and owl surveys) are done early in the spring (likely May) while the regular breeding bird surveys would be done in June. Depending on the level of detail required by the regulators, some of the plant surveys may need to be done early in the spring to catch early ephemeral species. All wildlife and plant surveys and their timing depend on consultation with the regulators to confirm required scope.

Timing for a field heritage resource assessment could be as early as spring 2013, provided assessments are conducted in snow-free conditions. Following completion of these activities and assuming a DO proposal is possible, the initial proposal could be submitted by mid-2013. If additional environmental and socio-economic study of feedstock harvesting is required by YESAB (likely for 2.0 MW_e plant, may be required for smaller plant), these studies should be scoped and initiated following a go decision on the Project and are expected to take 6 to 12 months to complete depending on the scope. The overall schedule and YESAA process is summarized in Figure 3.1.

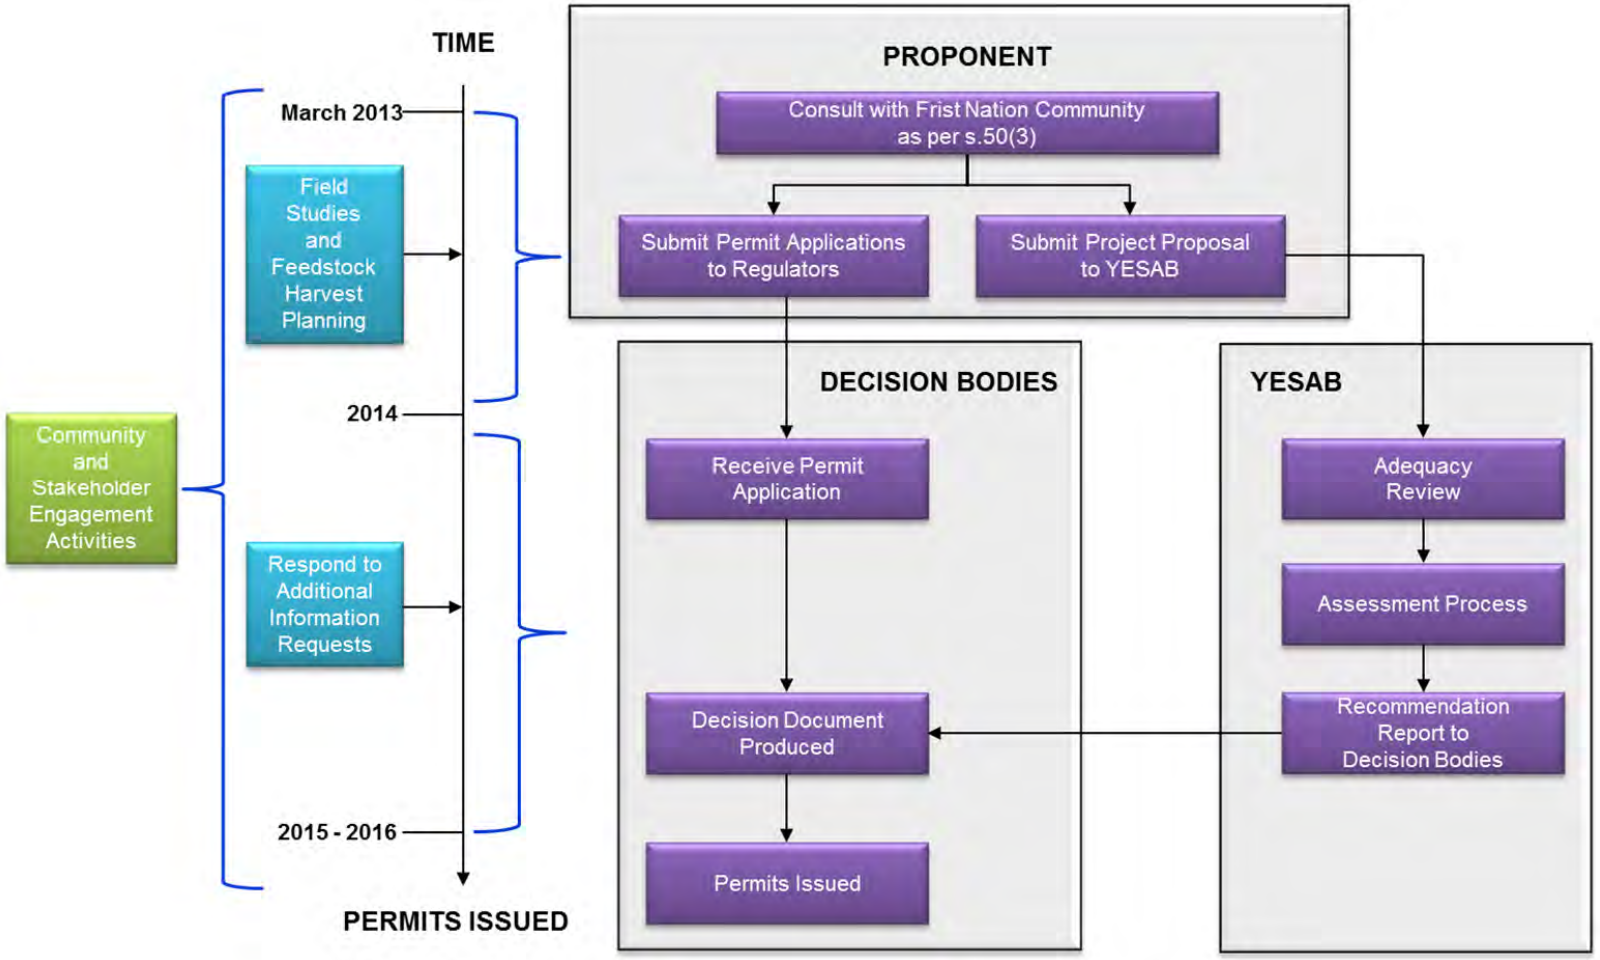


Figure 3.1 YESAA Simplified Process Flow Diagram for 2.0 MW Capacity

4.0 Risk, Financial & Operations Analysis

The Risk, Financial, and Operations Analysis section of the FEED focused on three critical areas, including: sources for project financing/funding, options for different business models for the formation of the new company (NEWCO), and financial assessment of the biomass plant (ROI, NPV, and sensitivities). Each of these topics is presented in the following subsections.

4.1 SOURCES OF PROJECT FINANCING

As part of the Phase 5 – Project Financing task, Stantec has conducted preliminary research into potential sources for project funding. At the kick-off meeting in Whitehorse on September 19, one potential source of funding discussed was Sustainable Development Technology Canada (SDTC). Stantec reviewed the workshop presentation for SDTC with the following comments.

4.1.1 Sustainable Development Technology Canada

SDTC operates two funds intended to stimulate investment in sustainable technologies. The first fund is the “SD Tech Fund™” which is 10 years old and aimed at development of emerging clean technologies. The key here is the word “emerging”. To be eligible, the Yukon biomass would have to be considered “unproven”[1].

The second fund managed by SDTC is the “NextGen Biofuels Fund™”. This fund is aimed at “large demonstration-scale facilities for next-generation renewable fuels and co-products.

Both of these funds were discussed with Paul Austin (SDTC, Vancouver office), to determine potential eligibility for the Yukon project.

Unfortunately, this project is likely to not qualify for either funding. The SD Tech Fund is strictly for new technologies or innovative use of clean technologies, and a proven biomass technology / waste heat application is not what SDTC is looking for in new applications. With regard to the NextGen Fund, it is for “first of a kind” type biofuel projects already in a continuous operation mode.

4.1.2 The ecoENERGY Innovation Initiative

“The ecoENERGY Innovation Initiative (ecoEII) received funding in Budget 2011, the Next Phase of Canada’s Economic Action Plan, for a comprehensive suite of research and development (R&D) and demonstration projects. The program’s objective is to support energy technology innovation to produce and use energy in a cleaner and more efficient way. This

[1] SDTC states in the presentation materials under the heading “SOI Don’ts” – Proven Technology = no need for SDTC

Initiative is a key component of the Government of Canada's actions to achieve real emissions reductions, while maintaining Canada's economic advantage and its ability to create jobs for Canadians. The ecoEII will also help in the search for long-term solutions to reducing and eliminating air pollutants from energy production and use."[2]

This funding source is currently engaged under the 'demonstration' division to support this FEED study. Continued funding from NRCan on the next phases of this project is possible and negotiations are ongoing.

4.1.3 Potential Funding Sources

Research indicates that there are other funding programs that may be applicable to the project. These will require direct follow-up with the applicable government agencies to determine if it is worthwhile to apply. Furthermore, once (if) a waste heat option is finalized, this may also lead to other funding opportunities.

From the Canadian Northern Economic Development Agency, there are the following programs:

4.1.3.1 Strategic Investments in Northern Economic Development (SINED)

SINED has been allocated $22 million funding per Territory for the years 2009-2014 as part of its Targeted Investment Program (TIP). The four areas of focus for TIP are building the knowledge base, enhancing the economic infrastructure base, capacity development, and economic diversification. It is possible that the Yukon project could qualify for funding as an economic diversification plan.

4.1.3.2 Community Economic Opportunities Program (CEOP)

The CEOP and CEDP funding provides project-based support and core operational support for First Nation communities for projects that lead to more community employment, greater use of land and resources, enhanced community infrastructure etc. The Yukon biomass project certainly will provide these economic benefits and may be a good candidate for this funding.

4.1.3.3 Community Infrastructure Improvement Fund (CIIF)

The CIIF program provides up to $1 million in funding for projects that improve community infrastructure. Recipients of the program must be not-for-profit entities, local/territory governments or First Nations. Infrastructure must be directly accessible to the public (i.e. district heating) and must be materially completed by March 31, 2014. There is some question whether the Yukon project would qualify due to restrictions pertaining to commercial activities.

[2] http://www.nrcan.gc.ca/energy/science/2003

Natural Resources Canada (NRCan), who is funding this Yukon feasibility study via its ecoEnergy Initiatives Program, may also have possible funding availability under grant programs as follows.

4.1.3.4 Aboriginal Economic Development in Forestry

The Canadian Forest Service (CFS) has been mandated by AFI to provide knowledge and facilitate coordination of federal support programs for Aboriginal economic forestry development, of which bioenergy is a priority focus. Limited multi-year funding may be available from AFI where it is determined that critical gaps exist in support from other programs that may pose a risk to project success. There is no formal application process involved. Instead, any funding will be subject to the CFS identifying the need and strategic value of the project as well as availability of the funding from AFI.

4.1.3.5 Biomass for Energy Program

Established in 2000, the Biomass for Energy Program focuses on research and development related to technologies used in the growing, harvesting and transportation of biomass feedstock. The program is also funded through the Canadian Forest Service.

The federal government Office of Energy Research and Development (OERD) offers another potential research and development grant program focusing on biomass technologies.

4.1.3.6 Bio-based Energy Systems and Technologies (BEST) Program

This program supports the research and development of technologies used to improve the supply, conversion and utilization of both existing and new biomass feedstock supply.

Finally, for taxable entities, accelerated Capital Cost Allowance provisions are available for capital assets used in the production of energy using renewable fuel sources. The provisions allow for an increased depreciation of equipment at a rate of 30% annually.

4.2 NEWCO BUSINESS MODELS

The purpose of this subsection is to provide a risk and qualitative analysis of the options available to NEWCO (Champagne and Aishihik First Nations, Yukon Energy and the Village of Haines Junction (VHJ)) for the ownership and operations of a 0.5 - 2.0 MW_e biomass energy system. The analysis is provided separately for both the feedstock harvesting (e.g. feedstock storage yard/wood chipping and logging) operations and the biomass plant operations.

Options:

Three ownership and operations options have been considered for each of the feedstock yard/logging operation and the biomass plant operation, resulting in a combined total of six options. These six possible options are provided in the following table.

Table 4.1 Business Model Options Analysis

	Feedstock Yard/Logging		Biomass Plant	
	Ownership	Operations	Ownership	Operations
Option 1	NEWCO	CAFN	NEWCO	NEWCO
Option 2	NEWCO	ISP	NEWCO	NEWCO
Option 3	NEWCO	CAFN	NEWCO	ISP
Option 4	NEWCO	ISP	NEWCO	ISP
Option 5	ISP	ISP	NEWCO	NEWCO
Option 6	NEWCO	CAFN	ISP	ISP

CAFN Champagne and Aishihik First Nations
ISP Independent Service Provider
NEWCO CAFN/Yukon Energy/Village of Haines Junction (a private entity)

Assumptions:

As part of this analysis, specific base assumptions have been made as follows:

- For options where an ISP is the owner, it is assumed that NEWCO will retain an option to acquire all assets at fair market value after a twenty-year period.
- For options where an ISP is the owner, it is assumed they will also be the primary operator. CAFN members will be used to the greatest extent possible and trained for eventual assumption of full operations over a maximum twenty-year period.
- Yukon Energy will hold a minority interest in NEWCO. They are interested in the plant operations but are not interested in the operations of the logging business.
- The Village of Haines Junction will hold a minority interest in NEWCO but will not participate in any of the operations.

4.2.1 Risk Analysis

The risk analysis used has been developed to show areas where actual results may differ from predicted. The risk analysis is semi-quantitative, with lower scores signifying a lower probability of occurrence and a lower severity of risk. Risk criteria have been broken out into two life-cycle categories reflecting the periods before and after the assets are placed into operations. The two categories are the "*design and construction period*" and the "*operations and transfer period*". The feedstock yard/logging operations and the biomass plant operations have been evaluated separately due to the distinctiveness of each of these project components.

Scoring:

The risk assessment considers both the probability of the risk occurring and the severity of impact if the risk does occur. The scoring uses a scale where 1=Low, 2= Medium and 3=High which can generally be interpreted as follows:

Table 4.2 Scoring Structure

Score	Probability	Severity
1 (Low)	*Unlikely* to occur for this project	Low impact unlikely to result in a loss that cannot be easily mitigated
2 (Medium)	*Possible* to occur for this project	Medium impact where the loss can mostly be mitigated
3 (High)	*Likely* to occur for this project	High impact where the loss may be significant

The total risk for each option is calculated as: **Total Risk = Probability x Severity**.

4.2.1.1 Feedstock Yard/Logging Analysis

The total risk scores for the feedstock yard/logging operations are:

Table 4.3 Risk Score Summary – Feedstock Yard/Logging

	NEWCO Owns/ NEWCO Operates	NEWCO Owns/ ISP Operates	ISP Owns/ ISP Operates
Design and Construction Period	16	18	14
Operations and Transfer Period	16	11	19
Total Risk Score	**32**	**29**	**33**

With the lower score reflecting lowest risk, Option 2 is the lowest risk option for feedstock yard/logging.

The following table shows the detailed scoring for the feedstock and logging ownership and operations options followed by a short narrative of the scoring rationale for each criterion.

Table 4.4 Risk Assessment – Feedstock Yard/Logging

FEEDSTOCK YARD / LOGGING RISK ASSESSMENT *(Low -1 , Medium - 2 , High - 3)*	OPTIONS								
	NEWCO / CAFN			NEWCO / ISP			ISP / ISP		
	Prob-ability	Sever-ity	Risk	Prob-ability	Sever-ity	Risk	Prob-ability	Sever-ity	Risk
DESIGN & CONSTRUCTION PERIOD									
Under or over designed (changes required to meet performance criteria or capex higher than necessary)	1	1	**1**	1	1	**1**	1	1	**1**
Constructability	2	2	**4**	2	2	**4**	1	1	**1**
Insufficient interest in RFP to stimulate competitive forces	1	3	**3**	1	3	**3**	1	3	**3**
Complexity of processes leading to increased time and cost	1	2	**2**	2	2	**4**	3	2	**6**
Permit/zoning risks	1	1	**1**	1	1	**1**	1	1	**1**
Scope / schedule creep	2	2	**4**	2	2	**4**	1	1	**1**
Default/breach of T&C's by consultants/contractors	1	1	**1**	1	1	**1**	1	1	**1**
Average Score			**16**			**18**			**14**
OPERATIONS & TRANSFER PERIOD									
Operational reliability standards not met	3	2	**6**	1	2	**2**	1	2	**2**
Operating cost variances	3	2	**6**	1	2	**2**	1	2	**2**
Electricity demand risk	1	1	**1**	1	2	**2**	1	2	**2**
Energy cost (feedstock) variation	0	0	**0**	0	0	**0**	0	0	**0**
Default/breach of T&C's by operator	1	1	**1**	1	3	**3**	1	3	**3**
Required maintenance not performed, diminishing value of asset	1	1	**1**	1	1	**1**	2	2	**4**
Market conditions change, increasing market value of the assets	1	1	**1**	1	1	**1**	3	2	**6**
Average Score			**16**			**11**			**19**
TOTAL RISK SCORE (**Lower** is better)			**32**			**29**			**33**

Following is an explanation of scoring for each life-cycle category:

Design and Construction Period:

The three options have close risk levels pertaining to the design and construction period. The risk of over or under designing the required facilities is quite low for all options primarily due to the requirements being low complexity. This is also true for overall constructability. Regarding tendering, the potential risk of there being insufficient interest in the project is again low as most consultants and contractors should have adequate capability to provide design and construction requirements. The risk level does differ between options when considering the complexity of processes. This is due primarily to the asset transfer back to NEWCO after twenty years if an ISP is owner, which can significantly increase time for contractual negotiations compared to a more standard arrangement. This option does, however, provide the lowest overall risk to NEWCO during the construction phase. Although permitting risk is not likely to be any different, the risks associated with scope and scheduling are lower where an ISP is owner. As the ISP is ultimately responsible for most construction risks, NEWCO will be effectively sheltered from this risk. Although there is possibly increased risk from a breach of terms and conditions by an ISP as an owner and/or operator, the fact that the project represents a longer term project with larger cash flows effectively makes it less likely that an ISP would default or breach contract than would a contractor in a design-build option with less at stake.

Operations and Transfer Period:

During the operating stage, the most significant period in the life cycle, the options where ISP is operator provide a lower risk exposure for NEWCO. The operating risk is primarily attributable to the entity responsible for operating the logging and feedstock operations. With NEWCO as operator, the lack of experience in these areas represents a high risk. The risk of electricity demand is low regardless of who is the owner. However, the severity of this risk will be greater where the ISP is operator as there is likely to be some form of contractual guarantee by NEWCO such as a take-or-pay agreement. This is not likely to be high however, due to the ability to keep workers active and stockpile feedstock if necessary. Other areas where an ISP operator provides a greater risk to NEWCO is the possibility, although small, that an ISP could default and/or breach the terms and conditions of the operating agreement. Although the operating agreement would most certainly contain recourse protection if a default or breach were to occur, the problems and lost time by key NEWCO personnel could be significant. Accordingly, this risk is likely to have serious impact if it were to occur.

Where the ISP is owner, it is assumed that the asset will be transferred back to NEWCO at fair market value (assumed net book value) after twenty years of operations. Due to potential, inaction, or uncontrollable market conditions, the eventual fair market value is likely to be different from predicted. The probability of this occurring is high, however the impact is considered only moderate at worst, especially if taking into consideration the impact in today's dollars. The condition of the asset at transfer is also highly dependent on the capital renewal

and maintenance plan of the ISP. The greater influence that NEWCO has over these areas, the more likely the asset condition will maintain a higher value. Therefore, where the ISP is owner (and NEWCO has least control) the risk will be greatest.

4.2.1.2 Biomass Plant Analysis

The total risk scores for the biomass plant operations are:

Table 4.5 Risk Summary – Biomass Plant

	NEWCO Owns/ NEWCO Operates	NEWCO Owns/ ISP Operates	ISP Owns/ ISP Operates
Design and Construction Period	24	24	15
Operations and Transfer Period	13	12	20
Total Risk Score	**37**	**36**	**35**

With the lower score reflecting lowest risk, Option 3 is the lowest risk for the biomass plant. The following table shows the detailed scoring for the logging and feedstock ownership and operations options followed by a short narrative of the scoring rationale for each criterion.

Table 4.6 Risk Assessment – Biomass Plant

BIOMASS PLANT RISK ASSESSMENT *(Low -1 , Medium - 2 , High - 3)*	OPTIONS								
	NEWCO / NEWCO			NEWCO / ISP			ISP / ISP		
	Prob-ability	Sever-ity	Risk	Prob-ability	Sever-ity	Risk	Prob-ability	Sever-ity	Risk
DESIGN & CONSTRUCTION PERIOD									
Under or over designed (changes required to meet performance criteria or capex higher than necessary)	2	3	**6**	2	2	**4**	1	1	**1**
Constructability	2	2	**4**	2	2	**4**	1	1	**1**
Insufficient interest in RFP to stimulate competitive forces	2	3	**6**	2	3	**6**	1	3	**3**
Complexity of processes leading to increased time and cost	1	2	**2**	2	2	**4**	3	2	**6**
Permit/zoning risks	1	1	**1**	1	1	**1**	2	1	**2**
Scope / schedule creep	2	2	**4**	2	2	**4**	1	1	**1**
Default/breach of T&C's by consultants/contractors	1	1	**1**	1	1	**1**	1	1	**1**
Average Score			**24**			**24**			**15**
OPERATIONS & TRANSFER PERIOD									
Operational reliability standards not met	2	2	**4**	1	2	**2**	1	2	**2**
Operating cost variances	2	2	**4**	1	2	**2**	1	2	**2**
Electricity demand risk	1	1	**1**	1	2	**2**	1	2	**2**
Energy cost (feedstock) variation	1	1	**1**	1	1	**1**	1	1	**1**
Default/breach of T&C's by operator	1	1	**1**	1	3	**3**	1	3	**3**
Required maintenance not performed, diminishing value of asset	1	1	**1**	1	1	**1**	2	2	**4**
Market conditions change, increasing market value of the assets	1	1	**1**	1	1	**1**	3	2	**6**
Average Score			**13**			**12**			**20**
TOTAL RISK SCORE (**Lower** is better)			**37**			**36**			**35**

Following is an explanation of the scoring for each life-cycle category:

Design and Construction Period:

The options where NEWCO is owner has a considerably higher risk level than does the ISP as owner option. This is primarily attributable to NEWCO having minimal knowledge and experience related to biomass generation systems. Although Yukon Energy has generation expertise, they do not have specific biomass experience. This fact impacts the risk that the project is over or under designed and constructability of the project. It is also quite likely that risk pertaining to insufficient interest in the RFP tender will be higher where NEWCO is operator. Where an ISP is owner, the project represents a longer term project with larger cash flows making it more attractive. Where the risk level is higher for an ISP owned project is regarding the complexity of processes, due primarily to the asset transfer back to NEWCO after twenty years. This can significantly increase the time required and complexity of contractual negotiations compared to a more standard arrangement. Where the risk associated with scope and scheduling is concerned, the ISP owned project is much less risky due to the ISP having the responsibility for most construction risks. There is however the possibly with an ISP operated project that they breach some terms and conditions. However, as the project is of a longer term nature, and with larger overall cash flows (as owner and operator), it is less likely that an ISP would default or breach contract.

Operations and Transfer Period:

Converse to the design and construction period, the option where ISP owns the biomass plant is riskier than where NEWCO is owner. This is largely a result of the requirement for the plant to be transferred back to NEWCO after twenty years, and the uncertainty regarding the condition and value of the asset at that time. Potential, action or inaction, or uncontrollable market conditions, can cause the eventual fair market value of the plant to be different from predicted. The probability of this occurring is high, however the impact is considered only moderate especially considering the impact in today's dollars. With the condition of the asset at year twenty being highly dependent on capital renewal and maintenance of the plant, the more control NEWCO has over these areas, the more likely the asset condition will maintain a higher value, making an ISP owned project riskier than a NEWCO owned project. Other areas where an ISP owner/operator provides a greater risk to NEWCO is regarding a potential default and/or breach of the terms and conditions of the operating/transfer agreements. Although the agreements would most certainly contain recourse protection for NEWCO, a default or breach could still create problems and lost time by key NEWCO personnel.

The option where the ISP is the operator does provide a lower risk exposure for NEWCO where operational reliability and cost variances are concerned attributed to the ISP greater knowledge and experience with biomass systems. The risk of electricity demand is low regardless of who the owners is, due mainly to the small size of generation output. However, the severity of this

risk will be greater where the ISP is operator as there is likely to be some form of contractual guarantee by NEWCO such as a take-or-pay agreement.

4.2.2 Risk Analysis Summary

The following table combines the three feedstock yard/logging and three biomass plant risk scores into a summary of the six possible options considered for these operations and ranks each option in terms of lowest risk.

Table 4.7 Risk Summary

	Feedstock Yard/Logging		Biomass Plant			
	Owner	Operator	Owner	Operator	TOTAL	RANKING
Option 1	NEWCO	CAFN	NEWCO	NEWCO		5
Risk Score	32		37		69	
Option 2	NEWCO	ISP	NEWCO	NEWCO		2
Risk Score	29		37		66	
Option 3	NEWCO	CAFN	NEWCO	ISP		4
Risk Score	32		36		68	
Option 4	NEWCO	ISP	NEWCO	ISP		1
Risk Score	29		36		65	
Option 5	ISP	ISP	NEWCO	NEWCO		6
Risk Score	33		37		70	
Option 6	NEWCO	CAFN	ISP	ISP		3
Risk Score	32		35		67	

Based on the analysis, Option 4 has the lowest risk profile. This option combines the benefits of NEWCO ownership control with the ISP industry specific operational expertise. Following very closely is Option 2, which substitutes NEWCO as operator for the biomass plant.

The deviation in scoring between the lowest and highest scores is five points (roughly 7%) suggesting that the risk profile deviation is not significant. Because of this, decision-making should be based on two criteria:

- Criteria 1 - The ability to control/mitigate the risks.
- Criteria 2 - The scale of the operation (0.5 MW versus 2.0 MW).

Referring back to the risk score summary previously provided in Table 1, it is clear that the risk profiles for NEWCO versus ISP as operator differ greatly between the design and construction and the operations and transfer periods. Where NEWCO is operator the greatest risk is during

the design and construction stages while with an ISP as operator the greatest risk is during the latter (and longer) operations and transfer stages. The greatest risks for NEWCO in the design and construction stage are the unfamiliarity with both the feedstock yard/logging and biomass requirements whereas the greatest risks where an ISP is operator are primarily due to not having control over operations. Much of the design and construction risk can be effectively mitigated by contracting the project and construction management to consultants with specific expertise. However, countering this is the increase in operations risk, which occurs as the scale of the operations increase. For example, with a smaller scale 0.5 MW operation the risks of NEWCO operating the plant is relatively low whereas for a larger scale 2.0 MW plant this risk is much higher. For the feedstock yard and logging operations, where NEWCO has no experience, the risk is high regardless of the plant size.

4.2.3 Financial and Operational Analysis

The qualitative financial and operations analysis used has been developed as a complimentary extension of the risk analysis to highlight NEWCO/CAFN and ISP specific strengths or weaknesses in knowledge and experience that are important to both the feedstock yard/logging operations and the biomass plant operations. The analysis is

Scoring:

The financial and operations criteria are scored using a simple scale from 1 to 3 as follows:

1 = *Low* level of knowledge and/or experience.

2 = *Medium* level of knowledge and/or experience.

3 = *High* level of knowledge and/or experience.

A separate evaluation was done for both the feedstock yard/logging operations and for the biomass plant operations due to the distinctive nature of each. Both evaluations used the same seven criteria as follows:

- Design and construction experience.
- Operations and maintenance experience.
- Industry and regulatory experience.
- Environmental and sustainability experience.
- Access to experienced labor.
- Administrative requirements (impact on NEWCO).

- Management and control (impact on NEWCO).

4.2.3.1 Feedstock Yard/Logging Analysis

The total qualitative financial and operations score for the feedstock yard/logging operations are:

Table 4.8 Financial and Operations Analysis – Feedstock Yard/Logging

FEEDSTOCK YARD / LOGGING FINANCIAL AND OPERATIONS ANALYSIS	OPTIONS Score (Low -1 , Medium - 2 , High - 3)		
	NEWCO / CAFN	NEWCO / ISP	ISP / ISP
Design and construction experience	1	2	3
Operations and maintenance experience	1	3	3
Industry/regulatory experience	2	3	3
Environmental/sustainability experience	1	3	3
Access to experienced labor	1	3	3
Administrative requirements (to NEWCO)	3	2	1
Management and control (to NEWCO)	3	2	1
TOTAL SCORE (**Higher** is better)	**12**	**18**	**17**

Following is an explanation of the scoring for each criterion:

Design and Construction Experience:

Design and construction of the feedstock yard/logging is an area where a slight advantage is held by the ISP due to their significant knowledge and experience specific to the industry. Although NEWCO will procure the design and construction from outside sources, they will still be required to ultimately oversee and approve design and construction. Where the ISP is operator but not owner, there could be benefit with them providing their experience as part of the design stage, but likely not during construction.

Operations and Maintenance Experience:

The ISP, with specific industry knowledge and experience will have a very significant advantage over NEWCO/CAFN who has minimal knowledge and experience in logging and biomass feedstock operations.

Industry Regulatory Experience:

The ISP, with specific industry knowledge and experience will have a significant advantage over NEWCO/CAFN who has minimal knowledge and experience in regulations pertaining to logging.

Experience in Environmental/Sustainability:

The ISP, with specific industry knowledge and experience will have a significant advantage over NEWCO/CAFN who have very minimal knowledge and experience in environmental and sustainability matters related to logging. Knowledge and experience in environmental and sustainability matters is fast becoming a critical requirement for businesses of all types.

Access to Experienced Labor:

The ISP, due to their presence in the feedstock yard/logging industry will also have good access to experienced labor while it is very unlikely that NEWCO/CAFN will have access to this type of skilled labor. Having access to skilled operators and maintenance staff is critical to reliability and efficient operations of the logging and feedstock operations. An advantage for a large ISP will be access to their own overall labor pool which may be deeper and more specialized. This provides added assurance where training, specialization and emergency staff replacement requirements are concerned.

Lower Administrative requirements (to NEWCO)

A disadvantage to outsourcing operations to an ISP is the increased administration burden required to oversee initial negotiations and the ongoing management of the contractual terms and conditions and the general relationship with the ISP. For the NEWCO owns and CAFN operates option there is minimal partnering so this is not a big issue. Where NEWCO owns and an ISP operates there is added administration for the ISP operating agreement. Where the ISP both owns and operates the transfer of assets back to NEWCO will require the most administrative resources for NEWCO.

Management and Control (to NEWCO):

The more ownership and responsibility for operations that NEWCO undertakes, the more management and control they will have. For the ISP own and operate option, NEWCO has little or no control over the physical assets and operations, however they do have contractual control inherent in the terms and conditions of the operations and transfer back agreements.

4.2.4 Biomass Plant Analysis

The total qualitative financial and operations score for the biomass plant operations are:

Table 4.9 Financial and Operations Analysis– Biomass Plant

BIOMASS PLANT FINANCIAL AND OPERTIONS ANALYSIS	OPTIONS		
	Score (Low -1 , Medium - 2 , High - 3)		
	NEWCO / CAFN	NEWCO / ISP	ISP / ISP
Design and construction experience	1	2	3
Operations and maintenance experience	1	2	3
Energy industry/regulatory experience	2	3	3
Environmental/sustainability experience	2	3	3
Access to experienced labor	1	2	3
Administrative requirements (to NEWCO)	3	2	1
Management and control (to NEWCO)	3	2	1
TOTAL SCORE (**Higher** is better)	13	16	17

Following is an explanation of the scoring for each criterion:

Design and Construction Experience:

Design and construction of the biomass plant is an area where a slight advantage is held by the ISP due to their significant knowledge and experience specific to the biomass industry. Although NEWCO has generation experience and will procure the design and construction from outside sources, they will still be required to ultimately oversee and approve design and construction. In the option where NEWCO owns and an ISP operates there could be some benefit with an ISP providing their experience as part of the design stage, but likely not during construction. Under Option 3, an ISP who has designed and constructed numerous biomass plant systems to satisfy many different requirements undoubtedly will have greater advantage and can be relied on to "get it right" with little to no risk.

Operations and Maintenance Experience:

NEWCO has good in-house capabilities via Yukon Energy but biomass systems would be new to the existing team. An ISP will draw on their significant capabilities to provide greater knowledge, innovation and solutions to problems that may arise.

Energy Industry/Regulatory Experience:

NEWCO has no energy and regulatory experience but is assisted by having Yukon Energy as a partner. The option where an ISP partners with NEWCO adds additional experience. Finally, an ISP, with specific biomass knowledge and experience is best equipped in specific biomass matters.

Experience in Environmental/Sustainability:

Knowledge and experience in environmental and sustainability matters has become a critical requirement for businesses of all types. In the utilities sector, an ISP brings the breadth and depth of knowledge and experience in these areas that NEWCO has only by way of the partnership with Yukon Energy. Adding the ISP experience to NEWCO would provide a similar level of expertise as an ISP can offer in these important areas.

Access to Experienced Labor:

Having access to skilled operators and maintenance staff is critical to reliability and efficient operations of utility systems. NEWCO has a well-trained staff via Yukon Energy. An advantage for an ISP will be their access to their own overall labor pool which may be deeper and more specialized, especially with biomass systems. This provides added assurance where training, specialization and emergency staff replacement requirements are concerned.

Lower Administrative Requirements (to NEWCO):

A disadvantage to outsourcing operations to an ISP is the increased administration burden required to oversee initial negotiations and the ongoing management of the contractual terms and conditions and the general relationship with the ISP. For the NEWCO owns and CAFN operates option there is minimal partnering so this is not a big issue. Where NEWCO owns and an ISP operates there is added administration for the ISP operating agreement. Where the ISP both owns and operates the transfer of assets back to NEWCO will require the most administrative resources for NEWCO.

Management and Control (to NSUH):

The more ownership and responsibility for operations that NEWCO undertakes, the more management and control they will have. For the ISP own and operate option, NEWCO has little or no control over the physical assets and operations, however they do have contractual control inherent in the terms and conditions of the operations and transfer back agreements.

Financial and Operations Analysis Summary:

The following table combines the three feedstock yard/logging and three biomass plant financial and operations analysis scores into a summary of the six possible options considered for these operations and ranks each option in terms of lowest risk.

Table 4.10 Financial and Operations Summary

	Feedstock Yard/Logging		Biomass Plant			
	Owner	Operator	Owner	Operator	TOTAL	RANKING
Option 1	NEWCO	CAFN	NEWCO	NEWCO		6
Score	12		13		25	
Option 2	NEWCO	ISP	NEWCO	NEWCO		2
Score	18		13		31	
Option 3	NEWCO	CAFN	NEWCO	ISP		5
Score	12		16		28	
Option 4	NEWCO	ISP	NEWCO	ISP		1
Score	18		16		34	
Option 5	ISP	ISP	NEWCO	NEWCO		3
Score	17		13		30	
Option 6	NEWCO	CAFN	ISP	ISP		4
Score	12		17		29	

Similar to the risk analysis, Option 4 places highest with Option 2 again being second. This is a confirmation of the importance of having industry experience specific to the feedstock yard/logging and biomass industries. Overall the deviation in scoring between the lowest and highest scores is ten points (roughly 29%) indicating that the industry experience is very critical to success. The difference between Option 4 and Option 2 is a much lower three points (8%) which indicates that NEWCO operating the biomass plant is less critical than having an ISP operate the feedstock yard/logging operations. This is logical as NEWCO has power generation knowledge, which, although not biomass specific, is at least beneficial where a smaller 0.5 MW operation is concerned, but would be less so where the plant size increases to 2.0 MW.

4.2.5 Summary of Analyses

Option 4 (NEWCO owns/ISP operates) ranks first in both the risk analysis (Table 5) and the financial and operations analysis (Table 8). However, following closely is Option 2 where NEWCO operates the plant. This is especially applicable where a smaller 0.5 MW plant is concerned.

The risk and financial and operations analysis demonstrates that “control”, “experience” and “scale” have the greatest impacts on risk and ultimately project success. NEWCO benefits greatly where they have most control over operations. However, total control also comes at the expense of not having the benefit of the ISP industry experience. Option 4 provides a trade-off where the lack of experience is addressed via an ISP. However, if the operation will be a smaller scale 0.5 MW plant, the benefit of an ISP operating the plant will not be as great, meaning that NEWCO should be able to operate the plant without much risk.

4.2.6 Conclusion

Applying this analysis to the size and scale of the biomass operation, the following ownership and operations models are the most appropriate for a smaller (0.5 MW) and larger (2.0 MW) plant operation.

Table 4.11 Recommended Owner/Operator Model

	Feedstock Yard/Logging		Biomass Plant	
Plant Size	**Owner**	**Operator**	**Owner**	**Operator**
0.5 MW	NEWCO	ISP	NEWCO	NEWCO
2.0 MW	NEWCO	ISP	NEWCO	ISP

As stated in the assumptions earlier in the report, where the ISP is the operator, the intention would be to increasingly employ workers from CAFN and provide training over a set period of time (i.e. 20 years).

4.3 FINANCIAL ANALYSIS

Using the preliminary engineering designs, financial analyses were prepared to determine the financial viability of the various installation scenarios. The results of these analyses are presented and explained in the following tables and charts.

It is important to note that the financial analyses do not currently include the capital cost for the district heating network. The capital cost for the installation of the network has been assumed to be covered under a separate project to be completed in conjunction with the biomass plant. The financial analyses do account for the O&M and revenue from operating the biomass plant in conjunction with the network (i.e., selling heat through the network)

The financial analyses were performed on multiple scenarios based on biomass plant size, building architecture, and vendors. Although only four options have been outlined in previous sections, ten different options were investigated for the financial analyses. Options #1 through #6 are all based on the technology offered by Community Power Corporation using the

preliminary engineering parameters discussed previously. The details of Options #1 through #6 are detailed below:

- Option #1 – Full Building Enclosure – 500 kW_e (Community Power Corp.).
- Option #2 – Full Architectural Enclosure – 500 kW_e (Community Power Corp.).
- Option #3 – Fuel Handling Enclosed – 500 kW_e (Community Power Corp.).
- Option #4 – Options for Expansion – 1 MW_e (Community Power Corp.).
- Option #5 – Options for Expansion – 2 MW_e (Community Power Corp.).
- Option #6 – Options for Expansion – 3 MW_e (Community Power Corp.).

Due to the savings in capital costs, the equipment provided by Proton Power was also analyzed, as described in Options #7 through #10 below. Options #7 through #10 are based on the replacing the CPC equipment with that provided by Proton Power. It should be noted that Proton Power has indicated it has the ability to provide containerized systems, but has not completed a project using this format to date (see Figure 4.1).

- Option #7 – Full Building Enclosure – 500 kW_e (Proton Power).
- Option #8 – Full Architectural Enclosure – 500 kW_e (Proton Power).
- Option #9 – Fuel Handling Enclosed – 500 kW_e (Proton Power).
- Option #10 – Options for Expansion – 2 MW_e (Proton Power).

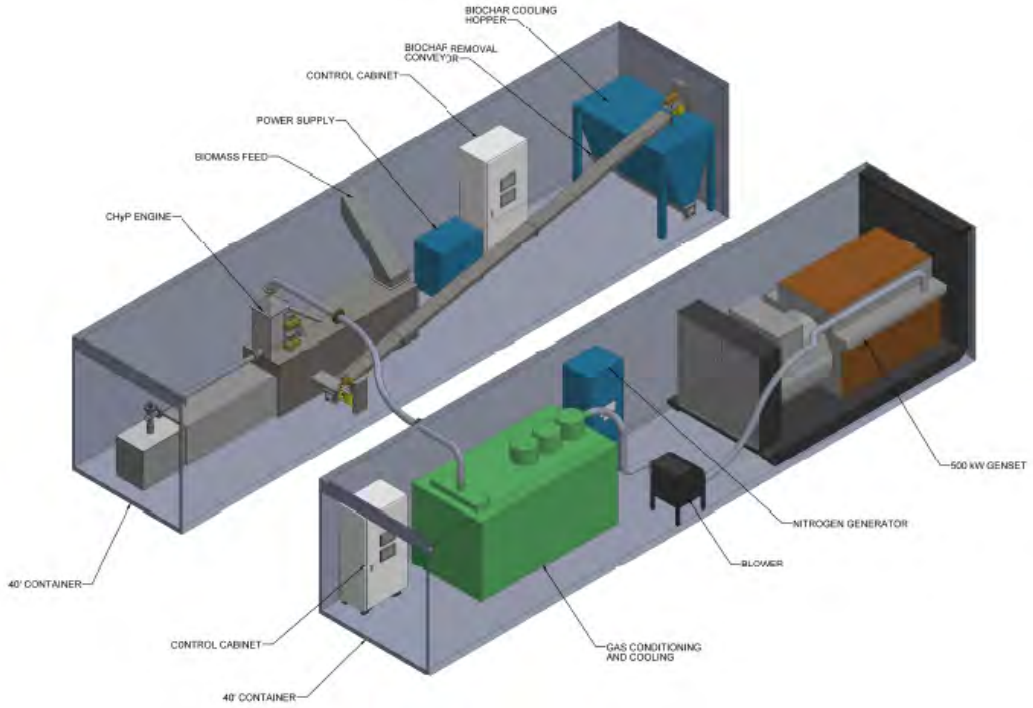

Figure 4.1 Potential Proton Power Containerized 500 kW_e Units

The primary difference between the inputs associated with CPC (Table 4.12) and those associated with Proton Power (Table 4.13) are the equipment costs and capacity factors (CPC has an 80% factor, Proton 92.5%). All other inputs remain the same, though in reality some variances may occur regarding the O&M costs.

Table 4.12 Financial Inputs: Options #1 - #6

Item	Option #1 500 kW_e	Option #2 500 kW_e	Option #3 500 kW_e	Option #4 1000 kW_e	Option #5 2000 kW_e	Option #6 3000 kW_e
CAPEX ($ Million)	$12.7	$13.5	$11.4	$22.5	$45.0	$67.5
Annual Fuel Consumption (ODT/yr)	3,000	3,000	3,000	6,000	12,000	18,000
Power (MWh/yr)	3,500	3,500	3,500	7,000	14,000	21,000
OPEX ($)	$285,000	$285,000	$285,000	$400,000	$630,000	$800,000

Table 4.13 Financial Inputs: Options #7 - #10

Item	Option #7 500 kW_e	Option #8 500 kW_e	Option #9 500 kW_e	Option #10 2000 kW_e
CAPEX ($ Million)	$8.5	$9.2	$7.3	$26.6
Annual Fuel Consumption (ODT/yr)	3,472	3,472	3,472	13,888
Power (MWh/yr)	4,052	4,052	4,052	16,208
OPEX ($)	$285,000	$285,000	$285,000	$630,000

In order to complete the financial analysis, several financial parameters needed to be defined. The financial assumptions outlined in Table 4.14 were employed to support this study. Assumptions for amortization, tax rate, and escalation are made on a consistent basis for all scenarios to facilitate comparison (Table 4.14). NEWCO's discount rate and electricity purchase price were assumed for the study.

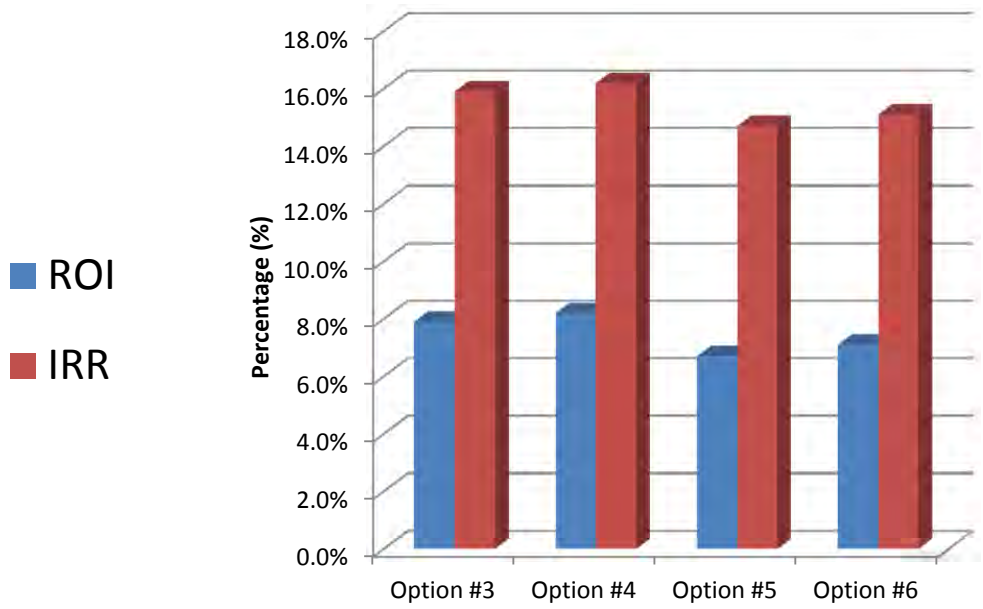
Using the base financial assumption, none of the ten (10) options proves viable. Each has ROE/ROI/NPVs that are negative. The main opportunity explored to make the options viable was to add a capital subsidy with could be achieve through funding grants. The amount of capital subsidy was taken as a percentage of total project costs to conduct this sensitivity.

Table 4.14 Financial Assumptions

Financial Assumptions			
Amortization:	Declining Balance:	20	Years
	Plant:	50.0	% (w/accelerated CCA class 43.2)
	Buildings:	4.0	% (w/CCA class 1)
	Equipment:	30.0	% (w/CCA class 43)
Capital Renewal Annual Rate:	Plant:	4.0	%
	Buildings:	2.0	%
	Equipment:	6.0	%
Weighted Average Cost of Capital:	WACC:	8	%
Inflation:	Annual Escalation:	3.0	%
	Feedstock Inflation Rate:	1.0	%
Equity:	NEWCO:	30	%
Long Term Debt :	Interest Rate :	5	%
Capital Subsidy (as % of Total Project):			
	Funding Low:	0	%
	Funding High:	80	%
Base Fuel Pricing:			
	Biomass:	Omitted	$/GMT
Biomass Power Sale Price:			
	Base:	$200	$/MWh
Biomass Heat Sale Price :			
	Base:	$185	$/MWh

The results of the financial analysis are provided in Table 4.15 in graphical and tabular form. The values of ROI and IRR were estimated using an assumed feedstock price of $50/GMT, 80% capital subsidy and an electricity selling price of $0.20/kWh, for a select number of options.

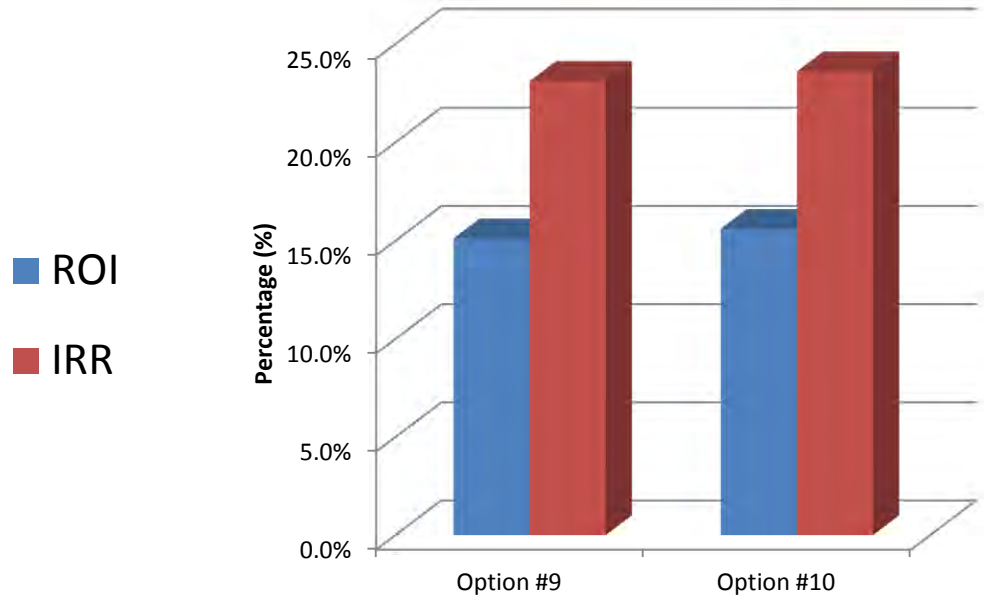
Table 4.15 Biomass Plant Return on Investment Performance: CPC



500 kW_e	**Item**	**Option #3 – 500 kW_e Fuel Enclosed $50/GMT, $200/MWh, 80% Capital Subsidy**
	Return on Investment (ROI)	7.9%
	Internal Rate of Return (IRR)	15.9%
1.0 MW_e	**Item**	**Option #4 - 1 MW_e Fully Enclosed $50/GMT, $200/MWh, 80% Capital Subsidy**
	Return on Investment (ROI)	8.2%
	Internal Rate of Return (IRR)	16.2%
2.0 MW_e	**Item**	**Option #5 - 2 MW_e Fully Enclosed $50/GMT, $200/MWh, 80% Capital Subsidy**
	Return on Investment (ROI)	6.7%
	Internal Rate of Return (IRR)	14.7%
3.0 MW_e	**Item**	**Option #6 - 3 MW_e Fully Enclosed $50/GMT, $200/MWh, 80% Capital Subsidy**
	Return on Investment (ROI)	7.1%
	Internal Rate of Return (IRR)	15.1%

Similar to the CPC ROI performance, the Proton Power could also reach positive ROIs with capital subsidy, although require significantly less due to their lower capital cost (note that only the 2 MW_e system was investigated for Proton Power and not 1 MW_e or 3 MW_e).

Table 4.16 Biomass Plant Return on Investment Performance: Proton Power



500 kW_e	**Item**	**Option #9 – 500 kW_e Fuel Enclosed $50/GMT, $200/MWh, 67% Capital Subsidy**
	Return on Investment (ROI)	15.1%
	Internal Rate of Return (IRR)	23.1%
2.0 MW_e	**Item**	**Option #10 – 2000 kW_e Fuel Enclosed $50/GMT, $200/MWh, 67% Capital Subsidy**
	Return on Investment (ROI)	15.6%
	Internal Rate of Return (IRR)	23.6%

As seen in the following two figures (Figures 4.2 and 4.3), the most viable options from each vendor in terms of ROE at the 0.5 MW_e capacity are CPC's Option #3 and Proton's Option #9. These refer to the plants with only fuel enclosure which have the lowest capital cost for this capacity. Therefore, the sensitivity analyses will only concentrate on these two options as book ends for project viability.

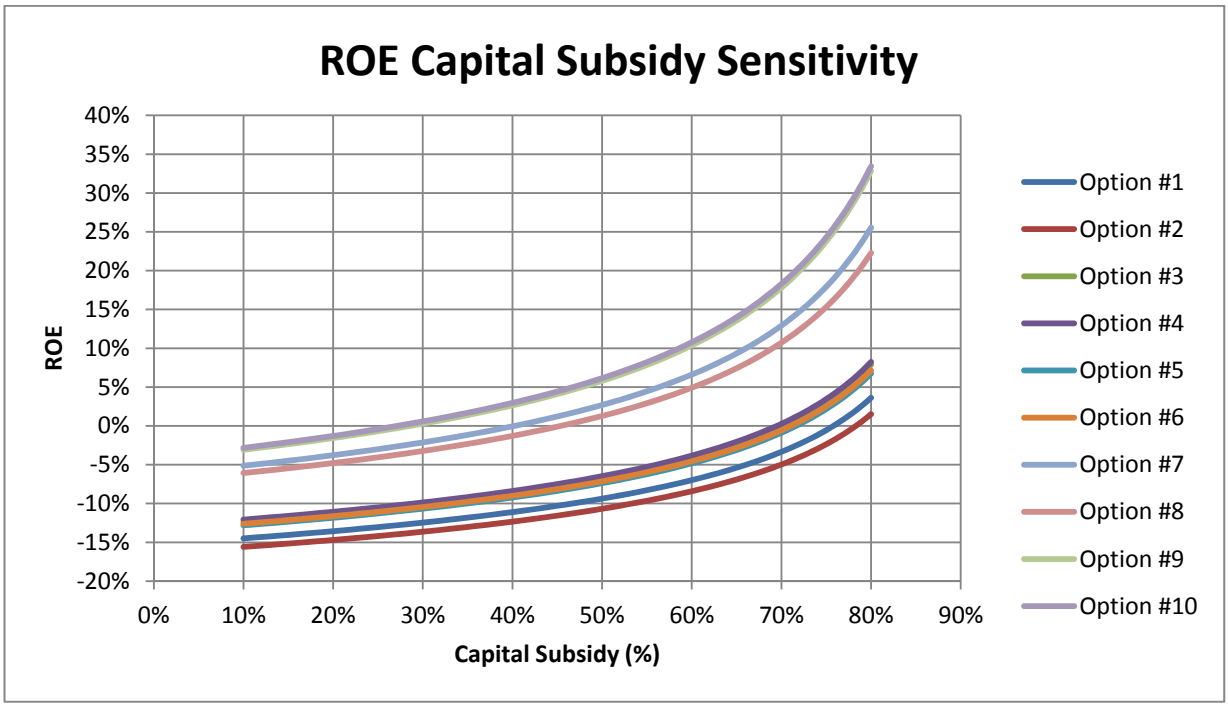


Figure 4.2 ROE Capital Subsidy Sensitivity

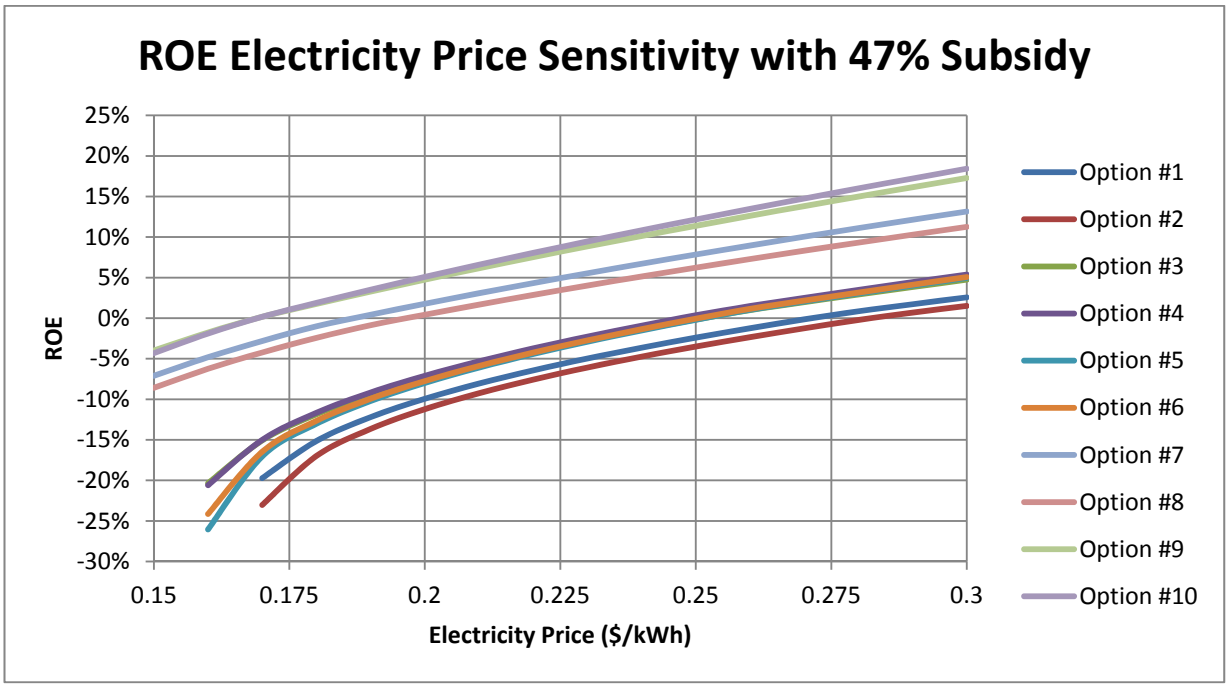

Figure 4.3 ROE Electricity Price Sensitivity

The previous figures also indicate the level of capital subsidy and/or electricity sale price required to achieve a desired ROE of 15%. In Figure 4.2, each option has no capital subsidy, and each option shows its lack of an ROE. As subsidies are increased, the Proton Power options pass over the 0% ROE mark with 30-40%subsidy, and achieve a 15% ROE at 67% for Option #9 and #10. The CPC options only start into positive ROE territory beyond the 70% subsidy mark.

In Figure 4.3, a combination of capital subsidy and increase in electricity sale price are considered to achieve a 15% ROE. The curves are based on the project achieving a 47% capital subsidy, and highlighting the impact of increasing the electricity sale price. For the best case scenario with Proton Power's Option #9, the electricity sale price would have to increase from $200/MWh to $280/MWh, to achieve the 15% ROE. For CPC, the project would only achieve a 5% ROE with 47% subsidy and a $300/MWh sale price.

4.3.1 Sensitivity Analyses

Four (4) additional variables affecting the success of biomass plant are fuel costs, O&M costs, district heating sales, and the district heating sale price. In order to understand the impact of these four (4) variables on the successful outcome of the installation, a range for each was considered and plotted based on impact to ROI and NPV. Each sensitivity analysis is presented in the following sub-section by variable, for each vendor.

4.3.1.1 Feedstock Price

For the two cases with fuel enclosures, Figure 4.4 was prepared to highlight the ROI and NPV for fuel costs from $50/GMT to $175/GMT. Fuel costs are market driven and subject to change outside the control of the facility design.

Similar to capital subsidy and electricity pricing, the project viability is strongly related to the feedstock pricing. Although there is no feedstock price that helps any option achieve a better financial viability, an increase to feedstock prices higher than would be available from existing operations (low end of the sensitivity, $50/GMT) would be detrimental to any gains from capital subsidy – doubling feedstock cost reduces ROE of Proton Power by half, to 7.5%.

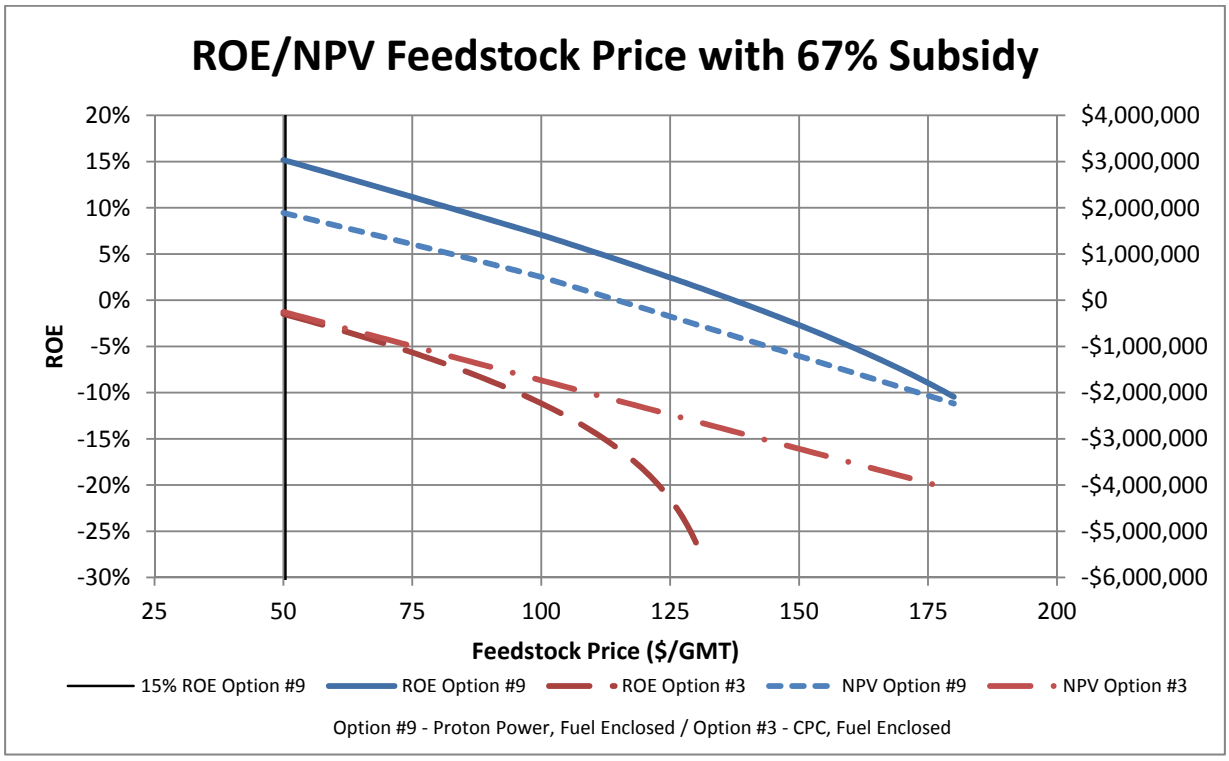

Figure 4.4 ROE/NPV Feedstock Price Sensitivity

4.3.1.2 Other Variables

For the two cases with fuel enclosures, Figure 4.5, 4.6, and 4.7 were prepared to highlight the ROI and NPV for plant O&M costs from $125,000 to $500,000 annually, district heating sales from 1,000 to 2,000 MWh annually, and district heating sale price from $110 to $250 / MWh. This variable are subject to change based on the facility/network design and vendor selected. The O&M costs in Figure 4.5 focuses on O&M specific to operating the biomass gasification system, O&M for the DH network and ORC are not considered.

Variations in O&M costs will affect the project's ROE by approximately 2.5% for every $50,000 annual. Similarly, an increase in DH sales by 500 MWh per year would increase the ROE by 2.5%. As the DH network is only projected to sell 1280 MWh/year, and the gasifier rejects over 5,000 MWh/year, the opportunity exists to expand the network in the future for increased sales.

The DH sale price in Figure 4.7 shows the impact of a variation in the sale price for 1,280 MWh per year. Currently valued based on the CTCG report at $185/MWh, this price will likely need to be indexed based on diesel fuel prices when the project is implemented. Current price offers a 2% savings over diesel.

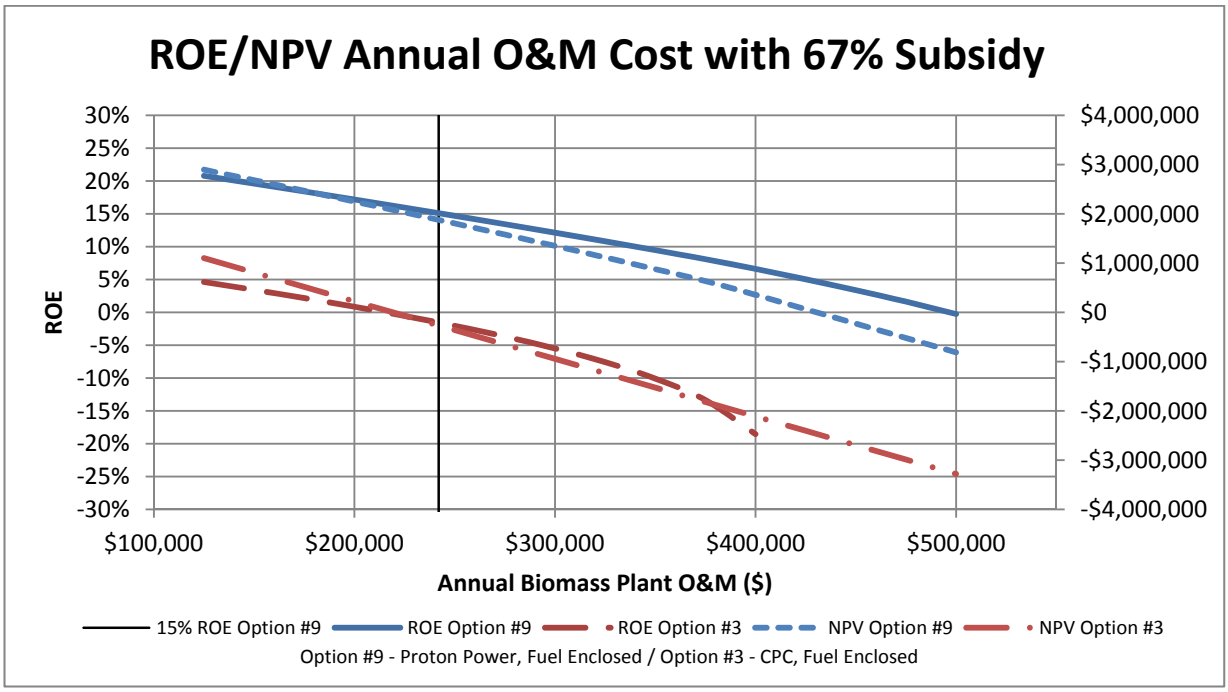

Figure 4.5 ROE/NPV Annual Plant O&M Price Sensitivity

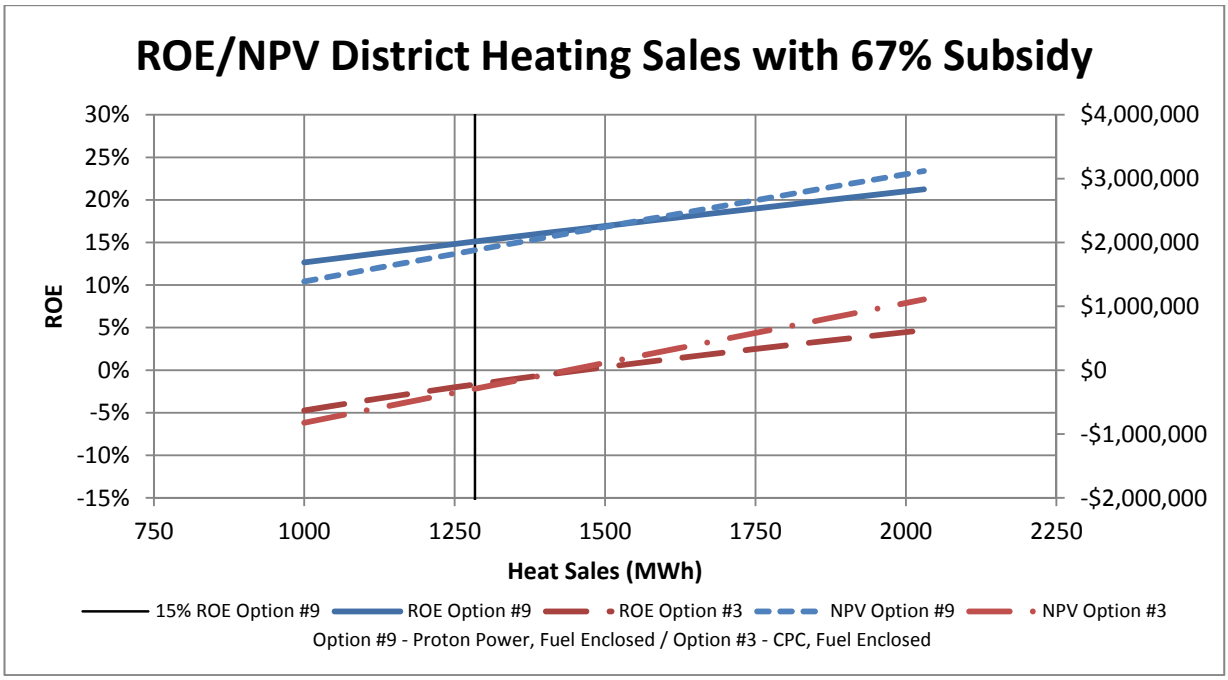

Figure 4.6 ROE/NPV District Heating Sales Sensitivity

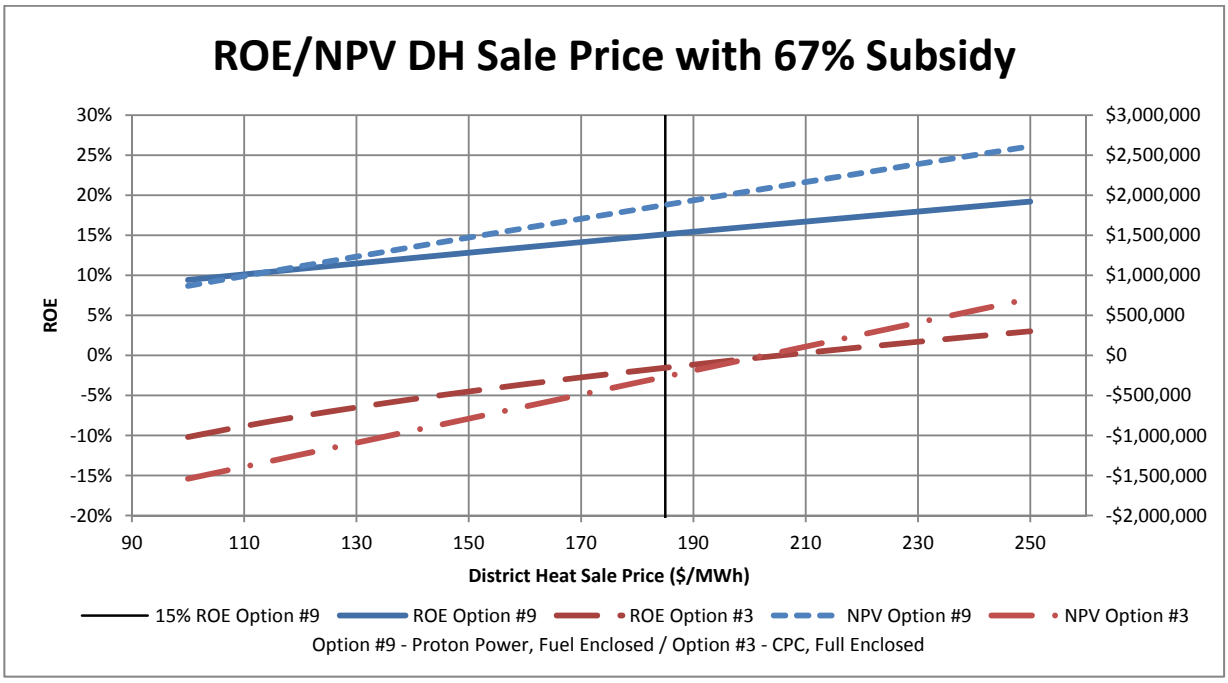

Figure 4.7 ROE/NPV District Heating Sale Price Sensitivity

4.3.1.3 Tornado Diagram

The figure on the following displays the impact of these key variables in a different manner. Figure 4.8 shows the results of independently adjusting the seven (7) key variables by ± 20% on the project ROE. The centerline of the graph represents the 15% ROE set point for Option #9 with 67% subsidy, while each bar is indicative of the positive or negative change in ROE resulting from a ± 20% change in a given variable. Table 4.17 shows the corresponding change in NPV for each variable as well as the specific ROE percentage. The variables are arranged from the most significant to the least significant based on the magnitude of their impact.

It is evident from Figure 4.8 that the most significant variable on the success of the project is the amount of capital subsidy provided, followed by electricity price potential, both discussed previously. Following these two factors, by decreasing influence, are project capital cost, plant O&M cost, district heat sale price, district heat annual sales and feedstock price.

The results of this analysis suggest that during the next level of study it will be vital to secure capital subsidies and or increases to the electricity sale price, as these are the greatest deciding factors in the outcome of the project. Further project definition through engineering can aid in acquiring a definitive value for capital and operating costs, as well as support firming up the DH system design and waste heat sale potential.

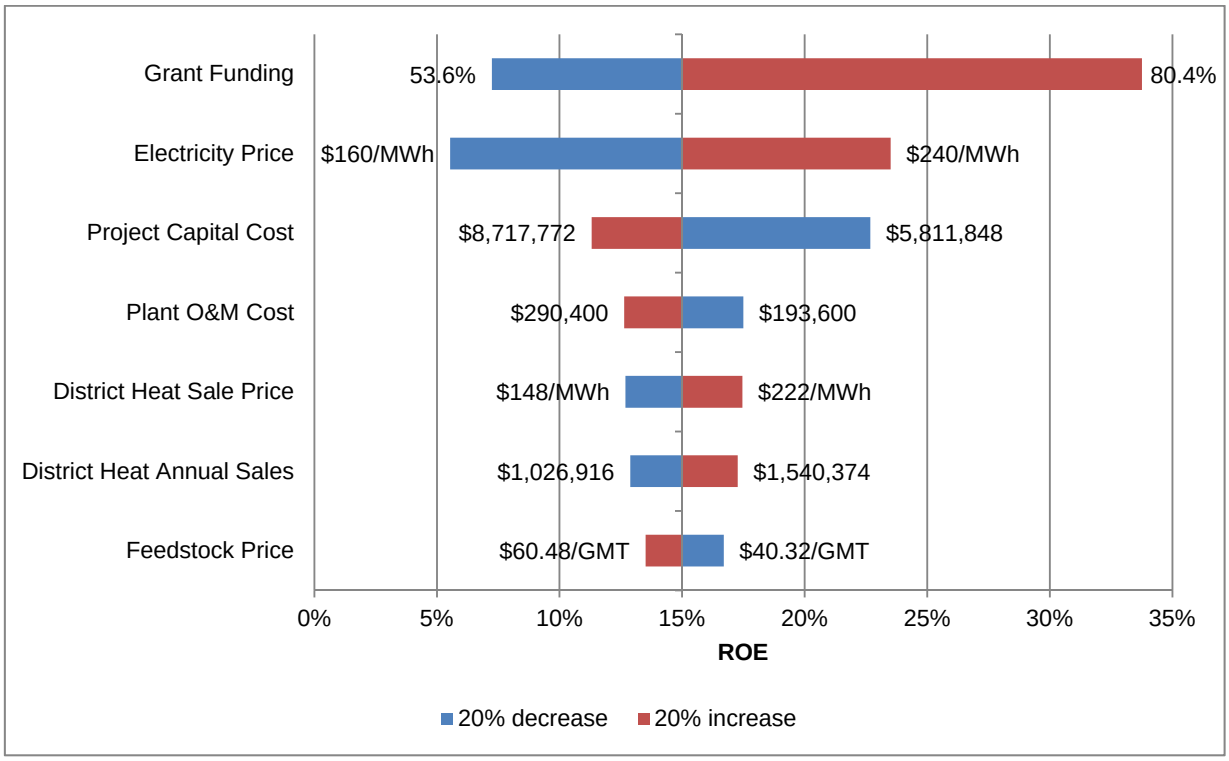

Figure 4.8 ROE/NPV District Heating Sale Price Sensitivity

Table 4.17 Tornado Diagram Results

	Variation	ROE	NPV
Grant Funding	+20%	33.76%	$2,804,710
	-20%	7.24%	$953,761
Electricity Price	+20%	23.51%	$3,233,005
	-20%	5.54%	$309,701
Project Capital Cost	+20%	11.31%	$1,548,366
	-20%	22.68%	$2,306,406
Plant O&M Cost	+20%	12.64%	$1,439,168
	-20%	17.50%	$2,306,886
District Heat Sale Price	+20%	17.46%	$2,298,968
	-20%	12.69%	$1,447,476
District Heat Annual Sales	+20%	17.27%	$2,312,515
	-20%	12.89%	$1,435,633

5.0 Next Steps

The FEED report outlines a series of challenges that exist for the project to be successful, whether it is feedstock security, technology risk or cost, or the need for financial support to bring the project to a reality. No project is without its challenges and, if financial support can be found, mitigation strategies could be developed to address requirements of regulators, enhanced policies (feedstock procurement) and the technical risks associated with the demonstration nature of the project.

Should the project partners decided to pursue the project to the next level of development to realize the potential for biomass gasification in the Yukon, the following sub-section outlines general tasks that would be required and a project implementation schedule.

5.1 NEXT LEVEL OF DEVELOPMENT

Looking beyond the conclusion of the FEED study, considered to be Phase 1 of the project, each area of the FEED will require additional work to bring greater definition and certainty to the project viability and requirements for support. With the completion of the FEED study, the project definition began to take shape but additional work and refinement needs to take place. To support bringing the project definition to the next level of study, work in each area of the project needs to be completed. The following statement of work includes, but is not limited to, phases of study to be completed ahead of detailed engineering and construction.

Phase 2 – Feedstock

Initial indications from the FEED show the potential to source feedstock from local sawmill and harvesting operations. The feedstock supply logistics and business models for this supply will have to be further refined in order to make the decision to proceed with detailed engineering.

- Procurement Logistics and Strategy.
    - Supplier Business Model.
    - Storage location options and retrieval*.
    - Chipping options and locations*.
    - Site Visits to Existing Operations.
    - Input to design.
    - Develop moisture content strategies*.
    - Alternative sources.

- Regulatory.
    - Security of supply w FMB*.
    - Confirm Strategy (who needs to be up to speed)*.
    - Regulatory approvals before EOI*.
- Procurement.
    - Expression of Interest (EOI) to Supply 500 kWe Plant*.
    - EOI Preparation*.
    - EOI Issued*.
    - Letters of Interest (LOI) Returned*.
    - LOIs Reviewed*.
    - Feedstock Assessment & Costing.
    - Procurement Plan.
    - Private Shortlisted Request for Proposal.
    - Formal Firm Proposals.
    - Procurement Contracting.

** Short-term items to support business case development (Phase 4)*

Phase 3 - Environmental Permitting

Based on the FEED study assessments completed, the current expectation is for a DO level assessment by YESAB. This needs to be confirmed and the proper impact assessment completed accordingly (including field studies, public consultation).

- Scoping Meeting with YESAB*.
- Field Surveys and Technical Analyses.
    - Wildlife and Wildlife Habitat (migratory birds, bats).
    - Wetlands and Vegetation.
    - Land Use/Traditional Use Consultation in Community (siting).
    - Archaeological and Heritage Resources.
- Impact Assessment Report.
    - Prepare Draft DO Proposal for Internal Review.
    - Client Review Period.
    - Preparation of Regulatory Draft DO Proposal.
    - Adequacy Review.
    - Respond to Information Requests from Adequacy Review.
    - DO Reviews Responses.

- Seeking Views and Information (public consultation).
- DO Reviews input from SVI.
- Potential further Information Requests.
- DO Prepares/Issues Recommendation or Referral.

- Permit Applications.

  - Community and Stakeholder Engagement*.
  - Prepare other Applications and Submit to Decision Bodies.
  - Decision Bodies Receive Recommendation from DO.
  - Review and Consideration by Decision Bodies.
  - Decision Bodies Issue Permits.

** Short-term items to support business case development (Phase 4)*

Phase 4 - Bridging Engineering & Business Case

The engineering and business case assessment completed as part of the FEED study provide direction on project approach and defined the project to the extent possible. With the knowledge gained, the next level of study can be completed ahead of detailed engineering to provide a Class 3 opinion of probable capital and operating costs as well as associated business case.

- Project Management & Local Support.

Bridging Engineering

- Engineering Design to support Waste Heat Integration.

  - Identification of buildings for the district heating network.
  - Contact building owners/operators to determine hook-up potential and assessment of current heat loads.
  - On-site assessment of buildings to determine building infrastructure requirements for energy transfer stations.
  - Heat load assessment to determine system sizing and which building to include in the network.
  - Prepare system design including but not limited to:
    - Main, distribution, and branch line sizing.
    - System control and metering infrastructure.
    - Energy transfer station sizing for each building.
  - Drawing and design package to support the development of a AACE Class 3 opinion of probable capital and operating cost for the system.

- Engineering Design to support Facility Design:
  - Gasification technology:
    - Develop and issue firm Request-for-Proposal for 500 kWe gasification technology.
    - Conduct bid comparison and select vendor for engineering design.
    - Plant design to support technology, grid interconnection, district heating interconnection, and fuel receiving.
  - Finalize site location:
    - Dependent on heating network design and feedstock storage requirements.
    - Conduct open house to solicit public input.
    - Select location, determine infrastructure requirements (grid interconnection, water/sewer), confirm land ownership and tax implications.
  - Materials Handling:
    - Confirm on-site/enclosed feedstock storage requirements.
    - Finalize fuel storage and reclaim method (loaders/bin, walking floor, other).
    - Support design, sizing and tie-in with selected technology vendor.
  - Plant Auxiliaries:
    - Confirm building/room sizing and infrastructure tie-in requirements.
    - Building services (lighting, HVAC).
  - Drawing and design package to support the development of an AACE Class 3 opinion of probable capital and operating cost for the system.
  - Project implementation schedule through to commercial handover.

Business Case

- Project support to develop business case, including:
  - Input into owner's applications for funding.
  - Determine model for heat sales and draft heat sale contract.
- Finalize business model and case as engineering is concluded, including:
  - Ownership model.
  - Sensitivity analyses.

Phase 5 - Detailed Engineering and Procurement

Phase 6 & 7 - Construction, Commissioning, Start-up, Commercial Handover

5.2 IMPLIMENTATION SCHEDULE

If the decision were made to proceed with the next level of development, three of the phases outlined above would need to start in 2013. Feedstock assessment will need to be further

defined and support the requirements of the YESAB submission for the project. In future years, the feedstock procurement strategy and final supply contracts will be critical project components. Environmental permitting will also need to begin in 2013 with a consultation with YESAB to ensure the project can proceed with a D.O. level screening and establish requirements for field studies, modelling, and other areas deemed critical. The environmental team will also support the public and First Nations consultation process on an on-going basis. The main driver for project refinement in 2013 will be the bridging engineering and business case refinement. This work, outlined above, will provide greater clarity to the facility design (looking at firm vendor quotes and cost savings measures) to arrive at a Class 3 opinion of probable capital cost. On the business case side, it will be necessary to secure draft heat contracts and power purchase pricing to provide greater certainty to future revenue streams. Confirmation of the potential revenue, along with plant and feedstock costing will facilitate the development of a more sound business case.

A high-level implementation schedule is presented in Table 5.1 for consideration. A more detailed potential implementation schedule (Gantt Chart) is presented in Appendix K.

The schedule in Appendix K represents a fast track schedule to indicate the scope of each phase and its earliest possible completion. Table 5.1 relaxes the need to complete more detailed feedstock activities and environmental permitting tasks (field studies) until 2014 instead of 2013. This reduces upfront costs, and facilitates further refinement of the business model ahead of proceeding with detailed engineering and ordering of equipment.

Table 5.1 Implementation Schedule

Phase	Task Description	2013	2014	2015	2016
2	Feedstock				
3	Environmental Permitting-DO Level				
4	Bridging Engineering & Business Case				
5	Detailed Engineering and Procurement				
6	Construction				
7	Start-up & Commissioning

1.0 Introduction / Study Progress

Stantec Consulting Ltd. (Stantec), in partnership with AFGOR Inc. (AFGOR), has been contracted to carry out Yukon Energy Corporation's (YEC) Front End Engineering Design (FEED) Study for the Yukon Bioenergy Demonstration Project in Haines Junction, Yukon. The objective of the study is a draft report to be delivered on January 15, 2013 covering the following project results:

- Evaluation and selection of a preferred technology for a small-scale bioenergy demonstration project in Yukon.
- Completion of a preliminary design for a preferred project location in Haines Junction, Yukon.
- Clearly defined business model.
- Identified additional funding sources.
- Business case analysis that will clarify the financial viability of the project.
- Technical, financial and regulatory risk management strategies.
- Drafted baseline conditions and impact assessment to form part of the project proposal submission to the Yukon Environmental and Socio-Economic Assessment Board related the bioenergy facility.
- Description of all environmental requirements associated with the project, as well as an outline of foreseeable potential project impacts, and mitigations that will be implemented to reduce project effects. The status and timelines for obtaining all required environmental approvals will also be outlined.
- Overview of engagement activities undertaken throughout 2012, and the results / outcomes of these activities (e.g. issues, challenges and opportunities identified), and a defined engagement and technology transfer strategy for the detailed design and subsequent phases of the project.

1.1 STUDY PROGRESS

This interim report is the first of two to be completed during the study, and represents project findings to date. Each chapter of this report represents progress in different areas of the project to meet the overall project objective. The three main areas of focus for the project are Engineering/Feedstock, Environmental/Engagement & Consultation, as well as Business

Planning. Progress to date in these three (3) areas is outlined below and forms the basis for this report.

- Engineering/Feedstock
    - Catalogue of Technologies (Task 6)
    - Technology Vendors
    - Technology Screening (Task 9)
    - Technology Costing (Task 7)
    - Technology Recommendation
    - Feedstock Characterization and Pre-processing (Task 10/11)
- Environmental / Engagement & Consultation
    - Engagement and Communications Plan (Task 16)
    - Regulatory Approvals Strategy (Task 36)
- Business Planning
    - Potential Funding Sources (Task 42)

2.0 Catalog of Technologies

The production of electricity through the conversion of biomass can be accomplished using a variety of different processes and a multitude of feedstocks. The production of bioenergy not only employs a previously underutilized fuel source, but also mitigates the effects of energy production on the environment. When selecting the appropriate technology, it is important to keep in mind the available feedstocks, required amount of generated electricity, environmental standards, capital cost, and process efficiency (McKendry, 2001). Accordingly, with timber being the sole feedstock at the present time, and the target energy production range being 2-4 MW, three different types of biomass conversion options will be investigated: gasification, pyrolysis and an externally fired gas turbine.

2.1 GASIFICATION

Gasification is a well-proven process that can be performed using either of two technologies – a simple system based on a fixed bed gasifier or fluidized bed technology of increased complexity. Within each of these types, further process options must be examined. Gasification involves the conversion of biomass to a gaseous fuel by heating in a gasification medium like air, oxygen or steam at temperatures greater than 800°C. Using this method, the chemical energy from carbon is converted into a combustible gas in two stages, unlike combustion where oxidation is complete in a single step. The quality of the product gas can be easily manipulated and allows for it to be more versatile in energy applications when compared to its biomass source.

The reactions associated with gasification are as follows:

Partial oxidation	$C + \frac{1}{2}O_2 \leftrightarrow CO$	$\Delta H = -268\ MJ/kgmole$
Complete oxidation	$C + O_2 \leftrightarrow CO_2$	$\Delta H = -406\ MJ/kgmole$
Water gas reaction	$C + H_2O \leftrightarrow CO + H_2$	$\Delta H = +118\ MJ/kgmole$

It can be seen above that the complete oxidation of carbon involves the greatest release of energy while partial oxidation accounts for 66% of the energy released during complete oxidation. The products from these reactions can then undergo further manipulation through the following reactions:

Water gas shift	$CO + H_2O \leftrightarrow CO_2 + H_2$	$\Delta H = -42\ MJ/kgmole$
Methane formation	$CO + 3H_2O \leftrightarrow CH_4 + H_2O$	$\Delta H = -88\ MJ/kgmole$

Because all of these reactions are reversible, altering the pressure, temperature and species concentrations allows for the tailoring of the product gas quality for the specific application. The resulting gas is therefore a mixture of carbon monoxide, carbon dioxide, methane, hydrogen and steam as well as unreacted nitrogen if air is used.

The source of oxygen in the reactions has a particular impact on the end result. While air is the most commonly used source, pure oxygen and steam can also be used. The calorific value (CV) of the gas is greatly affected by the oxygen source and typically will fall in the ranges seen below:

Low CV	4-6 MJ/Nm^3	Air and steam/air
Medium CV	12-18 MJ/Nm^3	Oxygen and oxygen/steam
High CV	40 MJ/Nm^3	Hydrogen and hydrogenation

For applications involving syngas combustion or use as engine fuel, low CV gas is most common while the higher CV gases are used as feedstock for further conversion into methane and methanol. Due to the cost of oxygen, air is normally utilized for processes up to 50MW. The overall efficiency of the gasification process is between 75% and 80%.

2.1.1 Fixed Bed Gasification

Fixed bed gasifiers are the customary method employed for gasification and operate at temperatures around 1000°C. Airflow direction distinguishes fixed bed gasifier types from one another. The two considered for this application are the updraft and downdraft configurations.

The updraft gasifier receives biomass feed through the top while the air is fed into the bottom of the unit through a grate. Above the grate, the residual solid remaining after the release of volatiles (or char) formed higher in the gasifier is combusted resulting in an internal temperature of approximately 1000°C. Ash falls through the grate at the bottom as hot gasses pass upwards into the reduction section. Further up in the devolatilization zone, the biomass is pyrolyzed. Here a fair amount of tar is formed and condenses partially on the biomass near the top of the gasifier and can leave in the product gas. In the top section the feed is dried and the gases are cooled to between 200°C and 300°C. The temperature is usually controlled by the addition of steam to the air or through humidification. The low temperature of the product means a high overall efficiency but also a high level of tar content in the product gas. A schematic of an updraft gasifier can be seen in Figure 1-1.

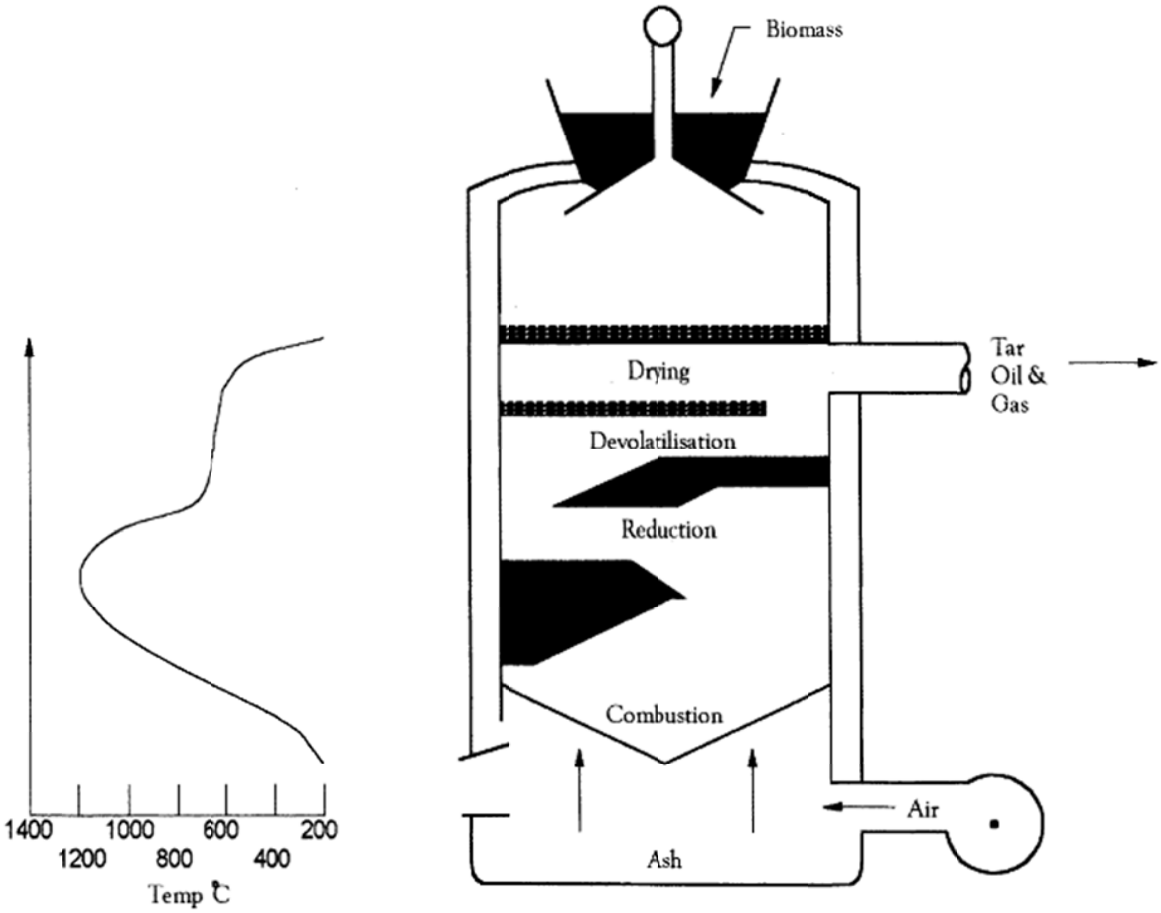

Figure 1-1: Schematic of Updraft Gasifier (McKendry, 2001)

The downdraft gasifier uses a co-current flow where the biomass feed and air move in the same direction. Since the gases leave the unit at a temperature between 900°C and 1000°C, the overall energy efficiency is low, resulting from the high heat content carried by the product gas. However, the heating of the gas allows for the partial cracking of tars formed during gasification and enables the production of gas with low tar content. While the tar content may be lower in a downdraft gasifier than the updraft design, the particulate content in the gas is much higher. A schematic of a down draft gasifier can be seen in Figure 1-2.

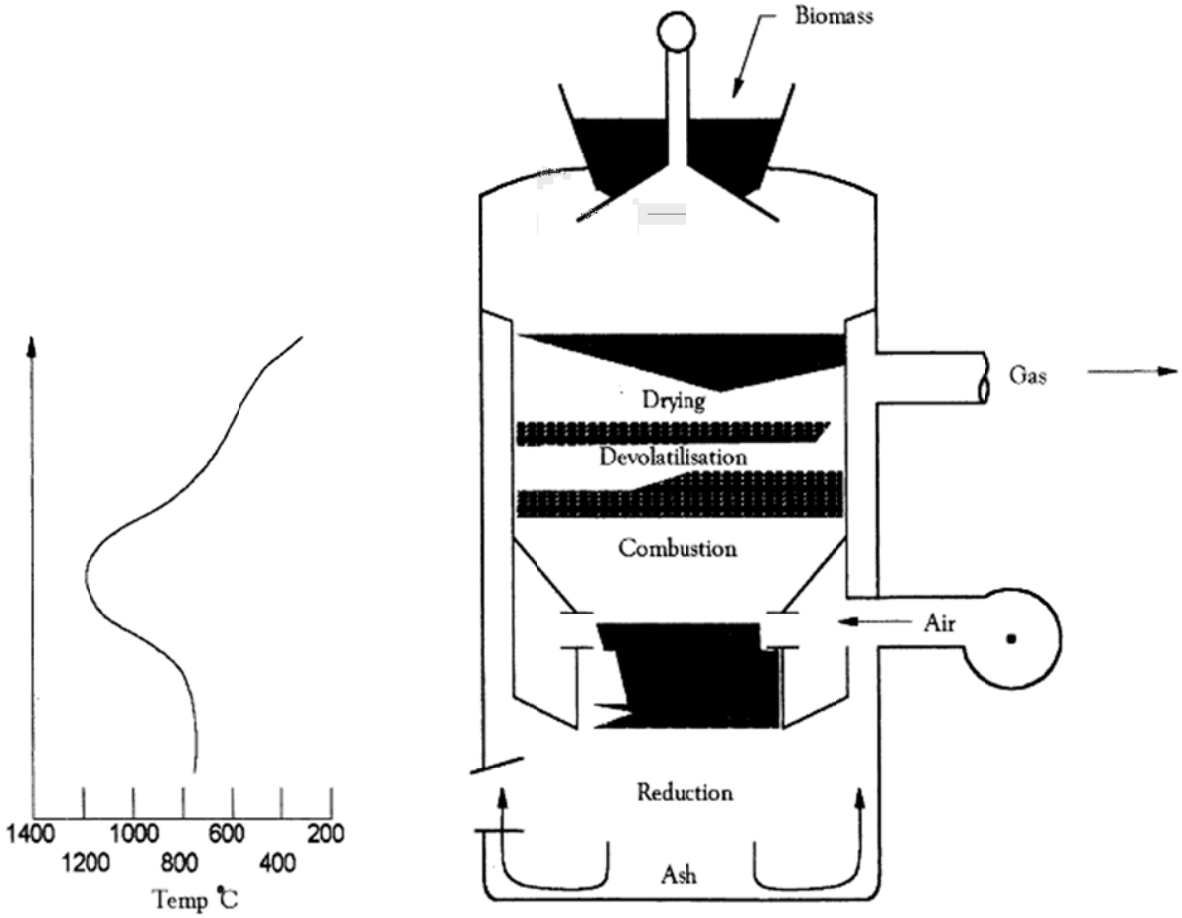

Figure 1-2: Schematic of Downdraft Gasifier (McKendry, 2001)

2.2 FLUIDIZED BED GASIFICATION

Fluidized bed gasification uses a bed of fine-grained material into which air is presented, thus fluidizing the bed material and guaranteeing close mixing of the bed material, combustion gas, and biomass feedstock. This mixing allows for a uniform temperature distribution in the gasification zone, which is the primary advantage over fixed bed gasifiers. The two foremost types of fluidized bed gasifiers are the circulating fluidized bed and bubbling bed types.

Circulating fluidized bed gasifiers are best suited for high capacity feed rates and are used in the paper industry for the gasification of bark and other forestry residues. The bed material circulates between the reaction vessel and a cyclone separator. (McKendry, 2001). The separator removes the ash while the bed material and char are returned to the reaction vessel, which helps to extend the solids residence time (Li, Grace, Lim, Watkinson, Chen, & Kim, 2004). A schematic of a circulating fluidized bed gasifier can be seen in Figure 1-3.

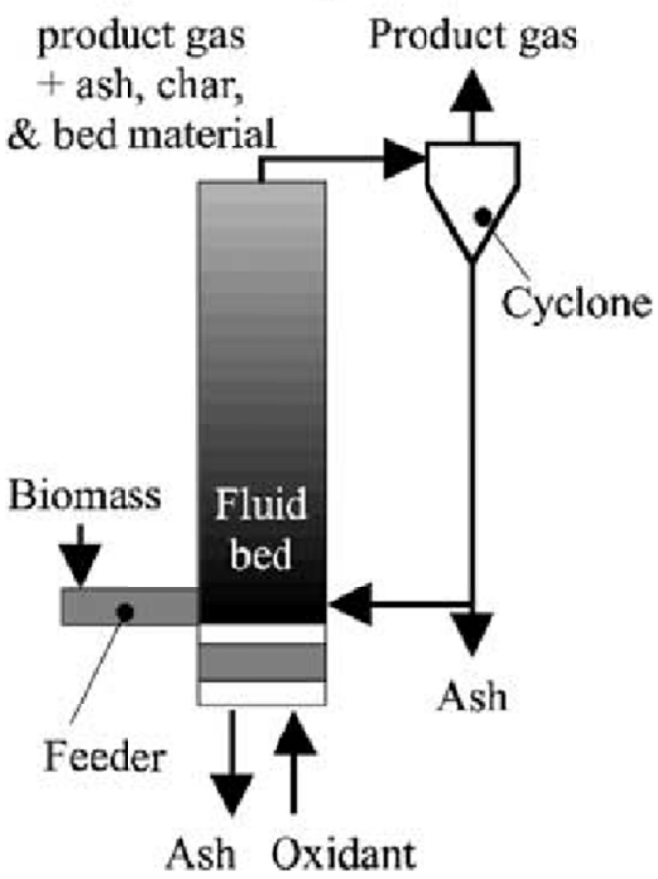

Figure 1-3: Circulating Fluidized Bed (Bridgwater, Toft, & Brammer, 2002)

Bubbling fluidized bed gasifiers are made up of a vessel with a grate located at the bottom for the introduction of air. The moving bed of fine-grained material is found just above the grate and is where the biomass feedstock is introduced. The bed temperature is maintained between 700°C and 900°C and is controlled by the air to biomass ratio. The biomass is then pyrolyzed in the hot bed forming a char with the gaseous compounds. Here the high molecular weight compounds are cracked via contact with the hot bed material resulting in a product gas with low tar content. A schematic of a bubbling fluidized bed gasifier can be seen in Figure 1-4.

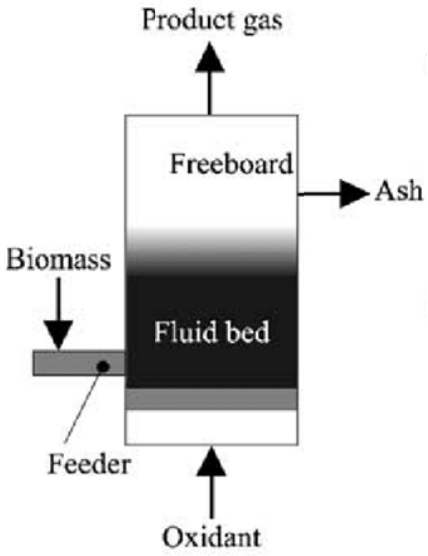

Figure 1-4: Bubbling Fluidized Bed (Bridgwater, Toft, & Brammer, 2002)

A major disadvantage to fluidized bed gasifiers is the potential for the slagging of the bed material. This is caused by the high ash content of the biomass. To avoid slagging, the bed temperature can be lowered, which results in an increased loss of char with the removal of ash. The amount of gas cleaning required is determined by the actual end-use of the gas. Fluidized bed gasifiers also produce a higher particulate load than fixed bed units. Some of these particles can be removed using cyclones. Depending on the amount of cleaning necessary, more sophisticated equipment may be needed. (McKendry, 2001). A summary of the advantages and disadvantages of different types of gasifiers can be seen in Table 1-1.

Table 1-1: Properties of Gasification Reactor Types (McKendry, 2001)

Reactor type	Advantages	Disadvantages
Fixed bed, updraft	Simple, inexpensive process Exit gas temperature about 250°C Operates satisfactorily under pressure High carbon conversion efficiency Low dust levels in gas High thermal efficiency	Large tar production Potential channeling Potential bridging Small feed size Potential clinkering
Fixed bed, down draft	Simple process Only traces of tar in product gas	Minimum feed size Limited ash content allowable Limits to scale up capacity Potential for bridging and clinkering
Fluidized bed, circulating	Flexible process Up to 850°C operating temperature	Corrosion and attrition problems Poor operational control using biomass
Fluidized Bed, bubbling	Flexible feed rate and composition High ash fuels acceptable Able to pressurize High CH_4 in product gas High volumetric capacity Easy temperature control	Operating temperature limited by ash clinkering High product gas temperature High tar and fines content in gas Possibility of high C content in fly ash

2.3 PYROLYSIS

Biomass can also be converted into a liquid fuel through a process called fast pyrolysis. (Brammer, Lauer, & Bridgwater, 2005). Pyrolysis is the thermal breakdown of biomass in the absence of oxidizing agents where the volatile components present in the biomass feed are vaporized in primary reactions by heating, leaving behind a char and ash residue. Pyrolysis always produces a gas, vapour that can be collected as a liquid and a solid char. Fast pyrolysis processes are designed and operated to maximize the liquid fraction at up to 75 wt% on a dry biomass feed basis. (Bridgwater, Toft, & Brammer, 2002). When compared to gas and solid, liquids have a high energy density and are easier to transport and store. The pyrolysis method has been used for commercial production of a variety of fuels, solvents, chemicals and other products from biomass feedstock. (Vamvuka, 2011). The liquid fuel or bio-oil possesses a lower heating value of approximately 16 MJ/kg and can be employed as a fuel in boilers, diesel engines or gas turbines for the production of heat, power or combined heat and power. (Brammer, Lauer, & Bridgwater, 2005). The bio-oil is a homogeneous mixture of organic

compounds and water in a single phase. The fuel properties compared to diesel and heavy fuel oil can be found in Table 1-2 below.

Table 1-2: Comparison of Pyrolysis Liquid and Conventional Fuel Oil Characteristics (Bridgwater, Toft, & Brammer, 2002)

		Bio-oil	Diesel	Heavy Fuel Oil
Composition	%C	48.5	86.3	86.1
	%H	6.4	12.8	11.8
	%O	42.5	-	-
	%S	-	0.9	2.1
Density	kg/m^3 at 15°C	1220	854	963
Viscosity	cSt at 50°C	13	2.5	351
Flash point	°C	66	70	100
Ash	wt%	0.13	<0.01	0.03
Sulphur	wt%	0	0.15	2.5
Water	wt%	20.5	0.1	0.1
LHV	MJ/kg	17.5	42.9	40.7
Acidity	pH	3	-	-

A principal advantage of fast pyrolysis is the possibility of storing the bio-oil intermediate. This separation is referred to as de-coupling and is unique to fast pyrolysis since the energy is stored in liquid form. De-coupling allows for the pyrolysis conversion step and the diesel engine generation step to operate independently. Peak load or seasonal power requirements can benefit from this scenario since a small fast pyrolysis plant could operate continuously to produce bio-oil that would be stored for engine use when needed.

Fast pyrolysis involves rapid heating of the biomass feedstock to a temperature of approximately 500°C followed by rapid quenching of the vapours in order to reduce secondary reactions. (Bridgwater, Toft, & Brammer, 2002)**.** The structural components of biomass, including hemicelluloses, cellulose, lignin and extractives, pyrolyze at different rates and by different pathways and mechanisms. The rate and extent of component breakdown are dependent on the reactor type, temperature, pressure, particle size and heating rate. Dehydration, cracking, isomerization, dehydrogenation, aromatization, coking and condensation reactions all occur during pyrolysis to produce water, carbon oxides, other gases, charcoal, organic compounds, tars and polymers. This complex reaction pathway can be seen Figure 1-5.

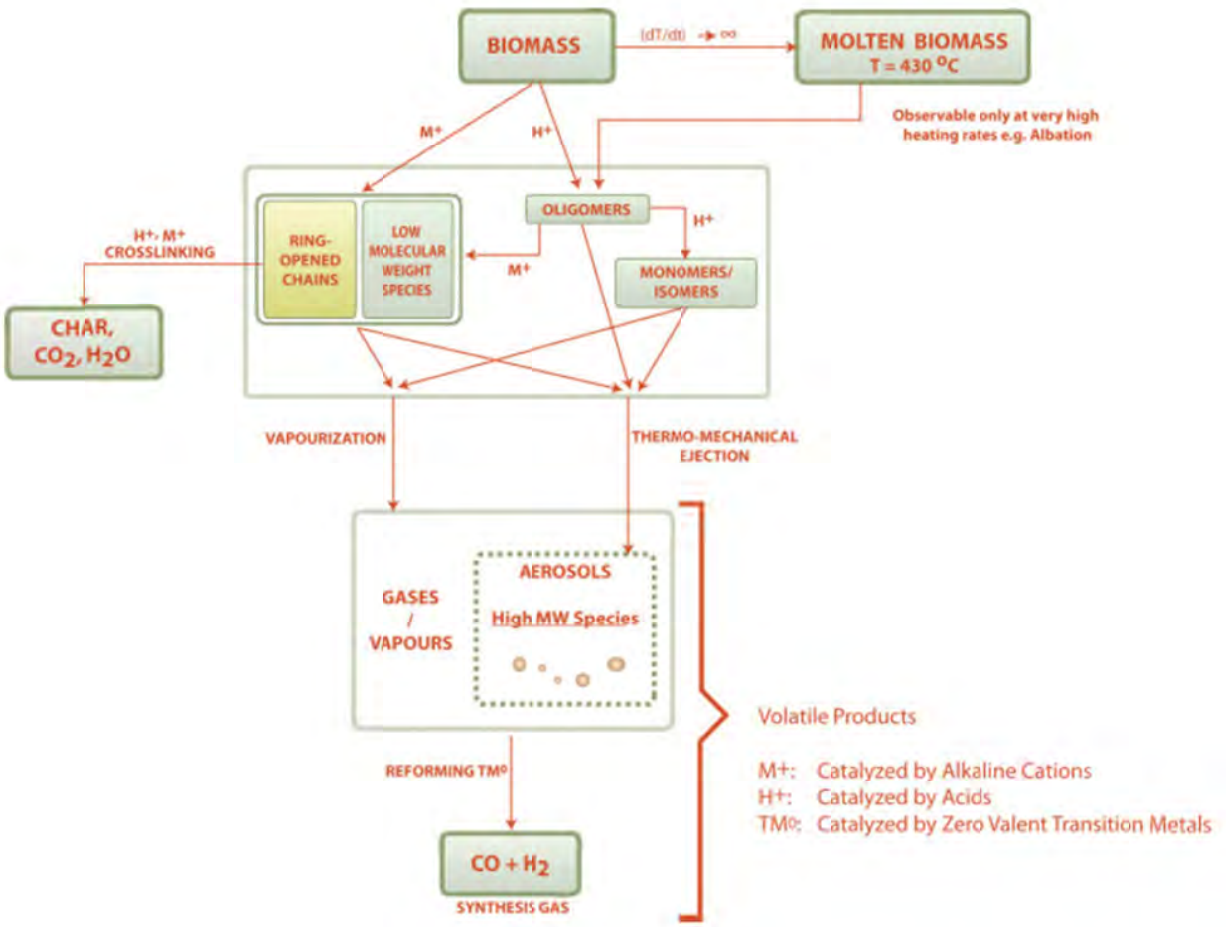

Figure 1-5: Mechanisms of Pyrolysis (Vamvuka, 2011)

Modern pyrolysis reactor configurations include fixed beds, moving beds, suspended beds, fluidized fixed beds, entrained flow reactors, stationary vertical shaft reactors, horizontal shaft kilns, inclined rotating kilns, single and multihearth reactors and a host of other designs. Fluidized beds are the most popular configurations, due to their ease and reliability of operation and ease of scaling to commercial plant sizes. They provide good temperature control and very efficient heat transfer to biomass particles. Liquid yields are typically 75 wt% on dry feed, with 10-15% char and gas making up the balance. Secondary reactions of the volatiles in the biomass matrix and additional heat supply from the in-bed heaters cause additional vapour cracking to char and non-condensable gases. The residence time of the reactants can be controlled by the flow of fluidizing gas, while special attention must be given to the system separating coke from the reaction products. (Vamvuka, 2011) Fluidized bed arrangements have been the most common reactors for fast pyrolysis, specifically the bubbling type. (Bridgwater, Toft, & Brammer, 2002). A comparison of reactor types can be seen in Table 1-3.

Table 1-3: Advantages and Disadvantages of Biomass Pyrolysis Systems (Vamvuka, 2011)

Reactor type	Advantages	Disadvantages
Fluid type	Good solids mixing High heat transfer rates Good temperature control Ease of scaling	Heat transfer to bed must be proven at large scale Max particle sizes up to 6 mm If circulating, increased complexity of system, char attrition and reactor wear
Entrained flow		Low heat transfer rates Limited gas/solid mixing Small particle sizes required
Rotating cone	Good solids mixing No carrier gas required Ease of scaling Small investment cost	Heat transfer to bed must be proven at large scale Small particle sizes required
Vacuum reactor	No carrier gas required Lower temperature required Can process larger particles	Low heat transfer rates Solids residence time high Liquid yield rather low
Ablative reactor	Heat transfer gas not required Lower temperature required Can process larger particles Compact design and intensive system	Reaction rates limited by heat transfer to the reactor Char abrasion Scaling is costly

Most fast pyrolysis processes demand a finely divided, substantially dry feed and some feed pretreatment is therefore typical before the reactor. Exceptions are ablative and vacuum pyrolysis, which both have the advantage of tolerating much larger feed sizes. In the majority of reactor setups particle size is constrained by a need to limit secondary reactions of the primary pyrolysis vapours with char formed at the particle surface. This is because the char catalyzes secondary reactions that reduce the liquids yield. The majority of feedstocks must also be dried before entering the reactor. Feed moisture content must be limited to improve liquid product yield and quality though some moisture enhances fuel properties such as viscosity. A maximum feed moisture content of 10% is usually specified while 7% moisture content is preferred (Bridgwater, Toft, & Brammer, 2002). A typical fast pyrolysis process is depicted in Figure 1-6 showing the necessary preparation steps, alternative reactors and product collection. (Bridgwater T. , 2006).

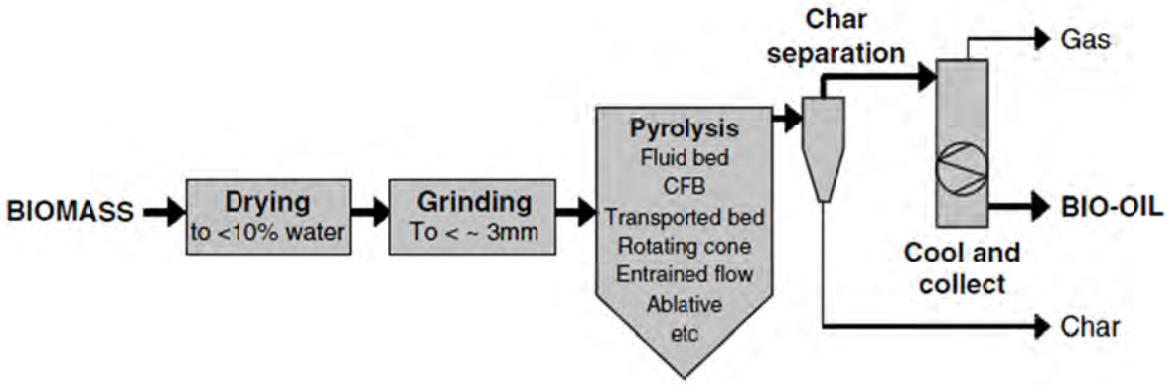

Figure 1-6: Conceptual fast pyrolysis process (Bridgwater T. , 2006)

Most development for electricity generation is focused on the use of raw pyrolysis liquids in gas turbine or diesel engine applications and has been successfully carried out. Pyrolysis liquids are very different from conventional diesel fuels but crude pyrolysis oil has been shown to burn well in engines. Ignition happens to be difficult but pilot-ignition has proven to solve this problem by using a small amount of an auxiliary fuel to ignite the main fuel. Less development has been done using gas turbines and fast pyrolysis. Earlier tests on a combustor rig designed to simulate a slurry-fed gas turbine revealed problems including entrained char in the bio-oil which blocked fuel injection systems; ash fouling downstream of the gas turbine; corrosion to turbine components; and increased smoke emissions. 1996 tests by Orenda in Canada have evaluated the firing of a 2.5 MW_e industrial gas turbine with better results. The turbine has been run successfully for several hours entirely on pyrolysis liquids while flame tunnel tests are examining the long-term resistance of turbine parts to corrosive attack from alkali metals in the ashes entrained in pyrolysis liquids. (Bridgwater, Toft, & Brammer, 2002).

2.4 EXTERNALLY FIRED GAS TURBINE

The burning of biomass in air, otherwise known as combustion, is used over a wide range of outputs to convert the chemical energy stored in biomass into heat, mechanical power, or electricity by employing a variety of process equipment such as stoves, furnaces, boilers, steam turbines, turbo-generators, etc. Combustion of biomass produces hot gases at temperatures of 800-1000°C. It is possible to burn any type of biomass but in practice combustion is only possible for biomass with a moisture content of <65%, unless the biomass is pre-dried.

The scale of combustion plants ranges from very small domestic heating applications to large scale industrial plants in the range of 100-300+ MW. Net bio-energy conversion efficiencies for biomass combustion power plants range from 20% to 40%. The higher efficiencies are obtained with systems over 100MW_e or when biomass is co-combusted in coal-fired power plants. (McKendry, 2001).

In the United States and around the world, direct combustion is the most common method of converting biomass resources into heat, power or combined heat and power. (Peterson & Hase, 2009) It contributes to over 97% of bioenergy production in the world. (Zhang, Xu, &

Champagne, 2010). A direct combustion system burns biomass to generate hot flue gas, which is either used directly to provide heat or fed into a boiler to generate steam. In a boiler system, the steam can be used to provide heat for industrial processes while a steam turbine can be used to generate electricity. (Peterson & Hase, 2009).

Fouling and corrosion of the combustor are typical issues associated with biomass combustion. These are considered to be detrimental because of the resulting reduction in heat transfer in the combustor. Fouling is commonly associated with the presence of alkali metals and some other elements (such as silicon, sulphur, chlorine, calcium and iron) in the biomass ash. With a series of complex reactions, these elements are deposited in the forms of chlorides, silicates or sulphates on the wall of the combustor or the surface of the heat transfer elements. (Zhang, Xu, & Champagne, 2010).

The two primary types of direct combustion boiler systems for biomass utilization are fixed-bed and fluidized-bed systems (Peterson & Hase, 2009), with increasing carrier gas velocity within the reactor. A higher gas velocity translates to an intensive mixing of the feedstock, which enhances the combustion efficiency and the heat exchange rate. (Zhang, Xu, & Champagne, 2010).

In a fixed-bed system, the biomass is fed onto a grate where it combusts as air passes through the fuel, releasing the hot flue gases into the heat exchanger section of the boiler to generate steam. (Peterson & Hase, 2009). The simplest fixed-bed system is comprised of one combustion room with a grate. As soon as the biomass feed is added to the furnace, it is pyrolyzed into volatile gases and chars. Primary and secondary air supplies are provided under and above the grate for the combustion of chars and volatile gases, respectively. The heat generated through the combustion of chars is responsible for providing enough heat for the pyrolysis of newly added biomass. Due to the high content of volatile matter in biomass fuels, a greater secondary air supply is required than the primary air supply. A fixed-bed biomass combustion system is typically operated at around 850-1400°C. Some common examples of fixed-bed systems include manual-fed, spreader-stoker, underscrew, through-screw, static grate, and inclined grate. (Zhang, Xu, & Champagne, 2010).

A fluidized-bed system, in contrast, feeds the biomass into a hot bed of suspended, incombustible particles, where the biomass combusts to release the hot flue gas. Manufacturers of fluidized-bed systems claim that this technology produces more complete combustion of the feedstock, resulting in reduced SO_2 and NO_2 emissions and improved system efficiency. Fluidized-bed boilers also can utilize a wide range of feedstocks. Fluidized-bed systems, however, have greater parasitic loads than stokers. (Peterson & Hase, 2009). The bed material is typically composed of silica sand, limestone, dolomite, or other non-combustible materials while the operating range is 700-1000°C. The bed materials act as the heat transfer media which are fluidized by the air flow coming from the bottom of the unit. The biomass which is amalgamated with the moving medium has high combustion efficiency. Fluidized-bed systems can be divided into bubbling fluidized bed and circulating fluidized bed, much like the aforementioned gasifiers. As a result of the high mixing intensity created by the upward-flowing air at a high velocity, circulating fluidized bed systems behave more efficiently than bubbling fluidized bed. In a circulating fluidized bed combustor, fuel particles and the bed materials are

separated from the fast flowing gas stream in the cyclone and then re-enter the reactor. Circulating fluidized-bed systems display several advantages, including the adaptation to various fuels with different properties, sizes, shapes and moisture (up to 60%) and ash content reaching 50%. (Zhang, Xu, & Champagne, 2010).

Electricity production via steam turbine has a conversion efficiency of 15% to 35% depending upon the manufacturer. The efficiency of a direct combustion biomass system is influenced by such things as moisture content of the biomass, combustion air distribution and amounts, operating temperatures and pressures, fuel feed handling, gas cleaning, distribution and mixing, and furnace retention time. (Peterson & Hase, 2009).

To circumvent the issues involved in gas cleaning, the fuel can be burned in a separate combustor and the turbine gases can be heated indirectly in a high-temperature gas-gas heat exchanger (Bridgwater A. , 1995). Externally fired gas turbines not only allow for this possibility of burning “dirty” fuel, it also utilizes the waste heat from the turbine in a recuperative process. (Kautz & Hansen, 2007), see Figure 1-7. However, an important concern with this method is the loss of efficiency due to the indirect heating of the turbine working gases as well as the temperature limit enforced by the heat exchanger materials. Despite the fact that indirect heating can improve the turbine reliability, there are costs gained in flue gas treatment and the gas-gas heat exchanger. (Bridgwater A. , 1995). Unfortunately, the costs of future commercial indirectly-fired gas turbines are difficult to predict and it is challenging to say confidence which combustion technology would provide the lowest generating costs. Indirectly-fired gas turbines do however appear to be a competitive energy-conversion technology for biomass in the future. The power-spectrum range for such gas turbines is 30-2000kW, making it necessary to purchase multiple units to reach the desired electricity production (Kautz & Hansen, 2007).

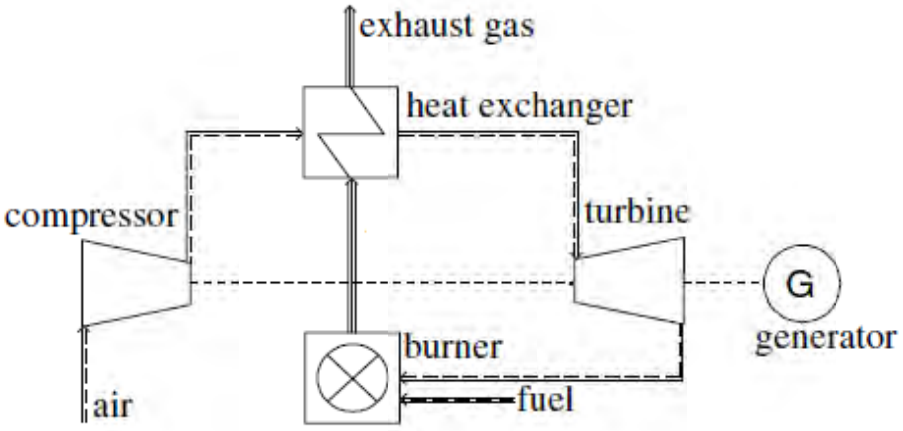

Figure 1-7: Externally Fired Gas Turbine (Kautz & Hansen, 2007)

3.0 Technology Assessment and Recommendation

Throughout the world one can find biomass gasification taking place from a scale suitable to heat a home, to that to power a country. The focus of this study is to concentrate on a gasification technology capable of producing a syngas for clean-up that can then be introduced to a reciprocating engine in the capacity range of 2 – 4 MW. Although the technology should be innovative, it must be at or near commercialization to facilitate its installation in a northern community (i.e., not for research but practical/reliable use). Several technologies also require the use of steam which is not available nor considered for generation. Two other biomass technologies are showcased for comparison (external fired gas turbine and pyrolysis-oil/ethanol/bio-oil).

To facilitate screening of the technologies, a ranking or scoring system has been established to support the technology recommendation. The criterion used for the ranking system as well as the points awarded by criterion are outlined in Table 3-1. The ranking system does not include items impacting all the biomass systems, such as feedstock availability, socio-economic viability, job creation, or permitting requirements as these are common to all the systems at this level of evaluation.

Table 3-1: Screening Criterion

Level of Development	R&D / Pilot – 0 Pst.	Demonstration – 3 Pts.	Commercial – 5 Pts.
Capacity Range	Outside 2-4 MW_e – 0 Pts.	Within 2-4 MW_e* - 5 Pts.	
Use of Engine for Power	No – 0 Pts.	Yes – 5 Pts.	
Gasification Complexity**	Advanced – 0 Pts.	Standard – 3 Pts.	Direct Comb. – 5 Pts.
Installation Base	1 Installation – 0 Pts.	2 Installations – 3 Pts.	More than two – 5 Pts.
Steam Required	Yes – 0 Pts.	No – 5 Pts.	
Achievable Score	**Minimum – 0 Pts.**	**Maximum – 30 Pts. (100%)**	

* Includes modular units capable of entering range (i.e. if maximum size is 1 MW_e, two units could be installed to enter desired range). Units significantly larger than the range will be excluded due to uncertainties regarding scale-down.

** Complexity is based on system design. Advanced is representative of dual bed or pressurized gasifiers, BFBs, and CFBs; Standard represents draft gasifiers (low to medium Btu syngas) to clean-up and the engine; Direct Combustion is for the externally fired gas turbine.

3.1 VENDOR TECHNOLOGIES

This sub-section presents the catalog of technologies considered and provides technology information as well as screening assessment.

Developer / Company:	Andritz-Carbona	**Location:**	Skive, Denmark
Owner:	I/S Skive Fjernvarme	**Status:**	Operational
Technology:	Bubbling Fluidized Bed	**Tech Status:**	Commercial
Capacity:	5.5 MW_e, 11 MW_{th}	**Application:**	CHP w/ District Heating

The Carbona plant was installed in 2005 as a demonstration unit for a new type of gasifier. Supported by the USDOE, the plant has achieved commercial operations and sells heat and power to the city of Skive. The installation is the only one by Andritz-Carbona, and in its current form supplies both boilers for steam generation and reciprocating engines. It is unclear if the unit can be scaled down, but is an advanced gasification system requiring steam.

Level of Development	Commercial – 5 Pts.
Capacity Range	Outside 2-4 MW_e – 0 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Advanced – 0 Pts.
Installation Base	1 Installation – 0 Pts.
Steam Required	Yes – 0 Pt.
Score	**10 Pts. (33%)**

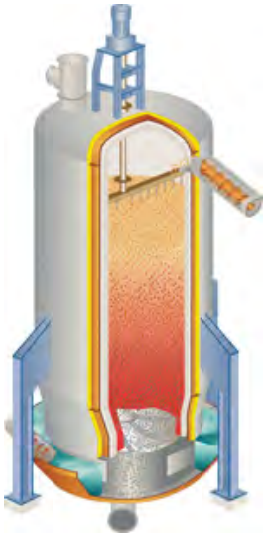
Developer / Company:	Babcock & Wilcox Vølund	**Location:**	Harboøre, Denmark 3 x Japan
Owner:	Babcock & Wilcox Vølund	**Status:**	Operational
Technology:	Updraft Gasifier	**Tech Status:**	Commercial
Capacity:	Harboøre: 1 MW_e, 3.5 MW_{th} Kani-city: 2 MW_e, 8 MW_{th} Yamagata: 2 MW_e, 8 MW_{th}	**Application:**	CHP w/ District Heating ORC

B&W Vølund's updraft gasifier has an extensive installation base using biomass and waste feedstocks. Majority of systems are steam based, with three noted above using reciprocating engines as desired. Reports indicate this updraft gasifier is Advanced from a complexity standpoint (complicated clean-up system and requires water treatment plant) as well the gasifier requires steam.



Level of Development	Commercial – 5 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Advanced – 0 Pts.
Installation Base	More than two – 5 Pts.
Steam Required	Yes – 0 Pt.
Score	**20 Pts. (67%)**

Developer / Company:	Biomass Engineering Ltd.	**Location:**	5 units in UK
Owner:	Various	**Status:**	Operational
Technology:	Downdraft Gasifier	**Tech Status:**	Commercial
Capacity:	Cumbria: 1 MW_e Mossborough: 0.25 MW_e,	**Application:**	CHP w/ District Heating

Biomass Engineering Ltd. has several installations of their downdraft gasifier operating In the UK. All units are equal or less than 1 MW_e in size. The two installations noted above are the only ones identified as having used a reciprocating engine, although testing has been conducted on a micro gas turbine as well. The downdraft gasifier does not require steam.

Level of Development	Commercial – 5 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.

Developer / Company:	FICFB (Vienna University and Repotec)	**Location:**	Güssing, Austria Oberwart, Austria
Owner:	Various	**Status:**	Operational
Technology:	Dual Bed (BFB & CFB)	**Tech Status:**	Demonstration
Capacity:	Güssing: 1 MW_e Oberwart: 2.7 MW_e,	**Application:**	CHP w/ District Heating ORC

Fast Internally Circulated Fluidized Bed (FICFB) was developed with dual fluidized beds (CFB combustor, BFB gasifier) to produce a high calorific value syngas. Although it has achieved this objective, the unit is advanced in complexity and is likely to enter the market in large-scale applications. The units have been run with reciprocating engines and organic Rankine cycle (ORC).

Level of Development	Demonstration – 3 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Advanced – 0 Pts.

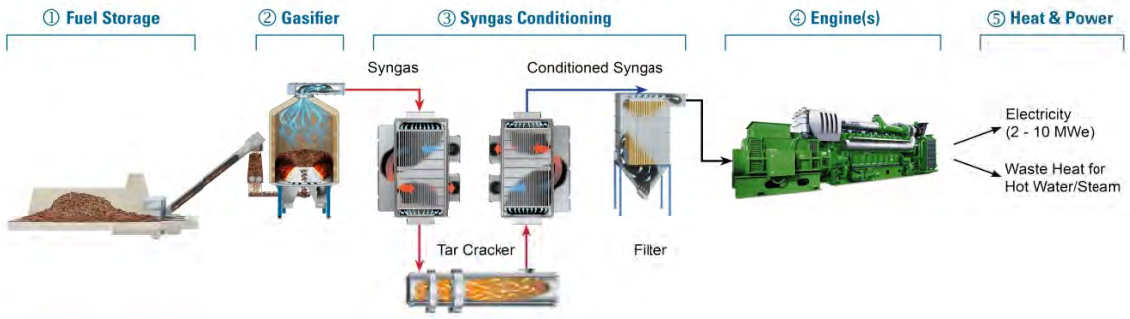
Developer / Company:	Nexterra Systems Corp.	**Location:**	Multiple – Oak Ridge, Vancouver, Victoria, North Carolina, New Westminster, UBC
Owner:	Various	**Status:**	Operational
Technology:	Dual Bed (BFB & CFB)	**Tech Status:**	Demonstration CHP
Capacity:	UBC: 2 MW_e, 3 MW_{th}	**Application:**	CHP w/ District Heating

Nexterra is the most recognizable Canadian gasification vendor. With installations of their gasifier throughout Canada and the USA, they have developed a solid platform for biomass gasification (low-medium calorific value syngas). Their most recent installation on the University of British Columbia campus is their first CHP using a reciprocating engine. The complexity of the system is Standard with an updraft gasifier and syngas clean-up. Nexterra's gasifier is well proven and does not require steam.

Level of Development	Demonstration – 3 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Standard – 3 Pts.
Installation Base	1 Installations – 0 Pts.
Steam Required	No – 5 Pt.
Score	**21 Pts. (70%)**

Nexterra Advanced Biomass Heat and Power System



SIMPLIFIED ILLUSTRATION

① Fuel Storage - wood residue delivered to storage facility and conveyed to gasifier.
② Gasification Technology - gasification process converts wood residue into clean, renewable synthetic gas or "syngas."
③ Syngas Conditioning Technology - syngas is conditioned and upgraded to meet fuel specification for engine.
④ Engine(s) - high-efficiency internal combustion engine(s) operates on syngas instead of natural gas to generate electricity & heat.
⑤ Heat & Power - systems will generate heat & electricity at small-scale (2 - 10 MWe) economically with efficiencies of up to 65%.

Developer / Company:	Pyroforce Energietechnologie AG	**Location:**	Nidwalden, Switzerland Güssing, Austria
Owner:	Pyroforce	**Status:**	Operational (Güssing not)
Technology:	2-zone downdraft	**Tech Status:**	Demonstration
Capacity:	Nidwalden: 1.2 MW_{el} Güssing: 0.35 MW_{el}	**Application:**	Syngas to engines

Pyroforce has a pilot/demonstration unit at an industrial site in addition to the two locations above. The Pyroforce system is based on a modular technology in a sense that each gasifier is only 150 kW_e and multiple units are used to achieve the required capacity. The gasifiers do not require steam.

Level of Development	Demonstration – 3 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Standard – 3 Pts.

Developer / Company:	Community Power Corporation (Afognak Native Corporation, Alaska)	**Location:**	33 locations in North America
Owner:	Various	**Status:**	Operational
Technology:	Downdraft Gasification	**Tech Status:**	Commercial
Capacity:	25 kW_e and 100 kW_e	**Application:**	Power, CHP

Community Power Corporation (CPC) develops modular gasification systems using a downdraft gasifier. They are available in 25 and 100 kW_e capacities, which can be combined to achieve any overall capacity (max. 3 MW_e). Complexity is low with a high degree of automation, and not steam or water wash requirements. CPC development was supported by the USDOE and NREL.

Level of Development	Commercial – 5 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.

CPC BioMax® GASIFICATION MODULE SCHEMATIC

Developer / Company:	Dynamotive Energy Systems	**Location:**	West Lorne, Ontario Guelph, Ontario
Owner:	Dynamotive Energy Systems	**Status:**	Operational
Technology:	Fast Pyrolysis	**Tech Status:**	Commercial
Capacity:	2.5 MW_e (West Lorne) 5 MW_e (Guelph)	**Application:**	Electricity, Specialty Products

Dynamotive's patented fast pyrolysis involves the rapid heating of a biomass feedstock in the absence of oxygen. Prepared feedstock is heated to a lower temperature than other pyrolysis systems thus having the benefit of higher overall energy conversion efficiency. Gas turbines are used commercially to produce electricity but leftover BioOil often results and is typically further processed into other chemicals. (Dynamotive, 2012)

Level of Development	Commercial – 5 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.

Developer / Company:	Ensyn	**Location:**	Tuscany, Italy Sabah, Malaysia Renfrew, Ontario
Owner:	Ensyn	**Status:**	Under Development, Operational (Ontario)
Technology:	Fast Pyrolysis	**Tech Status:**	Commercial
Capacity:	11-13 MW_e (Italy) 28-34 MW_e (Malaysia)	**Application:**	Power, CHP

Ensyn's patented Rapid Thermal Processing (RTP) technology uses heat to thermally crack carbon-based feedstock into high yields of higher-value liquids. Ensyn operates a fuel production facility in Renfrew, Ontario which produces commercial quantities of RTP liquids for clients. The RTP Renewable Fuel Oil can be injected directly into a turbine or diesel engine in a variety of combinations depending on the required output (Envergent Technolgies, 2010).

Level of Development	Commercial – 5 Pts.

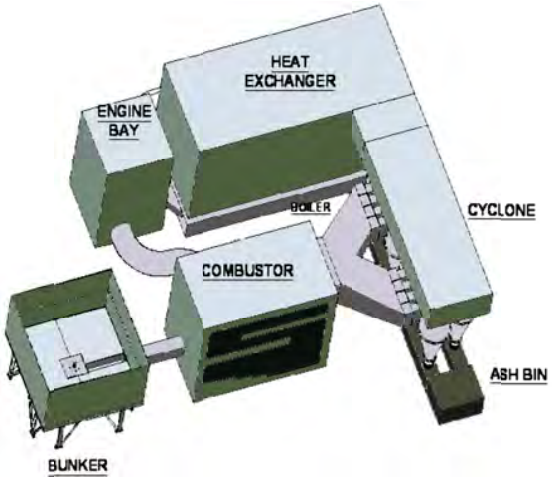
Developer / Company:	(1) Talbott's (2) Entropic	**Location:**	(1) Shropshire, England (2) University of Manitoba
Owner:	(1) Talbott's (2) Entropic	**Status:**	Operational
Technology:	Indirect Fired	**Tech Status:**	Demonstration
Capacity:	100 kW_e, 200kW_{th}	**Application:**	CHP

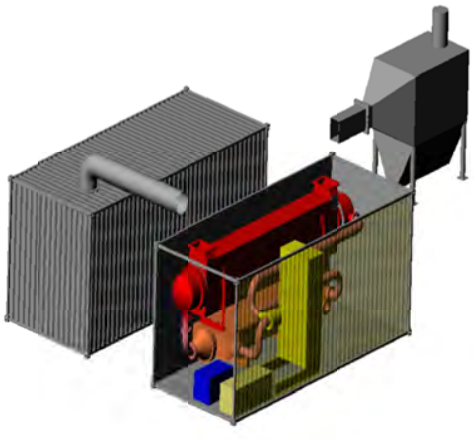
Tallbott's manufactures over 40 different systems at its UK factory with over 4000 installations worldwide. The BG100 generator was officially launched and installed at Harper Adams University College in Shropshire, England in 2006. The unit has been discontinued due to operations issues. They have since released a BG250 (250 kW_e, 600 kW_{th}), and have a BG25 and BG50, 25 kW_e and 50 kW_e respectively.

A similar product is available from Entropic in Port Coquitlam, BC, with their 100 kW_e version.

Level of Development	Demonstration – 3 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Micro Turbine for Power	Yes – 5 Pts.
Gasification Complexity	Direct Comb. – 5 Pts.
Installation Base	1 Installation – 0 Pts.
Steam Required	No – 5 Pts.
Score	**23 Pts. (77%)**



(1) Talbott's BG250



(2) Entropic HBC100

3.2 TECHNOLOGY SCREENING SUMMARY

A summary of the technology scorecards is presented in Table 3-2 on the following page. Reviewing each vendor's score, the top scores, greater than 20 pts, were ranked from one (1) to six (6). Given the criteria considered, the smaller, more modular systems in the smaller capacity ranges took the top two rankings: (1) Community Power Corp., and (2) Biomass Engineering Ltd. The other downdraft unit, Pyroforce ranked third (3) followed by the alternative external fired gas turbine unit (4) Talbott's/Entropic. The final two rankings represent the larger updraft systems: (5) Nexterra, and (6) B&W Vølund.

3.3 TECHNOLOGY COSTING

To provide an indication of installed costs for the unit, publically available information was compiled for the vendor installations. This information is not recommend for direct comparison purposes due to the lack of detail available, if any is available, as it is challenging to determine what equipment and installations costs are being included. Table 3-3 presents the findings for the installed costs summary for consideration.

Table 3-3: Vendor Published Costs per MW_e Installed ($ CAD 2012, 2.5%/yr inflation)

Vendor	Technology	Published Cost per MW_e
Andritz-Carbona	Bubbling Fluidized Bed	**$9.3M**
Babcock & Wilcox Vølund	Updraft Gasifier	**$7.0M**
Biomass Engineering Ltd.	Downdraft Gasifier	**$8.2M**
FICFB	Dual Bed	**$7.2M**
Nexterra	Updraft Gasifier	**$8.5M**
Pyroforce	2-Zone Downdraft	**$8.2M**
Community Power Corp.	Downdraft Gasifier	**$8.1M**
Dynamotive	Fast Pyrolysis	**$40M (21 x$10^6$ L/yr)**
Ensyn	Fast Pyrolysis	**$100M (87 x$10^6$ L/yr)**
Enerkem	Bubbling Fluidized Bed	**$80M (36 x$10^6$ L/yr)**
Talbott's	Indirect Fired	**$10.1M**

An average cost for the top six vendor's average out to approximately \$8.4M/MW_e. Using this as a baseline, and assuming some cost reduction for economies of scale, a 2 - 4 MW_e installation will have an approximate installed cost of \$16M - \$32M. This is primarily the cost of the biomass plant itself, and would exclude any waste heat recovery project.

Table 3-2: Summary of Vendor Scorecards

Technology	Developer/ Owner	Level of Development	Capacity Range	Engine for Power	Gasification Complexity	Installation Base	Steam Required	Score	Rank	Elec. Eff.*
Bubbling Fluidized Bed	Andritz-Carbona	5	0	5	0	0	0	10 (33%)		
Updraft Gasifier	Babcock & Wilcox Vølund	5	5	5	0	5	0	20 (67%)	6	
Downdraft Gasifier	Biomass Engineering Ltd.	5	5	5	3	3	5	26 (87%)	2	
Dual Bed	FICFB	3	5	5	0	3	0	16 (53%)		
Updraft Gasifier	Nexterra	3	5	5	3	0	5	21 (70%)	5	26%
2-Zone Downdraft	Pyroforce	3	5	5	3	3	5	24 (80%)	3	
Downdraft Gasifier	Community Power Corp.	5	5	5	3	5	5	28 (93%)	1	20%
Fast Pyrolysis	Dynamotive	5	5	0	0	3	5	18 (60%)		
Fast Pyrolysis	Ensyn	5	0	5	0	0	5	15 (50%)		
Bubbling Fluidized Bed	Enerkem	5	0	0	0	0	5	10 (33%)		
Indirect Fired	Talbott's	3	5	5	5	0	5	23 (77%)	4	13%

3.4 TECHNOLOGY RECOMMENDATION

The technology summary in the previous section ranked three (3) technologies as front runners based on their current installation base and applicability to general project requirements. In order to make a meaningful recommendation it is also important to assess as many known considerations as possible. Although this study is in its early stages (technology-wise), there are several other aspects for consideration to formalize a recommendation.

Feedstock supply: The supply of fuel is critical to the project and is being evaluated on an on-going basis. From the standpoint of technology, the supply requirements are directly related to the capacity of the unit. In this case, a 2 – 4 MW_e installation is currently under consideration and will require 30,000 – 50,000 GMT/yr of fuel (to be confirmed (TBC)). This is not a large amount of fuel, but is more than is currently available and will have to be secured.

Trained operators: There is currently no biomass thermal or gasification plant in Haines Junction or the Yukon, and it can be assumed that finding multiple skilled operators for the new plant will be a challenge. The larger and more complex the plant becomes, the greater the challenge to staff and maintain the plant for the long-term.

Plant Efficiency: Thermal power generation projects are not extremely efficient. Typical small/medium scale boiler/steam turbine units may reach approximately 20-25% gross plant efficiency, depending on unit size and equipment. A gasification unit in the same scale has the potential to achieve higher efficiencies (up to 40%) depending on the arrangement and unit performance. In either case, straight power generation will be discarding more than half of the heat input to the system as waste heat. This loss will have a large impact on the financial viability of the project, and is the principle driver for projects to consider cogeneration (waste heat recovery).

Waste heat recovery is already under consideration for this project, but is currently being sized as a result of the power generation capacity. Although this is a typical approach if the power requirement is fixed, in this case, it may not be the driving force due to the preliminary and unconfirmed sizing of the required electrical generating capacity. In most cogeneration applications, it is the waste heat usage that drives the size of the power generation unit to support its development. Furthermore, if there is variability to the heat load, than the peak heat load is not necessarily used to size the system (i.e., the existing system meets peak requirement and the new system deals with the baseload). Using Haines Junction district heating studies as an example, the peak load is 1.2 MW_{th} yet the average load is 300-500 kW_{th} (TBC). Assuming a gasification plant is 80% efficient, 40% to electricity and 40% to waste heat, the generation capacity of the unit should only be 300 - 500 kW_e as opposed to 2 – 4 MW_e.

Combining the vendor rankings and giving consideration to the aspects above, Stantec provides the following path forward for consideration. As the 2 – 4 MW_e plant capacity is the focus of the study, the project should base the plant on an updraft gasification design, and issue Requests for Quotation (RFQ) to B&W Volund and Nexterra.

If there is the opportunity to refine the desired size of the power plant and make it smaller, the RFQ should be extended to the other technology vendors. As a sensitively analysis to the main focus of the study, Stantec recommends this be undertaken. With respect to the aspects above: a smaller unit size would have a better opportunity to secure a feedstock supply (less volume), operation of the small units (CPC and Talbott's) are significantly less complicated than the other technologies considered (more automated/less hands-on); and the plant can be easily tailored to suit a viable use of the waste heat, maximizing the efficiency and sustainability of the unit. This approach is keeping with the results of the 2011 biomass workshop and at the conclusion of the FEED study, would give the project a fallback position if the 2 – 4 MW_e unit is determined to not be economically viable/accepted or the small units become more attractive.

4.0 Feedstock Characterization

Characterization of the feedstock is the first step to understanding the potential impacts to the biomass power plant. The feedstock can impact several areas of the plant's operations, including: pre-processing requirements, materials handling requirements/arrangements, and technology specific issues (gasification, syngas clean-up, emissions, waste streams). The preliminary data below represents a desktop analysis and preliminary results from AGFOR on-site assessment the week of October 8 – 12. These characterizations are based on publically available information and will be refined as the project progresses.

Based on preliminary assessments the majority, if not all, of the biomass feedstock will be White Spruce. Beyond the species, it is important to note that most of the available feedstock is dead. The chemistry provided in the tables below is for live wood (green) wood. Dead wood will have lost some of the volatiles and other chemicals, furthermore will have a very low moisture content (less than 25%, most likely 10 – 15%. Live / green wood can also be harvested, and maybe required to support moisture content requirements of the 2 – 4 MW biomass plant. The green wood does grow in low moisture conditions compared to other Canadian climates, and can be expected to have moisture content of approximately 35%. Blending of these two sources will be able to provide some level of moisture control. Biomass drying is not perceived to be a preprocessing requirement at this time based on these findings.

The following tables (5-1, 5-2, and 5-3) present the chemical properties of the available species that will be used and refined to support the development of the project.

Table 5-1: Proximate Analysis for White Spruce (Isenberg, 1980)

	Volatile Matter (wt%)	Fixed Carbon (wt%)	Ash (wt%)
White Spruce (Bark)	72.5	24.0	3.5

Table 5-2: Ultimate Analysis for Spruce, Popular, Pine (Francescato, 2008)

	% Dry Weight								Energy
	C	H	O	N	K	S	Cl	Ash	MJ/Kg
Spruce (with Bark)	49.8	6.3	43.2	0.13	0.13	0.015	0.005	0.6	18.8
Poplar	47.5	6.2	44.1	0.42	0.35	0.031	0.004	1.8	18.5
Pine	51.1	5.91	38.2	0.1				4.7	18.9

Table 5-3: Ultimate Analysis for Spruce, Popular, Pine (ECN Phyllis, 2008)

	mg/Kg Dry Weight								
	Al	**As**	**B**	**Ca**	**Cd**	**Cr**	**Cu**	**Fe**	**Hg**
Spruce*		0.3			0.6	0.9	4		
Poplar	10		6	4200	0.3		13	30	0

Spruce*				3.9		9.8	303		
Poplar	490	17	17		320	1.4	36		
Pine*				3.9		9.8	303		

* these values were general ones given to conifers i.e. not specific to species

4.1 MOISTURE CONTENT

When compared to fossil fuels, biomass has a relatively low heating value. This is due to its distinct characteristics – high moisture and high oxygen content. For typical biomass fuels, high moisture content is one of the biggest disadvantages. Although the combustion reactions are exothermic, the evaporation of water is endothermic. The heating value of the fuel is negatively correlated with the relative amount of water even when the moisture content is within the maximum acceptable limit.

Figure 5-1 displays the negative linear relationship between the moisture content and the heating value. As the moisture content increases, both the higher heating value (HHV) and the lower heating value (LHV) decrease. HHV and LHV are used to describe the heat production of a unit quantity of fuel during its complete combustion. Another important characteristic of biomass fuel is its elevated oxygen content. Usually, the oxygen content of biomass is as high as 35 wt% on a dry basis.

4.2 WOOD QUALITY CHARACTERISTICS

Beetle-killed wood retains 40% moisture for the first few years until the tree "greys" and the moisture content drops to around 30%. Some of the documentation from BC suggests that the moisture content of beetle-killed pine in cool, dry environments may drop to 13% - 18% over the proposed 20-year shelf life (Lewis & Hartley, 2006)

The above are all subject to microclimate and the moisture fluctuations.

The Haines Junction area meets the cool, dry environment criteria which reinforces preliminary findings to October 2012. The principle difference lies in the species: Pine in BC and White Spruce in the Haines Junction area. Moisture content is more a function of effect of climate on wood than of two coniferous species.

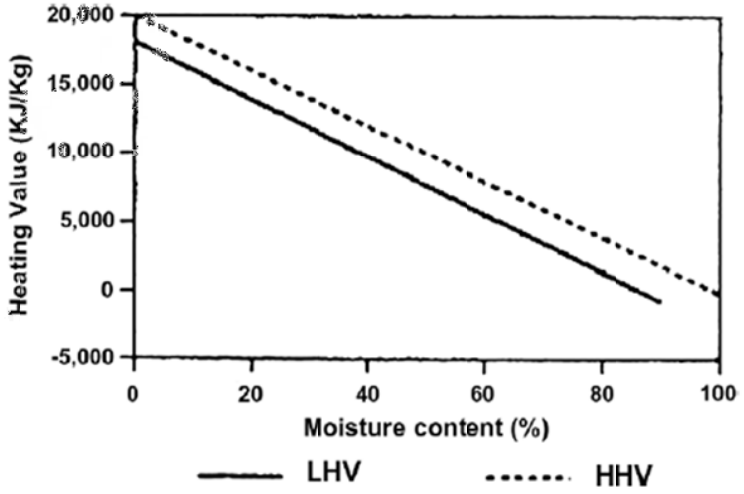

Figure 5-1: Relationship Between Heating Value and Moisture Content of Biomass Fuel (Zhang, Xu, & Champagne, 2010)

5.0 Engagement and Communication Plan

Stantec received a copy of the draft engagement and communications plan developed by the Steering Committee on 26 September 2012. The document was developed to provide a framework from which to build on as the project develops.

Elements of the plan were brought to action sooner than anticipated with the requirement for AGFOR to begin their assessment of the biomass feedstock. Gaston Damecour was in the Yukon to commence the assessment the week of October 8 – 12. During this time, Gaston had to engage several stakeholders as well as the Forestry Management Branch to understand the feedstock harvesting requirements.

In the coming weeks, Stantec will document and use Gaston's experience to refine the engagement and execution plan in consultation with the Steering Committee. A kick-off meeting with the Communications team (Janet, Tanis, & Amy) is currently scheduled for October 19, with the focus to identify a draft timeline for project activities. Identification of tentative dates and activates is requested by the Steering Committee for October 22.

General comments to the draft plan can be found in Appendix A.

6.0 Regulatory Approvals Strategy

6.1 OVERVIEW OF THE PROJECT EFFECTS ASSESSMENT AND REGULATORY REGIMES

Yukon government, First Nation government, and Federal government regulatory approvals and decisions are required before any construction activities may be undertaken for any project that may emerge from this and other related feasibility studies. These approvals and decisions, however, may only be made after the required screening assessment by the Executive Committee of the Yukon Environmental and Socio-economic Assessment Board (YESAB) of a Project Proposal submitted pursuant to the Yukon Environmental and Socio-economic Assessment Act (YESAA).

While such a project will have several activities which would make it assessable under YESAA, a screening level assessment by the YESAB Executive Committee would be required in accordance with Item 55 of Schedule 3 of the Assessable Activities, Exceptions and Executive Committee Projects Regulations as the Project will involve cutting 20,000 m^3 or more of standing or fallen trees or removing that amount of fallen or cut trees. The power plant (principle project) on its own would only trigger an assessment at the Designated Office level, but the principal project's interdependence1 with the accessory project, consisting of local feedstock procurement, raises the level of assessment.

Pending the issuance of a favorable YESAB Executive Committee screening (report and) recommendation, decision documents would be issued by any federal, first nation, and/or territorial government that will issue authorizations for the project to proceed (e.g., Air Emissions Permit, Timber Permit). Once the decision documents are issued permitting/licensing applications can be processed by the appropriate authority and authorizations subsequently issued to begin construction and commence operations.

6.2 YUKON LICENSING AND PERMITTING

The follow tables outline the Territorial, First Nations, and Federal government authorizations that may be required for the construction and operation of the proposed Biofuel Power Facility and the operation and maintenance of the associated feedstock. This list will be amended based as the technical aspects of the facility and harvesting become further defined as the Project progresses. The information below has been based on the Permit and Authorization Guide for Yukon Activities (2005) and information currently available for the Government of Yukon, Champagne and Aishihik First Nations, and Federal Government agencies online.

[1] **Interdependence** – if the principal project could not proceed without the undertaking of another project, the two may be considered to form a single project.

6.2.1 Power Facility

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Air Emissions greater than 5Mbtu-hr	YG Environment Act, Air Emissions Regulation	Air Emissions Permit	Environment Yukon	
Release of Air Pollutants	YG Environment Act, Air Emissions Regulation	Air Emissions Permit	Environment Yukon	
Ozone Depleting Substance Use	YG Environment Act, Air Emissions Regulation	Ozone Depleting Substances/halocarbons permit	Environment Yukon	Requirement to be determined based on design
Special Waste Management	YG Environment Act, Special Waste Regulations	Special Waste Facility, Disposal and Generator Permit	Environment Yukon	Requirement to be determined based on design
Solid Waste Disposal	YG Environment Act, Solid Waste Regulations	Facility Permit	Environment Yukon	
Storage Tank/Petroleum Tank Use	YG Environment Act, Storage Tank Regulations	Application for Operation, Closure, Abandonment or Renovation to Storage Tanks/Permit	Community Services, Protective Services	Requirement to be determined based on design
Water Use or Deposit of (Water) Waste	Waters Act	Water Use License	Yukon Water Board	Requirement to be determined based on water use quantities
Potable Water Supply	Public Health Act, Drinking Water Regulation	Drinking/Potable Water Permit	Health and Social Services, Public Health and Safety	

Land Acquisition, Title to Land	Land Titles Act	Issuance of Title	Justice	Requirement to be determined based on land parcel
Tenure for Land Lease or Agreement of Sale	Territorial Lands Act	Application for Land	Energy, Mines & Resources	Requirement to be determined based on land parcel
Tenure for Land Lease	CAFN Lands Act	CAFN Lands Disposition (Lease for commercial or industrial purposes)	CAFN heritage, Lands and Resources	Commercial lease of land requires CAFN Lands Committee review of application and Chief and Council approval
Temporarily Using or Occupying Commissioner's Land	Territorial Lands Act	Land Use Permit	Energy, Mines & Resources	Requirement to be determined based on land parcel
Temporarily Using or Occupying CAFN Settlement Land	CAFN Lands Act	CAFN Lands Disposition (easement, right of way)	CAFN heritage, Lands and Resources	
Facility Construction	YG Land Services	Building Permits	YG Community Services, Building Safety	
	Building Standards Act	Plumbing Permit	YG Community Services, Building Safety	

	Public Health & Safety Act, Sewage Disposal Systems Regulation	Sewage Disposal Permit	Health & Social Services, Environmental Health Services	Requirement to be determined based on design
	Electrical Protection Act	Electrical Permit	YG Community Services, Building Safety	
	Gas Burning Devices Act	Gas Installation Permit	YG Community Services, Building Safety	Requirement to be determined based on design
Clearing or Installing a Utility Right-of-Way	Territorial Lands Act	Land Use Permit, Disposition Approval	Energy, Mines & Resources	Requirement to be determined based on design
Construction of New Road Access	Territorial Lands Act	Land Use Permit	Energy, Mines & Resources	Requirement to be determined based on site location
Construct Road Access on Highway Right-of-Way	Highways Regulation	Access Permit	Highways & Public Works	Requirement to be determined based on site location
Temporary use of CAFN Settlement Land / use or alteration of resources on surface of land	CAFN Traditional Activities Protection Act	TAPA Permit	CAFN Heritage, Lands and Resources Dept.	Permits issued by Director
Activities in a Habitat Protection Area	Wildlife Act, Wildlife Regulation	Permission for Activity	YG Environment	Requirement to be determined based on site location
Activities in a Wildlife Area	Wildlife Area Regulation	Wildlife Permit	YG Environment	Requirement to be determined based on site location

Harmful Alteration, Disruption or Destruction of Fish Habitat	Fisheries Act	Fisheries Act Authorizations S.35.2	Fisheries and Oceans Canada (DFO)	Requirement to be determined based on site location and construction
Destruction of Fish by Means other than Fishing	Fisheries Act	Fisheries Act Authorizations S.32	Fisheries and Oceans Canada (DFO)	Requirement to be determined based on site location and construction
Obstruction of Fish Passage	Fisheries Act	Fisheries Act Authorization S.22	Fisheries and Oceans Canada	Requirement to be determined based on site location and construction
Bridge Crossing	Waters Act; Territorial Lands Act; Navigable Waters Act (as necessary)	Water License; Land Use Permit; Navigable Water Authorization	Yukon Water Board; Energy, Mines & Resources; Transport Canada	Requirements to be determined based on site location and construction
Navigable Water work	Navigable Water Protection Act; Territorial Lands Act	Application for an Approval of Proposed Works	Fisheries and Oceans Canada (DFO); Energy, Mines & Resources	Requirements to be determined based on site location and construction

***Also of note:** Yukon Forest Resources Act and regulations concerning the construction and operation of a wood processing facility.

6.2.2 Feedstock/Harvest

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Timber Harvesting	Timber Harvest Plan, Forest Resources Act	Timber Resource License	YG Forestry	
Timber cutting on CAFN Settlement Land for commercial purposes	CAFN Traditional Activities Protection Act	TAPA permit	CAFN (Heritage, Lands and Resources Department)	
Burn Wood Refuse	Forest Protection Act, Forest Protection Regulation	Burning Permit	Community Services, Protective Services	
Land Acquisition, Title to Land	Land Titles Act	Issuance of Title	Justice	Requirement to be determined based on land parcel
Tenure for Land Lease or Agreement of Sale	Territorial Lands Act	Application for Land	Energy, Mines & Resources	Requirement to be determined based on land parcel
Temporarily Using or Occupying Commissioner's Land	Territorial Lands Act	Land Use Permit	Energy, Mines & Resources	Requirement to be determined based on land parcel
Construction of New Road Access	Territorial Lands Act	Land Use Permit	Energy, Mines & Resources	Requirement to be determined based on site location

Construction of new road access – forest resource use	Yukon Forest Resources Act; Forest Resource Road Regulations	Forest Resource Road License/permit	Energy, Mines & Resources	Requirement to be determined based on site location
Construct Road Access on Highway Right-of-Way	Highways Regulation	Access Permit	Highways & Public Works	Requirement to be determined based on site location
Activities in a Habitat Protection Area	Wildlife Act, Wildlife Regulation	Permission for Activity	YG Environment	Requirement to be determined based on site location
Activities in a Wildlife Area	Wildlife Area Regulation	Wildlife Permit	YG Environment	Requirement to be determined based on site location
Transportation of Bulk Commodity	Bulk Commodity Haul Regulations	Bulk Commodity Haul Agreement	Highways & Public Works	Requirement to be determined based on transportation quantities
Oversize Trucking	Highways Act	Over Dimensional or Over Weight Vehicle Permits	Highways & Public Works	Requirement to be based on transportation methods

Assessment of historic resources as part of the timber harvest planning or road construction	Historic Resources Act	Archaeological permit	Department of Culture and Tourism	Required to conduct heritage assessments in the field
Other research projects	Examples: Scientists and Explorers Act (Yukon) Fisheries Act Migratory Birds Act CAFN TAPA based TK policy	Various authorizations	Canadian Wildlife Service; Dept Fisheries and Oceans; Yukon Culture and Tourism; Yukon Environment; CAFN	Quite likely necessary if project will include fish and wildlife monitoring

Note: The intent of this chapter is to provide a draft regulatory strategy from which to build on as the project develops and more definitive information becomes available. Stantec is committed to working with YEC and CAFN to define regulatory requirements on and on-going basis of the biomass plant and the feedstock supporting it.

6.3 YESAB

The scope of Stantec's work includes the delivery of a draft Project Proposal for the Biofuel Power Facility that meets the requirements as set out by the Yukon Environmental and Socio-economic Assessment Act (YESAA). Based on preliminary discussions with the Project Team, this submission will be designed for an Executive Committee level assessment. The Feedstock Harvest component of the Project will not be included in the Project Proposal at this time, but will be addressed in a separate technical and regulatory recommendation report aimed at informing a Yukon Environmental and Socio-economic Board (YESAB) submission at a future date. Assessment methods to be used are based on a structured approach that align with YESAB's direction which first assesses potential Project-specific effects and then potential cumulative effects. The following is Stantec's understanding of the assessment process based on YESAA and previous project and professional experience.

.1 **Scoping of Assessment**: identification of Valued Environmental and Socio-economic Components (VCs) relevant to the Project and the assessment including scoping the geographic and temporal boundaries for each VC.

.2 **Baseline Conditions**: baseline analysis including a reviewing current and potential future VC conditions. Examination of the possible interactions between the Project and VCs with a focus on identifying potential effects of concern to be carried forward for assessment.

.3 **Effects Assessment and Mitigation**: after baseline conditions without the Project and proposed mitigations are considered, assessment of the significance of the residual effects that remain. Qualitative and quantitative approach to positive and adverse effects on VCs.

a. **Cumulative Effects Assessment**: consideration of the potential cumulative effects arising from Project effect interactions with other projects, past, existing or future. To be considered a cumulative effect, the other past, existing and future projects being considered in the assessment must affect a VC that is also being affected by the principal project; in this way the projects act cumulatively upon a valued component.

b. **Residual Effects**: summaries of the type and extent of any residual environmental effects of the Project after implementation of the proposed mitigation, including characterization with rationale as to whether adverse residual environmental and socio-economic effects are significant or not significant, as defined in S. 58 of YESAA. Included as part of mitigation are any plans for responding to any known or predicted residual effects, and procedures

for identifying and responding to effects that were not predicted or foreseen.

.4 **Monitoring and Adaptive Management**: development of recommendations for monitoring and adaptive management of residual Project-specific and cumulative effects.

6.4 SCOPING OF THE ASSESSMENT

This step includes:

- Identifying issues of concern related to the Project,
- Selecting VCs for further examination that include both Environmental and Socio-economic,
- Identifying potential sources and pathways of effects from the Project to each VC selected,
- Identifying spatial and temporal boundaries for assessing effects of the Project for each selected VC; and
- Identifying other actions and effects pathways that may act cumulatively with the Project to affect the same VCs.

As stated in Stantec's Project Proposal, a number of Valued Components have been anticipated for various phases or activities associated with the physical works of the proposed Project. From a preliminary perspective, these can be defined as follows:

Table 6.1: Potential Interactions of the Power Facility with the Environment

Phases, Activities or Physical Works Associated with the Power Facility	Atmospheric Environment*	Water Resources	Freshwater Environment	Terrestrial Environment	Health and Safety	Land Use and Infrastructure	Archaeological and Heritage Resources	Traditional and Aboriginal Resources	Transportation	Labour and Economy	Effects of Environment on Project
Construction	1	1	0	1	1	1	1	1	1	1	1
Operation	1	1	0	1	1	1	0	1	1	1	1
Decommissioning and Abandonment	1	1	0	0	1	1	0	0	0	1	1

KEY
0 = No interaction. The environmental effects are not significant and not considered further in the assessment.
1 = Interaction occurs; however, based on past experience and professional judgement the interaction would not result in significant environmental effect, even without mitigation; or interaction would not be significant due to application of codified environmental protection practices that are known to effectively mitigate the predicted environmental effects. The environmental effects are not significant and not considered further in the assessment.
2 = Interaction could result in environmental effect of concern even with mitigation; the potential environmental effects are considered further in this assessment.

*Stantec assessment methodology incorporates air quality, greenhouse gases and acoustic quality under the Atmospheric VC.

Table 6.2: Potential Interactions of the Feedstock Harvest with the Environment

Phases, Activities or Physical Works Associated with the Feedstock Harvest	Atmospheric Environment	Water Resources	Wildlife Resources*	Vegetative Resources*	Health and Safety	Land Use and Infrastructure*	Archaeological and Heritage Resources*	Traditional and Aboriginal Resources*	Transportation	Labour and Economy	Effects of Environment on Project
Construction	1	1	2	2	1	2	2	2	1	1	1
Operation	1	1	2	2	1	2	2	2	1	1	1
Decommissioning and Abandonment	0	0	1	1	0	0	0	0	0	0	1

KEY
0 = No interaction. The environmental effects are not significant and not considered further in the assessment.
1 = Interaction occurs; however, based on past experience and professional judgement the interaction would not result in significant environmental effect, even without mitigation; or interaction would not be significant due to application of codified environmental protection practices that are known to effectively mitigate the predicted environmental effects. The environmental effects are not significant and not considered further in the assessment.
2 = Interaction could result in environmental effect of concern even with mitigation; the potential environmental effects are considered further in this assessment.

*Rankings subject to change as substantial unknowns exist regarding the site location. If feedstock harvesting represents a large footprint, higher rankings for wildlife, traditional pursuits, heritage/cultural uses, tourism (including viewscapes and related tourism land uses such as guiding, outfitting, etc.). There may be substantial unknowns regarding the possible mitigation measures.

The scope of this assessment will be focused on components that could be linked to the Project; as set out in the YESAB Guide to Assessment, both project-specific issues and regional issues that are relevant to the project need to be considered in the establishment of VCs. Therefore Valued Components have potential to be modified throughout the feasibility study, to be finalized upon its completion. Similarly, determination of VCs and environmental and socio-economic scoping requires input from local communities and interested parties; in this case, that may involve field studies and consultation that may not be completed by the end date of this Project phase. This should be noted and VCs revisited when a final Project Proposal for the Feedstock and Facility components is completed.

Other scoping considerations include the identification of spatial and temporal boundaries for the assessment of the Project effects on selected VCs. At this time, both of these boundaries have yet to be determined as the Project location, phases and schedule have not been set. However, YESAB Guides provide definitions which will be adhered to when they are chosen:

Construction Phase: This phase generally consists of the estimated time required to complete the construction of the Project, including commissioning of the facilities.

Construction Footprint Area: Construction Footprint Area is the geographic area needed for construction and operation of the physical infrastructure associated with Power facility (i.e. power access, access road, the plant, office, log storage yard, chipping plant, chip storage – conveyor, hopper, etc.).

Operation Phase: The time period following construction, through the life of the relevant components of the project, during which time the project will be used for its primary purpose of power generation.

Decommissioning Phase: The time period following operation when the Facility is no longer being utilized for its primary purpose; this may include transitioning the facility to another use or closure and abandonment.

Project Study Region: A Project Study Region for examining potential environmental and socio-economic effects has yet to be defined. Once defined, the extent of a baseline assessment for each VC required will be added.

6.5 BASELINE CONDITIONS

For use in assessing the Project's environmental and socioeconomic effects, the baseline conditions for the selected VCs will be considered through a desktop analysis. Baseline conditions will be characterized using published data and information generated in the Feasibility Study. Information may also be obtained through consultation with interested and informed parties and potential field surveys (to be conducted as required at a later date and not as part of the scope of Stantec's current assignment).

In summary, baseline conditions for each VC are proposed to be based on:

- **Atmospheric Environment:** (Air quality, greenhouse gases and sound quality)- for air: inferred from existing ambient data measured in Whitehorse as well as any available local qualitative or quantitative information (existing sources of emissions in the area); for greenhouse gases: existing provincial inventory of GHG emissions as reported to Environment Canada; for sound: inferred based on monitoring data for areas of similar land use based on Stantec's professional judgment;

- **Water Resources:** Summary of existing municipal water supply in the area of the Project and discussion of any nearby surface or groundwater resources based on readily available data.

- **Wildlife Resources:** Summary of existing wildlife in the Project area based on readily available previously conducted studies and local information.

- **Vegetative Resources:** Summary of existing vegetation on the Project site based on a qualitative assessment of the site and any readily available desktop information (recommendations for field assessment requirements to be provided).

- **Health and Safety:** Summary of existing Yukon Energy health and safety program, records.

- **Land Use and Infrastructure:** Summary of existing land use and infrastructure on the Project site and directly adjacent sites.

- **Archaeological and Heritage Resources:** Summary of readily available documentation on archaeological and heritage resource potential on the Project site.

- **Traditional and Aboriginal Resources:** Summary of readily available documentation and discussion of any information obtained through consultation on traditional and aboriginal use of the Project site.

- **Transportation:** Summary of readily available information on traffic volumes and road way level of service designations in Haines Junction.

- **Labour and Economy:** Summary of readily available information on existing employment stats, economic drivers in Haines Junction.

- **Effects of Environment on the Project:** Summary of readily available climatic data (wind speeds, precipitation levels, temperature normal).

6.6 EFFECTS & MITIGATION

Once baseline data is collected for each VC, the assessment will consider the effects of the Project, as well as other actions which may act cumulatively with the Project, on the selected VCs. Effects are examined for the construction, operation and decommissioning phases of the Project. Where required, mitigation to minimize environmental effects on each VC will be included in the assessment. Further details summarizing VC-specific effects will be incorporated as existing conditions are established through site determination process.

6.6.1 Cumulative Effects Assessment

The cumulative effects assessment (CEA) is integral to the assessment approach and examines the likely effects of the Project in combination with the likely effects of other past, existing and future projects and activities.

The assessment of potential cumulative effects will be conducted for all environmental and socio-economic VCs. Each assessment begins with a screening that involves determining whether or not all three of the following conditions are met:

- The Project results in a demonstrable or measureable residual environmental effect on the VC.
- The Project-specific residual environmental effect on the VC does or is likely to act in a cumulative fashion with the effects of past, existing or future projects and activities in the area (i.e. there is not spatial or temporal overall of effects).
- There is a reasonable expectation that the Project's contribution to cumulative environmental effects will affect the viability or sustainability of the VC.

Cumulative effects assessment proceeds beyond a screening-level assessment for an effect only when all three of these conditions are met. Although YESAA does not require that a project proposal submission to the Executive Committee consider cumulative effects, it is standard practice in environmental assessment and will be included as part of the submission. The cumulative effects analysis conducted is designed to assist in determinations regarding whether there will be any significant adverse cumulative environmental or socio-economic effects.

The cumulative effects framework suggested by YESAB is similar to that of a federal assessment and includes:

- The identification of regional VCs.
- The compilation of cumulative effects VC baseline information.

- The determination of spatial boundaries for the assessment.
- Identification of other projects and activities and a determination regarding their residual effects.
- The determination of the temporal boundaries of the assessment.
- Identification of potential cumulative effects, the characterization of such effects and identification of mitigation measures.
- Determination of significance of identified cumulative effects.
- Consideration of other Projects including:
  - Other projects for which proposals have been submitted under Subsection 50(1) of YESAA;
  - Existing or proposed activities in or outside Yukon that are known to the Designated Office, Executive Committee or Panel of the Board from information provided to it or obtained by it under YESAA.
  - Those projects whose effects are likely to act in combination with the anticipated effects of the proposed Project.

Similar to other assessment frameworks, where adverse cumulative effects are considered likely, mitigation measures will be designed and determinations made regarding the significance of the residual adverse cumulative effects after the application of those mitigation measures.

6.7 RESIDUAL EFFECTS AND EVALUATION OF SIGNIFICANCE

Significance will be evaluated by comparing residual effects against VC thresholds such as standards or guidelines, targets, or acceptable limits of change. Land use objectives or trends may also be used, as per local regulatory guidance. YESAB Guides detail further acceptable criteria that can be used to evaluable the significance of adverse residual effects from the Project after recommended mitigation measures are considered.

6.8 DETERMINATION OF SIGNIFICANCE

Adverse and likely effects are critical in the determination of significance in the assessment process. In relation to YESAA, this determination must include the recognition of traditional and local knowledge including:

- The need to protect the rights of Yukon Indian persons under final agreements.

- The special relationship between Indian Yukon persons and the wilderness environment of Yukon.

- The cultures, traditions, health and lifestyles of Yukon Indian persons and other residents of Yukon.

Similar to federal assessment practice, YESAB Guides detail the following criteria to evaluate the significance of adverse residual environmental and socio-economic effects:

Direction or Nature of the Effect: Positive, neutral, or negative/adverse; in the case of socio-economic effects, effects may at times be considered to be both positive and negative.

Magnitude of the Effect (level of detectability of effect):

- Low (effect unlikely to be detectable or measurable, or below established thresholds of acceptable change; for some environmental assessments, less than 5% of the VC population or area is affected).

- Moderate (effect could be detectable within normal range of variation with a well-designed monitoring program,10 or below established thresholds of acceptable change; for some environmental assessments, from 5 to 10% of the VC population is affected).

- High (effect would be readily detectable without a monitoring program and outside normal range of variation, or exceeds established thresholds of acceptable change; for some environmental assessments, greater than 10% of the VC population or area is affected).

Geographic or Socio-Economic Extent of the Effect:

- Low (effect extends only within the Construction Footprint Area).

- Moderate (effect extends beyond footprint and is within the Project Study Region; for socio-economic effects, extends to include the community of Mayo).

- High (effect extends beyond Project Study Region and is within Yukon, or extends outside Yukon.

Duration of the Effect (how long the effect would last):

- Low (short-term effects lasting less than one year, or not materially beyond the duration of the construction phase of the Project).
- Moderate (medium-term effects lasting from 1 to 10 years, or no more than one-generation span of the species affected).
- High (long-term effect lasting more than 10 years or more than one generation of the species affected; effects lasting throughout a major portion of the operations phase of the Project).

Frequency of the Effect (how often the impact would occur):

- Low (never, once, seldom).
- Moderate (occasionally).
- High (continuously - on a regular basis or at regular intervals).

Reversibility of the Effect (is the effect reversible and if so can it be reversed in the short or long term):

- Complete Reversibility (immediate, or reversible over very short periods i.e., less than one year).
- High Reversibility (good probability of effect being reversible, periods 1 to 10 years or no more than one-generation span of the species affected).
- Low Reversibility (Irreversible, or reversible over the period of more than one generation of the species affected).

Ecological or Socio-Economic Context (sensitivity to environmental or socio-economic disturbance, capacity to adapt to change):

- Low (VC is resilient to imposed change).
- Moderate (VC has some capacity to adapt to imposed change).
- High (VC is fragile and has low resilience to imposed change).

The assessment of significance for environmental effects determines a clear overall direction of change (positive, neutral or negative/adverse) for the VC. In contrast, the assessment of significance for socio-economic effects must also consider the following:

- The relevance of perceptions in affecting how people view changes.
- Differing perspectives and values among different groups of people about their community and region, as well as their individual and family circumstances.
- The problems inherent in assessing separately effects on different aspects or components (i.e., different VCs) of people‘s lives that each contribute to an overall —effectll on any group of people, i.e., effects may be either positive or negative, depending on the people affected, and may be both positive and negative when different groups are affected differently or when different VCs are considered for the same group.

Definitions for the likeliness of adverse residual effects will be distilled from the above and identified by the Project Team as the study progresses.

6.9 MITIGATION AND ADAPTIVE MANAGEMENT/MONITORING

The Executive Committee level screenings require suggested monitoring methods in order to manage effects. Monitoring effects is necessary in order to determine the success and suitable of mitigation measures, and to ensure predicted effects were accurate. Unanticipated effects will also be identified through monitoring and adaptive management designs.

7.0 Sources of Project Financing

As part of the Phase 5 – Project Financing task, Stantec has conducted preliminary research into potential sources for project funding. At the kick-off meeting in Whitehorse on September 19th, one potential source of funding discussed was Sustainable Development Technology Canada (SDTC). Stantec reviewed the workshop presentation for SDTC (attached) and provide the following comments.

7.1 SUSTAINABLE DEVELOPMENT TECHNOLOGY CANADA

SDTC operates two funds intended to stimulate investment in sustainable technologies. The first fund is the "SD Tech Fund™" which is ten years old and aimed at development of emerging clean technologies. The key here is the word "emerging". To be eligible, the Yukon biomass would have to be considered "unproven"[2].

The second fund managed by SDTC is the "NextGen Biofuels Fund™". This fund is aimed at "large demonstration-scale facilities for next-generation renewable fuels and co-products.

Both of these funds were discussed with Paul Austin (SDTC, Vancouver office), to determine potential eligibility for the Yukon project.

Unfortunately this project is likely to not qualify for either funding. The SD Tech Fund is strictly for new technologies or innovative use of clean technologies, and a proven biomass technology / waste heat application is not what SDTC is looking for in new applications. With regard to the NextGen Fund, it is for "first of a kind" type biofuel projects already in a continuous operation mode.

7.2 POTENTIAL FUNDING SOURCES

Research indicates that there are other funding programs that may be applicable to the project. These will require direct follow-up with the applicable government agencies to determine if it is worthwhile to apply. Furthermore, once (if) a waste heat option is finalized, this may also lead to other funding opportunities.

From Canadian Northern Economic Development Agency there are the following programs.
Strategic Investments in Northern Economic Development (SINED)

SINED has been allocated $22 million funding per Territory for the years 2009-2014 as part of its Targeted Investment Program (TIP). The four areas of focus for TIP are building the knowledge base, enhancing the economic infrastructure base, capacity development, and

[2] SDTC states in the presentation materials under the heading "SOI Don'ts" – Proven Technology = no need for SDTC

economic diversification. It is possible that the Yukon project could qualify for funding as an economic diversification plan.

7.2.1 Community Economic Opportunities Program (CEOP) /

The CEOP and CEDP funding provides project-based support and core operational support for First Nation communities for projects that lead to more community employment, greater use of land and resources, enhanced community infrastructure etc..

7.2.2 Community Infrastructure Improvement Fund (CIIF)

The CIIF program provides up to $1 million in funding for projects that improve community infrastructure. Recipients of the program must be not-for-profit entities, local/territory governments or First Nations. Infrastructure must be directly accessible to the public (i.e. district heating) and must be materially completed by March 31, 2014. There is some question whether the Yukon project would qualify due to restrictions pertaining to commercial activities.

From Natural Resources Canada (NRCan), who is funding this Yukon feasibility study via its ecoEnergy Initiatives Program, may also have possible funding availability under grant programs as follows.

7.2.3 Aboriginal Economic Development in Forestry

The Canadian Forest Service (CFS) has been mandated by AFI to provide knowledge and facilitate coordination of federal support programs for Aboriginal economic forestry development, of which bioenergy is a priority focus. Limited multi-year funding may be available from AFI where it is determined that critical gaps exist in support from other programs that may pose a risk to project success. There is no formal application process involved. Instead, any funding will be subject to the CFS identifying the need and strategic value of the project as well as availability of the funding from AFI.

7.2.4 Biomass for Energy Program

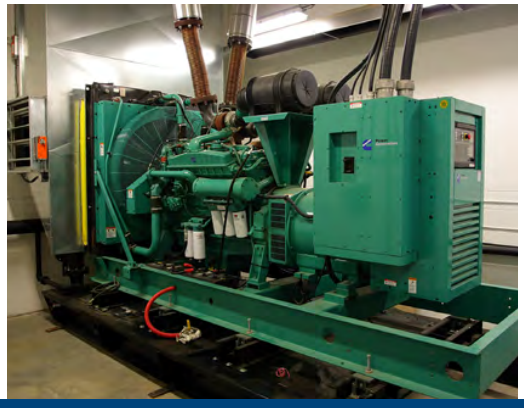
Established in 2000, the Biomass for Energy Program focuses on research and development related to technologies used in the growing, harvesting and transportation of biomass feedstock. The program is also funded through the Canadian Forest Service.

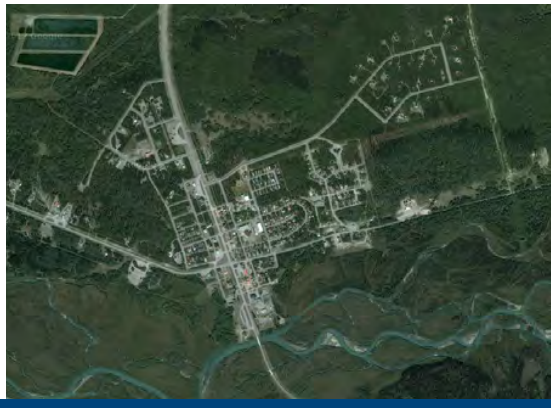
As part of the federal government Office of Energy Research and Development (OERD) is another potential research and development grant program focusing on biomass technologies.

7.2.5 Bio-based Energy Systems and Technologies (BEST) Program

This program supports the research and development of technologies used to improve the supply, conversion and utilization of both existing and new biomass feedstock supply.

Finally, for taxable entities, accelerated Capital Cost Allowance provisions are available for capital assets used in the production of energy using renewable fuel sources. The provisions allow for an increased depreciation of equipment at a rate of 30% annually.





APPENDIX B

Interim Report #2

Front End Engineering Design (FEED) Study
Yukon Bioenergy Demonstration Project
in Haines Junction, Yukon

Yukon Energy Corporation

5.1 NEXTERRA 5.1
5.2 COMMUNITY POWER CORPORATION 5.1

6.0 PATH FORWARD 6.4

1.0 Introduction / Report Objective

Stantec Consulting Ltd. (Stantec), in partnership with AFGOR Inc. (AFGOR), has been contracted to carry out Yukon Energy Corporation's (YEC) Front End Engineering Design (FEED) Study for the Yukon Bioenergy Demonstration Project in Haines Junction, Yukon. The objective of the study is a draft report to be delivered on January 26, 2013 covering the following project results:

- Evaluation and selection of a preferred technology for a small-scale bioenergy demonstration project in Yukon.
- Completion of a preliminary design for a preferred project location in Haines Junction, Yukon.
- Clearly defined business model.
- Identified additional funding sources.
- Business case analysis that will clarify the financial viability of the project.
- Technical, financial and regulatory risk management strategies.
- Drafted baseline conditions and impact assessment to form part of the project proposal submission to the Yukon Environmental and Socio-Economic Assessment Board related the bioenergy facility.
- Description of all environmental requirements associated with the project, as well as an outline of foreseeable potential project impacts, and mitigations that will be implemented to reduce project effects. The status and timelines for obtaining all required environmental approvals will also be outlined.
- Overview of engagement activities undertaken throughout 2012, and the results / outcomes of these activities (e.g. issues, challenges and opportunities identified), and a defined engagement and technology transfer strategy for the detailed design and subsequent phases of the project.

1.1 REPORT OBJECTIVE

This interim report is the second of two to be completed during the study, and represents project findings with respect to vendor site visits completed in November. This report seeks to highlight findings from the vendor site visits, as well as provide a high level financial assessment of the

vendor installations. The financial assessment is drawn from information provided by the vendors/owners, as well as publically available information.

The vendor site visits were completed on November 5 and 6, 2012. A site visit of Nexterra's installation at the University of British Columbia (UBC) was completed on November 5, while visits to Entropic at the University of Manitoba (U of M) and Community Power Corporation (CPC) at the Pineland Forest Nursery in Hadashville, Manitoba was completed on November 6, 2013.

A six (6) person team represented the project during the visits, three (3) from Stantec and three (3) from the Steering Committee. Stantec representatives included Chris van Driel (Project Manager), Rick Grey (Mechanical Lead), and Michael Wright (Electrical, Instrumentation, and Controls Lead). Steering Committee (SC) representatives included Shannon Mallory (Deputy Project Manager – Yukon Energy (YEC)), Ray Well (SC Co-Chair, Champagne and Aishihik First Nations (CAFN)), and Hector Campbell (SC member, YEC).

This report is broken into five chapters, one (1) for each site visit, one (1) for the financial assessments, and the final chapter to summarize the path forward.

2.0 Nexterra Visit – November 5, 2012

The site visit for Nexterra took place at 10:00 am on Monday, November 5, 2012 on the UBC campus. The visit was facilitated by Phil Beaty, Vice President, Strategic Relationships, for Nexterra, and Brent Sauder, Director, Strategic Initiatives for UBC. Initially the group met in a conference room on campus to discuss the university's experience during the project's development and execution. This was followed by a guided tour of the facility with the Nexterra representative and operating staff only. During the visit the plant was operational.

2.1 PROJECT OVERVIEW

This project was kick-started by John Grace of UBC based on his academic research into gasification and more specifically gas conditioning/clean-up. UBC and Nexterra wanted a demonstration sized plant to prove the concept and facilitate R&D at the university. Based on the UBC concept, GE came in as a partner and supported the development.

UBC is unique in that it is its own municipality with its own substation. The challenge in BC is the low power rates brought on by their hydro resources. That said; UBC still had the desire to demonstrate a BC technology in BC. On the waste heat side, they are also in the process of converting their existing steam district heating system over to hot water.

For UBC the social license was the first step, with five (5) sites initially under consideration. Faculty members were quick to get onboard for the research ability, and the community soon adopted a "yes, in my backyard" mentality. In the end the unit was located on the edge of the campus in order to reduce truck traffic for fuel deliveries. During full operation, UBC receives three (3) trucks a day, with enough storage for a three (3) day weekend.

On the permitting side UBC requested the strictest emission regulations be met. To that end, UBC requested that the system be designed and will be tested to meet Metro Vancouver requirements, as well as those in the USA jurisdictions of San Joaquin Valley and Massachusetts. The facility is further equipped with a local and external air shed monitoring system.

Building construction was initially completed using standard steel building formats. During the project's development UBC worked with FP Innovations and selected a new construction method – cross linked timber or CLT. The current facility uses CLT for the roof and walls of the building.

The Nexterra system does require trained operators to run the facility. Operators would require similar skills to that of boiler operators, and if a hot water system was installed, they would not require steam tickets. That said, a 4th to 3rd class ticket would be a starting point for skilled

operator requirements. Although the system is fairly automated, skilled operators are required to react quickly in an upset condition. As a minimum, the system requires two (2) full-time staff on-site 24 hours a day / 7 days a week. Currently the UBC plant operates in eight (8) hours shifts, requiring a minimum of eight (8) trained operators to support the plant.

2.2 SITE TOUR

Following the sit-down discussions, the group toured the plant installation. The following photos follow the sequence of the tour with highlights as noted for information.

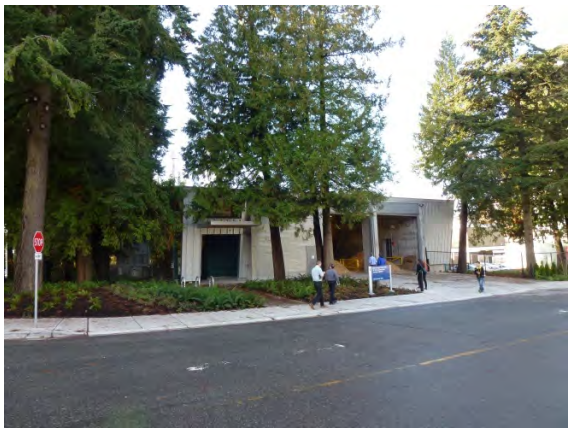

Figure N1: Building Exterior

Figure N2: Fuel Receiving

Located directly on campus, the facility's architectural design made it difficult to distinguish between other buildings on campus. Plant footprint is approximately 90' x 180'. Fuel is received and unloaded using walking-floor transport trucks.

Figure N3: Gasifier Fuel

Figure N4: Fuel Rejects

Figure N5: Fuel Reclaim System

Figure N6: Fuel Processing

The Nexterra unit currently runs on chips brought in through a third party. Fuel is reclaimed from the fuel bunker and processed with a disc screen (for size and contaminant control) and a magnet (to prevent metals from entering with the fuel).

Figure N7: Biomass Dryer

Figure N8: Fuel on Dryer Belt

After fuel processing, the biomass is fed to a single pass dryer. Fuel is wet when received (approximately 40%) and needs to be dried to 20% moisture content by weight, before entering the gasifier. Both bottom and fly ash from the unit is sent to landfill, spent activated carbon (from the filtration system) is disposed of by burning in the oxidizer.

Figure N9: Metering Bin Ahead of Gasifier

Figure N10: Single Nexterra Gasifier

Following the dryer, fuel is fed to the day bin for storage and then onto the metering bin prior to being fed into the gasifier. For UBC, Nexterra installed two parallel gas paths to facilitate the generation of electricity and heat using the engine, and a second path using an oxidizer to generate heat and steam to service the district energy network.

Figure N11: Thermal Oxidizer

Figure N12: Thermal Stack

Figure N13: Water Heater

Figure N14: Electrostatic Precipitator

Figure N15: Cross Laminated Timbers

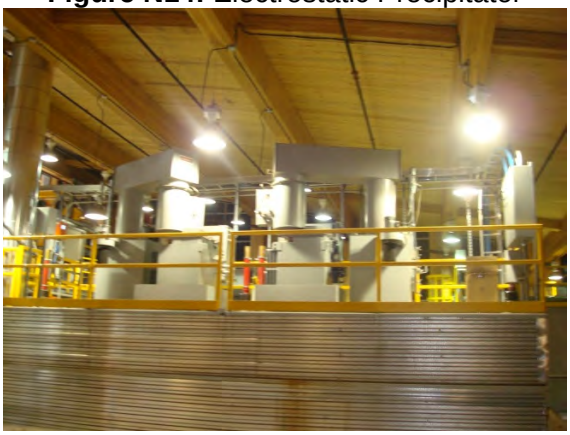

Figure N16: Auxiliary Equipment

Due to the proprietary nature of the installation, photos could not be taken of the syngas clean up equipment. Rather than entering the oxidizer and water heater as shown above, the syngas for the engine enters a series of vertical vessels used to cool the gas and reheat it, before and after the tar cracker. The tar cracker, as its name suggests, is used to 'crack' and breakdown tars that are present in the syngas (to prevent damage to the engine).

Figure N17: 2 MW_e Jenbacher Engine

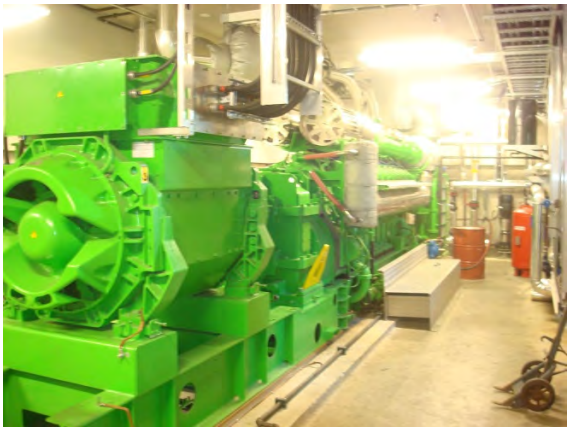

Figure N18: 2 MW_e Jenbacher Engine

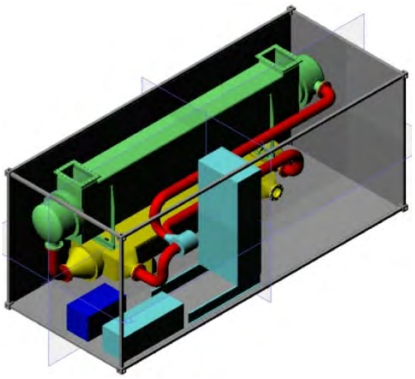
After the tar cracker the gas is cleaned by injecting a sorbent and collecting the particulate in a filtration system (bag house). From the filtration system the gas is feed to the Jenbacher reciprocating engine. The UBC installation features a Jenbacher 620 GS, a 20-cylinder reciprocating engine capable of delivering approximately 3.3 MW_e of electricity on natural gas. As the biomass syngas has a lower calorific value then natural gas, the unit is derated and limited in the peak power it can generate. The 620 is guaranteed to generate the 2 MW_e based on syngas from Nexterra.

2.3 OVERALL IMPRESSION

General impression of the group following the visit was that the installation was very large and more complex than expected. The size of the facility, number of operators, and perceived complexity of operation did not seem appropriate for a unit to be located in Haines Junction. The capital cost, maintenance requirements, parts availability, and service technician/operator skill set were also of concern. Mr. Beaty re-iterated that the UBC unit was the first of its kind and Nexterra is not actively marketing it. It will be more than a year before annual performance numbers are available, and only then would Nexterra begin to entertain installing their second unit.

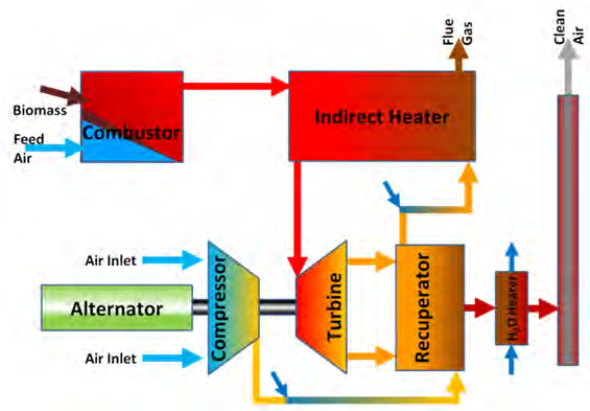
3.0 Entropic Visit – November 6, 2012



The site visit for Entropic took place at 9:00 am on Tuesday, November 6, 2012 on the University of Manitoba (U of M) campus. The visit was facilitated by Dr. Eric Bibeau, NSERC/Manitoba Hydro Industrial Research Chair in Alternative Energy and co-founder of Entropic. Initially the group met in Dr. Bibeau office on campus to discuss the Entropic's technology and product development. This was followed by a guided tour of the installation with Dr. Bibeau. During the visit the plant was not operational and it was unclear when it would achieve "demonstration" status.

3.1 PROJECT OVERVIEW

Entropic is in the R&D stages of their technology. The concept is to design a biomass system with a small footprint that can compete on a conventional technology's price point of \$4M/MW_e. Using the price point as a basis Dr. Bibeau and this team are trying to apply a hybrid Brayton Cycle to achieve high efficiency power generation in a modular package of 250 kW_e.



The Entropic design builds upon that of the indirect fired Brayton Cycle. The principle difference is in the thermodynamics in that they inject water at critical points in the process to increase unit efficiency. Although only currently theoretical in models, the team at U of M are trying to get their unit up and running. Should they be successful, the hybrid design touts the benefits of maximized energy transfer through increase mass through the turbine, decreased turbine inlet temperature (therefore reduced stress on the unit), maximize equipment capacities, and overall increase in efficiency – to double that of a standard externally fired unit.

3.2 SITE TOUR

Following the sit-down discussions, the group toured the plant installation. The following photos follow the sequence of the tour with highlights as noted for information.

Stantec

INTERIM REPORT #2 – VENDOR VISITS
FRONT END ENGINEERING DESIGN (FEED) STUDY

Entropic Visit – November 6, 2012
December 3, 2012

Figure E1: Unit is Located Inside the Trailer

Figure E2: Unit Inside the Trailer

The Entropic unit is located inside a trailer/container in a private research area of the university campus. The unit occupies approximately a third of the container.

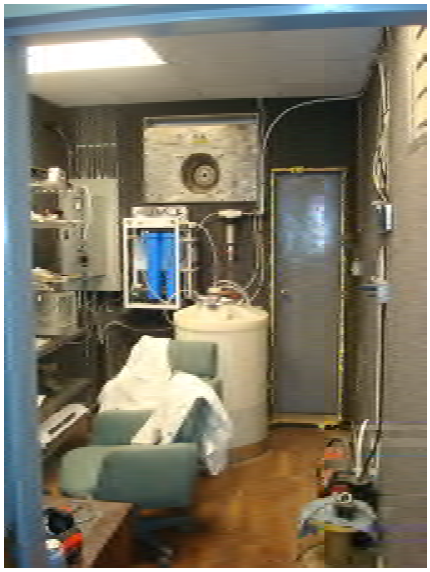


Figure E3: Control Room and Water Treatment Area

Figure E4: Unit from Rear of Trailer

The control room and water treatment area are located in the back quarter of the trailer. Water treatment requires the use of a reverse-osmosis (RO) unit to purify the water before use. Water is injected into the air/syngas and must be pure of contaminants.

Figure E5: 100 kW_e Micro-Turbine

Figure E6: Propane Combustion Chamber

In contrast to the Jenbacher which occupies and entire room, the micro-turbine used by Entropic was significantly smaller and more compact. The unit as shown contains the air compressor, turbine, and generator/alternator. As the unit is not yet operational, it is currently fired on propane instead of biomass for testing purposes. No biomass handling equipment was available for review.

3.3 OVERALL IMPRESSION

General impression of the group following the visit was that this technology/vendor was not appropriate for future consideration. The technology is not near a viable status for consideration on this project, though appears promising.

4.0 CPC Visit – November 6, 2012

The site visit for Community Power Corporation (CPC) took place at 1:00 pm on Tuesday, November 6, 2012 at Pineland Forest Nursery in Hadashville, Manitoba. The visit was facilitated by Carl Peterson, Field Engineer, for CPC. This unit is located on and integrated to Pineland's operations, but is owned by Manitoba Hydro. Jeremy Langner is the Project Manager for Manitoba Hydro (MH), but was unavailable at the time of the site visit. Mr. Langner did provide Stantec with some information on the project as a follow-up to the visit. The General Manager of Pineland, Trevor Stanley, was also unable to attend the site visit, but joined the group later in the evening to answer questions and discuss the project. The tour of the unit took place immediately upon arrival, with questions & answers carrying the group through until departure. During the visit the plant was operational.

4.1 PROJECT OVERVIEW

The following overview was developed from follow-up information provided by Mr. Langner.

The CPC system is manufactured in a series of five (5) 20 ft. shipping containers. Shipping the unit in this containerized form allows the majority of the work to be performed at the manufacturer's facility. The Pineland system was installed in June and July 2012, and Manitoba Hydro/CPC/Pineland have been testing it ever since. The unit has been run to peak capacity and has been able to generate a maximum of approximately 120 kW_e of electricity gross, with about 20 kW_e of parasitic loss. Pineland is also recovering heat off of the engine's cooling jackets and exhausts, and sending this to a thermal loop to heat greenhouses. The heat supplements Pineland's existing 2 MWth biomass boiler, located in an adjacent building.

The CPC system uses a stainless steel downdraft gasifier with air injection points throughout the fixed bed. There is a vibrating grate that can dump material if required. The temperature profile is precisely controlled throughout the bed to insure good gas quality. This allows the filtration system to be very simple – filter bags with backup carbon safety filters. This filters out a very fine carbon dust from the gas. The gas is then sent to two (2) 8.1 L V8 spark-ignition engines, each connected to a 65 kW_e alternator. Another feature of the system is the biomass dryer that uses heat from the gas cooling heat exchanger to dry the feedstock. This allows MH/Pineland to accept up to 45% moisture content, and dry down to approximately 15% moisture.

With regards to fuel rates and flows, MH currently pays in the range of $55 to $65 per tonne as delivered for their biomass supply. The wood chips come from several sources within 2 hours or less of the project site. The fuel consumption is stated by CPC as 90 kg of dry biomass per

hour, however, MH have not been running consistently enough to determine a more accurate figure. The CPC system can accept ¼" x ¼" through 2" x 2" chips.

As far as maintenance costs are concerned, MH does not have enough data to provide concrete figures. It will highly depend on the number of oil changes per month. CPC has specified an oil change every 10 days. MH are also budgeting the equivalent of 1 hour per day of daily checks, and 2 to 3 man-days per month spent on gasifier maintenance. During this initial start-up phase, these numbers are expected to be higher.

Operating efficiency is also difficult to determine giving the limited operating hours. Assuming MH/Pineland are burning 90 kg/hr for 100 kW of output (net), and the biomass has a higher heating value of 20 MJ/kg (dry), MH would have a net electrical efficiency of approximately 20%. MH believes that the total efficiency will be at least double when they include the heat.

In a discussion with the Mr. Peterson, CPC typically provides four weeks of commissioning and start-up services. This includes two (2) weeks on-site for commission the unit and systems, one (1) week of full-time training for site personnel, and one (1) week of field supervision following the training. Beyond the four (4) weeks, Mr. Peterson indicated that CPC monitor the unit remotely for any system warnings or errors. As for the level of skill required to operate the units, Mr. Peterson indicated that the majority of operators are ex-electricians or ex-mechanics. Ex-electricians are preferred give the system electronics and potential advantage when troubleshooting problems, but both have been successful at operating the units.

4.2 SITE TOUR

Upon arriving the group toured the plant installation. The following photos follow the sequence of the tour with highlights as noted for information.

Figure C1: Plant Exterior

Figure C2: Fuel Receiving

The five (5) container system is located on a concrete pad next to the fuel storage/receiving building.

Figure C3: Fuel Storage Interior

Figure C4: Fuel Bin (3 Days Storage)

The existing fuel storage building was retrofitted with the new fuel bin for the CPC plant. The bin is loaded from the top, and can hold sufficient fuel for three (3) days of operation.

Figure C5: Auger Supplying Biomass

Figure C6: Biomass Dryer

An auger carries the biomass from the bin to the biomass dryer located in the first of the five (5) containers. The dryer is used to dry the incoming biomass fuel, and uses hot air from the syngas cooling process to dry the fuel. The desired moisture content is around 15% (16.5% during the visit).

Figure C7: Downdraft Gasifier

Figure C8: Gasifier Bottom Ash

Following the biomass dryer, fuel and air enter the gasifier. Ash is collected at the bottom of the gasifier and conveyed to a storage bin outside the container. Bins need to be checked regularly, and emptied approximately every two (2) days (48 hours).

Figure C9: Downdraft Gasifier

Figure C10: Gasifier Bottom Ash

Leaving the gasifier, the hot syngas is cooled using fresh/filtered air, which is in-turn, sent to the biomass dryer to dry the incoming biomass. The cooled syngas is sent to the container above to be filtered.

Figure C11: Carbon Filters

Figure C12: Fly Ash Collection

The filters are located in the container above the gasifier in a series of five (5) cabinets (four (4) online, one (1) offline for cleaning. Fly ash that is collected is sent to the barrels on the outside of the unit that need to be emptied every 100 hours.

Figure C13: Engine #1 (Front of Container)

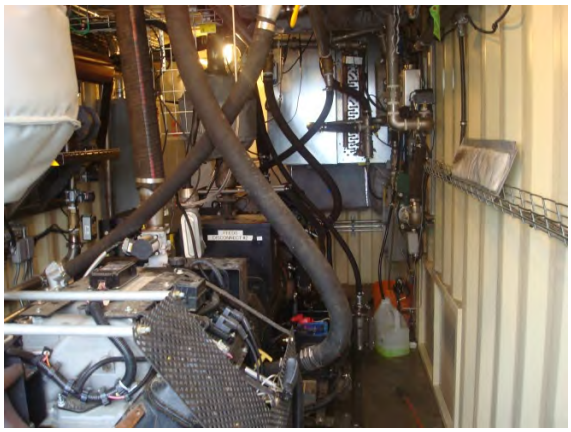

Figure C14: Engine #2 (Rear of Container)

Cleaned syngas from the filters in delivered to the two engines in the final process container. The two V8 spark ignition engines are located in the same container (with little room to spare).

Figure C15: Control Room/Container

Figure C16: Heat Recovery

The final container of the set houses the control room and all the units' electrical equipment. The control interface is a custom built interface to support unit operations. The CPC unit does integrate waste heat recovery in its operation by way of hot water being sent to the existing biomass boiler house hot water heater. The hot water displaces the need to use their biomass boiler. The hot water loop is currently running with 40°C - 60°C temperature difference, but will be looking to achieve 50°C - 70°C once running consistently.

4.3 OVERALL IMPRESSION

General impression of the group following the visit was that this technology/vendor was the most appropriate of the three for Haines Junction. Apart for the small capacity (100 kW_e) the plants simplicity, operations, level of operator skill required, and proven heat recovery potential make is a strong candidate for installation in the Yukon.

5.0 Financial Assessment

Before attending the site visit, Stantec envisioned being able to provide the Steering Committee (SC) with a detailed breakdown of the vendor's installation for review and comparison. Unfortunately, the vendor's/owner's of the systems were not interested in sharing these details with the project team. Some information has been received on general project parameters and Stantec has tried to pull together some online resources to fill in the blanks. The following subsections outline the finding for the Nexterra UBC installation and the CPC Pineland installation. Entropic data is not available and therefore not considered.

5.1 NEXTERRA

Data for Nexterra was achieve through two sources, the first being Phil Beaty of Nexterra[1] and the second publically available information from UBC during their Board of Governors approval process. During this process, Nexterra re-iterated that they "are not currently marketing the Nexterra/GE Jenbacher high efficiency CHP solution. Accordingly we are not offering typical price and delivery information."

From the UBC documentation[2]:

Equipment Procurement	$12,500,000
Field Installation	$3,800,000
Building Design & Construction	$6,400,000
Site Services	$1,200,000
Landscape and Office Relocation	$1,300,000
Contingency	$800,000
Total Project Capital Cost	**(2009) $26,000,000** **(2012 @ 2.0%/yr) $28,100,000**

Of this projected capital cost, 23% was to be provided by UBC and other private sources, while 29% was to be received through Provincial funding programs, and the remaining 48% through Federal government funding (mainly Clean Energy Fund, SDTC, and NRCan). Recent correspondence with Nexterra puts a new project capital cost at $18M - $20M but excludes the building, foundations, and balance of plant equipment (which is not detailed).

5.2 COMMUNITY POWER CORPORATION

Data for CPC was achieved through two sources, the first being Jeremy Langner with Manitoba Hydro[3] regarding the Pineland installation and the second, a publically available pre-feasibility

[1] Personal correspondence, Phil Beaty to Chris van Driel, Nexterra Site Visit, 16 November 2012
[2] The University of British Columbia, Request for Decision, 9 September 2009, Bioenergy Research and Demonstration Project.
[3] Personal correspondence, Jeremy Langner to Chris van Driel, Pineland Forest Nursery Presentation, 27 November 2012

study[4] conducted by Manitoba Hydro using a BioMax 100 as an option for combined heat and power at another location.

From the Manitoba Hydro documentation:

Capital Cost	
Equipment Procurement[4]	$500,000
Biomass Storage and Handling[4]	$84,000
Heat Recovery[4]	$60,000
Foundation, Piping, Interconnection[3]	$130,000
Contingency	$80,000
Total Project Capital Cost	**(2010) $854,000** **(2012 @ 2.0%/yr) $889,000**

Operating Cost	
Average O&M ($20/MWh x 782.6 MWh)	$15,653
Fuel Cost ($60/tonnes x 596 tonnes)	$35,772
Contingency (5%)	$2,571
Total Project Operating Cost	**(2010) $54,000** **(2012 @ 2.0%/yr) $56,000**

Fuel cost of $60/tonnes is in line with the average values of $55 - $65/tonne provided for Pineland.

Revenue	
Electricity ($53/MWh x 782.6 MWh)	$41,500
Thermal ($45/MWh x 1171 MWh)	$52,700
Contingency (5%)	$5,000
Total Project Revenue	**(2010) $99,200** **(2012 @ 2.0%/yr) $103,200**

Simple Payback	
Project Revenue	$103,200
Operating Cost	$56,000
Total Project Revenue	**$47,200**
Project Capital Cost	$889,000
Simple Payback	**19 Years**

Stantec

INTERIM REPORT #2 – VENDOR VISITS
FRONT END ENGINEERING DESIGN (FEED) STUDY

Financial Assessment
December 3, 2012

Using the Manitoba Hydro data as a baseline, Stantec has altered the figures to provide a relative comparison to the figures expected if the site was to be in the Yukon. These figures are not firm, but used to highlight the potential outlook for the project. Stantec's options are limited to provide this information as little background data or details were provided on where the figures were drawn from in the initial study or the basis for their assumptions. The Yukon Construction Factor and Average O&M increases are assumed values as little basis is provided for a more thorough analysis. Fuel cost of $125/tonnes is in line with current expectations for fuel pricing (to be confirmed), and electricity and thermal heating pricing derived from previous biomass reports by Morrison Hershfield.

Capital Cost	
Equipment Procurement[4]	$500,000
Biomass Storage and Handling[4]	$84,000
Heat Recovery[4]	$60,000
Foundation, Piping, Interconnection[3]	$130,000
Contingency	$80,000
Total Project Capital Cost	(2012 @ 2.0%/yr) $889,000
Yukon Construction Factor	**(x1.75) $1,556,000**
Operating Cost	
Average O&M ($40/MWh x 783 MWh)	$31,000
Fuel Cost ($125/tonnes x 600 tonnes)	$75,000
Contingency (5%)	$5,000
Total Project Operating Cost	**$111,000**
Revenue	
Electricity ($200/MWh x 783 MWh)	$157,000
Thermal ($150/MWh x 1171 MWh)	$176,000
Contingency (5%)	$17,000
Total Project Revenue	**$350,000**
Simple Payback	
Project Revenue	$350,000
Operating Cost	$111,000
Total Project Revenue	**$239,000**
Project Capital Cost	$1,556,000
Simple Payback	**7 Years**

6.0 Path Forward

Based on the impressions of the project team during the site visits, it was clear that Entropic unit was not to be considered moving forward, and that the path forward regarding unit capacity should be re-considered. As such the Steering Committee was asked to confirm their desire to continue pursuing a 2 – 4 MW_e unit using Nexterra as one of the main technology providers. Following a Steering Committee meeting, the decision was made to revise the technologies under consideration and allow for a 500 kW_e to 2 MW_e unit to be considered. This would facilitate the smaller units, namely CPC and similar vendors, to offer a multiple of their current offering to achieve a capacity that could be considered.

Currently a Request for Quotation has been issued to a series of vendors, including Nexterra and CPC, to respond with budgetary quotes for the installation of a system in Haines Junction, Yukon.

ROOF PLAN

SCALE: 1:100

NOTES:

1. FOR BUDGET PRICING, USE SUPPLIER'S STANDARD BUILDING PACKAGE SPECIFICATIONS.
2. BUILDING SUPPLY TO INCLUDE:
   A. ALL STRUCTURAL AND MISCELLANEOUS STEEL COLUMNS, ROOF BEAMS, PURLINS, GIRTS, SAG RODS, BRACING AND TIES, FRAMED OPENINGS AND EDGE ANGLES.
   B. COLUMN ANCHORAGE, ALTHOUGH THERE WILL BE A 1200 DADO WALL (BY OTHERS) COLUMNS WILL BE FOUNDED AT SLAB LEVEL (EL. 100).
   C. METAL ROOF, COMPLETE WITH INSULATION (R50) FLASHING AND TRIM.
   D. METAL WALL PANEL, COMPLETE WITH INSULATION (R30) FLASHING AND TRIM. UNINSULATED METAL DUST WALL (COMPLETE WITH GIRTS) WILL BE REQUIRED ADJACENT TO COL LINE B
   E. ALL DOORS (MANDOORS 900x2100 NOMINAL) EXCEPT WHERE NOTED).
   F. WEATHER HOODS AT FANS (1500 WIDE x 1000 PROJECTIONS). FANS WILL BE SUPPLIED BY MECHANICAL CONTRACTOR.
   G. ROOF-TOP VENTILATORS.
3. PROVIDE SEPARATE DELIVERY PRICE FOR HAINES JUNCTION, YUKON.
4. FRAME ON LINE 6 TO BE DESIGNED FOR FUTURE EXPANSION TO EAST (7315 BAY)

NRCAN SUBMISSION

Environmental and Socioeconomic Impact Assessment (EIA): Haines Junction Biomass Energy Project

Prepared for:

Yukon Energy Corporation
2 Miles Canyon Road
Whitehorse, YT Y1A 6S7

Prepared by:

Stantec Consulting Ltd.
845 Prospect Street
Fredericton, NB E3B 2T7

Project No. 133545658
May 24, 2013

EXECUTIVE SUMMARY

Project Overview

The Project considered in this assessment is a 0.5 MW to 2 MW biomass energy plant located in Haines Junction, Yukon Territories. The plant would generate electrical power which would be supplied to the grid as well as thermal energy which would be used to heat local buildings. The plant would be primarily fueled by beetle killed wood to be harvested from areas within approximately 50 to 70 km. This assessment was drafted in consideration of preliminary information available based on the Front End Engineering Design Study which included a preliminary feedstock harvesting study. The objective of the draft assessment is to establish the scope of assessment for the Project and provide preliminary findings on potential environmental and socio-economic effects associated with the plant for use in the decision making process by the Project steering committee. Further development of this assessment will occur if a go decision is made on the Project with the final objective of providing a complete proposal to the Yukon Environmental and Socio-economic Assessment Board (YESAB). In particular, detailed assessment of forest harvesting has not been completed as details of these activities have not yet been fully defined.

Project Description and Schedule

The Proponents of the Project are Yukon Energy Corporation (YEC) and Champagne and Aishihik First Nations (CAFN). A number of other partners have been instrumental in the development of the Project.

Regulatory and Policy Context

The Project will require a *Yukon Environmental and Socio-economic Assessment Act* (*YESAA*) submission although the level of assessment may be different depending on the scale of project to be registered. This is discussed in the strategy section of the FEED Study for consideration by the steering committee.

First Nations and Community Consultation

A summary of the First Nations and Community Consultation Plan is provided in Chapter 2.0 of this assessment. To date, one open house has been held. Questions and feedback from this event indicate that there is support for the Project in the community and that the scope of studies planned should address community issues and concerns.

Effects Assessment

The assessment of potential effects has been completed based on expected effects from this Project, desktop literature review and in consideration of initial consultation with First Nations and the public on their interests and values. Valued Components (VCs) have been identified for environmental and socio-economic aspects and baseline conditions have been established based on desktop literature review and consultation. Preliminary findings for each VC have been developed in consideration of the plant operation and will require updates once the Project location and infrastructure are finalized. Updates will also include a more detailed assessment of feedstock harvesting activities.

The Atmospheric Environment has been identified as a VC and defined to include air quality, sound quality and greenhouse gas (GHG) emissions. In consideration of existing conditions and estimated Project emissions of air contaminants, ambient air quality is expected to remain well below regulatory objectives during operation of the plant. Annoyance from noise is not expected to be caused by the plant if it is located at least 500 m from residences (to avoid sleep disturbance). If the plant is located in a building this distance could be less. Further study is recommended to include confirmatory predictions using vendor information and a baseline sound pressure level survey in the area where the plant will be located. The chipping operation will likely need to be located 500 to 1,000 m from residences and sensitive receptors (such as the school or other areas of frequent land use) to avoid annoyance.

Minimal influence on water resources is expected as the plant will use little to no water (depending on vendor) and should be located at least 30 m away from surface water sources. Feedstock (in chip form) will be stored indoors to avoid siltation to surface water run-off.

Significant environmental effects on vegetation and wildlife are not expected based on the species documented in Haines Junction. Field work will be done as a confirmatory measure once the site is chosen.

Additional consultation is required in relation to traditional ecological knowledge and traditional activities and culture to confirm any constraints that should be considered.

Known and documented heritage resources have been confirmed and will be avoided in locating the plant. A field survey would be conducted prior to initiating any ground breaking activities.

Transportation infrastructure is not expected to be noticeably influenced as a result of the Project. Truck traffic is estimated at 3 to 15 trucks per week to supply feedstock during Operation. Similar or less traffic is expected during Construction.

The Project will require resources for construction and operation, therefore a positive effect on labour and economy is expected. Planning of forest harvesting will include consideration of existing land users to ensure that other land users such as existing harvesters, trappers, outfitters and wilderness tourism are not negatively affected.

Human health and well-being should not be affected by the Project. The plant would be operated within applicable regulations which have been developed to protect human health and well-being.

1.0 INTRODUCTION

The Project considered in this assessment is a 0.5 MW to 2 MW biomass energy plant located in Haines Junction, Yukon Territories. The plant would generate electrical power which would be supplied to the grid as well as thermal energy which would be used to heat local buildings. The plant would be primarily fueled by beetle-killed wood to be harvested from areas within approximately 50 to 70 km.

1.1 PROJECT OVERVIEW

The Champagne and Aishihik First Nations (CAFN), the Dakwakada Development Corporation, Yukon Energy Corporation Cold Climate Innovation of the Yukon Research Centre, and the Village of Haines Junction are investigating the potential for a biomass fuelled energy plant in the community of Haines Junction, Yukon Territories (herein referred to as "the Project"). The plant would provide some much-needed renewable electricity for the territory as well as building heating for one or more buildings in Haines Junction via the waste heat from the power plant exhaust gases. Use of combined heat and power technology will maximize the efficiency of the process and use of the renewable resource. Currently the size of the facility is still under consideration with 0.5 MW to 2 MW electrical output being reviewed. There is potential to start with a small demonstration type project of 0.5 MW, gain operating experience and potentially proceed with expansion of the site up to 2 MW as local expertise is developed. The long term vision of the Project Team includes diverse options including further district heating which could include a greenhouse project utilizing waste heat that could supply regional need for vegetables and decrease local reliance on the Alaska Highway for food transport. The production of renewable energy plus the added benefits of increased forest resource use and possible agricultural use could create additional employment opportunities for the local community and help the region become more self-sufficient.

The Project described and assessed herein is based on preliminary information available at the Front End Engineering and Design (FEED) stage and includes the following primary components:

- construction and operation of a 0.5 MW to 2 MW bioenergy plant using gasification and reciprocating engine technology, located in Haines Junction; and
- fuel processing and handling equipment to be located at or nearby the bioenergy plant (sufficient to process approximately 10,000 to 40,000 m^3 biomass annually).

The power and waste heat transmission linear infrastructures are not assessed in detail as the final locations for this infrastructure are not available at the front end engineering design (FEED) stage. It is currently anticipated that waste heat from electrical generation would be used to heat the Haines Junction School and possibly other buildings, depending on the size of unit selected.

The activities associated with forest feedstock harvesting are presented at a high level in this report; however, site specific environmental assessment is beyond the scope of this assessment. Recommendations for further study and assessment are noted where identified by the environmental assessment team. Follow-up and monitoring are identified based on the information available during the FEED stage of the Project.

1.1.1 Project Purpose

The purpose of the Project is to install and operate a bioenergy plant to increase the use of local biomass as a fuel and to support energy security and the local forest industry. Local agriculture may also be developed in the form of greenhouses that are heated by using the waste heat from the biomass plant. Biomass is a locally available, renewable resource. It is considered an economical choice in the Yukon Territory by Yukon Energy, and is alignment with Yukon Government policies including the Yukon Energy Strategy and the Yukon Climate Change Action Plan. The forests surrounding Haines Junction incurred substantive levels of spruce beetle kill in the 1990's and those areas are the primary targeted feedstock for this Project. The shelf life of that wood is not currently well understood however it is currently considered by some to be a major forest fire threat and has been shown to be suitable fuel for the technology proposed for this Project.

Biomass or wood based fuels are considered greenhouse gas or carbon neutral (are not considered to contribute to increased GHGs in the atmosphere). This is because trees and other vegetation sequester carbon dioxide, a greenhouse gas as they live and grow, and store it until they die and decay, or are harvested and burned. Although burning wood and other biomass produces carbon dioxide, essentially no more is produced through burning than was consumed by the tree as it lived; therefore, as long as new trees are allowed to grow in place of those harvested over the long term, the carbon balance is maintained. The use of biomass along with other forms of renewable energy (such as wind, hydroelectric and solar) are considered key mitigating actions to reduce global GHG emissions.

According to the 2011-12 CAFN Annual Report (CAFN 2012a), the CAFN Council has identified special focus on three pillars: Wellness and Healing; Economic Development; and building vibrant Traditional Culture. This Project would support the pillar of economic development through the creation of facility and forest harvesting related employment opportunities. The CAFN is striving to develop the Project in consideration of traditional culture, wellness and healing as well. CAFN signed a Memorandum of Understanding with the Village of Haines Junction (VOHJ) and Dakwakada Development Corporation (DDC). The CAFN, VOHJ and DDC have a strategic interest in creating a business opportunity to generate electrical energy and provide low cost heating. This Project aligns with the objectives of the Memorandum of Understanding (MOU) which include:

- working together to develop a renewable energy development strategy for CAFN Traditional Territory that respects and reflects economic, environment and community interests;
- promoting an equal relationship that fosters dialogue to assess energy project potential and identification of priorities; and
- enhancing economic opportunities for CAFN in their Traditional Territory.

Members of the CAFN community and members of the public have also voiced a genuine concern for the increasing risk of forest fire in the area due to the large volume of trees killed by the Spruce Bark Beetle, in the area surrounding Haines Junction, as these trees are lower in moisture than green wood. In terms of CAFN's readiness to harvest the forest resources in a strategic fashion, the CAFN has completed a Strategic Forest Management Plan as well as an Integrated Landscape Plan for their Traditional Territories (CAFN 2005, EMR 2006). These documents include assessment of forest

resources, management priorities and guidelines for timber harvest project planning. Therefore, the CAFN is ready from a planning perspective to proceed with responsible execution of additional forest harvesting as required. Through this type of project, the CAFN will have an additional viable use for forest biomass available on their Traditional Territories and will be able to put their planning tools into action. Harvesting priorities include spruce bark beetle-killed areas and areas most sensitive to forest fire or which pose a larger risk of loss in the event of fire (near communities).

1.1.2 Project Benefits

The Project benefits are summarized as follows:

- use of a renewable, Yukon based fuel resource;
- maximizing the energy outputs of the resource through combined heat and electricity generation;
- reducing the local reliance and consumption of fossil fuels (buildings to be heated by the Project currently burn diesel for heating);
- reduction in some emissions of air contaminants through an associated reduction in fossil fuel use for local building heat;
- economic opportunities in Haines Junction associated with plant and forest based jobs; and
- creation of an additional use for forest harvested biomass surrounding Haines Junction.

1.2 PROPONENT INFORMATION

1.2.1 Project Team

The Proponents of the Project include Yukon Energy Corporation (YEC) and Champagne and Aishihik First Nations (CAFN). The current plan for Project ownership is that CAFN would be the majority owner of the Project, likely in partnership with YEC. The ultimate structure of ownership and operational control of the Project is one of the primary tasks of the feasibility studies currently underway. The evaluation is considering the risks associated with various models for ownership and operation of both the plant and harvesting operations. In any event it is expected that CAFN members will be used to the greatest extent possible and trained for eventual assumption of full operations over a maximum 20 year period. Yukon Energy will hold a minority interest in the Project in relation to the plant, but are not interested in the operations of the logging business.

Consideration of outsourcing operations to an independent service provider is part of the overall risk assessment and feasibility study for the Project. In terms of the plant site, Yukon Energy has expertise and experience in ownership and operation of generating facilities, although this would be their first involvement with biomass. CAFN does not have previous generation experience, however they have expertise is forest harvesting and forest resource management as demonstrated through their leadership in the development of the Strategic Forest Management Plan (SFMP) and have a strong interest in providing jobs to CAFN community members as part of the Project. Thus the Proponents are

considering the best ownership and operational scenario, to minimize risk to the Project and maximize community gains.

Established in 1987, Yukon Energy is a publicly owned electrical utility that operates as a business, at arms-length from the Yukon government. They are the main generator and transmitter of electrical energy in Yukon and work with their parent company Yukon Development Corporation to provide Yukoners with a sufficient supply of safe, reliable electricity and related energy services.

There are almost 15,000 electricity consumers in the territory. Yukon Energy directly serves about 1,700 of these customers, most of whom live in and around Dawson City, Mayo and Faro. Indirectly, they provide power to many other Yukon communities (including Whitehorse, Carcross, Carmacks, Haines Junction, Ross River and Teslin) through the Yukon Electrical Company Limited. Yukon Electric buys wholesale power from Yukon Energy and sells it to retail customers in the territory.

Yukon Energy has the capacity to generate approximately 132 megawatts of power. Ninety two megawatts of that are provided by our hydro facilities in Whitehorse, Mayo and Aishihik Lake (40 megawatts at Whitehorse, 37 megawatts at Aishihik and 15 megawatts at Mayo), 39 megawatts by diesel generators (which we currently only use as back-up) and 0.8 megawatts by two wind turbines located on Haeckel Hill near Whitehorse.

Yukon Energy is regulated by the *Business Corporations Act*, the *Public Utilities Act* and the *Yukon Water Act*. Our headquarters are located near the Whitehorse Rapids hydro plant in Whitehorse, with community offices in Mayo, Faro and Dawson City (Yukon Energy 2013).

CAFN established itself as a self-governing First Nation in 1993, after more than 20 years of negotiations. CAFN's rights to the Yukon portion of its traditional lands and resources were confirmed with the signing of the Champagne and Aishihik First Nations Final Agreement between CAFN, the Government of Canada and the Government of Yukon.

CAFN was one of the first four Yukon First Nations to conclude their final agreements. In addition, the self-government agreement provides CAFN with the power to enact laws on a wide range of matters affecting the rights of its citizens. On September 17, 1998 the Champagne and Aishihik First Nations made history by passing three acts: the *Income Tax Act*, *Fish and Wildlife Act*, and the *Traditional Pursuits Act*. These acts became effective on January 1, 1999.

A variety of municipal services, (housing, roads, water and sewer) as well as social services (health, nutrition, employment and training) are fully administered by the First Nations' government. The Department of Lands and Resources, which also includes Heritage and Economic Development, manages CAFN's traditional lands and integrates education and training of its citizens.

CAFN has undergone radical change in the last 100 years. Not long ago, the Southern Tutchone people of this region lived as part of the land. Today, they are working on the establishment of their own government and CAFN is becoming the steward of its homeland as it builds a sustainable economy.

1.2.2 Policies and Visions on Environmental and Sustainable Development

YEC and CAFN have converging values when it comes to environmental responsibility and sustainable development and both organizations have environmental stewardship ingrained in their policies, guiding principles and values. Further information on YEC's environmental policy can be found on their website at http://www.yukonenergy.ca/about/policies/environmental/.

CAFN has published a number of strategic plans in relation to sustainable development that will directly guide the implementation of this Project including their Vision Statement and Strategic Plan. CAFN's guiding documents can be accessed on their website at http://www.cafn.ca/.

CAFN's Land Claim Agreement provides for the ownership of some 2,427 square kilometers of land. It also continues to provide guaranteed access to fish and wildlife resources. Most importantly, the agreement establishes the CAFN government as co-managers of all natural and cultural resources in its traditional territory. CAFN is now a full partner on the Kluane National Park Management Board, the Alsek Renewable Resources Council and has representation on numerous other regional and territorial boards that make recommendations on heritage, educational, environmental and economic issues.

1.3 REQUIRED AUTHORIZATIONS AND REGULATORY APPROVALS

Yukon government, First Nation government, and federal government regulatory approvals and decisions are required before any activities (construction and operation) may be undertaken for any project that may emerge from this and other related feasibility studies. These approvals and decisions, however, may only be made after the required assessment by the Yukon Environmental and Socio-economic Assessment Board (YESAB) of a Project Proposal submitted pursuant to the Yukon *Environmental and Socio-economic Assessment Act* (*YESAA*).

1.3.1 *YESAA* Screening Requirements

While this type of project will have several activities which would make it assessable under *YESAA*, a screening level assessment by the YESAB Executive Committee would be required in accordance with Item 55 of Schedule 3 of the Assessable Activities, Exceptions and Executive Committee Projects Regulations as the Project will involve cutting 20,000 m^3 or more of standing or fallen trees or removing that amount of fallen or cut trees. The power plant (principal project) on its own would only trigger an assessment at the Designated Office level (Executive Committee assessment required for wood-fired electrical generating stations with a production capacity of 5 MW or more), but the principal project's interdependence with the accessory project, consisting of local feedstock procurement, raises the level of assessment to a screening.

The expected biomass consumption for the plant ranges from 10,000 m^3 to 40,000 m^3 annually (0.5 to 2 MW). Therefore the smaller plant may only require a Designated Office (DO) proposal submission. The requirements will be confirmed through consultation with YESAB prior to submission.

1.3.2 Applicable Legislation, Regulations, and Permits

Pending the issuance of a favorable YESAB Executive Committee screening or DO decision, the proponent is able to pursue any required federal, First Nation, and/or territorial government authorizations for the project to proceed (*e.g.*, Air Emissions Permit, Timber Permit). Once the decision documents are issued, the permitting/licensing applications can be processed by the applicable authority and authorizations subsequently issued to begin construction and commence operations.

The territorial, First Nations, and federal government authorizations that may be required for the construction and operation of the proposed Bioenergy Facility and associated feedstock harvesting are shown in the following tables (Tables 1.3.1 and 1.3.2). This list will be amended based as the technical aspects of the facility and harvesting become further defined as the Project progresses. The information below is based on the Permit and Authorization Guide for Yukon Activities (2013) and information currently available for the Government of Yukon (YG), Champagne and Aishihik First Nations and Federal Government agencies online.

The Strategic Forest Management Plan and Integrated Landscape Plan for the CAFN Traditional Territory (TT) are the overarching guiding documents for forest management and harvesting in CAFN TT as set out in the provisions under Chapter 17 of the CAFN Final Agreement. Timber harvesting activities and associated feedstock harvesting activities should be assumed to require consistency with their direction, otherwise the activities would not get authorized. Higher performance standards exist in this plan than exist under other forms of regulation.

Renewable Resource Councils (RRCs) are local management bodies in the Yukon established in areas where individual land claim agreements have been signed. RRCs are a voice for local community members in managing renewable resources, such as fish, wildlife, habitat and forestry matters, specific to their Traditional Territory. RRCs provide strong input into planning and regulation by the territorial, federal and First Nations governments. RRCs also play an important advisory role to the territorial management board for fish and wildlife by raising awareness of specific issues and providing local and traditional information.

The Alsek Renewable Resource Council (ARRC) is the applicable RRC for the Haines Junction community and surrounding CATT. The ARRC's jurisdiction is the Champagne and Aishihik Traditional Territory (CATT) which includes the Yukon communities of Haines Junction, Canyon Creek, Takhini, Mendenhall, Silver City, Kloo Lake, Aishihik and Klukshu (YFWMB 2013).

The ARRC began its work in 1995 after the signing of the Champagne and Aishihik First Nations (CAFN) Final Agreement. The Final Agreement created the ARRC as the "primary instrument for local renewable resources management."

Table 1.3.1 Bioenergy Facility Regulatory Requirements

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Air Emissions greater than 5 Mbtu-hr	• *Yukon Government Environment Act* • *Air Emissions Regulation*	• Air Emissions Permit	• Environment Yukon	
Release of Air Pollutants	• *Yukon Government Environment Act* • *Air Emissions Regulation*	• Air Emissions Permit	• Environment Yukon	
Ozone Depleting Substance Use	• *Yukon Government Environment Act* • *Air Emissions Regulation*	• Ozone Depleting Substances/ Halocarbons Permit	• Environment Yukon	Requirement to be determined based on design.
Special Waste Management	• *Yukon Government Environment Act* • *Special Waste Regulations*	• Special Waste Facility • Disposal and Generator Permit	• Environment Yukon	Requirement to be determined based on design.
Solid Waste Disposal	• *Yukon Government Environment Act* • *Solid Waste Regulations*	• Facility Permit	• Environment Yukon	Requirement to be determined based on design.
Storage Tank/Petroleum Tank Use	• *Yukon Government Environment Act* • *Storage Tank Regulations*	• Application for Operation, Closure • Abandonment or Renovation to Storage Tanks/Permit	• Community Services, Protective Services	Requirement to be determined based on design.
Water Use or Deposit of (Water) Waste	• *Waters Act*	• Water Use License	• Yukon Water Board	Requirement to be determined based on water use quantities.
Potable Water Supply	• *Public Health Act* • *Drinking Water Regulation*	• Drinking/Potable Water Permit	• Health and Social Services • Public Health and Safety	
Land Acquisition, Title to Land	• *Land Titles Act*	• Issuance of Title	• Justice	Requirement to be determined based on land parcel.
Tenure for Land Lease or Agreement of Sale	• *Territorial Lands Act*	• Application for Land	• Energy, Mines & Resources	Requirement to be determined based on land parcel.
Tenure for Land Lease	• *CAFN Lands Act*	• CAFN Lands Disposition (lease for commercial or industrial purposes)	• CAFN Heritage, Lands and Resources	Commercial lease of land requires CAFN Lands Committee review of application and Chief and Council approval.

Table 1.3.1 Bioenergy Facility Regulatory Requirements

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Temporarily Using or Occupying Commissioner's Land	• *Territorial Lands Act*	• Land Use Permit	• Energy, Mines & Resources	Requirement to be determined based on land parcel.
Temporarily Using or Occupying CAFN Settlement Land	• *CAFN Lands Act*	• CAFN Lands Disposition (easement, right-of-way)	• CAFN Heritage, Lands and Resources	
Facility Construction	• *Yukon Government* Land Services	• Building Permits	• YG Community Services • Building Safety	
	• *Yukon Government Forest Resources Act*	• Timber Resource Processing Permit	• Forest Management Branch	Requirement for construction, operation of any timber processing facility.
	• *Building Standards Act*	• Plumbing Permit	• YG Community Services, Building Safety	
	• *Public Health & Safety Act* • *Sewage Disposal Systems Regulation*	• Sewage Disposal Permit	• Health & Social Services • Environmental Health Services	Requirement to be determined based on design.
	• *Electrical Protection Act*	• Electrical Permit	• YG Community Services, Building Safety	
	• *Gas Burning Devices Act*	• Gas Installation Permit	• YG Community Services, Building Safety	Requirement to be determined based on design.
Clearing or Installing a Utility Right-of-Way	• *Territorial Lands Act*	• Land Use Permit, Disposition Approval	• Energy, Mines & Resources	Requirement to be determined based on design.
Construction of New Road Access	• *Territorial Lands Act*	• Land Use Permit	• Energy, Mines & Resources	Requirement to be determined based on site location.
Construct Road Access on Highway Right-of-Way	• *Highways Regulation*	• Access Permit	• Highways & Public Works	Requirement to be determined based on site location.
Temporary Use of CAFN Settlement Land / Use or Alteration of Resources on Surface of Land	• *CAFN Traditional Activities Protection Act*	• TAPA Permit	• CAFN Heritage, Lands and Resources	Permits issued by Director.
Activities in a Habitat Protection Area	• *Wildlife Act* • *Wildlife Regulation*	• Permission for Activity	• YG Environment	Requirement to be determined based on site location.
Activities in a Wildlife Area	• *Wildlife Area Regulation*	• Wildlife Permit	• YG Environment	Requirement to be determined based on site location.

Table 1.3.1 Bioenergy Facility Regulatory Requirements

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Harmful Alteration, Disruption or Destruction of Fish Habitat	• *Fisheries Act*	• Fisheries Act Authorizations S.35.2	• Fisheries and Oceans Canada	Requirement to be determined based on site location and construction.
Destruction of Fish by Means Other than Fishing	• *Fisheries Act*	• *Fisheries Act* Authorizations S.32	• Fisheries and Oceans Canada	Requirement to be determined based on site location and construction.
Obstruction of Fish Passage	• *Fisheries Act*	• *Fisheries Act* Authorization S.22	• Fisheries and Oceans Canada	Requirement to be determined based on site location and construction.

Facility or Activity	Act or Regulation	Approval/Permit Required	Lead Agency	Comments
Construct Road Access on Highway Right-of-Way	• *Highways Regulation*	• Access Permit	• Highways & Public Works	Requirement to be determined based on site location.
Activities in a Habitat Protection Area	• *Wildlife Act* • *Wildlife Regulation*	• Permission for Activity	• YG Environment	Requirement to be determined based on site location.
Activities in a Wildlife Area	• *Wildlife Area Regulation*	• Wildlife Permit	• YG Environment	Requirement to be determined based on site location.
Transportation of Bulk Commodity	• *Bulk Commodity Haul Regulations*	• Bulk Commodity Haul Agreement	• Highways & Public Works	Requirement to be determined based on transportation quantities.
Oversize Trucking	• *Highways Act*	• Over Dimensional or Over Weight Vehicle Permits	• Highways & Public Works	Requirement to be based on transportation methods.
Assessment of Historic Resources as Part of the Timber Harvest Planning or Road Construction	• *Historic Resources Act*	• Archaeological Permit	• Department of Culture and Tourism	Required to conduct heritage assessments in the field.
Other Research Projects	Examples: • *Scientists And Explorers Act* (Yukon) • *Fisheries Act* • *Migratory Birds Act* • CAFN TAPA Based Traditional Knowledge Policy	Various Authorizations	• Canadian Wildlife Service • Fisheries and Oceans Canada • Yukon Culture and Tourism • Yukon Environment • CAFN	Quite likely necessary if project will include fish and wildlife monitoring.

2.0 FIRST NATIONS, OTHER GOVERNMENT AND COMMUNITY CONSULTATIONS

2.1 CONSULTATION REQUIREMENTS

Section 50(3) of the *Yukon Environmental and Socio-Economic Assessment Act* (YESAA) lists the following First Nations and stakeholder consultation requirements:

> *"Before submitting a proposal to the Executive Committee, the proponent of a project shall consult any first nation in whose territory, or the residents of any community in which, the project will be located or might have significant environmental or social economic effects."*

Section 3 of YESAA states:

> *"Where, in relation to any matter, a reference is made in this Act to consultation, the duty to consult shall be exercised:*
>
> *(a) by providing, to the party to be consulted,*
>
> *(i) notice of the matter in sufficient form and detail to allow the party to prepare its views on the matter,*
>
> *(ii) a reasonable period for the party to prepare its views, and*
>
> *(iii) an opportunity to present its views to the party having the duty to consult; and*
>
> *(b) by considering, fully and fairly, any views so presented."*

2.2 CONSULTATION OVERVIEW AND APPROACH

The overarching aim of Project consultation efforts is to generate awareness, understanding and support within the local communities of Haines Junction and Champagne and Aishihik First Nations, and to reach an accurate and complete understanding of the concerns and interests that local communities and interested stakeholders may have with regard to the construction and operation of a biomass energy generation facility. The goals of Project consultation efforts are as follows:

- create and maintain awareness and understanding of the project among the general public, decision-makers, key stakeholders, and interested First Nations (particularly Haines Junction residents and Champagne and Aishihik First Nations citizens), including potential costs and benefits, and timelines and opportunities for engagement;
- identify stakeholders and potentially interested First Nations, build and maintain strong relationships with those groups, and ensure that engagement occurs at the right level, at the right time, in the right way;
- identify, document and monitor issues and concerns that arise during the engagement process

- identify planning, design and management measures that can be used to avoid, mitigate or resolve potential negative environmental and socio-economic impacts;
- encourage the sharing of traditional land use and traditional knowledge information by interested and potentially affected First Nations groups; and
- provide early notification of the project and ensure that there are adequate opportunities for First Nations, stakeholder and public input.

2.3 PUBLIC CONSULTATION PLAN

The project involves consultation and relationship-building over a number of different phases spanning several years. As the Project progresses from the initial feasibility assessment through the internal assessment of potential environmental and socio-economic effects and then into the external impact assessment process, the Project Team will consult with interested First Nations, stakeholders and the general public through a mix of targeted meetings, open house sessions and information updates on Project partner websites. The depth of consultation will depend on stakeholders as shown in Table 2.3.1 below.

Table 2.3.1 Consultation Levels

Consultation Level	STAKEHOLDER TYPE
Collaborate	Stakeholders that are responsible for driving the Project.
Involve	Stakeholders who have a high-level of engagement with the Project and are involved in the decision-making process.
Consult	Stakeholders who need to have a good understanding of the Project and will be invited to provide input at critical points (*e.g.*, Federal, Territorial, and FN Resource Management Agencies, FN citizens and local residents, industry, land users and owners, planning groups and committees, NGOs, ENGO).
Inform	Stakeholders who require a broad level of awareness of the project Stakeholders who may be influential or important.

To cultivate relationships with First Nations and key stakeholders that have an active interest in the Project, meetings will be held to provide updates on the Project, discuss planned work, listen to concerns and assess areas of interest. The Project Team may also choose, where appropriate, to engage with particular First Nations and stakeholder groups when planning and conducting specific Project tasks.

The project will be located within the traditional territory of the CAFN and they are the primary First Nation that will be engaged with regard to the Project. While it is highly unlikely that the Project will have an effect on the traditional territories of other First Nations, there is potential that the following First Nations and First Nations associations may express some interest in the Project and may request more information and dedicated meetings:

- Carcross/Tagish First Nation;
- Council of Yukon First Nations – Natural Resources and Environment;
- Kluane First Nation;

- Kwanlin Dun First Nation;
- Little Salmon Carmacks First Nation;
- Ta'an Kwäch'än Council; and
- White River First Nation.

As the Project progresses, the Project Team will communicate by letter with interested First Nations at key regulatory milestones to disseminate Project documentation and keep those groups up-to-date.

Following submission of the project proposal, YESAB will conduct their formal First Nation and public consultation review process. During that process, the Project Team may be asked to respond to queries or concerns. The Project Team will continue to meet with stakeholders and First Nation groups to resolve ongoing issues as appropriate and public meetings may be held to provide further opportunities for participation and input.

Under YESAA, the knowledge and views of Yukon First Nations and their citizens will be sought out by regulators. Notification will be sent to all First Nations whose territory the project may be located on or where the project might have significant environmental or socio-economic effects. First Nations will have the opportunity to participate and share their views and information during the comment period for the assessment.

In the YESAA, it is explicitly stated that traditional knowledge is a factor that must be considered and incorporated into an impact assessment. Specific meetings will be held with the CAFN to plan and carry out required traditional land use or traditional knowledge studies. These studies will provide essential Project-specific information for integration into the environmental and socio-economic impact assessment.

2.4 CONSULTATION TECHNIQUES

The following are techniques available for use by the Project Team to engage interested First Nations, stakeholders and the general public:

- letters and email correspondence;
- face to face meetings;
- workshops and open houses:
    - project information sheets and posters (distributed to local government offices, libraries, local recreational centers, community bulletin boards, schools, First Nation band offices);
- radio and television advertisements;
- targeted media interviews;
- website and social media; and

- advertisements in community newspapers.

All feedback from First Nations and stakeholders will be tracked in a shared information management system. Speeches and presentations will be documented in a similar manner; the identities of those who attended the event and the nature of feedback received will be documented. Information on communications activities will be available on demand to the Project team and the data will be regularly updated. Public consultation completed to date is summarized in Table 2.4.1. Some more informal meetings with individual stakeholders have also been completed to date.

Table 2.4.1 Consultation Events To-Date

Location	Description	Date	Venue
Haines Junction, Yukon	Open House geared engaging CAFN members and Haines Junction residents, building support, disseminating information and gathering preliminary issues and concerns.	January 23, 2013	Da Ku Cultural Centre 280 Alaska Highway Haines Junction, Yukon

2.5 KEY CONCERNS RAISED DURING CONSULTATION

The first open house for the Project was held in Haines Junction on Jan. 23, 2013. A detailed summary has been prepared by the Proponent and will be considered in the development of future public and First Nations communications as well as in shaping the Project in the next stages. The open house included presentations on the technologies being considered, the preliminary feedstock availability assessment, environmental issues being considered and the waste heat recovery component of the Project.

Approximately 75 to 80 members of the community attended including CAFN members and general public as well as representatives from the Village of Haines Junction and Forest Management Branch. Questions and comments received during the session are summarized as follows and have been considered in the development of this assessment:

- concern that the engines be the most efficient available were raised;
- use of generated heat during the summer;
- proximity of the biomass plant to the Village and noise levels;
- pros and cons of using a gasification system versus a conventional steam system;
- effect of cold climate of Haines Junction on functioning of biomass plant;
- whether live trees will be used as fuel in addition to beetle-killed trees;
- whether the technology will be available in all CAFN communities;
- what is the capacity of the ‘green zone’ to regenerate (related to the Forest Management Zones defined in the local Integrated Landscape Plan);

- maximum distances that a biomass plant can be located from inhabited areas and still be economic;
- potential impacts on wood supplies for wood cutting industry and whether price of firewood will increase;
- location of plant;
- need for heating and jobs in the local communities;
- forest fire concerns;
- ash disposal;
- plant size and capacity to utilize beetle-killed wood;
- whether similar plants could be located in Burwash and Destruction Bay;
- cost of heating infrastructure;
- responsibility for hiring and maintenance;
- which businesses (CAFN and non-businesses) may realize benefits; and
- whether excess heat could be stored during summer for the winter.

2.6 KEY CONCERNS ANALYSIS

No new issues were raised during the first consultation event beyond those aspects that are either currently being evaluated or are planned for subsequent stages of the Project. Overall, First Nations and public in attendance were supportive of the Project and concerns were focused around avoiding issues with current harvesting activities (competition for forest resources), maximizing local job development and addressing the growing risk of forest fire from dead standing trees in beetle kill zones.

3.0 PROJECT DESCRIPTION

This chapter provides an overview of the project location and study area characteristics, the Project technology and infrastructure and the schedule for permitting, construction, operation and eventual decommissioning.

3.1 PROJECT LOCATION

The geographic location of the Project is in the Village of Haines Junction in the Yukon Territory. The Project location is shown in Figure 3.1.1. The community of Haines Junction has its beginnings as a highway construction camp built in 1942 at the junction of the Alaska Highway and Haines Road.

3.1.1 Local Climate

The Climate in the Ruby Ranges Ecoregion, which includes the Haines Junction area and a large swath of the Champagne and Aishisik Traditional Territory (CATT – Figure 3.1.1), is characterized as the driest in the Yukon Territory. This ecoregion receives only 250-300 mm of precipitation annually, resulting from a rain shadow produced by the St. Elias Mountains to the west (Yukon Ecoregions Working Group, YEWG 2004). The Shakwak Valley, where Haines Junction is situated, experiences the coldest temperatures of the Ecoregion, ranging from -30° to -35° C in January (YEWG, 2004). Permafrost is present in most of the ecoregion, except in the southern portion in and around Haines Junction (YEWG 2004). Climate in the Yukon Southern Lakes Ecoregion is also relatively arid. Only 200 to 325 mm of precipitation occurs in the Yukon Southern Lakes, again due to the rain shadow from the St. Elias-Coast Mountains. Mean annual temperature ranges from -1° to -4°C throughout the ecoregion, and is colder in the northwest than in the southeast, with the lowest temperatures occurring in January ranging from -21° to -25°C (YEWG 2004). Permafrost underlies less than a quarter of the area within the ecoregion, in part due to the arid climate described above (YEWG 2004).

3.1.2 Study Area Boundaries

The preliminary study area is focused on the Village of Haines Junction as the specific plant site has not yet been chosen, nor have the areas for additional harvesting been finalized. The location of the plant site will likely be within 400 m of larger buildings in Haines Junction as this is the approximate limitation for use of waste heat from the plant. The village and key buildings being considered for waste heat use are shown in Figure 3.1.2. The potential location being used for FEED is also shown in Figure 3.1.2. This location is considered as the preliminary site location in this assessment and is a greenfield site (has not been recently developed). Excluding the harvesting area(s), the plant and construction activities will cover an area of approximately 2.8 hectares (ha).

3.1.3 Village Services

The following description of services has been gathered from Haines Junction's Integrated Community Sustainability Plan and CAFN's Integrated Community Sustainability Plan (Village of Haines Junction 2007, CAFN 2009a).

Figure 3.1.1 Project Location

Figure 3.1.2 Preliminary Range of Sites for Waste Heat Use

Recreational facilities in Haines Junction include an arena, curling rink, swimming pool, outdoor basketball court and a skateboard park. There is also a community library with public internet access, a youth centre, and a community hall. Haines Junction is served by a local community Health Centre, a volunteer ambulance service, a locally based social worker, and a locally based counselor. Recently, a Seniors' Centre has opened with limited hours.

The RCMP operates a detachment in Haines Junction and the local Haines Junction Community Justice Committee provides alternative justice systems.

There is a volunteer fire department, with staff trained in first aid and CPR. St. Elias Community School offers kindergarten to Grade 12 and the Haines Junction campus of Yukon College offers full-time academic upgrading programs and delivers a variety of continuing education courses. The campus's location near the St. Elias Mountains provides opportunities for such courses as avalanche training, wilderness guiding and wilderness survival. Youth employment training, early childhood courses and office administration are also offered.

The Yukon Electrical Co. Ltd. supplies hydroelectric power from Aishihik Lake, with diesel generator back-up. The village has a piped water supply that is also available to some properties owned by CAFN. Other areas use trucked-in, chlorinated well water or personal wells.

3.1.4 Traditional Territory

The CAFN's Land Claim Agreement provides for the ownership of some 2,427 square kilometers of land. It also continues to provide access to fish and wildlife resources. CAFN is a full partner on the Kluane National Park Management Board, the Alsek Renewable Resources Council and has representation on numerous other regional and territorial boards that make recommendations on heritage, educational, environmental and economic issues.

Haines Junction is not a traditional CAFN settlement but is located on well used travel routes. The original name for the area was Dakwakada, meaning high cache, which indicates that the area was an important hunting and fishing region. The community only gradually became a place where CAFN people permanently settled in the 1940s and 1950s after Haines Junction began to grow as a regional centre. The number of First Nation residents increased sharply beginning in the 1960s when the federal government relocated families from Champagne and Aishihik to the community.

3.1.5 Yukon Land Use Planning Region

In Yukon, the Umbrella Final Agreement introduced a new regional land use planning process. Currently there are eight planning regions in Yukon with borders generally following the traditional territories of Yukon First Nations. The Project is located in the Kluane planning region (Kluane and Champagne & Aishihik TT). The region does not yet have an approved regional land use plan. The objectives of regional planning in the Yukon (under the Final Agreements) are:

- Minimizes actual or potential land use conflicts. These conflicts will likely grow worse without planning;

- Recognizes and promotes the cultural values of Yukon First Nations people. Certain cultural activities are intrinsically linked to the land;

- Ensures Sustainable Development by developing social, cultural, economic and environmental policies that apply to the management, protection and use of land, water and resources in an integrated and coordinated manner;

- Spells out how and where land uses may or may not occur, and so increase the land use certainty. In some cases, land use plans may help avoid legal action between different land users (YLUPC 2011).

Both YESAA and Land Use Plans are concerned with how and where development occurs and YESAB is an important component in implementing land use plans. In reviewing proposed projects, YESAB must consult The Yukon Land Use Planning Council (YLUPC) as to whether the project conforms to the land use plan, and how the project can conform to the plan, if it doesn't already. Although conformity with the plan does not determine whether a project can proceed or not, it will be factored into the decision (YLUPC 2011).

3.1.6 Consistency with Other Plans

The Project would be executed in harmony with planning tools used by Champagne and Aishihik First Nations including the Integrated Community Sustainability Plan (ICSP) (CAFN 2009a) published in 2009 and the Strategic Forest Management Plan (SFMP) and the Integrated Landscape Plan (ILP) (EMR 2006). The ICSP included a number of focus areas that are consistent with this Project including energy efficiency upgrades, renewable energy generation and potential for incorporation of a community greenhouse. The Village of Haines Junction completed its Integrated Community Sustainability Plan in 2007 with similar priorities noted in comparison to the CAFN ICSP.

Details of requirements for the Project to proceed in conjunction with the SFMP and ILP are outlined in each VC section as applicable. As this plan relates to forest management, further specifics of how the Project would ensure consistency with the ILP will be confirmed in the next stage of study.

3.2 PROJECT INFRASTRUCTURE AND TECHNOLOGY

The technology for the Project is the use of a biomass gasification process to fuel a reciprocating engine. This technology has been selected as a gasifier is the only biomass technology that will allow for the use of a reciprocating engine which can be used to generate electricity without steam while also generating waste heat that can be used for building heating. Steam boiler and steam turbine combinations can also be used for these purposes but require more advanced training for operators and this expertise is not readily available in the Yukon, especially in small communities such as Haines Junction. Thus, the gasifier/reciprocating engine combination is considered the best choice for small Yukon communities wishing to use a combined heat and electrical power generating technology. The gasifier and engine technology is discussed further in the following section.

3.2.1 Gasifier and Engine Technology

Gasification is a process that converts a carbon-containing solid material into a gas (called synthetic gas or simply “syngas”) for use in applications such as electricity generation, heating, or chemical manufacturing. The chemical reactions to produce syngas take place in a vessel known as a gasifier. The temperature, pressure, and concentration of certain chemical species in the gasifier affect the chemical composition of the syngas. In general, syngas formed from biomass or woody material contains carbon monoxide, carbon dioxide, methane, hydrogen, steam, and unreacted nitrogen if air is used.

A simple block diagram of a gasification system is provided in Figure 3.2.1.

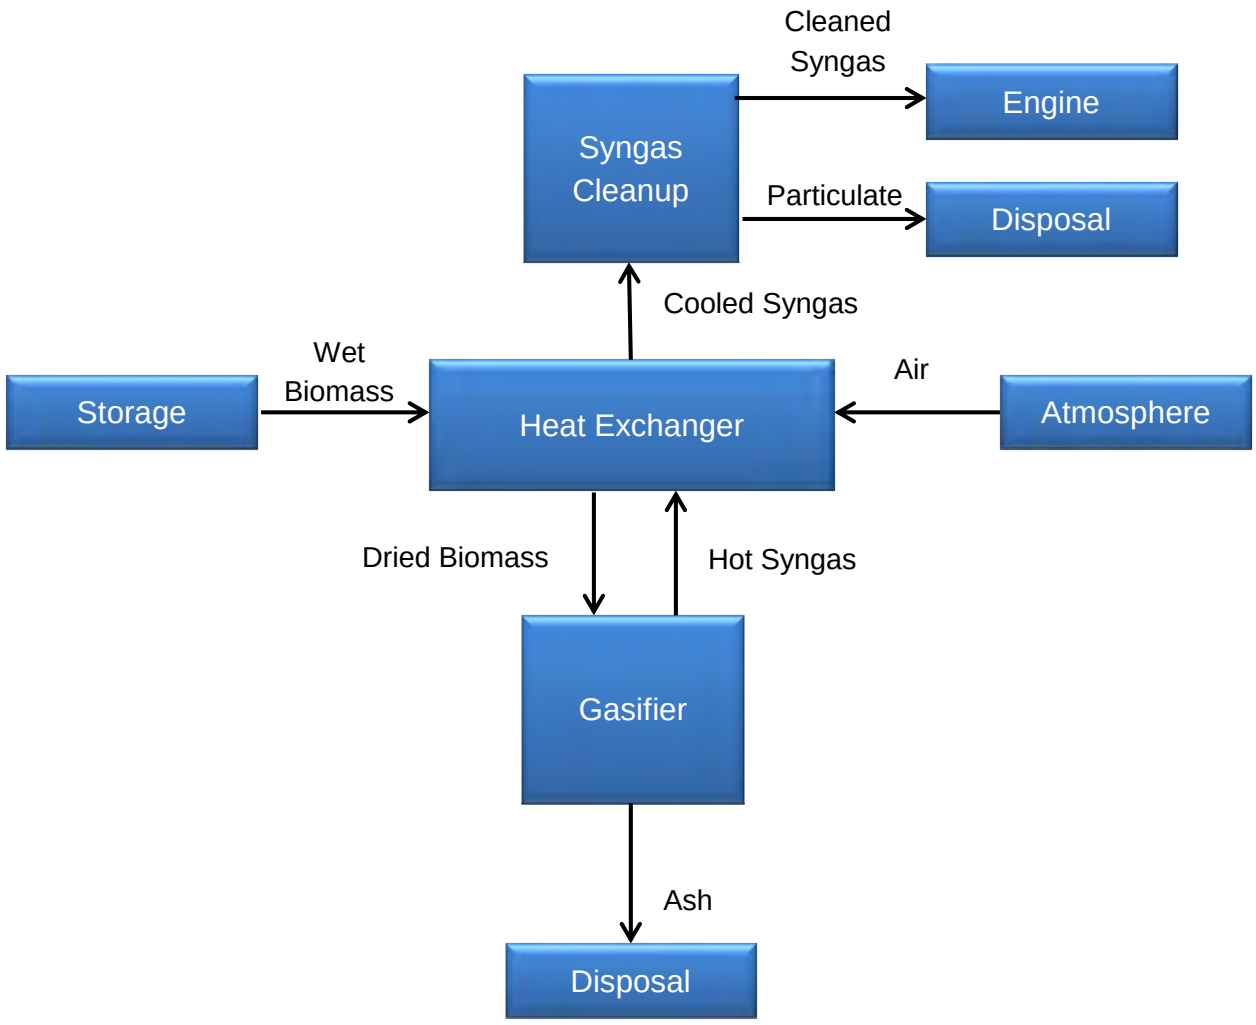

Figure 3.2.1 Simplified Block Diagram of a Gasification System

In a gasifier, the biomass feedstock is added in chip form (feedstock must be chipped using a mobile or stationary chipper) to the vessel along with air (a source of oxygen). In applications where the presence of nitrogen would be undesirable, pure oxygen or hydrogen is used instead. Temperatures in a gasifier can vary from 200°C to 1,000°C. Hot syngas from the gasifier is typically passed through a

heat exchanger to dry the incoming feedstock and cool the gas. This cooled gas is then filtered to minimize the particulate concentration and tar in the gas. This clean-up stage is important to decrease the wear on downstream equipment, such as a reciprocating engine. As an added benefit, the syngas cleanup reduces the release of particulate matter to the atmosphere. Ash is also generated by the gasifier and is collected for disposal in a landfill that is capable of handling such waste. This ash (sometimes called biochar due to its natural origin) could also potentially be used for other applications such as soil application or as a component of asphalt.

The FEED study is currently considering a biomass gasification system to generate 0.5 MW_e to 2 MW_e (megawatt of electric energy) using a reciprocating gas engine. Further details are available in the FEED study.

3.2.1.1 Case Studies

As this technology is quite novel (use of a gasifier, reciprocating engine combination), the following case studies are briefly described to provide additional details of potential technologies and required infrastructure. As part of the FEED study, the Project team visited three organizations to study their gasification systems and evaluate the potential for these systems to meet the Haines Junction Project objectives.

The Community Power Corporation (CPC) operates a 100 kW_e system at Pineland Forest Nursery in Hadashville, Manitoba. The system is housed in five shipping containers (each 6 m in length) with a separate fuel storage building. In addition to electricity generation, heat is recovered and used to heat greenhouses on-site. The system includes a stainless steel downdraft gasifier, a heat exchanger to dry incoming biomass, carbon filters to clean the syngas, and two V8 spark ignition engines for electricity generation. The control interface and electrical equipment are housed in a control room. The biomass supply is wood chips.

The exterior of the plant is shown in Photo 1.

Photo 1: Exterior of CPC Gasifier Plant

On the other end of the capacity envelope being considered for this Project, Nexterra operates a gasification system on the Vancouver campus of the University of British Columbia (UBC) for the production of electricity (2 MW_e) and heat. The system, including wood chip storage, is housed in a building, approximately 27 m x 55 m (90 feet by 180 feet), on the campus. Following screening, woodchips are dried in a single pass dryer then stored in bins. An updraft gasifier converts the biomass to syngas and ash. Nexterra uses a proprietary syngas cleanup system that includes tar cracking (for the breakdown of tar) and a bag house filtration system. The cleaned syngas is fed either to a 20 cylinder reciprocating engine to generate with a capacity of 2 MW_e or to a thermal oxidizer to generate heat and steam for district energy network.

The engine used to generate electricity from Nexterra syngas is shown in Photo 2.

Photo 2: Engine Used by Nexterra System

The FEED study completed by Stantec is based on a combination of CPC 100 kW_e units to form a 0.5 MW_e facility. Three options for a 0.5 MW_e facility were considered in the FEED Study.

3.2.2 Waste Heat Uses

Cleantech Community Gateway (CTCG) completed a study to review options for waste heat use from several electrical production scenarios, entitled *Haines Junction Bioenergy Project – Evaluation of Waste Heat Potential* (CTCG 2012). These options are considered integral to the development of the Project in relation to the biomass energy plant sizing and siting. Three options for the use of recovered heat were evaluated by CTCG: District Energy System (DES), Organic Rankin Cycle (ORC), and Controlled Environment Agriculture (CEA, *i.e.*, greenhouses). Each option is summarized in the following paragraphs.

For a 0.5 MW_e system that produces hot water, CTCG recommended that the hot water be used to heat one building such as the Haines Junction School or another building of similar heat requirement. The school's peak heat demand is 360 kW, which is slightly less than the peak thermal output of a 0.5 MW_e system. According to the CTCG report, in order for the use of waste heat to be economical, the length of the heat supply pipe between the power plant and the school must be approximately 350 m or less. The FEED study preliminary site selected was based on this parameter and review of available parcels of land.

The feasible radius for heating several select local buildings is provided in Figure 3.1.2.

CTCG noted that a 3 MW_{th} (megawatt thermal energy) power plant would be required to meet the peak heating requirements of the seven buildings identified as potential DES customers:

- Haines Junction School;
- Fire Hall;
- Convention Centre;
- Arena Complex;
- Swimming Pool and Community Hall Complex;
- YK Government Administration Building; and
- CAFN Cultural Centre and Kluane National Park Visitor Information Centre.

When considering the economics of a Direct Energy System (DES), a smaller network including the school, convention centre, arena complex, and the swimming pool and community hall has a lower risk and better economics.

An Organic Rankine Cycle (ORC) generator can be used to generate additional power using the waste heat. Two ORC generators were considered in the CTCG study. With respect to technical risk, district energy systems are considered to have low technical risk when designed and installed correctly. Integration of an ORC generator would require more substantive innovation, development, and testing, the cost of which is not currently known. Hence there is a higher technical risk and capital cost with the ORC generator than the DES. The CTCG concluded that the ORC option is not recommended for this Project.

Controlled Environment Agriculture (CEA) seeks to control lighting, temperature, nutrients, hydroponics, and air control in a greenhouse. Such a system in Haines Junction could potentially create a local food supply. CTCG made assumptions based on a CEA system in Alaska (Chena Hot Springs) and used standardized inputs to model the potential viability of a CEA greenhouse for Haines Junction. The results of the assessment indicate that a greenhouse with dimensions of 10.7 m by 47.5 m (35 ft by 156 ft) could supply Haines Junctions with 100% of its demand for tomatoes, cucumbers, and lettuce.

The CTCG found that a greenhouse is not likely to be economically feasible in Haines Junction without some form of subsidy or strategy to decrease operating costs. However, with respect to the socioeconomic impacts, a greenhouse may be of value to the community, potentially resulting in an increase in health and overall community wellness that may be worth the investment.

3.2.3 Fuel Harvesting and Handling

Biomass would be harvested from green forest management zones (Figure 3.2.2) as defined in the CAFN Integrated Landscape Plan (ILP).The specific areas associated with this Project will be further defined in the next stage of the Project. Chipping of the harvested trees would be required to prepare the feedstock for gasification. The chipping could be done with a mobile chipper at the roadside, at the plant or at a dedicated secondary log storage and chipping site. The logistics of chipping have not been finalized. These would also be confirmed in the next stage, as suppliers/harvesters are confirmed. The chips would be stored inside at the plant, with capacity for approximately 7 days being kept onsite.

3.2.4 Auxiliary Infrastructure

Auxiliary infrastructure associated with the gasifier/reciprocating engine system include electrical equipment (*e.g.*, transformer, metering) and building space for offices and feedstock storage (and gasifier/engines if not in self-contained shipping containers).

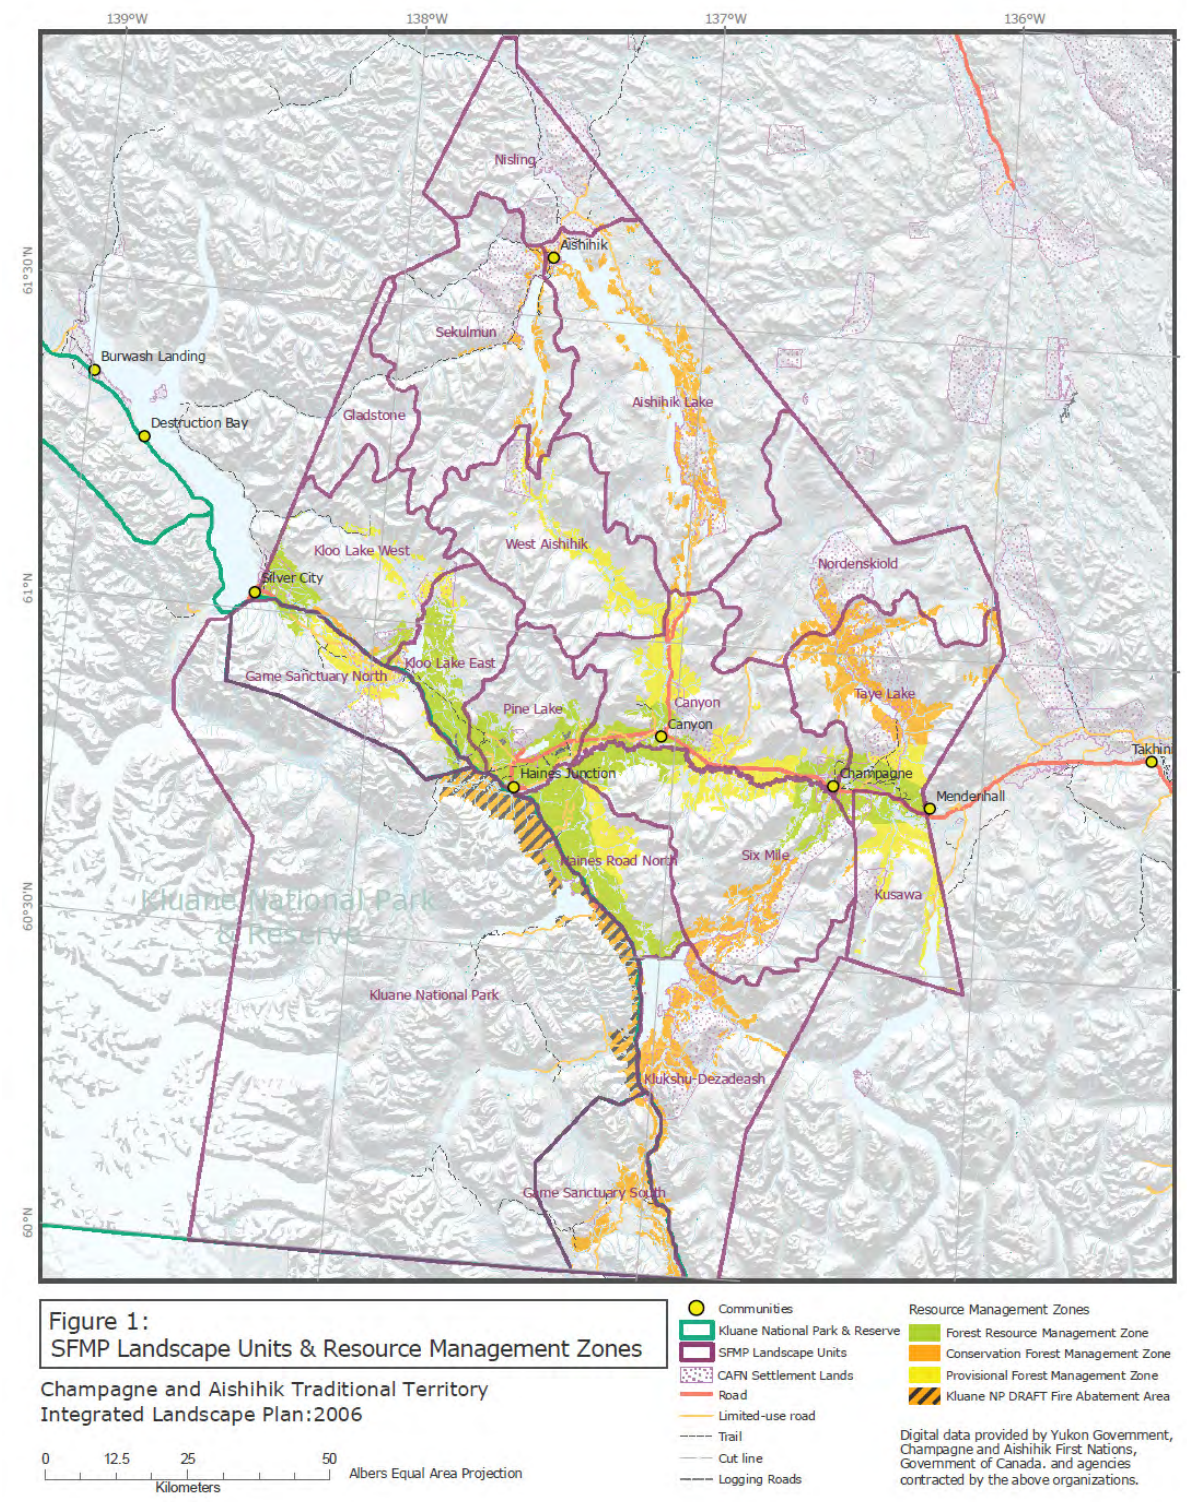

Figure 3.2.2 SFMP Landscape Units and Resource Management Zones

3.3 EMISSIONS AND WASTES

3.3.1 Air Contaminant and GHG Emissions

3.3.1.1 Construction

Since the Project involves modest construction requirements due to its relatively small scale, the releases of air contaminants and greenhouse gases to the atmosphere due to construction activities are expected to be small.

There will be nominal (essentially zero) emissions from the use of heavy construction equipment (*e.g.,* heavy-duty trucks) at the site, as well as some limited amounts of fugitive dust associated with ground preparation activities at the plant site. The transportation of construction materials and equipment to and from the Project site will also result in releases air contaminants and greenhouse gases to the atmosphere. Emissions from these sources, however, are not expected to be substantive and are expected to be generally confined to the Project site.

Forest harvesting construction activities may also result in moderate amounts of combustion gases and fugitive dust emissions from mobile equipment in the event that construction of new logging roads are required. Based on the preliminary feedstock harvesting assessment completed (as part of the FEED study), no new roads would be required to supply a 0.5 MW_e plant.

3.3.1.2 Operation

Operation of the Project will result in emissions of combustion gases and particulate matter to the atmosphere from the engine exhaust stacks. Two operational scenarios are considered for the Project, since the specific size of the operation is not yet confirmed. Based on the FEED study the size of the plant may range from 0.5 MW to 2 MW (electric energy). Therefore the emissions are estimated for the 0.5 MW and 2 MW cases to establish the range of emission rates for each air contaminant.

Where the Project is in the early design stages, multiple vendors are still being considered to supply the biomass gasifier and engine equipment. The air contaminant emissions estimates provided below are based on information provided by a specific vendor currently being considered for the Project (Community Power Corporation (CPC) 2012). The vendor emissions are for a 0.1 MW unit and have been scaled up for the scenarios below. Direct scaling is considered conservative as in practice 0.5 MW can be achieved using four (4) 0.1 MW units while emissions have been based on five units. The greenhouse gas (GHG) emissions are estimated by mass balance using the fuel consumption data from the vendor information. For assessment purposes, the units were assumed to operate continuously (*i.e.*, 24 hours per day, 365 days per year).

Estimated emissions for both Project operational scenarios considered are provided in Table 3.3.1.

Table 3.3.1 Estimated Emissions During Operation of the Project

Air Contaminant/GHG[1]	Scenario 1 0.5 MW Case (t/a)	Scenario 2 2 MW Case (t/a)
Nitrogen Oxides (NO_X)	2.8	11.2
Carbon Monoxide (CO)	1.2	4.6
Sulphur Dioxide (SO_2)	0.4	1.4
Total Suspended Particulate Matter (TSP)	0.012	0.048
Particulate Matter < 2.5 Microns ($PM_{2.5}$)	0.012	0.048
Carbon Dioxide (CO_2)[2]	6,700	26,780

Notes:
1. Estimates are based emissions information provided in vendor proposal for 0.1 MW, directly scaled up for larger units.
2. CO_2 emissions associated with biomass combustion are reported separately under the Environment Canada reporting program as these emissions are considered part of the global carbon cycle.

The operation of the Project which would supply heating to local buildings in addition to generation of electricity is expected to offset some air contaminant and greenhouse gas emissions currently resulting from diesel combustion for space heating of community buildings.

The releases of other GHGs (CH_4 and N_2O) from the operation of the Project are expected to be nominal, and are therefore not considered further in the assessment.

Releases of other air contaminants, specifically hazardous contaminants such as volatile organic compounds (VOCs), polycyclic aromatic hydrocarbons (PAHs) and dioxins and furans from the Project could occur in small amounts and are expected to be similar to that of other modes of biomass combustion.

Emissions of the hazardous air contaminants with largest expected emissions, *i.e.*, the air contaminants with the highest US EPA AP-42 biomass combustion emission factor, were estimated (US EPA 2003). Based on the US EPA AP-42 Emission Factors, benzene (C_6H_6) and formaldehyde (HCHO) are the air contaminants that are likely to be released in the highest quantities during Operation of the Project. Benzene emissions are estimated to range from 0.11 t/a to 0.44 t/a and formaldehyde emissions are estimated to range from 0.12 t/a to 0.47 t/a, depending on the scale of the Project (0.5 MW and 2 MW scenarios considered in the estimates). The emissions were estimated using the AP-42 emission factors and the energy input from the biomass fuel from the CPC proposal (CPC 2012). Discussion of how these emissions compare to other forms of heat and energy is provided in the Atmospheric Environment Section 5.2.

The gasification process is operated with relatively dry biomass (15% moisture) at a high temperature and the syngas produced is cleaned and filtered prior to combustion, which helps to reduce the release particulate matter to the atmosphere. The combustion of syngas in an internal combustion engine also serves to reduce emissions of hydrocarbons as a result of higher operating pressures and temperatures than that of a boiler. In addition, the annual volume of biomass consumed during Operation is relatively small.

Further details on the emissions from the Project and are provided in Section 5.2 of this document.

3.3.2 Sound Emissions

During Construction, the potential exists for unwanted sound ("noise") to be generated that could be considered to be a nuisance to nearby residents and land users, primarily as a result of the operation of heavy equipment required to complete construction activities. Equipment deliveries and construction traffic accessing the site, although not expected to be substantive, may result in slightly increased traffic levels in the community and possibly increased sound pressure levels at nearby locations.

During Operation of the Project, the potential exists for noise to be generated from the plant as well as harvesting operations. The biomass energy plant components will be housed within buildings and/or containers to reduce the resulting sound emissions from the gasifier and engines. The wood chipper location is currently unknown, as is the technology to be used.

The estimated sound pressure level from the operation of a 0.5 MW gasification plant is 81 dB_A at 4.5 m (10 feet), based on the maximum sound pressure level provided by CPC (CPC 2012).

The estimated sound pressure level from the operation of a 2 MW gasification plant is 87 dB_A at 4.5 m (10 feet), based on the maximum sound pressure level provided by CPC (CPC 2012).

Wood chipping of whole trees is known to be a noisy activity. A UK study on sound emissions from mobile chippers found that at a distance of 8 m of the chipper, sound pressure levels (based on 11 chippers) ranged from 89 to 99 dB_A (Health and Safety Laboratory 2008).

These sound pressure levels are used to estimate sound pressure levels at various distances from the Project, in Section 5.2.

3.3.3 Construction and Operational Solid Wastes

Solid waste generated during the construction phase would be disposed of in an approved landfill.

Operational solid wastes may include particulate matter collected by the syngas cleaning system (if required based on the design), char removed from the gasifier, and wastes associated with maintenance activities (*e.g.*, oily rags, cleaners). All wastes generated would be disposed of in an approved landfill.

3.4 PROJECT PHASES AND SCHEDULING

The Project schedule depends on the size of biomass plant selected following the FEED Study review. Preliminary schedules for the potential envelope of Project sizes are provided in Figure 3.4.1.

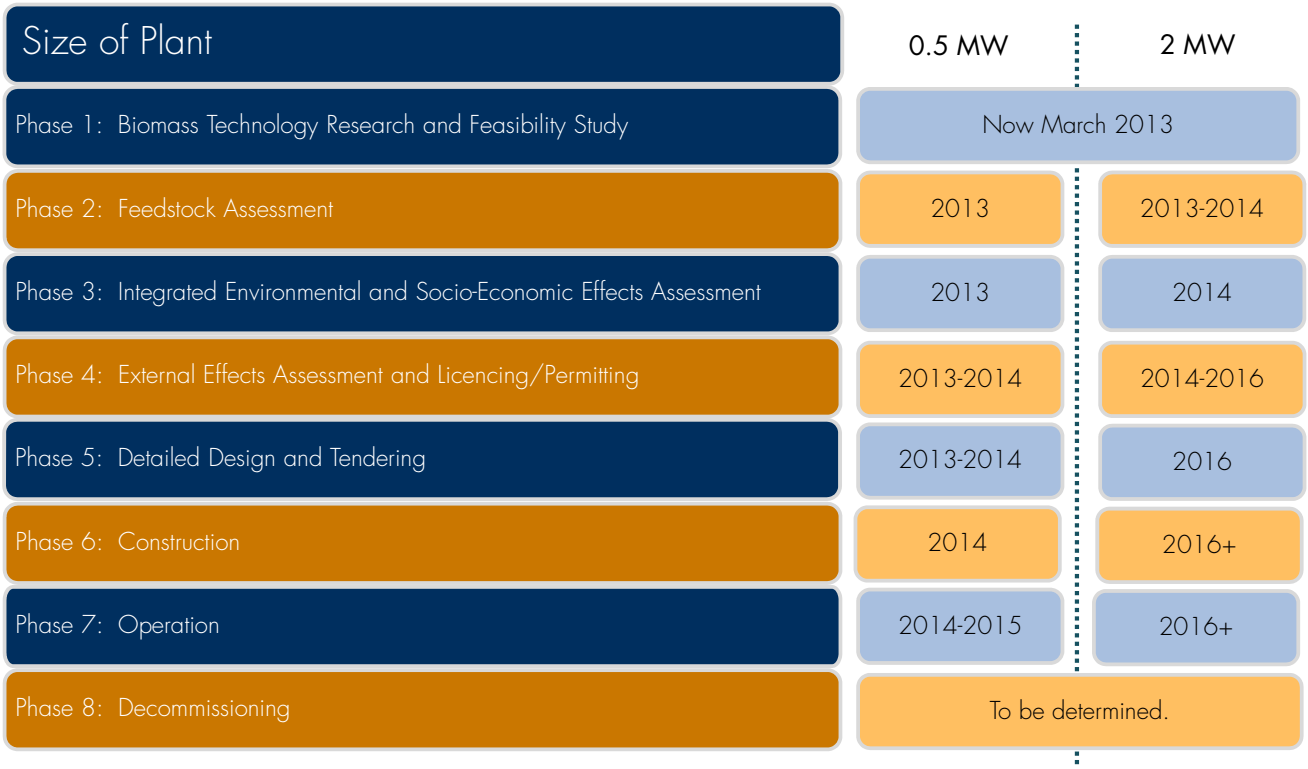

Figure 3.4.1 Project Phases and Schedule

3.5 ALTERNATIVES

Gasifier and reciprocating engine technology is the ideal choice for northern communities who wish to generate combined heat and power as steam is not required. Steam plants and systems require operators with power engineering certification and these professionals are not readily available in northern communities. Gasifer, reciprocating engine systems can be operated by trained mechanics or electricians which is more suited to the existing work force in the north. As the site has not been selected, an alternatives discussion will be delayed until siting is finalized. Alternatives for siting are being considered based on technically feasible locations (close enough for heat recovery), visually acceptable, appropriate land use and sufficient set-backs to limit noise complaints. Traditional and current activities and culture will also play an important role in Project siting, with areas of importance for these activities to be defined through the consultation process.

4.0 DESCRIPTION OF EXISTING ENVIRONMENTAL AND SOCIO-ECONOMIC CONDITIONS

Existing conditions for environmental and socio-economic conditions in relation to the Project location and valued components are summarized in this Chapter. This information is provided for use in the assessment of potential environmental and socioeconomic effects from the Project.

4.1 ENVIRONMENTAL CONDITIONS

A summary of existing environmental conditions in the vicinity of the Project is provided in this chapter. The summary is based on existing literature and sources of information that are available in the area of the Project. Field reconnaissance has not been conducted at this time.

4.1.1 Study Area and Physiography

The Village of Haines Junction is located at kilometer (km) 1,632 of the Alaska Highway at the intersection of Haines Highway. Haines Junction is approximately 158 km west of Whitehorse, the capital city of Yukon Territory. The village is located between mountain ranges of the Kluane Ranges, the Dezadeash Range, and the Ruby Range. The Auriol Range (of the Kluane Ranges) is the closest range to the village and is situated approximately 5.5 km southwest of Haines Junction. The village situated within Shakwak Valley, which covers the area from Pine Lake southwest to the Auriol Range. Haines Junction is located north of the main branch of Dezadeash River. The village is the gateway to Kluane National Park and Reserve.

4.1.2 Surficial Geology, Terrain, and Soils

EBA Engineering Consultants Ltd. (2003) encountered alternately clayey tills and fine grained glaciolacustrine depositing consisting of silt and clay with occasional sand and gravel lenses during drilling of well No. 5 in Haines Junction. During the drilling program an artesian sand and gravel aquifer was encountered below the alternating layers at a depth of 329 m continuing to 369.2 metres below ground level.

Bedrock geology in the Ruby Ranges is characterized by three geological terranes and two faults, with highly metamorphosed sedimentary and granitic rocks covering most of the area (YEWG 2004). The surficial geology of the ecoregion is comprised of steep bedrock exposures, colluvium and talus slopes at high elevation, moraine and glaciofluvial gravelly sands at mid-elevation, and silt-clay deposits from the Lake Sekulmun-Aishihik glacial lake retreat at lower elevations (YEWG 2004). Bedrock geology in the Yukon Southern Lakes ecoregion is divided up into three zones; coarse-grained, crystalline metamorphic and granitic rocks in the east and west and mafic volcanic, limestone and clastic sediments in the central zone. Surficial geology in characterized by deposits laid down during the most recent glacial retreat period, the McConnell, and vary throughout the ecoregion (YEWG 2004:210).

4.1.3 Transportation

The Yukon Government (YG) Transportation and Planning Branch conducts annual traffic counts and publishes a summary report to inform interested parties (Government of Yukon 2011a). The following average summer daily traffic (ASDT), and average annual daily traffic (AADT) are considered relevant to the Project. The Alaska Highway South of Haines Junction has an ADT of 579 (based on 70 days of counts) while the Alaska Highway to the North was counted at 491 AADT and a ASDT count of 720, showing a notable increase due to summer tourism. Haines Road counts for 2011 were 227 AADT and 370 for ASDT. Traffic counts east of Haines Junction on the Alaska Highway show a slight decline from 1994 to 2011 (0.8% decrease).

4.1.4 Groundwater Resources

The location of the biomass plant will be within Haines Junction, although the exact location is not finalized. Based on technical constraints for the use of waste heat from the plant, the plant must be located within approximately 400 m of larger buildings within the village (*e.g.*, the school and cultural centre).

The Village of Haines Junction has five developed municipal wells. As of 2012, well number 3 and well number 5 are the only wells currently being used as supply wells. In 2010 the total water consumption of the village was 140,088 cubic metres (m^3) (J. Gibson Environmental Consulting 2011). The municipal water system has recently undergone upgrades to increase production and storage capacity of water for the village. The upgrades factored in population growth and increased industry in the area. As part of the upgrades, well No. 4 was decommissioned.

There are ten private wells located in and around Haines Junction. These wells are associated with business (*e.g.*, gas station, motel), a subdivision, the school, the experimental farm, and some private residences.

All the wells in Haines Junction have been installed in overburden materials; there are no known bedrock wells. According to a 2003 report by EBA Engineering Consultants Ltd. (EBA Engineering Consultants Ltd. 2003), the aquifers in the area have component of dips from south to north.

Groundwater samples were collected following a pump test on well number 5 (conducted by EBA Engineering Consultants Ltd. in July 2003). They reported that the analytical results were below the Canadian Council of Ministers of the Environment (CCME) Canadian Drinking Water Quality Guidelines for all parameters.

Areas to be harvested as sources of feedstock have not been identified at this time. Once selected, information regarding groundwater resources at these sites, if available/applicable, will be included in this report.

4.1.5 Traditional Ecological Knowledge

Minimal published information is available on traditional ecological knowledge. and formal consultation has not been conducted specifically to define relevant Traditional Ecological Knowledge (TEK). Details

on TEK in the area will be provided as part of the next stage of the assessment based on consultation with CAFN and the Haines Junction community.

4.1.6 Additional Existing Conditions

The existing conditions for the VCs being considered in detail in this assessment are summarized in Chapter 5 as follows:

- Atmospheric Environment, including air quality, greenhouse gas emissions and sound quality are discussed in Section 5.2.2.
- Terrestrial Environment including vegetation, wildlife and wetland habitat are summarized in Section 5.3.2.
- Freshwater Resources are summarized in Section 5.4.2.
- Heritage Resources are summarized in Section 5.5.2; and
- Traditional Activities and Culture are summarized in Section 5.6.2.

4.2 SOCIO-ECONOMIC CONDITIONS

4.2.1 Champagne Aishihik First Nation

The Champagne and Aishihik First Nations (CAFN) is a self-governing First Nation with Traditional Territories in the Yukon Territory and Northern British Columbia. CAFN has a total population of approximately 1,238 (as of June 2012) with 712 people residing in the Yukon Territory.

The CAFN was named after two of its historic settlements: Champagne, located on the Dezadeash River; and Aishihik, situated at the headwaters of the Alsek River drainage. Formerly, the Southern Tutchone population was located throughout the region in other villages including Kloo Lake, Klukshu, Canyon, Shäwshe and Hutshi.

Their main administrative center is located in Haines Junction. The CAFN also maintains an office in Whitehorse.

Of the Yukon's fourteen First Nations, the CAFN is one of the largest in the Yukon. Its traditional territory covers 41,000 square kilometers, 29,000 of which are located in the Yukon and 12,000 in British Columbia. The easterly portion of CAFN's traditional territory lies in the Yukon River watershed where the Yukon River flows into the Bering Sea, while the larger, westerly portion lies in the Alsek River watershed where the Alsek River flows into the Gulf of Alaska. Much of Kluane National Park (Yukon) and all of Tatshenshini-Alsek Park (BC) lie within CAFN's traditional territory.

4.2.2 Labour and Economy

Occupations in Haines Junction are predominantly trades, sales and service, business, and management. Other occupations in the village include science, government, industry, processing and manufacturing, health, and arts, culture, and sports.

4.2.3 Public Health and Well-being

YEC has a comprehensive health and safety program that has been developed in accordance with the Yukon Occupational Health and Safety Act and regulations. Yukon Energy has entrenched health and safety training and procedures in every day operation and ensures that policies, practices, and procedures are clear to employees, and are consistently applied. Training on safe practices and procedures is a responsibility taken very seriously. Ongoing reviews, regular inspections and periodic audits are conducted to identify areas for improvement in health and safety practices with the goal of continuous improvement in mind.

4.2.4 Land Use and Infrastructure

The Village of Haines Junction does not have a land use plan (VOHJ 2007). The proponent will consider acceptable land use when planning for the Project and will consult with the Village in locating the Project.

5.0 ENVIRONMENTAL AND SOCIO-ECONOMIC EFFECTS ASSESSMENT

The overall assessment approach is described in this section.

5.1 ASSESSMENT APPROACH

The approach to the effects assessment includes scoping, studying the potential Project-environment interactions, estimating releases to the environment, assessing the potential environmental effects, establishing significance of the effects, and providing consideration of follow-up and monitoring that may be required.

Scoping of the assessment includes:

- identifying issues of concern related to the Project,
- selecting Valued Components (VCs) for further examination that include both Environmental and Socio-economic aspects;
- identifying potential sources and pathways of effects from the Project to each VC selected;
- identifying spatial and temporal boundaries for assessing effects of the Project for each selected VC; and
- identifying other actions and effects pathways that may act cumulatively with the Project to affect the same VCs.

5.1.1 Valued Environmental and Socio-Economic Components

A number of Valued Components have been anticipated for various phases or activities associated with the physical works of the proposed Project. Based on currently available Project information, these are defined as in Table 5.1.1. Consideration has been given to the plant as well as the feedstock harvesting activities.

Table 5.1.1 Potential Interactions of the Project with the Environment

Phases, Activities or Physical Works Associated with the Power Facility	Atmospheric Environment	Groundwater Resources	Freshwater Environment	Vegetation Environment	Wildlife Resources	Human Health and Wellbeing	Land Use and Infrastructure	Heritage Resources	Traditional Activities and Culture	Transportation	Labour and Economy	Effects of Environment on Project
Plant Site												
Construction	1	1	0	1	1	1	1	2	1	1	1	1
Operation	2	1	0	1	1	1	1	0	1	1	1	1
Decommissioning and Abandonment	1	1	0	0	0	1	1	0	0	0	1	1
Forest Feedstock Harvesting												
Construction	1	0	2	1	1	1	1	2	1	1	1	1
Operation	1	0	2	2	2	1	1	2	2	1	1	2
Decommissioning and Abandonment	1	0	1	1	0	0	0	0	0	0	1	0

KEY

0 = No interaction. The environmental effects are not significant and not considered further in the assessment.

1 = Interaction occurs; however, based on past experience and professional judgement the interaction would not result in significant environmental effect, even without mitigation; or interaction would not be significant due to application of codified environmental protection practices that are known to effectively mitigate the predicted environmental effects. The environmental effects are not significant and not considered further in the assessment.

2 = Interaction could result in environmental effect of concern even with mitigation; the potential environmental effects are considered further in this assessment.

The current scope of impact assessment does not include detailed assessment of potential interactions of Feedstock Harvesting with the environment; however, Table 5.1 above has been drafted based on expected interactions with both the plant site and feedstock harvesting. There are unknowns regarding the possible mitigation measures required for harvesting activities. The higher rankings are focused on wildlife, traditional pursuits, trapping, and heritage/cultural values and other land use (guiding, recreational uses, outfitting, wilderness tourism).

Based on the rankings provided in Table 5.1.1 above, the Project will result in an interaction with the following VCs (*i.e.*, a ranking of 1), during one or more phases of the Project:

- Groundwater Resources;
- Human Health and Wellbeing
- Land Use and Infrastructure;
- Transportation; and
- Labour and Economy.

Further discussion is provided below.

Groundwater Resources

Groundwater is the water held beneath the earth's surface in the pores, fractures, crevasses, and seams of bedrock and surficial geology. Groundwater Resources refer specifically to the value and function of groundwater in maintaining stream flow for ecological habitat and in supplying fresh water for human use. Groundwater availability for ecological and human uses and its susceptibility to chemical degradation or physical depletion by human activities is determined by the natural chemical and physical properties of the surficial and bedrock geology in which it is found.

Interactions between the Project and Water Resources have been ranked as 1 in Table 5.1.1 because the Project will not substantively alter the water requirements during any phase, and the existing water supply will continue to be used throughout the Operation of the Project. The maximum conceivable water consumption of this Project is estimated at 3.2 m^3/day or less depending on the vendor selected.

Water resources in Yukon are regulated at the federal and territorial level under a number of Acts and regulations.

Relevant acts, policies and guidelines related to the protection of water quality include the following:

- Yukon *Environmental and Socio-economic Assessment Act*;
- Yukon *Waters Act* and *Regulations*; and
- water quality guidelines (Canadian Council of Ministers of the Environment).

Groundwater resources are included as a VC because they provide potable, commercial, and industrial water supply to the population of Haines Junction. The potential for the disruption or contamination of the groundwater drinking supply for nearby residents therefore requires assessment.

Possible effects to Groundwater Resources include a change in groundwater quantity and a change in groundwater quality. It is unlikely that there will be effects to the quantity of groundwater in Haines Junction resulting from the Project as the village's water treatment system was recently upgraded. In addition, due to mitigation included Section 6.0 (Accidents, Malfunctions, and Unplanned Events), a contingency plan will be in place during operation for accidental spills at the plant. At this time the location of feedstock harvesting is unknown, however, vibration from large machinery may affect the water quality of any drinking water wells in the vicinity of harvesting operations.

In the event that the feedstock harvesting site is located near drinking water wells the potential effects will be evaluated. Mitigation measures may include baseline sampling and monitoring of the well(s) during operation to confirm that the water quality is not affected.

Follow-up may include monitoring of any drinking water wells in the vicinity of feedstock harvest operations. Additionally, investigation of any residential well owner complaints may be conducted, with application of industry standard remedial measures to rectify an effect.

In consideration of the nature of the interactions and relation to existing legislation and environmental policy in respect of Groundwater Resources, significant adverse environmental effects of the Project on Water Resources during all phases of the Project are not anticipated. Groundwater Resources are not considered further in this document.

Human Health and Wellbeing

Interactions between the Project and Human Health and Wellbeing have been ranked as 1 because Project activities, if not carried out in a careful and safe manner, could result in risks to the public or workers. Occupational exposure of Project workers to an industrial site carries with it a number of health and safety concerns, which are subject to territorial occupational health and safety legislation.

Yukon Energy has, and will continue to have, many measures in place to protect safety, including worker health and safety policies, and limited access to the facility. The Project would comply with emissions limits, which are established to be protective of health.

The Project will necessarily comply with all requirements of the Yukon Occupational Health and Safety Act and Regulations; thus, the environmental effects of the Project on Health and Safety will not be significant from the perspective of worker safety and occupational exposure. There are no features of the Project that would result in a higher potential for Accidents, Malfunctions, or Unplanned Events to occur as compared to similar industrial projects. Prior to commissioning of the plant, an emergency response plan would be developed to handle potential accidents, malfunctions and unplanned events that may occur in a safe manner. Employees hired to work at the plant or in harvesting activities would be provided with all required health and safety training prior to beginning work.

Procedures would be developed for the safe operation of the plant to minimize the likelihood of a work place accident or unplanned event that could affect the public.

As the Project involves consumption of spruce bark beetle-killed wood that is very dry and is suspected to be creating increased potential of forest fires surrounding Haines Junction, there could be a reduced likelihood of health and safety issues associated with implementation of the Project.

Based on the above, no substantive interactions between the Project and Health and Safety are anticipated. Therefore, significant adverse environmental of the Project on Health and Safety during all phases of the Project are not anticipated, and are not considered further.

Land Use and Infrastructure

As the location of the Project is not currently known, the extent of potential effects on land Use and Infrastructure cannot be fully assessed at this time. Land use by First Nations communities is considered as part of the Traditional Activities and Culture section.

Transportation

Interactions between the Project and Transportation have been ranked as 1 in Table 5.1.1 because of Project-related traffic to and from the plant site and forest harvesting areas during Construction and Operation. Materials will be delivered to, and transported away from, the Project site by truck. During

Construction, Project components and other materials will be required. During Operation, biomass will be transported to the site and small shipments of ash will be transported away from the site.

Road Transportation is governed by the Yukon *Highways Act* and the Yukon *Motor Vehicle Act* and associated regulations. The Project will adhere to the restrictions and limitations included in these and applicable federal acts and regulations.

Traffic during Construction for materials and equipment deliveries is expected to be very low and is estimated at several trucks per week as well as several passenger vehicles. The estimated traffic is a total of 3 to 15 trucks per week during Operation depending on the size of plant installed. This increased traffic can easily be accommodated by existing truck routes.

There may be a requirement to dispose of some general construction wastes during Construction, which will be transported to existing recycling operations or to an approved sanitary landfill for disposal. However, the volumes of waste materials to be managed and transported from the site during Construction are expected to be very low, as most or all of the infrastructure would be fabricated offsite.

Ash generated during Operation will be trucked off-site to the landfill, composting facilities or other approved locations. Based on the quantities of ash generated at the site, it is expected that less than 1 shipment per week would be required.

During Operation of the Project, a reduction in the number of fuel oil trucks travelling to Haines Junction may occur as less diesel would be required in the buildings using the plant's waste heat.

Based on the above, no substantive interactions between the Project and Road Transportation are anticipated. The Project-related traffic is expected to be confined to existing truck routes and the addition of 15 trucks per day is not expected to result in a noticeable change in traffic volumes on these routes for the purposes of efficient and safe road transportation. Therefore, the potential environmental effects on Road Transportation during all phases of the Project are rated not significant, and are not considered further.

Labour and Economy

Interactions between the Project and Labour and Economy have been ranked as 1 in Table 5.1.1 because activities and physical works associated with all phases of the Project will result in job creation and business expenditure. Labour and Economy refers to the importance of employment opportunities and economic growth on a local and regional scale within the Yukon. The Proponent is committed to hiring CAFN citizens and other local and Yukon residents, where available.

During Construction, the Project is expected to create direct construction labour employment for construction contractors for site clearing and preparation as well as infrastructure work over the 8 month Construction period. The extent of job creation is dependent on whether the plant is located in a building and if so, what type of building is chosen. The total capital investment of the Project is estimated at approximately C$7 to $45 million dollars (depending on the option chosen).

The Project will generate additional employment during Operation; through employment at the plant site as well as in forest harvesting. The extent of employment is dependent on the plant technology and

size chosen as well as the methods used for harvesting. Regardless of the methods employed, several new jobs will be created in Haines Junction in both technical trades and forest resource management.

Employment opportunities will also occur during Decommissioning and Abandonment of the Project, at the appropriate time, although not currently contemplated.

Employment in the Yukon is regulated at the territorial level under the Employment Standards Act and Regulations.

The potential effects on labour and economy could also extend beyond the Project to • outfitters and tourism, commercial trapping and fishing and other forestry and agriculture. To reduce land use conflicts and any potential negative effects on others in relation to proposed activities on-site or along the access route, the Proponent will continue to consult with other users and communicate its plans and the timing of proposed activities to other resource users (*e.g.*, trappers, outfitters, and known subsistence harvesters) who may be affected by the Project, as soon as practicable and prior to commencement of the activity.

Given the lifespan of the Project and the potential for other future development activity in the area, it is a challenge to predict with certainty the full range of socio-economic effects that will occur. However, as the Project will only require a small fraction of available feedstock for Operation and will be planned to proceed in harmony with existing land use, negative effects are expected to be very small if they do occur.

Key socio-economic indicators for the Project will be monitored by the Proponent (*e.g.*, number of local, Yukon, other employees and value of local, Yukon goods and services). This will provide for an understanding of the Project‘s socio-economic effects, identification of any emerging or unanticipated effects, and the opportunity for the Proponent or other parties to respond as appropriate.

The effects monitoring and adaptive management related to Terrestrial Environment (Section 5.4) and Freshwater Resources (Section 5.5) may also be relevant in terms of potential effects on other local or regional economic activities, such as outfitting, tourism, and trapping. More information on proposed mitigation and adaptive management measures can be found in the sections referenced.

Overall, the increased demand for labour and anticipated employment opportunities and related economic spin-offs of the Project are expected to result in positive environmental effects on Labour and Economy. As such, positive environmental effects on Labour and Economy as a result of the Project are anticipated and are not discussed further.

VCs Ranked as 2

Based on the rankings provided in Table 5.1.1 above, the Project may result in a significant interaction with Atmospheric Environment (ranking of 2 during Plant Operation), Freshwater Environment (ranking of 2 for Feedstock Harvesting), Vegetation Environment (ranking of 2 during Feedstock Harvesting, Wildlife Resources (ranking of 2 for Feedstock Harvesting), Heritage Resources (ranking of 2 during Plant Operation and Feedstock Harvesting), Traditional Activities and Culture (ranking of 2 during Feedstock Harvesting) and Effects of the Environment on the Project (ranking of 2 during Feedstock Harvesting). These VCs are thus assessed in greater detail in the detail VC sections of this chapter.

The scope of this assessment is focused on components that could be linked to the Project; as set out in the YESAB Guide to Assessment, both Project-specific issues and regional issues that are relevant to the Project need to be considered in the establishment of VCs. Therefore, VCs have potential to be modified throughout the next stage of assessment (revisions based on decisions made following the FEED Study review). Similarly, determination of VCs and environmental and socio-economic scoping requires input from local communities and interested parties; in this case, that may involve field studies and consultation that have not been completed in this Project phase. Therefore, VCs and rankings will be revisited during the completion of the final Project Proposal for the Feedstock and Facility components.

5.1.2 Project Interactions with the Bio-Physical and Human Environment

The Project activities that may interact with the bio-physical and human environments are identified and described for each VC.

5.1.3 Description of Effects Mechanisms

For each VC, one or more measurable parameters will be identified for the potential Project-related and cumulative environmental effects. The magnitude of the change in these measurable parameters will be used to characterize the Project environmental effects and to evaluate the significance of the potential environmental effects.

5.1.4 Temporal and Spatial Boundaries

The temporal boundaries for the assessment will be defined based on the timing and duration of Project activities and the nature of the interactions with each VC. The purpose of a temporal boundary is to identify when an environmental effect may occur in relation to specific Project phases and activities.

The spatial boundaries for the assessment will be defined based on the geographical extent of the environmental effects (*i.e.,* the zone of influence) for each VC. Generally, the spatial boundaries will be referred to as the Assessment Area.

At this time, both of these boundaries have yet to be determined. However, YESAB Guides provide definitions which will be adhered to when they are finalized. The preliminary phases and footprints and defined in Section 3 (Project Description) and provided here for ease of review.

Construction Phase: This phase generally consists of the estimated time required to complete the construction of the Project, including commissioning of the facilities.

Construction Footprint Area: Construction Footprint Area is the geographic area needed for construction and operation of the physical infrastructure associated with Power facility (*i.e.,* power access, access road, the plant, office, maintenance building, log storage yard, chipping plant, chip storage, conveyor, hopper, *etc*.)

Operation Phase: The time period following construction, through the life of the relevant components of the Project, during which time the Project will be used for its primary purpose of power generation.

Decommissioning Phase: The time period following operation when the Facility is no longer being used for its primary purpose; this may include transitioning the facility to another use or closure and abandonment.

Project Study Region: A broader Project Study Region for examining potential environmental and socio-economic effects has yet to be defined.

5.1.5 Mitigation of Project Effects

Standard mitigation measures that have been developed by the "Ex Comm" under Section 37 of the *YESAA* will be included in the design and operation of the Project. Further, any additional mitigation required to reduce potential environmental effects to acceptable levels (below the threshold of significance, see Section 5.1.7) will be proposed and included in the assessment.

5.1.6 Characterization of Residual Effects

Residual environmental effects are those that remain after mitigation has been applied. Each residual environmental effect will be described for each VC and each Project phase. Residual effects will be assessed for significance.

Environmental effects for each VC will be characterized for each applicable Project phase and presented in an environmental effects summary table. The following criteria will be used to characterize potential residual environmental effects:

- **Direction –** the ultimate long-term trend of the environmental effect (*i.e.,* positive or adverse);
- **Magnitude –** the amount of change in a measurable parameter or variable relative to existing (baseline) conditions;
- **Geographic Extent –** the area where an environmental effect of a defined magnitude occurs (*e.g.,* site-specific, local, regional);
- **Duration –** the period of time required until the VC returns to its baseline condition or the environmental effect can no longer be measured or otherwise perceived (*e.g.,* short-term, medium-term, long-term, or in some cases permanent);
- **Frequency –** the number of times during the Project or a specific Project phase or activity that an environmental effect might occur (*e.g.,* one time or multiple times) in a specified time period;
- **Reversibility –** the likelihood that a measurable parameter will recover from an environmental effect, including through active management techniques (*e.g.,* habitat restoration); and
- **Ecological or Socio-economic Context –** the general characteristics of an area in which the Project is located, as indicated by past and existing levels of human activity.

A key for each environmental effects summary table will provide summary criteria that will be modified as necessary for each VC based on the specific boundaries (temporal, spatial) and significance criteria selected for each VC.

5.1.7 Determination of Significance of Residual Effects

The criteria or standards for determining the significance of environmental effects will be identified for each measurable parameter in each VC, beyond which a residual environmental effect would be considered significant. These will be generally selected in consideration of provincial and federal regulatory requirements, standards, objectives, or guidelines that are applicable to the VC. In the absence of standards or criteria, significance criteria will be suggested by the Study Team for consideration by the decision making regulatory authorities.

5.1.8 Project Interactions with Other Projects (Cumulative Effects)

A cumulative environmental effects assessment will be conducted for those Project-related environmental effects that may overlap (spatially or temporally) with other projects and activities that have been or will be carried out.

The environmental effects of other past and existing projects are generally reflected in the existing baseline environment and will therefore be considered in the Project-related environmental effects assessment for each VC.

Other projects that may overlap spatially or temporally with the Project will be identified.

5.1.9 Cumulative Effects Assessment Methods

The assessment of each cumulative environmental effect will begin with a description of the environmental effect and the mechanisms whereby the Project environmental effects may interact with other projects and activities in the Assessment Area. Where possible, the cumulative environmental effects will be quantified in terms of the degree of change in the appropriate measurable parameter(s).

5.1.10 Mitigation of Cumulative Effects

Similar to Project-related environmental effects, mitigation measures that would reduce the cumulative environmental effects will be described.

5.1.11 Characterization of Residual Cumulative Effects

Residual cumulative environmental effects will be described and assessed, taking the proposed mitigation into account. The cumulative environmental effects will be characterized where applicable and appropriate in terms of the direction, magnitude, geographic extent, frequency, duration, reversibility, and ecological or social-economic context.

5.1.12 Effects Monitoring and Adaptive Management

Follow-up programs are used, where applicable, to verify environmental effects predictions and effectiveness of mitigation measures. Monitoring programs are compliance programs used to verify that mitigation has been applied. Appropriate follow-up and/or monitoring programs are proposed where a need has been identified or where the scientific certainty of the environmental effects predictions or the effectiveness of the mitigation warrants the need for such programs.

5.2 ATMOSPHERIC ENVIRONMENT

The Atmospheric Environment is considered a VC as the atmosphere is a pathway for transport of air contaminants to humans, wildlife and vegetation as well as the built environment. If not properly managed, releases of air contaminants to the atmosphere may cause adverse environmental effects on the air, the land and the waterways in the vicinity of the Project.

Greenhouse gas (GHG) emissions are considered a major factor in climate change and are thus also assessed in relation to changes in GHG emissions from the Project.

Changes to air quality during Construction are expected to be limited to potential fugitive dust during ground preparation. Changes to air quality during Operation of the Project are possible due to emissions from the combustion of gasified biomass and from trucks used to deliver feedstock and/or materials to the site and move feedstock onsite.

Changes to sound quality during Construction and Operation of the Project are possible due to sound emissions from mobile and stationary equipment.

Measurable parameters and significance criteria for air quality are defined based on regulatory ground-level concentration standards and objectives, while for GHG emissions these are based on current best practice guidance from the CEA Agency. For sound quality, measureable parameters and significance criteria are defined based on sound pressure level guidelines.

The assessment of the Atmospheric Environment was centered on a 10 km x 10 km area centred near the Project site.

Existing conditions are defined based on published data from Environment Canada and Yukon Environment. An air contaminant and GHG emissions inventory was developed for Operation of the Project, as this is likely to generate the highest emissions of air contaminants and GHGs emissions during the Project life. Dispersion modelling of specific contaminants, selected due to substantive emissions, was performed for Operation to predict the ground-level concentrations of those contaminants. The results of the modelling were compared to ambient air quality standards and objectives.

The dispersion modelling results showed that during Operation the ambient concentrations are likely to be well below the ambient standards and objectives for the operational scenarios considered.

The estimated GHG emissions from Operation are considered to be low (less than 50,000 tonnes of carbon dioxide equivalent (CO_2e)).

Sound pressure levels during Construction are anticipated to attenuate to 55 dB_A within 600 to 1,500 m of the site (depending on activity). Construction activities are transient and will not take place during nighttime to help reduce annoyance and avoid sleep disturbance. Therefore, although Construction within 600 to 1,500 metres will generate perceivable noise, annoyance will be limited in duration and extent and occur during daytime hours only.

Sound pressure levels during Operation of the plant (excluding the chipper) are anticipated to attenuate to a nighttime background level (assumed at approximately 40 dB_A) within 600 metres of the site,

considering the 2 MW_e case and as a conservative estimate. However, wood chipping activities may be noticeably noisy and may cause widespread annoyance within 1,000 m. It is thus recommended that annoyance be mitigated by procuring the lowest noise generating chipper feasible, locating the chipper at least 1,000 m from the nearest permanent resident and/or installing noise mitigation such as a barrier between the chipper and the nearest residences to reduce noise transmission.

Thus, as will be demonstrated by the analyses that follow, with the proposed mitigation and environmental protection measures, the residual environmental effects on the Atmospheric Environment during all phases of the Project are rated not significant.

5.2.1 Scope of the Assessment

The scope of the environmental assessment of Atmospheric Environment is defined in consideration of the nature of the regulatory setting, the issues identified during public and First Nations engagement activities, potential Project-VEC interactions, and existing knowledge.

The Atmospheric Environment is considered a Valued Component (VC) for a number of reasons, as follows.

- The atmosphere and its constituents are needed to sustain life and maintain the health and well-being of humans, wildlife, vegetation and other biota.
- The atmosphere is a pathway for the transport of air contaminants to the freshwater, marine, terrestrial and human environments, presenting the contaminants in the form of varying atmospheric concentrations or in particle phase or gas phase deposition.
- If not properly managed, releases of air contaminants to the atmosphere from the Project may cause adverse environmental effects on the air, the land, and the waterways in the vicinity of the Project.
- GHG emissions accumulate in the atmosphere and are believed to be a major factor in producing the greenhouse effect which is believed to influence climate.
- If not properly managed, sound emissions in the form of noise (unwanted sound) from the Project may cause adverse environmental effects on the sound quality in the vicinity of the Project.

The Atmospheric Environment has therefore been selected as a VC due to the potential for Project-related activities to cause adverse environmental effects through processes that occur in the atmosphere.

In this assessment, the approach is to select the environmental effects, select the associated measurable parameters (concentrations, emissions rates of GHG or air contaminants) to be considered, establish boundaries for the assessment, characterize the environmental effects, establish the significance criteria, assess the residual environmental effects (with mitigation such as emission control equipment), determine significance, and prepare a follow-up or monitoring program as applicable.

5.2.1.1 Key Issues and Identification of Potential Effects

Potential interactions between the Project and the Atmospheric Environment are highlighted and those aspects of the Project that may cause environmental effects, either positive or adverse, are identified. The Project may interact with the Atmospheric Environment in the following ways:

- combustion of gasified biomass will generate air contaminant emissions in the form of particulate matter and combustion gases;
- construction and operation of the Project will result in sound emissions;
- equipment movement on-site, trucks used to deliver feedstock, equipment and/or materials to the site, and passenger vehicles will generate combustion gases and greenhouse gases as well as sound emissions during construction and operation;
- earthworks and on-site earth moving activities during construction will generate particulate matter in the form of fugitive dust; and
- removal of vegetation from forested areas to be used as fuel for the Project will result in combustion emissions from harvesting equipment, fugitive dust and a reduction in the availability of carbon dioxide sinks currently associated with the forested areas.

The potential environmental effects to be assessed are associated with Project-related releases of air contaminants and GHGs to the atmosphere during Construction, Operation, and Decommissioning of the Project.

5.2.1.2 Regulatory/Policy Setting

The regulatory requirements for assessing environmental effects on Atmospheric Environment in environmental assessments are prescribed by both the federal and territorial governments.

Air quality is regulated in the Yukon pursuant to the *Air Emissions Regulation* under the *Environment Act* (Government of Yukon 1998). The requirements for facilities that are sources of air contaminants are described in the Regulation and as part of the permitting process (Part V of the Air Emissions Regulation). Ambient air quality standards for Criteria Air Contaminants (CACs) are presented in the Yukon Ambient Air Quality Standards document. The releases of GHGs are not currently regulated in the Yukon.

Federally, the main instrument for managing air quality is via the *Canadian Environmental Protection Act* (*CEPA*) as well as from Canada-Wide Standards that have been developed under the CCME Canada-Wide Accord on Environmental Harmonization. The standards may include qualitative or quantitative standards, guidelines or objectives for protecting the environment and human health. A number of these exist to protect air quality, including those for benzene (not an ambient standard); dioxins and furans for specific industries, mercury for specific industries, and ambient air quality objectives for $PM_{2.5}$ and O_3.

The emissions of air contaminants from the Project and the predicted downwind ground-level concentrations (GLC) are compared to applicable Yukon Environment ambient air standards or

emissions limits, as well as to Canada-Wide Standards (CWS), where they exist. The ambient standards are developed by the regulatory agencies, including Yukon Environment and Environment Canada, and others such as the British Columbia Ministry of Environment (BCMOE), to provide threshold values for assessing the extent of the potential environmental effects on air quality, human health and the environment.

The ambient air quality standards and objectives used in the assessment are presented in Table 5.2.1. These thresholds are a combination of the territorial, provincial and federal values from the Yukon, British Columbia and Environment Canada, respectively.

Table 5.2.1 Ambient Air Quality Standards and Objectives

Compound	Averaging Period	Yukon Ambient Air Quality Standards* (µg/m³)	Other Ambient Air Quality Standards or Criteria (µg/m³)
Total Suspended Particulate Matter (TSP)	24-hour Annual	120 60 (geometric mean)	-- --
Particulate Matter Less than 10 microns (PM_{10})	24-hour	--	50 [2]
Particulate Matter Less than 2.5 microns ($PM_{2.5}$)	24-hour	30	30 [1]
Sulphur Dioxide (SO_2)	1-hour 24-hour Annual	450 (172 ppbv) 150 (57 ppbv) 30 (11 ppbv)	-- -- --
Nitrogen Oxides (NO_X) as Nitrogen Dioxide (NO_2)	1-hour 24-hour Annual	400 (213 ppbv) 200 (106 ppbv) 60 (32 ppbv)	-- -- --
Carbon Monoxide (CO)	1-hour 8-hour	14,885 (13 ppmv) 5,725 (5 ppmv)	-- --

For GHG emissions and climate, the federal government recently released the latest version of *A Climate Change Plan for the Purposes of the Kyoto Protocol Implementation Act* in May 2012 (Environment Canada 2012a). Canada officially withdrew its participation in the Kyoto Protocol in December 2011; however, the federal government is still committed to addressing climate change. In October 2010, the final *Passenger Automobile and Light Truck Greenhouse Gas Emission Regulations* established fleet average GHG emission standards for new vehicles in model years 2011 through 2016. Standards for the 2017 to 2025 model years are in development. In August 2011, the federal government proposed regulations to apply a GHG performance standard to new coal-fired electricity generation plants for the purpose of encouraging a phase-out of traditional coal-fired electricity generation. Proposed regulations for the reduction of GHG emissions from new on-road heavy-duty vehicles were announced in April 2012.

With respect to federal guidance on assessing GHG emissions and climate change, the Canadian Environmental Assessment Agency (“CEA Agency”) has not updated its 2003 guidance (CEA Agency 2003). This EIA Report includes an assessment of emissions from the Project and from the related industrial sector. Further, where Project emissions are medium or high, preparation of a GHG Management Plan is required.

In relation to sound quality, there are no overarching noise guideline levels, regulations, or standards currently established in the Yukon Territory for limiting acceptable noise levels from industrial facilities. The Yukon Government generally requires that sound emissions from any activity not disturb the peace and quiet of persons outside the premises or vehicle (Government of Yukon 2002a).

Under Health Canada's *Useful Information for Environmental Assessments* (Health Canada 2010), construction activities that last for less than 2 months may be considered temporary and do have any sound pressure level guidance. For construction phases less than one year in duration, Health Canada recommends using the US EPA method from their 1974 document on noise (US EPA 1974), where an equivalent day-night average ("L_{DN}") of 55 dB_A outdoors is considered the threshold for widespread complaints. For construction phases greater than one year in duration and during operation the Health Canada guidance is based on the change in percentage of highly annoyed due to the noise. L_{DN} is an energy-weighted average, similar to the equivalent sound pressure level, L_{eq}, for a full day, except that the night time hour (22:00 to 07:00) levels are artificially weighted by an additional 10 dB_A to reflect increased sensitivity of the community to sound levels during those hours. The percentage highly annoyed is estimated for the baseline condition and for the baseline plus the construction condition. The guideline indicates that the increase from the estimated percent highly annoyed of the baseline condition to the construction of a project should not be greater than 6.5%. The algorithm to calculate the percent highly annoyed is defined by ISO 1996-1:2003 (Canadian Standards Association 2003).

As the Haines Junction School is the nearest sensitive receptor to the preliminary Project site, guideline levels from the World Health Organization (WHO) for schools are also considered. The sound pressure level in an outdoor playground area should not exceed 55 dB_A or 35 dB_A indoors (WHO 1999).

With respect to perception of noise, a 3 dB change in sound pressure level is considered to be the threshold of which a change in sound pressure level is noticeable (Hoover & Keith Inc. 1981). A change of 10 dB_A gives a perception that the sound is twice as loud (Hoover & Keith Inc. 1981).

These regulatory requirements form the basis for the assessment of the potential environmental effects on Atmospheric Environment and are discussed in more detail in the following sections.

5.2.1.3 Selection of Measureable Parameters

The environmental assessment of the Atmospheric Environment is focused on the following aspects:

- Change in Air Quality;
- Change in GHG Emissions; and
- Change in Sound Quality.

The Atmospheric Environment has been divided into three key factors for consideration in the EIA, reflecting key Project-atmospheric interactions: Air Quality, Climate Change and Sound Quality.

- Air Quality is defined as a measure of the constituents of ambient air, and includes the presence and the quantity of these constituents including air contaminants in the atmosphere. The aspect of concern is defined as a Change in Air Quality, reflecting potential changes resulting from emissions from the Project.

- GHG Emissions and Climate, for the purpose of this assessment, are defined as the presence and quantity of GHGs in the atmosphere. The aspect related to climate change to be assessed is the net emissions of greenhouse gases (GHG) as a result of the Project.

- Sound Quality in the outdoor environment may be adversely affected by the Project. Noise is defined as unwanted sound and is usually present through a range of frequencies. The audible frequencies for humans are in the range of 20-20,000 Hertz (Hz). In this assessment, the environmental effects of sound emissions from the Project on Sound Quality in the area surrounding the Project are assessed.

The assessment of Changes in Air Quality, GHG Emissions and Sound Quality in the atmosphere requires knowledge of the constituents making up and present in the atmosphere, both in magnitudes and as trends. This knowledge is established by measuring concentrations of air contaminants and GHG as well as sound pressure levels in the atmosphere at strategic locations for extended or representative periods of time.

The measurable parameters used for the assessment of the environmental effect presented above and the rationale for their selection are provided in Table 5.2.2.

Table 5.2.2 Measurable Parameters for Atmospheric Environment

Environmental Effect	Measurable Parameter	Rationale for Selection of the Measurable Parameter
Change in Air Quality	Ambient ground-level concentrations of Criteria Air Contaminants	• Regulatory objectives, guidelines and/or standards exist provincially and federally for SO_2, NO_X, CO, TSP, PM_{10} and $PM_{2.5}$, as well as specific hydrocarbon compounds.
Change in GHG Emissions	GHG emissions - CO_2, CH_4 and N_2O (in units of CO_2 equivalents or CO_2e)	• Greenhouse gases have been identified as a major contributor to climate change worldwide, thus management of GHG emissions has become a concern for the general public, industry and government.
Change in Sound Quality	Sound Pressure Levels, A-weighted scale (dB_A)	• Ambient sound pressure levels are characterized using a logarithmic decibel (dB) scale, with the A-weighted (dB_A) scale being the most commonly used for environmental sound assessments. Measured parameters for environmental sound or noise (defined as unwanted sound) are often expressed as an "equivalent sound level" (L_{eq}) which represents an equivalent energy level over a specified period of time (*e.g.*, 1-hour or 24-hours).

The magnitude of GHG emissions is expressed in units of CO_2e. The term "greenhouse effect" is commonly used to describe the earth's heat balance that maintains temperature, humidity and precipitation regimes and makes the earth habitable for humans and other forms of life. Increases in the ambient concentrations of CO_2 and other GHGs such as CH_4 and N_2O, over recent decades are believed by many to have changed the heat balance resulting in a warming of the planet. The ability to trap heat in the atmosphere varies with each GHG. This difference is expressed in terms of global warming potential (GWP). The GWP is established relative to CO_2 (*e.g.,* CH_4 has approximately 21 times the warming ability as CO_2). The relative contribution to the greenhouse effect, and both the emissions and concentrations of each GHG in the atmosphere, are commonly expressed in terms of its carbon dioxide equivalent, or CO_2e, by accounting for the GWP of each GHG.

5.2.1.4 Spatial Boundaries

The spatial boundaries for the environmental effects assessment of the Atmospheric Environment are defined below.

Project Development Area (PDA): The PDA is the most basic and immediate area of the Project. The PDA is limited to the area of physical ground disturbance associated with the Project, and consists of an area that includes the area of physical disturbance associated with the biomass plant. It will be revised following final site selection and detailed design and ultimately include the plant site and the area associated with biomass feedstock harvesting (including forest roads). The PDA is the area represented by the physical Project footprint as defined in Chapter 3.1.2 above.

Local Assessment Area (LAA): The LAA includes a 10 km x 10 km area centred on the plant site. The LAA is the maximum area within which Project-related environmental effects are likely to occur. The LAA includes the PDA and any adjacent areas where Project-related environmental effects may reasonably be expected to occur.

Regional Assessment Area (RAA): The RAA is limited to and includes the Yukon Territory for air quality, and extends nationally and globally for greenhouse gas emissions. For sound quality, the RAA is considered to extend 2 km from the PDA as no measurable cumulative effects related to sound quality would occur beyond this area. The RAA is the area within which the Project's environmental effects may overlap or accumulate with the environmental effects of other projects or activities that have been or will be carried out. The extent to which cumulative environmental effects for Atmospheric Environment may occur depend on physical and biological conditions and the type and location of other past, present, and reasonably foreseeable future projects or activities that have been or will be carried out, as defined within the RAA.

5.2.1.5 Temporal Boundaries

The temporal boundaries for the assessment of the potential environmental effects of the Project on the Atmospheric Environment include the phases of Construction, Operation, and Decommissioning.

5.2.1.6 Residual Effects Significance Criteria

For a Change in Air Quality, a significant adverse residual environmental effect is one that degrades the quality of the ambient air such that the maximum Project-related ground-level concentration plus the conservative background level of the air contaminant being assessed frequently exceeds the respective ambient air quality objective, guideline or standard. "Frequently" is defined as once per week for 1 hour objectives, once per month for 24 hour objectives or any exceedance of annual average objectives.

For a Change in GHG Emissions (related to climate change), following guidance from the CEA Agency, "the environmental assessment process cannot consider the bulk of GHG emitted from already existing developments. Furthermore, unlike most project-related environmental effects, the contribution of an individual project to climate change cannot be measured" (CEA Agency 2003). It is, therefore, recognized that it is not possible to assess significance related to a measured environmental effect on climate change on a project-specific basis. At the same time, it is recognized that a scientific consensus is emerging in respect of global emissions of GHG and consequent changes to global

climate as generally representing a significant cumulative environmental effect. Project emissions of GHG will contribute to these cumulative environmental effects, but the contribution, although measurable and potentially important in comparison to local and territorial levels, will be very small in a global context. Policies and regulations are being developed by the Government of Canada for regulating GHG emissions for specific sources or industry sectors.

Thus, instead of setting a specific significance criterion for environmental effects on GHG emissions or climate change and determining whether and how it can be met, the assessment involves estimating Project-related GHG emissions and considering the magnitude, intensity, and duration of Project emissions as directed by the CEA Agency guidance (CEA Agency 2003). Three categories are described in the CEA Agency guidance: low, medium and high. In this EIA, these are attributed quantitatively based on evaluation of GHG emissions from other industrial facilities and regulatory thresholds (such as reporting thresholds for GHG emissions to provincial and federal programs). For the purpose of assessment of magnitude of the Project GHG emissions, (on a tonnes CO_2e per annum basis), the following criteria have been developed.

- Less than 50,000 tonnes is considered low (as below this reporting to the federal program is not required).
- Between 50,000 and 500,000 tonnes is considered medium.
- Greater than 1 million tonnes is considered high.

Where the GHG emissions are considered to be either medium or high, a GHG Management Plan must be prepared.

For a Change in Sound Quality with respect to sound pressure levels, a significant adverse residual environmental effect on the Acoustic Environment is one where Project-related sound emissions during Construction cause the sound pressure levels at the nearest noise sensitive area or receptor (NSA) to frequently exceed the US EPA guidance of 55 dB_A (L_{DN}) and during Operation cause the percent of highly annoyed receptors to increase by 6.5%. “Frequently” is defined as twice (*i.e.*, two days) per week.

5.2.2 VC Existing Conditions

5.2.2.1 Air Quality

As noted earlier, the Project is located in an area that is primarily rural, in the community of Haines Junction. There are no other substantive sources located nearby. Existing emissions of air contaminants are limited to household and institutional (school, other smaller community buildings) heating appliances burning wood or oil and motor vehicle fuel combustion.

There are no ambient air quality monitoring stations in the area of the Project. The nearest air quality monitoring station is located in Whitehorse, approximately 130 km to the east of the Project site. In the absence of any other ambient air quality monitoring information near the Project site, existing conditions in the Project area are based on the most recent monitoring data from the Whitehorse station. Ambient concentrations of particulate matter < 2.5 microns ($PM_{2.5}$), nitrogen dioxide (NO_2), carbon monoxide

(CO), and ozone (O_3) are measured at the station. The most recently available monitoring data were obtained from Yukon Environment and Environment Canada. Ambient air quality data is collected at Whitehorse by Environment Canada as part of the National Air Pollution Surveillance Program (NAPS) (Environment Canada 2012b).

Based on the information provided by Environment Canada, there have been equipment operational issues over the last few years; therefore, there are some gaps in the data. Thus, data from 2008-2010 were used to establish the existing conditions with respect to ambient air quality in the area.

The publication from Yukon Environment, entitled *Yukon State of the Environment Interim Report – An Update from Environmental Indicators 2012* provides an additional description of existing and historical ambient air quality conditions in the Whitehorse Area (Yukon Environment 2012a).

Based on the information provided in the environment report, there were 15 days with exceedances of the $PM_{2.5}$ ambient standard in 2009. As noted above, there are some gaps in the data; in 2009 the months of January and February are missing due to equipment operational issues. The average concentration of $PM_{2.5}$ in 2009 is also higher than in recent years. This is likely attributed to a substantive increase in wildfires in the summer of 2009. There were no measured concentrations exceeding the 24-hour $PM_{2.5}$ Yukon Standard in 2008 or in 2010.

For NO_2 and CO, no exceedances of the Yukon ambient air quality standards were measured in 2008, 2009 or 2010 at the Whitehorse station. Further, based on the monthly average data from Environment Canada the NO_2 and CO concentrations are relatively low, most of the time.

For O_3, there were no exceedances of the 8-hour average Canada-wide Standard for the period of 2008 to 2010.

The 2010 annual average NO_2, CO, and O_3 concentrations measured at the Whitehorse station are 5.5 $\mu g/m^3$, 0.4 $\mu g/m^3$, and 32 $\mu g/m^3$, respectively. The 2010 annual average $PM_{2.5}$ concentration measured at Whitehorse is 1.9 $\mu g/m^3$. The 2010 annual average concentrations are based on data from the beginning of January to the end of May, as data from June to December were unavailable for 2010 due to station operational issues, as noted above.

The measured air contaminant concentrations at Whitehorse are likely to be higher than ambient concentrations in Haines Junction, given Haines Junction is a smaller, more rural community and Whitehorse is a larger centre with more sources of emissions, specifically vehicle traffic and increased stationary combustion related to heating. However, due to the regional nature of ambient ozone concentrations, the concentrations measured at Whitehorse would likely be similar to what would be observed in Haines Junction.

In summary, as there are no substantive sources of emissions in the in the vicinity of the Project or in region, the air quality in the Project area is considered to be good, as the rate of compliance with the ambient standards is greater than 95% for the period of 2008 to 2010. Occasionally during winter under certain meteorological conditions (calm winds, atmospheric temperature inversion), smoke from home heating has been observed at ground level.

5.2.2.2 Air Contaminant and GHG Emissions

The existing air contaminant and GHG emissions sources in the Haines Junction area consist mainly of combustion emissions associated with space heating of public buildings and houses located in the community, power generation in small diesel generators (very infrequent) and vehicle emissions. Emissions also result from natural events/releases such as forest fires (during the summer months).

Air contaminant and GHG emissions from institutional sources related to space heating requirements in the Haines Junction area are provided in Table 5.2.3. The emission rates are estimated using US EPA emission factors for diesel combustion (US EPA 2010) and the estimated diesel fuel offset volumes from the *Haines Junction Bioenergy Project – Evaluation of Waste Heat Potential Final Report* dated December 10, 2012, prepared by Clean Technology Community Gateway (CTCG 2012).

Table 5.2.3 Estimated Existing Space Heating Emissions – Haines Junction

Building	Emission Rate (t/a)						
	NO_X	CO	SO_2	TSP	PM_{10}	$PM_{2.5}$	CO_2
School	0.082	0.021	0.88	8.2E-03	4.5E-03	3.4E-03	91.9
Convention Centre	0.019	4.8E-03	0.20	1.9E-03	1.0E-03	8.0E-04	21.4
Arena & Pool Complex	0.13	0.033	1.4	0.013	7.1E-03	5.5E-03	147
Fire Hall and Yukon Government Building	0.085	0.021	0.91	8.5E-03	4.6E-03	3.5E-03	95.2
Total	**0.32**	**0.080**	**3.4**	**0.032**	**0.017**	**0.013**	**356**

Greenhouse gases (GHG) of primary concern include carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), among others. Territorial GHG emissions in 2010, including industrial facilities, vehicles and natural sources, were 340 kilotonnes of carbon dioxide equivalent (CO_2e) (Environment Canada 2012c). No facilities in the Yukon Territory reported GHG emissions to Environment Canada in 2010, indicating none are over 50,000 t CO_2e (Environment Canada 2011).

Canada's GHG emissions in 2010 were 692,000 kilotonnes CO_2e (Environment Canada 2012c). Yukon's contribution to national GHG emissions is <1%. GHG emissions due to stationary combustion account for 324 kilotonnes CO_2e in 2010 (Environment Canada 2012c), which represents approximately 0.05% of Canada's 2010 emissions.

Carbon dioxide emissions globally are estimated to be 34 Gt per year (Climate Analysis Indicator Tool (CAIT 2012). Canada's contribution to global GHG emissions is approximately 2%.

5.2.2.3 Sound Quality

Sound Quality in the outdoor environment can be influenced by a variety of natural and anthropogenic sources. These may include unwanted sounds (noise) from stationary and mobile sources, noise from industrial equipment, vehicle traffic, and the operation of heavy equipment such as bulldozers, trucks, or diesel generators. It is also well known that sound propagation and the potential environmental effects of noise on nearby receptors is heavily influenced by weather conditions such as temperature, humidity, wind direction and wind speed. Local topographical features such as hills or wooded areas may serve to attenuate sound levels. Also, large reflective surfaces such as water bodies may serve to reflect sound to more distant locations than would occur in their absence. There may also be sound reflections if the atmospheric mixing height is low (a few hundred metres), or if solid structures are located close to sources of noise emissions.

Existing sound levels in the immediate vicinity of the proposed Project have not been documented in this or any previous work. Local traffic is expected to be the main contributor. However, given the nature of the area within the community of Haines Junction, existing sound levels are expected to be typical of a small rural community with higher sound pressure levels near the main throughways. According to the ERCB (2007), a typical sound level on a quiet street during daytime hours is 50 dB_A. Based on the experience of the Study Team, sound pressure levels at night in a quiet rural community may be between 30 and 40 dB_A.

5.2.3 Potential Project VC Interactions

5.2.3.1 Project Effects Mechanisms

Each Project activity and physical work for the Project is listed in Table 5.2.4. The activities are ranked as 0, 1, or 2 based on the level of interaction each activity or physical work will have with the Atmospheric Environment.

Table 5.2.4 Potential Project Environmental Effects to the Atmospheric Environment

Project Activities and Physical Works	Potential Environmental Effects		
	Change in Air Quality	Change in GHG Emissions	Change in Sound Quality
Construction			
Site preparation	1	1	2
Physical construction of the facility structures and installation of equipment	1	1	2
Commissioning	1	1	1
Construction of infrastructure for feedstock harvesting	1	1	1
Operation			
Operation and Maintenance of Plant Site	2	2	2
Feedstock Harvesting	1	1	1
Decommissioning, Reclamation and Closure			
Plant Site	1	1	1
Harvested Areas	1	1	1

Project-Related Environmental Effects
Notes:
Project-Related Environmental Effects were ranked as follows:
0 = No interaction. The environmental effects are rated not significant and are not considered further in this report.
1 = Interaction will occur. However, based on past experience and professional judgment, the interaction would not result in a significant environmental effect, even without mitigation, or the interaction would clearly not be significant due to application of codified practices and/or permit conditions.. The environmental effects are rated not significant and are not considered further in this report.
2 = Interaction may, even with codified mitigation and/or permit conditions, result in a potentially significant environmental effect and/or is important to regulatory and/or public interest. Potential environmental effects are considered further and in more detail in the EA.

The Project activities during Construction, Operation and Decommissioning may result in emissions of sound, air contaminants and GHGs to the atmosphere. These emissions may cause adverse environmental effects on the Atmospheric Environment, specifically a Change in Air Quality, Change in GHG Emissions and Change in Sound Quality during Operation.

During Construction, air contaminant and GHG emissions and noise are likely to occur; however, given the relatively small scale of the Project, emissions of air contaminants, GHGs and noise are not likely to be substantive. Fugitive dust is expected to be the largest potential concern during Construction and can be mitigated using water application if needed (during windy, dry periods). Effort to re-vegetate the surrounding area as soon as possible during Construction will also limit the potential for dust generation. Based on the small site footprint and scope of Construction required, these activities are not evaluated in detail and are considered a 1.

During Operation, feedstock harvesting activities may result in air contaminant, GHG and sound emissions to the atmosphere. However, these emissions are expected to be in remote locations, periodic and are not likely to be substantive, given that a large portion or all of the feedstock required for the Project can be sourced from existing forestry operations in the area, depending on the scale of the Project. These activities are therefore not evaluated in detail and are ranked as 1. Once the Project scale has been confirmed, the assessment of feedstock harvesting activities may need to be re-visited, as required.

Project activities during Decommissioning are expected to result in sound emissions and releases of air contaminants and GHGs in magnitude that are similar to or less than those associated with Construction and Operation activities; thus these are not evaluated in detail and are considered a 1.

Thus, in consideration of the nature of the interactions and the planned implementation of known and proven mitigation, the potential environmental effects of all Project activities and physical works that were ranked as 0 or 1 in Table 5.5, including cumulative environmental effects, on the Atmospheric Environment during any phase of the Project are rated not significant, and are not considered further in the assessment.

5.2.3.2 Assessment of Environmental Effects

A summary of the environmental effects assessment and prediction of residual environmental effects resulting from interaction ranked as 2 on the Atmospheric Environment (Operation of plant site for air quality and Construction and Operation for Sound Quality) is provided in Table 5.2.5.

Table 5.2.5 Summary of Residual Project-Related Environmental Effects on the Atmospheric Environment

Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics						Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects?	Recommended Follow-up or Monitoring
			Direction	Magnitude	Geographic Extent	Duration and Frequency	Reversibility	Ecological/Socio-economic Context					
Change in Air Quality • Combustion gases. • Particulate matter (dust).	Operation	• Implement idling reduction program. • Implement equipment maintenance program. • Continuous emissions monitors (specifically O_2) in exhaust stack to optimize combustion. • Process closely monitored and controlled for optimum operation. • Syngas cleaned and filtered prior to combustion in engines. • Biomass stored inside to minimize potential dust emissions and help control moisture content to maximize gasification and combustion efficiency.	A	L	L	LT/ C	R	D	N	M	L	Y	One source emissions testing campaign is recommended to confirm vendor emission guarantees.
	Residual Environmental Effects for all Phases								N	M	L	Y	

Table 5.2.5 Summary of Residual Project-Related Environmental Effects on the Atmospheric Environment

Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics						Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects? Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics										Recommended Follow-up or Monitoring
			Direction	Magnitude	Geographic Extent	Duration and Frequency	Reversibility	Ecological/Socio-economic Context	Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects?	

KEY

Direction
- P Positive.
- A Adverse.

Magnitude
- L Low: (Air Quality is not affected or slightly affected but is well below objectives, guidelines, or standards; GHG Emissions < 10,000 t CO_2e/a; sound pressure levels at or below background)
- M Medium: (Air Quality is affected to values that are near but largely below the objectives, guidelines, or standards; GHG Emissions < 50,000 and > 10,000 t CO_2e/a; sound pressure levels above background and below limits)
- H High: (Air Quality is degraded to values that may substantially exceed objectives, guidelines, or standards; GHG Emissions > 50,000 t CO_2e/a; sound pressure levels exceed limits)

Geographic Extent
- S Site-specific: Within the PDA.
- L Local: Within the LAA.
- R Regional: Within the RAA.

Duration
- ST Short term: Occurs and lasts for short periods (*e.g.,* days/weeks).
- MT Medium term: Occurs and lasts for extended periods of time (*e.g.,* years).
- LT Long term: Occurs during Construction and/or Operation and lasts for the life of Project.
- P Permanent: Occurs during Construction and Operation and beyond.

Frequency
- O Occurs once.
- S Occurs sporadically at irregular intervals.
- R Occurs on a regular basis and at regular intervals.
- C Continuous.

Reversibility
- R Reversible.
- I Irreversible.

Ecological/Socio-economic Context
- U Undisturbed: Area relatively or not adversely affected by human activity.
- D Developed: Area has been substantially previously disturbed by human development or human development is still present.
- N/A Not Applicable.

Significance
- S Significant.
- N Not Significant.

Prediction Confidence

Confidence in the significance prediction, based on scientific information and statistical analysis, professional judgment and known effectiveness of mitigation:
- L Low level of confidence.
- M Moderate level of confidence.
- H High level of confidence.

Likelihood

Likelihood of a significant environmental effect occurring, based on professional judgment:
- L Low probability of occurrence.
- M Medium probability of occurrence.
- H High probability of occurrence.

Cumulative Environmental Effects?
- Y Potential for environmental effect to interact with the environmental effects of other past, present or foreseeable projects or activities in RAA.
- N Environmental effect will not or is not likely to interact with the environmental effects of other past, present or foreseeable projects or activities in RAA.

5.2.3.3 Mitigation Measures

The following mitigation measures, through careful design and planning, will be employed to avoid or reduce the environmental effects of the Project on the Atmospheric Environment potentially resulting from the environmental effects mechanisms described above.

- Continuous emissions monitors (specifically O_2) of exhaust gases to control combustion and minimize emissions;
- Gasification and combustion processes closely monitored and controlled for optimum operation to reduce air contaminant emissions;
- Filtration of syngas prior to combustion to remove any tar formation from the gasification process;
- Biomass stored inside to minimize potential dust emissions and help control moisture content to maximize gasification and combustion efficiency;
- Construction and Decommissioning activities and trucking to and from the site (feedstock transport) limited to daytime hours only to minimize sound pressure levels at night;
- Use of mufflers on heavy equipment and vehicles to reduce sound emissions;
- Equipment enclosed in buildings where feasible or located to minimize sound pressure levels at off-site sensitive receptors; and
- Location of the chipper at least 1,000 m from nearest permanent residence or further review of noise generation of specific chipper required for a low noise model or incorporation of mitigation such as a barrier to attenuate noise.

5.2.3.4 Characterization of Residual Effects

As described in the text below, the results of the dispersion modelling indicate that for the three Project configuration scenarios considered for Operation, exceedances of the applicable ambient air quality standards, objectives and criteria are unlikely to occur. In most cases the predicted ground-level concentrations were well below the ambient standards and objectives.

During Operation, with respect to air contaminant emissions, it is expected that emissions of NO_2 and CO are likely to increase slightly over the existing conditions following implementation of the Project, due to the combustion of gasified biomass. However, a decrease in SO_2 emissions over the existing condition is also expected, as biomass contains less sulphur than fossil fuels. The reduction in SO_2 emissions is expected due to a reduction in fossil fuel consumption for space heating requirements of public buildings in the community. The magnitude of the increases and reductions in air contaminant emissions are dependent on the size selected for the Project as well as the final stack design, as this will dictate how many individual heating systems in community buildings are decommissioned and how emissions from the Project are dispersed.

GHG emissions are likely to range from 6,700 to 26,780 t/a of CO_2 due to biomass combustion, depending on the ultimate scale of the Project. Emissions of CO_2 account for the majority of the total GHG emissions. However, CO_2 emissions from biomass combustion are reported separately under the Environment Canada reporting system, since carbon dioxide emissions from biomass are considered carbon neutral as the emissions are part of the global carbon cycle. Emissions of other GHGs including CH_4 and N_2O are expected to be nominal, given the relatively low volumes of fuel consumed during Operation. Therefore, given the Project is to replace existing fossil fuel fired heating systems in the community; a small offset of GHG emissions is expected following implementation of the Project, ranging from 90 to 350 t/a CO_2.

To estimate sound pressure levels at distances from sources, the Study Team used the inverse square law which indicates that sound energy dissipates approximately 6 dB for a doubling of distance (ERCB 2007). This calculation does not account for attenuation from atmospheric or ground absorption (terrain effects) and hence is considered conservative.

The Study Team estimated the sound pressure levels of heavy equipment used for tree clearing, site preparation, and facility installation using typical equipment types and engine horsepower. The Construction phase is anticipated to take less than one year. Tree cutting can be a noisy activity and may cause sound pressure levels to exceed 55 dB_A within 1,500 metres. Noise from earth moving activities may exceed 55 dB_A on occasion within approximately 600 m from the activity. These are conservative estimates as the effects of terrain, treed areas, and buildings were not taken into account. Construction activities are transient and will not take place during nighttime to help reduce annoyance and avoid sleep disturbance. Therefore, although Construction within 600 to 1,500 metres will generate perceivable noise, annoyance will be limited in duration and extent and occur during daytime hours only. The L_{DN} criterion of 55 dB_A will likely be exceeded within 1,500 m of tree cutting, and may be exceeded on occasion within 600 m of earth moving activities. As the Project site is relatively small, Construction is expected to cause a short term disturbance. A 8-month period is anticipated for Construction.

The estimated sound pressure level from Operation of a 2 MW_e gasification plant is 87 dB_A at 4.5 m (10 feet), based on the maximum sound pressure level provided by CPC (CPC 2012). The sound from the facility would attenuate from 87 dB_A to 55 dB_A approximately 120 m from the site, as a conservative estimate. Based on the expected baseline noise levels in the village, it is estimated that the 2 MW_e facility would not be highly audible during daytime beyond 120 m. At night, the plant may be audible up to 325 m from the site; however at that level would not be highly audible and would not be expected to cause sleep disturbance (may be perceived as a dull hum on very quiet evenings outdoors).

The nearest sensitive receptor (the school building) is approximately 160 m from the proposed site in the FEED study. WHO indicates that the sound pressure level in an outdoor playground area should not exceed 55 dB_A and also indicate an indoor level of 35 dB_A for schools (WHO 1998). Since building walls are capable of decreasing sound levels by 10-20 dB_A (no windows open) (WHO 1998), meeting the outdoor limit of 55 dB_A results in meeting the indoor limit of 35 dB_A. Therefore as long as the plant is located greater than 120 m away from the school, noise from Operation of the facility is not expected to exceed WHO guidelines.

The percentage highly annoyed (% HA) by noise in the existing case was estimated to be approximately 2.2%, based on an assumed daytime sound pressure level of 50 dB_A and a nighttime sound pressure level of 40 dB_A. A 10 dB_A penalty was added to the nighttime sound pressure level, as per guidance from US EPA and Health Canada. For Project Operation, the % HA at a location 120 m away (where the Project contribution to sound pressure level is 55 dB_A during day and night), in addition to the existing case, was estimated to be 4.8%. Therefore the change in % HA is 2.6%, which is below the 6.5% significance criterion. The significance criterion would be exceeded if the Project contribution to sound pressure levels exceeds 60 dB_A (approximately 75 m or closer for the 2 MW_e case) at a sensitive receptor.

The location of the wood chipping operation is not currently known. Based on the reference wood chipping sound pressure level information (Health and Safety Laboratory 2008), noise from the chipper would be noticeable over background within approximately 500 to 1,000 m from the wood chipper (depending on technology of wood chipper used). At closer than 200 to 400 m, the noise would be highly audible (perceived as a doubling of background noise). As stated above, these are conservative estimates as screening effects were not taken into account. Therefore the noise from the wood chipping operations during daytime hours is not expected to be noticeable beyond 1,000 m. Wood chipping is only expected to be required for several hours per day and not every day. Wood chipping would be scheduled to avoid evening, nighttime and early morning hours as well as weekends. If the chipper is to be located within 1 km of permanent residents, the school or other areas considered noise sensitive, further assessment would be completed to establish background sound pressure levels at the location as well as the actual sound levels for the required chipper. Effort would be made in selection of the chipping equipment as well as through noise mitigation (such as barriers) as required to reduce the noise at the nearest sensitive receptor to 3 dB or less above background levels (where the noise would be just perceivable).

Dispersion Modelling

Dispersion modelling of air contaminant emissions resulting from Operation of the Project was conducted to predict resulting ground-level concentrations downwind. This technical evaluation was used to inform the assessment of environmental effects on Air Quality. Emissions during construction activities were not modelled as the releases will be short-term in duration (during the construction period) and the air contaminant emissions are likely to be less than those during Operation.

As noted above, since the Project is in the early design stages, the scale and configuration of the Project operation is not yet confirmed. Therefore, three scenarios currently being considered for the Project were modelled as follows:

- **Scenario 1:** 0.5 MW biomass gasifier and engines with two 8 metre exhaust stacks;
- **Scenario 2:** 2 MW biomass gasifier and engines with eight 8 metre exhaust stacks; and
- **Scenario 3:** 2 MW biomass gasifier and engines with one 20 metre exhaust stack.

These scenarios are expected to conservatively evaluate the range of potential technology configurations that could be chosen. The maximum short term and long term (annual) average ground-level concentrations are predicted with the most recent version of the AERMOD dispersion model.

The inputs required for the dispersion modelling consist of three components: meteorological data; receptor grid and terrain data; and point source characteristics and emissions data.

Hourly meteorological data (*e.g.*, wind speed and direction, temperature) from the beginning of January 2006 to the end of December 2011 were obtained from the National Climatic Data Centre (NCDC 2012) for the Whitehorse Airport, the nearest representative surface station to the Project site. Twice daily, upper air sounding data were also obtained for the Whitehorse weather station, the nearest representative upper air station to the Project site (NOAA 2012). The raw data for the area were used to calculate stability parameters and mixing layer depths (mixing heights) with AERMET, the AERMOD meteorological pre-processor.

A receptor grid covering the LAA was established for the dispersion modelling, consisting of a 10 km x 10 km Cartesian receptor grid with the Project site near the center of the grid. The receptor grid spacing was 100 m apart for the 6 km by 6 km grid centered near the Project and 500 m apart for the remainder of the 10 km x 10 km domain. Terrain elevation data used in the development of the receptor grid were obtained from the Yukon Environment GIS Data (Yukon Environment 2012b).

The source data required to run the AERMOD model includes the following:

- Physical location of the point sources;
- Emission rate of the selected air contaminant;
- Physical height of the emission source (stack height);
- Diameter of the stack at its exit (stack exit diameter);
- Average stack exhaust gas exit velocity; and
- Average stack exhaust gas temperature.

The source parameters and emission rates required for the dispersion modelling were obtained from emissions data provided by equipment vendors (CPC 2012).

The model input parameters and emission rates included in the modelling for Operation of the Project are provided in Tables 5.2.6 and 5.2.7, below.

Table 5.2.6 Model Inputs – Source Parameters

Source	Location (m)		Stack Height (m)	Stack Diameter (m)	Average Stack Gas Exit Temperature (K)	Average Stack Gas Exit Velocity (m/s)
	UTM X	UTM Y				
Scenario 1						
Engine Stack 1	363,155	6,738,485	7.6	0.2	647	10.0
Engine Stack 2	363,162	6,738,479	7.6	0.2	647	10.0

Scenario 3						
Engine Stack	0.36	0.15	0.045	1.5E-03	1.5E-03	1.5E-03

Additional details on the source parameters and emissions rates used in the modelling are provided in the Emission and Wastes section in the Project Description (Section 3.3).

The effects of downwash due to wind flow over and around the surrounding buildings are considered in the modeling. Since building wake effects may influence the predictions, building heights and widths were included in the input file using the US EPA Building Profile Input Program (BPIP-PRIME) so those effects would be considered in the analysis (US EPA 1997).

After running AERMOD, output files were generated for the maximum 1-hour, 8-hour and 24-hour predicted concentrations and annual average concentrations at each receptor for the complete 6-year time period spanned by the meteorological input file.

Measured ambient air quality data were used to characterize the baseline and establish background concentrations used in the modelling. The incremental changes related to Project activities during Operation were considered in the context of these baseline values by adding maximum model-predicted values to measured ambient (*i.e.*, background) values.

To conservatively estimate baseline ambient air concentrations for relevant averaging periods in the Study Area, monitoring data from the nearest ambient station to the Project site were considered. The nearest ambient air quality monitoring station to the Project site is located in Whitehorse, approximately 130 km to the east. For averaging periods of 24 h or less, the maximum of the monthly hourly averages from 2008-2010 were used in conjunction with the OMOE relation for determination of alternate averaging periods. For annual averaging periods, the average of the monthly concentrations was used.

The background concentrations of the Criteria Air Contaminants (CAC) used in the modelling analysis are presented in Table 5.2.8. Ambient baseline values were estimated wherever data were available for all relevant averaging periods. For certain air contaminants, limited or no ambient data were available. For the cases where no data are available, the background concentrations are assumed to be negligible. Where limited data are available, details of the specific data treatment are specified in the table below.

Table 5.2.8 Ambient Background CAC Concentrations Used for Modelling

Criteria Air Contaminant	Averaging Period	Background Concentration Used ($\mu g/m^3$)	Additional Notes
SO^2	1-hour	--	No data available, SO_2 not monitored at Whitehorse station.
	24-hour	--	
	Annual	--	
NO_2	1-hour	19.9	Estimated using maximum of monthly hourly average concentrations measured at the Whitehorse station in 2008. 24-hour average background concentration estimated using OMOE relation. Annual background concentration based on the average of the 2008 monthly average values.
	24-hour [1]	8.2	
	Annual	7.1	
CO	1-hour	1.1	Estimated using maximum of the monthly hourly average concentrations measured at the Whitehorse station from 2008-2010 and OMOE relation.
	8-hour [1]	0.61	
TSP	24-hour[1]	4.3	No data available, TSP not monitored at Whitehorse station. In absence of ambient data for TSP, $PM_{2.5}$ background concentration used for 24-hour averaging period. For annual average, the average of the monthly $PM_{2.5}$ concentrations from 2008-2010 was used.
	Annual	2.5	
PM_{10}	24-hour[1]	4.3	No data available, PM_{10} not monitored at Whitehorse station. In absence of ambient data for PM_{10}, $PM_{2.5}$ background concentration was used.
$PM_{2.5}$	24-hour[1]	4.3	Estimated using maximum of the monthly hourly average concentrations measured at the Whitehorse station from 2008-2010 and OMOE relation.

Notes:
[1] Ambient background concentrations (24 h or weekly) were converted to an alternate averaging period using the following equation described in Table 7-1 in the OMOE's document "Procedure for Preparing an Emission Summary and Dispersion Modelling Report", dated July 2009: $C_0 = C_1 \times (t_1/t_0)^n$ where C_0 = the concentration at the averaging period t_0, C_1 = the concentration at the averaging period t_1, and n = 0.28.

Although no SO_2 data are available for the Yukon, as the Project will result in decreased SO_2 emissions in Haines Junction, this is not considered a technical limitation.

Dispersion Modelling Results

The maximum predicted ground-level air contaminant concentrations (including background) for each operational scenario modelled are provided in Table 5.2.9, 5.2.10 and 5.2.11.

Table 5.2.9 Maximum Predicted Ground-level Concentrations – Scenario 1

CAC	Averaging Period	Background ($\mu g/m^3$)	Location		Maximum Predicted Concentration ($\mu g/m^3$)	Maximum Predicted Concentration Plus Background ($\mu g/m^3$)	Objective/ Guideline or Standard ($\mu g/m^3$)	Percentage of Objective/ Guideline or Standard

The maximum predicted concentrations of the modelled air contaminants, including background, were well below the ambient air quality standards and objectives for the three scenarios modelled. The operational configuration for Scenario 3 results in the lowest downwind concentrations; this is due to better dispersion of the stack exhaust plume which results from having a higher stack (20 m in height). Although the emission rates are lower for Scenario 1, the shorter stack (approximately 8 m in height) results in less dispersion downwind which in turn causes higher ground-level concentrations.

Concentration contour plots of the 1-hour maximum predicted ground-level NO_2 concentrations are provided below in Figures 5.2.1, 5.2.2 and 5.2.3, for each scenario. The highest predicted concentrations generally occur in the immediate vicinity of the Project site.

Ground-level concentrations of selected hazardous air contaminants were also modelled for each scenario. The estimated 24-hour ground-level concentrations were predicted for the air contaminants expected to be released in the largest quantities (benzene and formaldehyde), as noted above in Section 3.3. The estimated 24-hour benzene and formaldehyde concentrations were compared with Ontario Ministry of the Environment Ambient Air Quality Criteria (OMOE 2012). The estimated 24-hour benzene and formaldehyde ground-level concentrations were below the OMOE ambient criteria of 2.3 $\mu g/m^3$ and 65 $\mu g/m^3$, respectively, for each modelled scenario.

5.2.4 Assessment of Cumulative Effects

In addition to the Project environmental effects discussed above, an assessment of the potential cumulative environmental effects was conducted for other projects and activities that have potential to cause environmental effects that overlap with those of the Project, as identified in Table 5.2.5. The potential cumulative environmental effects to the Atmospheric Environment are presented in Table 5.2.12. In the table each interaction with other projects is ranked as 0, 1, or 2 with respect to the nature and degree to which important Project-related environmental effects overlap with those of other projects and activities.

Table 5.2.12 Potential Cumulative Environmental Effects to the Atmospheric Environment

Other Projects and Activities With Potential for Cumulative Environmental Effects	Potential Cumulative Environmental Effects		
	Change in Air Quality	Change in GHG Emissions	Change in Sound Quality
Industrial Land Use (Past or Present)	1	1	1
Forestry and Agricultural Land Use (Past or Present)	1	1	1
Current Use of Land and Resources for Traditional Purposes by Aboriginal Persons (Past or Present)	1	1	1
Recreational Land Use (Past or Present)	1	1	1
Residential Land Use (Past or Present)	1	1	1
Industrial Land Use (Future)	1	1	1
Forestry and Agricultural Land Use (Future)	1	1	1
Current Use of Land and Resources for Traditional Purposes by Aboriginal Persons (Future)	1	1	1
Recreational Land Use (Future)	1	1	1
Planned Residential Development (Future)	1	1	1

Cumulative Environmental Effects

Notes:

Cumulative environmental effects were ranked as follows:

0 = Project environmental effects do not act cumulatively with those of other Projects and Activities.

1 = Project environmental effects act cumulatively with those of other Project and Activities, but are unlikely to result in significant cumulative environmental effects OR Project environmental effects act cumulatively with existing significant levels of cumulative environmental effects but will not measurably change the state of the VC.

2 = Project environmental effects act cumulatively with those of other project and activities, and may result in significant cumulative environmental effects OR Project environmental effects act cumulatively with existing significant levels of cumulative environmental effects and may measurably change the state of the VC.

With respect to Forestry and Land Use, logging equipment and trucks release combustion gases, GHGs, and sound emissions and may cause fugitive road dust emissions during Operation in the areas harvested for Project feedstock. These emissions are transient as the logging operations move from site to site, and are limited to emissions from the operation of heavy equipment. As such, cumulative environmental effects from the Project and Forestry and Land Use are not expected to be substantive most of the time.

Existing Industrial Land Use near the Project includes the Yukon Electrical Company Diesel Plant in Haines Junction. The operation of the diesel plant is infrequent, typically during periods of electrical grid outages. Given there are no substantive industrial sources with frequent emissions in the area of the Project, the interactions between the other sources and the Project with respect to a Change in the Air Quality, a Change in GHG Emissions, and a Change in Sound Quality are likely to be minimal.

At this time, no future Industrial Land Use projects are known. The interaction between any future projects and the Project would be addressed by the EA for a future project.

With respect to Residential Land Use, air contaminant and GHG emissions from space heating requirements could combine with Project emissions at the ground-level on occasion, specifically during times with poor dispersion. However, given the small magnitude of the emissions due to residential space heating, cumulative environmental effects from the Project and Residential Land Use are not expected to be substantive most of the time.

It is not expected that Current Use of Land and Resources for Traditional Purposes by Aboriginal Persons will be substantively affected by the Operation of the Project as air contaminant emissions released from the Project will disperse from the site and ground-level concentrations will return to background levels.

The Project has the potential to interact with the recreational areas near the Project with respect to a Change in Air Quality and a Change in GHG Emissions during Operation. However, given the emissions from the Project are relatively low, negligible cumulative effects are expected with respect to Recreational Land Use.

Sound emissions from Current Use of Land and Resources by Aboriginal Persons for Traditional Purposes, Recreational Land Use and Residential Land Use are generally minimal and close to background sound levels. As such, substantive interactions between their environmental effects and those of the Project are not anticipated.

At this time, there are no known planned or future residential developments considered near the Project. The interaction between any future projects and the Project would be addressed by the EA for a future project.

5.2.4.1 Mitigation of Cumulative Environmental Effects

Mitigation measures for the Project Case were discussed previously for Project-related environmental effects (Section 5.2.3.3). The mitigation measures proposed for the Project-related environmental effects are also anticipated to be effective in mitigating any cumulative environmental effects, as would the mitigation associated with other past and future projects and activities.

5.2.5 Determination of Significance

5.2.5.1 Residual Project Environmental Effects

With the proposed mitigation and environmental protection measures, the residual environmental effect of a Change in Air Quality during all phases of the Project is rated not significant. This conclusion has been determined with a high level of confidence based on the conservative assumptions and emission factors used to estimate air contaminant emissions.

With the proposed mitigation and environmental protection measures, the residual environmental effect of a Change in GHG Emissions during all phases of the Project is rated not significant. This conclusion has been determined with a high level of confidence based on the conservative assumptions and emission factors used to estimate GHG emissions.

With the proposed mitigation and environmental protection measures, the residual environmental effect of a Change in Sound Quality during all phases of the Project is rated not significant. This conclusion has been determined with a high level of confidence based on the conservative assumptions used to estimate sound pressure levels.

5.2.5.2 Residual Cumulative Environmental Effects

The characterization of the potential cumulative environmental effects and associated mechanisms, combined with the proposed mitigation measures proposed in Section 5.2.4.2 demonstrate that the residual cumulative environmental effect of a Change in Air Quality is rated not significant. This determination has been made with a moderate level of confidence due to the preliminary nature of data available for the Project activities and the site location.

The characterization of the potential cumulative environmental effects and associated mechanisms, combined with the proposed mitigation measures proposed in Section 5.2.4.2 demonstrate that the residual cumulative environmental effect of a Change in GHG Emissions is rated not significant. This determination has been made with a moderate level of confidence due to the preliminary nature of data available for the Project activities.

The characterization of the potential cumulative environmental effects and associated mechanisms, combined with the proposed mitigation measures proposed in Section 5.2.4.2 demonstrate that the residual cumulative environmental effect of a Change in Sound Quality is rated not significant. This determination has been made with a moderate level of confidence due to the preliminary nature of data available for the Project activities, including Project location.

The proposed mitigation measures demonstrate that the Project contribution to the cumulative environmental effects on a Change in Air Quality, a Change in GHG Emissions, and a Change in Sound Quality is rated not significant. This determination has been made with a moderate level of confidence.

5.2.6 Summary Consultation Influence on the Assessment

At the time of writing, consultations in the community are on-going. A summary of the consultations as they apply to Atmospheric Environment will be provided following the completion of the consultations for the Project.

5.2.7 Effects Monitoring and Adaptive Management

During Operation, it is recommended that one stack testing campaign be conducted following commissioning of the Project to confirm vendor emissions guarantees. Given the current uncertainty of the scale and operational configuration of the Project, some parts of the assessment of Atmospheric Environment may need to be updated, specifically with respect to feedstock harvesting.

Ambient air quality monitoring is not warranted, given relatively small scale of the Project with relatively low emissions and the absence of substantive existing emission sources. There are no other warranted follow-up programs for air quality.

If sound complaints are received during Construction and/or Operation, monitoring may be implemented to confirm that sound pressure levels are within acceptable levels.

5.3 TERRESTRIAL ENVIRONMENT

5.3.1 Scope of the Assessment

This section defines the scope of the environmental assessment of the Terrestrial Environment in consideration of the nature of the regulatory setting, issues identified during public and First Nations engagement activities, potential Project-VC interactions, and existing knowledge.

5.3.1.1 Key Issues and Identification of Potential Effects

5.3.1.2 Regulatory/Policy Setting

The assessment of the Terrestrial Environment for the Project has been completed in accordance with the requirements of the *Yukon Environmental and Socio-Economic Assessment Act* (*YESAA*). The *YESAA* is not specific with respect to which aspects of vegetation and wildlife are to be assessed. However, the Yukon Environmental and Socio-economic Assessment Board (YESAB) does provide guidance in the Proponent‘s Guide to Information Requirements for Executive Committee Project Proposal Submissions (YESAB 2005).

The Project has the potential to interact with the Terrestrial Environment by changing terrestrial habitats, including wetlands, and/or populations of vascular plants and/or wildlife species that are important in a socio-economic or environmental context, including species at risk (SAR), as defined federally by the *Species at Risk Act* (*SARA*), or species of conservation concern (SOCC), defined here as species ranked S1, S2, or S3 by the Yukon Conservation Data Centre (YCDC), with a general status rank of May Be At Risk, or Sensitive as determined by the Canadian Endangered Species Conservation Council (CESCC), and/or that have undergone an assessment by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC), but not yet included on Schedule 1 of *SARA*. Additional species considered in this assessment as SOCC include species that will be assessed by COSEWIC. SOCC are species that, unlike SAR, are not afforded direct protection by legislation. SOCC are placed on lists as a precautionary measure that reflects an observed trend in their provincial population status.

Additional guidance for the feedstock component of the Project can be found in the “Strategic Forest Management Plan (SFMP)”, the “Integrated Landscape Plan (ILP) for the Champagne and Aishihik Traditional Territory”, and the YESAB “Proponent’s Guide: Completing a Forestry Project Proposal”. The SFMP was developed to provide direction for sustainable forest management in the CATT. The ILP was developed to provide guidance for projects involving forestry harvest and site planning. The SFMP directs the ILP to identify areas where forest harvesting should or should not take place. At a broad scale the ILP has identified these areas based on a number of factors, including:

- cultural;
- traditional;

- tourism;
- viewscapes;
- wilderness;
- wildlife;
- biological diversity;
- connectivity;
- community safety from wildfire risk;
- timber; and
- economy.

The Forestry Project Proposal Guide is a document designed to accompany the Project Proposal Form for Forestry. The completed form contains information that the YESAB requires to conduct an environmental and socio-economic assessment.

5.3.1.3 Selection of Measureable Parameters

The environmental assessment of the Terrestrial Environment is focused on the following environmental effects:

- Change in Terrestrial Populations; and
- Change in Wetlands.

The Project has the potential to affect the Terrestrial Environment through changes in abundance of wildlife and wildlife habitat, and degradation in habitat quality, all of which influence terrestrial populations of wildlife and plants. These potential changes could possibly influence the loss, or sustained presence of terrestrial populations and the maintenance of biodiversity in the region. In light of the value placed on terrestrial populations and wetlands by regulatory agencies, stakeholders, and the public, the environmental assessment of the Terrestrial Environment is focused on these environmental consequences which encompass the critical aspects of the VC.

The measurable parameters used for the assessment of the environmental effect presented above and the rationale for their selection is provided in Table 5.3.1.

Table 5.3.1 Measurable Parameters for Terrestrial Environment

Environmental Effect	Measurable Parameter	Rationale for Selection of the Measurable Parameter
Change in Terrestrial Populations	Loss of Vascular Plant SAR or SOCC (number of individuals)	• Addresses loss of known locations of rare vascular plants within the territory that are disturbed as a result of the Project.
	Loss of Wildlife SAR or SOCC (number of individuals)	• Loss of Wildlife SAR or SOCC (number of individuals)
	Changes to community structure or composition	• Addresses changes to the community structure and/or composition at a temporal scale.
	Loss of Migratory Birds (number of individuals)	• Addresses the concern of loss of individuals of migratory birds, including their nests, eggs, and young.
	Direct Habitat Loss (ha)	• This includes habitats for many wildlife and vascular plant species (such as old growth forests) and will also include an evaluation of the rarity of habitats affected.
	Loss of Old Growth Forest	• Old growth forests are important to biodiversity as well as regulators, First Nations, and other residents of Yukon Territory.
Change in Wetlands	Loss of wetland area (ha)	• Wetlands provide habitat for many wildlife and vascular plant species and will also include an evaluation of the rarity and proportion of wetlands affected.
	Loss of wetland function	• Wetlands can provide a number of functions, including hydrological, socio-economic, and ecological.

The measurable parameters in Table 5.4.1 were based on the professional judgment of the Study Team. Measurable parameters have clear units of measurement and are indicative of change in the Terrestrial Environment.

5.3.1.4 Spatial Boundaries

The spatial boundaries for the environmental effects assessment of the Terrestrial Environment are defined below.

Project Development Area (PDA): The PDA is the most basic and immediate area of the Project. The PDA is limited to the area of physical ground disturbance associated with the Project, and consists of an area that includes the area of physical disturbance associated with the biomass plant and associated facilities as well as the area associated with biomass feedstock harvesting (including forest roads, to be defined in detail upon further study). The PDA is the area represented by the physical Project footprint as defined in Chapter 3.1.2 above.

Local Assessment Area (LAA): The LAA includes a 10 x 10 km centred on the PDA. At present, the feesdstock harvesting area has not been identified; however a qualitative assessment of the harvesting area has been undertaken. The LAA is the maximum area within which Project-related environmental effects can be predicted or measured with a reasonable degree of accuracy and confidence. The LAA includes the PDA and any adjacent areas where Project-related environmental effects may reasonably be expected to occur. The LAA will be redefined to include areas of forest harvesting activities once the forest harvesting activities associated with the Project have been defined.

Regional Assessment Area (RAA): The RAA is limited to and includes the Yukon Territory. The RAA is the area within which the Project's environmental effects may overlap or accumulate with the environmental effects of other projects or activities that have been or will be carried out. The extent to which cumulative environmental effects for Vegetation and Wetland Resources may occur depend on physical and biological conditions and the type and location of other past, present, and reasonably foreseeable future projects or activities that have been or will be carried out, as defined within the RAA.

5.3.1.5 Temporal Boundaries

The temporal boundaries for the assessment of the potential environmental effects of the Project on the Terrestrial Environment include the phases of Construction, Operation, and Decommissioning. The preliminary Project schedule is provided in Section 3.4.

5.3.1.6 Administrative and Technical Boundaries

The assessment of the potential environmental effects of this Project on the Terrestrial Environment includes a consideration of populations of species that are listed under various federal and territorial acts and regulations. Existing habitat information used for the EA includes YCDC occurrences for species of special status in the vicinity of the Project, and information on Environmentally Significant Areas (ESAs). Information used for the assessment of potential environmental effects on the Terrestrial Environment was obtained from the *SARA*, the *MBCA*, 1994, the *Federal Policy on Wetland Conservation*, the *YESAA*, YCDC, the *Yukon Forest Protection Act*, the *Yukon Forest Resources Act*, the *Territorial Lands Act* (Yukon), and Yukon *Wildlife Act*, and the *Yukon Act* . Additional knowledge of vegetation and wetlands potentially affected by the Project is based on other information provided by the above sources, and the professional judgment of the Study Team.

Canada's indigenous species, subspecies, and distinct populations that are considered "At Risk" are protected under the *SARA*. The *SARA* provides legal protection to species and the conservation of their biological diversity. The purposes of the Act are to prevent species from becoming extirpated or extinct, to provide for the recovery of endangered or threatened species, and encourage the management of other species to prevent them from becoming at risk. Designation under the Act follows recommendation and advice provided by COSEWIC to the Government of Canada. The COSEWIC is responsible under the *SARA* for assessing the biological status of each rare species in Canada. Under the *SARA*, the Governor in Council may accept the assessment and add the species to Schedule 1 of the *SARA*, decide not to add the species to Schedule 1, or may refer the assessment back to COSEWIC for further information or consideration.

Subsection 79(1) of the *SARA* stipulates that every person who is required by or under an Act of Parliament to ensure that an assessment of the environmental effects of a project is conducted must, without delay, notify the competent minister or ministers in writing of the project if it is likely to affect a listed wildlife species or its critical habitat. Additionally, *SARA* Subsection 79(2) states that where a federal environmental assessment is being carried out in relation to a project that may affect a listed wildlife species or its critical habitat, the person responsible for ensuring the assessment is conducted must:

- identify potential adverse effects on the listed wildlife species and its critical habitat;

- if the project is carried out:
    - ensure that measures are taken to avoid or lessen those adverse effects and to monitor them; and
    - ensure that such measures are consistent with any applicable recovery strategy and action plans.

Under the *SARA*, there are three schedules; species officially protected are listed under Schedule 1 of the *SARA* and designated as "Extinct, Extirpated, Endangered, Threatened, and Special Concern" by COSEWIC are protected by that Act. Species listed as "Special concern" are not protected by the prohibitions of Sections 32-36 of the *SARA*; however, they do not require that provincial or regional management plans are development to protect the species. Species of special concern are considered species at risk as Section 79 requirements of the Act apply to these species. "Listed Species" refer to species listed in Schedule 1 of the *SARA* and includes species designated as extirpated, endangered, threatened, or of special concern. Listed species are identified on the Species at Risk Public Registry.

Schedule 1 of the *SARA* is the official list of wildlife species at risk. Once a species is "listed", the measures to protect and recover a listed wildlife species are implemented. Species that were designated at risk by the COSEWIC prior to the existence of the *SARA* require reassessment before being placed on Schedule 1. These species are listed on Schedule 2 if they were previously assessed by COSEWIC as endangered or threatened, and on Schedule 3 if they were previously assessed by COSEWIC as special concern. Both Schedules 2 and 3 are not provided with legal protection under the *SARA*.

Migratory birds are protected federally under the *Migratory Birds Convention Act* (*MBCA*) (1994), which states that "...no person shall disturb, destroy or take a nest, egg, nest shelter, eider duck shelter, or duck box of a migratory bird…" without a permit. The Act includes prohibition of "incidental take" of migratory birds or their nests as a result of activities such as those required for the Project.

Wildlife species are protected in the territory under the Yukon *Wildlife Act*. The Act reserves the right to place prohibitions, restrictions, or measures to be observed or implemented for the protection or survival of a population or species designated as "specially protected". Section 5 of the regulations lists several specially protected species, including:

- Cougar (*Puma concolor*);
- Gyrfalcon (*Falco rusticolus*);
- Peregrine Falcon (*Falco peregrinus*);
- Trumpeter Swan (*Cygnus buccinators*); and
- Chisana Caribou Herd.

The *Yukon Act* also offers protection from being hunted to wildlife species declared by order of the Governor in Council to be in danger of becoming extinct.

Forests are protected in the territory under the *Forest Protection Act*, the *Forest Resources Act*, and the *Territorial Lands Act*. These acts regulate the harvesting of forestry resources (through a permitting process), construction of forestry roads, and activities surround fires in forested areas, as well as many other activities.

Wetlands are protected federally under the *Federal Policy on Wetland Conservation.* The objective of this policy is to *"…promote the conservation of Canada's wetlands to sustain their ecological and socio-economic function now, and in the future*…" Coordination of implementation of the policy is the responsibility of Environment Canada, specifically the Canadian Wildlife Service and the Environmental Conservation Branch. Although there is no specific federal legislation regarding wetlands, they may be protected federally under the *SARA*, if they contain critical species habitat for Species At Risk, the *MBCA*, 1994, if they contain nests of migratory birds, and/or the *Fisheries Act*, if the wetland contributes to existing or potential fish habitat.

5.3.1.7 Residual Effects Significance Criteria

Residual environmental effects rating criteria for the potential environmental effects of the Project on the Terrestrial Environment are applied to the evaluation of a loss of plant populations, SAR, or SOCC.

A *significant residual adverse environmental effect* on the Terrestrial Environment is defined as a Project-related environmental effect that results in any of the following:

- On secure species, one that affects terrestrial populations or habitat in such a way as to cause a decline in abundance or change in distribution of common and secure population(s) such that populations will not be sustainable within the RAA.

- On any Endangered or Threatened Species at Risk, one that results in a non-permitted contravention of any of the prohibitions stated in Sections 32-36 of *SARA*. Sections 32-36 stipulate that it is an offence to capture, take, possess, collect, and sell endangered or threatened species. It is also illegal to damage or destroy the residence, for example the nest or den, of an endangered or threatened species.

- On any species of special status (SAR or SOCC), one that alters the terrestrial habitat within the spatial boundaries physically, chemically, or biologically, in quality or extent, in such a way as to cause a change or decline in the distribution or abundance of a viable plant or wildlife population that is dependent upon that habitat such that the likelihood of the long-term survival of these populations within the RAA is substantially reduced as a result.

- On any species of special status (SAR or SOCC), one that results in the direct mortality of individuals or communities such that the likelihood of the long-term survival of these rare, uncommon and/or non-secure population(s) within the RAA is substantially reduced as a result.

- For wetland environments, one that results in a non-compensated net loss of wetland area and function.

5.3.2 VC Existing Conditions

The Terrestrial Environment includes vascular plant and wildlife (including birds) species and communities, and their habitats, including both upland and wetland habitats. The assessment focuses on important habitats and vascular plant and wildlife species at risk (SAR), as defined by the federal *Species at Risk Act* (*SARA*), or species of conservation concern (SOCC), defined here as species ranked S1, S2, or S3 by the YCDC, and with a status rank of At Risk, May Be At Risk, or Sensitive as determined by the CESCC. Additional species considered in this assessment as SOCC at the request of Environment Canada include species that will be assessed by COSEWIC in the coming year. Other species, communities, and habitats in the Yukon are secure, and although they may be affected by the Project, are not of particular sensitivity to the potential environmental effects.

5.3.2.1 Vegetation

Haines Junction is located in the Ruby Ranges ecoregion of the Boreal Cordillera ecozone. Vegetation in the lower boreal forest areas of the ecoregion include white spruce (*Picea glauca*), black spruce (*Picea mariana*), dwarf willow (*Salix herbacea*), birch (*Betula* sp.), ericaceous shrubs, and to a lesser extent, lodgepole pine (*Pinus contorta*). In poorly draining areas black spruce, scrub willow, birch, and various mosses can be found. Subalpine areas include alpine fir (*Abies lasiocarpa*) and lodgepole pine, while the highest elevated alpine areas of the ecoregion have plant communities that consist of mountain avens (*Dryas octopetala*), dwarf willow, birch, ericaceous shrubs, graminoid species, and mosses (The Ecological Framework of Canada n.d.).

Haines Junction has three species of trees; white spruce, trembling aspen (*Populous temuloides*), and balsam poplar (*Populous balsamifera*). The Project site is classified as a white spruce forest. A search of the YCDC did not indicate that there are any plant SAR or SOCC that have been identified in the vicinity of the site (B. Bennett pers. comm. 2012). There is currently only one plant listed by the *SARA* in the Yukon. The Baikal sedge (*Carex sabulosa*) is listed on Schedule 1 as Threatened, S2 by the YCDC, and as At Risk in the territory by the CESCC). The Baikal sedge can be found in sand dune habitats; the habitat at the Project site is not suitable for the sedge (B. Bennett, pers. comm. 2012). There are three additional plant SOCC found in the Yukon; the Yukon draba (*Draba yukonensis*, listed as endangered by COSEWIC, S1 by YCDC, and May be at Risk by CESCC), spiked saxifrage (*Saxifraga spicata*, awaiting review by COSEWIC in 2013, listed at May be at Risk by CESCC, and S1S2 by YCDC), and Yukon podistera (*Podistera yukonensis*, awaiting review by COSEWIC in 2013, listed at May be at Risk by CESCC, and S2 by YCDC). No suitable habitat is found at the Project site for these plants SOCC (B. Bennett pers. comm. 2013).

There are 170 recorded invasive plant species in the Yukon, each with its own invasiveness rank and general abundance with Yukon Environment. The spread of invasive species threatens biodiversity and is of concern to native species and habitats. Nineteen of these species are considered highly invasive and are listed below in Table 4.1.1.

Table 5.3.2 Highly Invasive Plant Species in Yukon Territory

Common Name	Scientific Name	Invasiveness Rank	Abundance	Persistence
Crested Wheat Grass	*Agropyron cristatum*	1	C	1
Smooth Brome	*Bromus inermis*	1	C	1
Spotted Knapweed	*Centaurea maculosa*	1	X	3
Creeping (Canada) Thistle	*Cirsium arvense*	1	R	2
Narrow-leaved Hawksbeard	*Crepis tectorum*	1	C	1
Leafy Spurge	*Euphorbia esula*	1	R	2
Field Hawkweed	*Hieracium caespitosum*	1	R	2
Oxeye Daisy	*Leucanthemum vulgare*	1	R	1
Narrow-leaved (Altai) Lyme Grass	*Leymus angustus*	1	R	2
Dalmatian Toadflax	*Linaria dalmatica*	1	X	3
Butter-and-eggs	*Linaria vulgaris*	1	C	1
Lucerne	*Medicago falcata*	1	C	1
White Sweetclover	*Melilotus alba*	1	C	1
Yellow Sweetclover	*Melilotus officinalis*	1	C	1
Reed Canary Grass	*Phalaris arundinacea*	1	?	1
Field Snow-thistle	*Sonchus arvensis ssp. uliginosus*	1	C	1
Common Tansy	*Tanacetum vulgare*	1	U	2
Scentless Chamomile	*Tripleurospermum inodoratum*	1	R	1
Tufted Vetch	*Vicia cracca*	1	C	2

Notes:
Invasiveness Rank
1 - Highly invasive - may displace or replace native ecosystems.

General Abundance
C = Common – widespread, established.
R = Rare, known from only one or two localities.
U = Unknown.
X = Possibly not persistent.
? = Possibly native.

Persistence
1 = Widespread.
2 = Local.
3 = Not persistent.

Source: Government of Yukon 2012a, Yukon Introduced Plants, January 2012 accessed at: http://www.env.gov.yk.ca/animals-habitat/invasiveplants.php.

Spruce bark beetle (*Dendroctonus rufipennis*) infestation in the region has had an impact on the age class and stand height of forests in the region (CAFN 2005). Large stands of dead wood are now found in many areas throughout the CAFN region. The beetle attacks semi-mature and mature white spruce, boring into the tree to create a cavity for eggs. Once hatched, larvae bore into the phloem. The beetles are carriers of a fungus that affects the phloem tubes of the trees and helps the beetles weaken the trees. Stands of dead trees are wildfire hazards and are of concern, especially near residential areas.

The closest wetlands to Haines Junction are located adjacent to the southern municipal boundaries of the village and are associated with Dezadeash River (see Figure 5.3.1).

Figure 5.3.1 Terrestrial Environment

The location of the source feedstock has not been identified at the time of writing. Once selected, information regarding vegetation (including invasive species) and wetlands at the sites will be included in this report.

5.3.2.2 Wildlife

Wildlife typically encountered in the Ruby Ranges ecoregion include caribou (*Rangifer tarandus*), grizzly bears (*Ursus arctos horribilis*), black bears (*Ursus americanus*), Dall sheep (*Ovis dalli*), moose (*Alces alces*), foxes (*Vulpes* sp.), wolves (*Canis* sp.), hares (*Lepus* sp.), ravens (*Corvus corax*), rock ptarmigan (*Lagopus muta*), willow ptarmigan (*Lagopus lagopus*), and golden eagles (*Aquila chrysaetos*) (The Ecological Framework of Canada n.d.).

A search of the YCDC did not indicate that there are any wildlife SAR or SOCC that have been identified in the vicinity of Haines Junction (B. Bennett, pers. comm. 2012). While no SAR or SOCC have been identified, it is always possible to encounter Barn Swallows (*Hirundo rustica*, designated as Threatened by COSEWIC and Sensitive by CESCC) nesting in old buildings. It has also been suggested that there is potential nesting habitat for Olive-sided Flycatcher (*Contopus cooperi*, listed in Schedule 1 of the *SARA* as Threatened and ranked At Risk by CESCC) and Common Nighthawk (*Chordeiles minor*, listed in Schedule 1 of the *SARA* as Threatened and ranked At Risk by CESCC) in the village (B. Bennett pers. comm. 2012). The possibility of encountering grizzly bears (designated as Special Concern by COSEWIC and Sensitive by CESCC) also exists (B. Bennett pers. comm. 2012). Additional SAR and SOCC in the Yukon are listed in Table 4.2, below.

Table 5.3.3 Additional Wildlife Species at Risk and Species of Conservation Concern in Yukon Territory

Common Name	Scientific Name	*SARA* Schedule and Status	COSEWIC Rank	CESCC Rank (2010)	YCDC S-Rank
Northern Long-eared Bat	*Myotis septentrionalis*	No schedule, no status	Endangered	Sensitive	S3
Little Brown Bat	*Myotis lucifugus*	No schedule, no status	Endangered	Secure	S1S3
Canada Warbler	*Wilsonia canadensis*	Schedule 1, Threatened	Threatened	At Risk	S1B
Red Knot	*Calidris canutus roselaari*	Schedule 1, Threatened	Threatened	-	-
Wood Bison	*Bison bison athabascae*	Schedule 1, Threatened	Threatened	At Risk	S2S3
Woodland Caribou (boreal population)	*Rangifer tarandus caribou*	Schedule 1, Threatened	Threatened	-	S1
Western Toad	*Anaxyrus boreas*	No schedule, no status	Special Concern	Sensitive	S3
Horned Grebe	*Podiceps auritus*	No schedule, no status	Special Concern	Sensitive	S3B
Peregrine Falcon	*Falco peregrinus anatum/tundrius*	Schedule 1, Special Concern	Special Concern	Sensitive	S3B
Rusty Blackbird	*Euphagus carolinus*	Schedule 1, Special Concern	Special Concern	Sensitive	S3B
Short-eared Owl	*Asio flammeus*	Schedule 1, Special Concern	Special Concern	Sensitive	S3B
Buff-breasted Sandpiper	*Tryngites subruficollis*	No schedule, no status	Special Concern	May be at Risk	S1B

Common Name	Scientific Name	*SARA* Schedule and Status	COSEWIC Rank	CESCC Rank (2010)	YCDC S-Rank
Collared Pika	*Ochotona collaris*	No schedule, no status	Special Concern	Sensitive	S3
Polar Bear	*Ursus maritimus*	Schedule 1, Special Concern	Special Concern	May be at Risk	S1
Wolverine (western population)	*Gulo gulo*	No schedule, no status	Special Concern	Sensitive	S3
Woodland Caribou (northern mountain population)	*Rangifer tarandus caribou*	Schedule 1, Special Concern	Special Concern	-	S3
Bank Swallow	*Riparia riparia*	No schedule, no status	Upcoming assessment in 2013	Secure	S5B
Red-necked Phalarope	*Phalaropus lobatus*	No schedule, no status	Upcoming assessment in 2014	Sensitive	S3B
Evening Grosbeak	*Coccothraustes vespertinus*	No schedule, no status	To be determined	Sensitive	S3B

Notes:

S1 = Critically Imperiled—Critically imperiled in the jurisdiction because of extreme rarity or because of some factor(s) such as very steep declines making it especially vulnerable to extirpation from the jurisdiction.

S2 = Imperiled—Imperiled in the jurisdiction because of rarity due to very restricted range, very few populations, steep declines, or other factors making it very vulnerable to extirpation from jurisdiction.

S3 = Vulnerable—Vulnerable in the jurisdiction due to a restricted range, relatively few populations, recent and widespread declines, or other factors making it vulnerable to extirpation.

S4 = Apparently Secure—Uncommon but not rare; some cause for long-term concern due to declines or other factors.

S5 = Secure—Common, widespread, and abundant in the jurisdiction.

S#S# = Range Rank — A numeric range rank (*e.g.*, S2S3 or S1S3) is used to indicate any range of uncertainty about the status of the species or ecosystem. Ranges cannot skip more than two ranks (*e.g.*, SU is used rather than S1S4).

B = Breeding—Conservation status refers to the breeding population of the species in the nation or state/province.

Wild Species: The General Status of Wild Species in Canada

At Risk: Species for which a formal, detailed risk assessment (COSEWIC status assessment or provincial or territorial equivalent) has been completed and that have been determined to be at risk of extirpation or extinction (*i.e*. Endangered or Threatened). A COSEWIC designation of Endangered or Threatened automatically results in a Canada General Status Rank (Canada rank) of At Risk. Where a provincial or territorial formal risk assessment finds a species to be Endangered or Threatened in that particular region, then, under the general status program, the species automatically receives a provincial or territorial general status rank of At Risk.

May Be At Risk: Species that may be at risk of extirpation or extinction and are therefore candidates for a detailed risk assessment by COSEWIC, or provincial or territorial equivalents.

Sensitive: Species that are not believed to be at risk of immediate extirpation or extinction but may require special attention or protection to prevent them from becoming at risk.

Secure: Species that are not believed to belong in the categories Extinct, Extirpated, At Risk, May Be At Risk, Sensitive, Accidental or Exotic. This category includes some species that show a trend of decline in numbers in Canada but remain relatively widespread or abundant.

Source Wild Species: The General Status of Wild Species in Canada' website Available at: http://www.wildspecies.ca/ranks.cfm?lang=e (CESCC 2012).

The Fish and Wildlife Branch of Yukon Environment maintains data on key areas where wildlife are found during important stages of their life cycle. Key Wildlife Areas (see Figure 5.3.1) located within the Village of Haines Junction municipal boundary include those for Sharp-tailed Grouse (*Tympanuchus phasianellus*) at the northern boundary and moose at the southeastern boundary. Just outside the municipal boundary there are key areas for grizzly bear (east of the village) and an additional area for moose (southwest of the village). An additional search using the Yukon Energy, Mines, and Resources lands viewer mapping application also displayed a spring staging area for geese east of the village.

The location of the biomass plant and the areas for feedstock harvesting have not been identified at this time. Once selected, targeted field surveys will be conducted at the sites and will be included in this report.

5.3.3 Potential Project VC Interactions

Table 5.4.2 below lists each Project activity and physical work for the Project, and ranks each interaction as 0, 1, or 2 based on the level of interaction each activity or physical work will have with the Terrestrial Environment.

Table 5.3.4 Potential Project Environmental Effects to the Terrestrial Environment

Project Activities and Physical Works	Potential Environmental Effects	
	Change in Terrestrial Populations	Change in Wetlands
Construction		
Site Preparation	2	0
Physical Construction of the Facility Structures And Installation of Equipment	2	0
Commissioning of the plant	1	0
Construction of Infrastructure for Feedstock Harvesting	2	1
Operation		
Operation and Maintenance of Plant site	1	0
Feedstock Harvesting	2	1
Decommissioning, reclamation, and closure		
Plant Site	1	0
Harvested Areas	1	1

Notes:
Project-Related Environmental Effects were ranked as follows:
0 No interaction. The environmental effects are rated not significant and are not considered further in this report.
1 Interaction will occur. However, based on past experience and professional judgment, the interaction would not result in a significant environmental effect, even without mitigation, or the interaction would clearly not be significant due to application of codified practices and/or permit conditions. The environmental effects are rated not significant and are not considered further in this report.
2 Interaction may, even with codified mitigation and/or permit conditions, result in a potentially significant environmental effect and/or is important to regulatory and/or public interest. Potential environmental effects are considered further and in more detail in the EA.

Construction

VCs With No Interaction With the Project (Ranking of 0)

During Construction, site preparation, construction of the facility structures and installation of equipment, and commissioning of the plant have been ranked as 0 for potential change in wetlands. There are no wetlands in the vicinity of the proposed biomass plant site (based on FEED site selection), and as such, no potential for the Project to directly impact wetland habitat. Therefore, a change in wetlands resulting from these Project activities is rated not significant.

VCs With Interactions That Would Not Result in Significant Environmental Effects (Ranking of 1)

During Construction, commissioning of the plant has been ranked as 1 for potential change in terrestrial populations. Once site preparation and construction of the building are complete, there are no further

disturbances expected on the site. If present, the locations any sensitive habitats, SAR, or SOCC within the PDA will have been identified during field surveys and as such, all commissioning activities will be conducted away from these areas.

Construction of infrastructure for feedstock harvesting has been ranked as 1 for potential changes in wetlands. At this time, information surrounding the harvesting of feedstock is not known. Table 5.4.2 will be revised once the forest harvesting activities associated with the Project have been defined and field surveys have been conducted.

Operation

VCs With No Interaction With the Project (Ranking of 0)

During Operation, operation and maintenance of the plant site has been ranked as 0 for potential change in wetlands. There are no wetlands present at the proposed plant site and therefore, there is no potential for operation and maintenance activities at the site to directly impact wetland habitat. As a result, a change in wetlands resulting from these Project activities is rated not significant.

VCs With Interactions That Would Not Result in Significant Environmental Effects (Ranking of 1)

During Operation, operation and maintenance of the plant site has been ranked 1 for potential change in terrestrial populations. In the event sensitive habitats, SAR, or SOCC are discovered on the site during field surveys, it would be ensured that operation and maintenance activities would be conducted away from these areas. Indirect environmental effects could also be associated with Accidents, Malfunctions, and Unplanned Events; however, contingency plans will be put in place during Operation to address such events.

Feedstock harvesting has been ranked as 1 for potential change in wetlands. At this time the source of feedstock is unknown. If feedstock is to be collected in the vicinity of wetland habitat, there could be potential for erosion and sedimentation, as well as changes in hydrology in wetlands due to the removal of the trees. Implementation of established and effective erosion and sedimentation controls will be used during all harvesting activities, limiting the magnitude of any potential interactions. Any hydrological changes in wetlands will be compensated for, and thus are rated not significant. The assessment of feedstock harvesting in relation to wetlands will be revised once the forest harvesting activities associated with the Project have been defined and field surveys have been conducted.

Decommissioning, Reclamation, and Closure

VCs With No Interaction With the Project (Ranking of 0)

During decommissioning, reclamation, and closure of the Project activities at the plant site have been ranked as 0 for potential change in wetlands. There are no wetlands present at the proposed plant site and therefore, there is no potential for decommissioning activities at the site to directly impact wetland habitat. As a result, a change in wetlands resulting from these activities is rated not significant.

VCs With Interactions That Would Not Result in Significant Environmental Effects (Ranking of 1)

Decommissioning, reclamation, and closure activities at the plant have been ranked as 1 for potential change in terrestrial populations. Decommissioning activities would be governed by regulations current at the time of the activities and reclamation plan would be developed at that time. The site would likely be redeveloped for other purposes or left to re-vegetate naturally.

The decommissioning, reclamation, and closure of harvested areas has been ranked as 1 for both potential environmental effects. While the activities and location of feedstock harvesting have yet to be determined, it is likely that these activities would include the removal of access roads. If access roads were being removed in areas in the vicinity of wetlands erosion and sedimentation controls would be in place prior to work being conducted. Reclamation efforts would likely involve re-forestation efforts in the previously harvested areas.

Thus, in consideration of the nature of the interactions and the planned implementation of mitigation, the potential environmental effects of all Project activities and physical works that were ranked as 0 or 1 in Table 5.4.2, including cumulative environmental effects, on the Terrestrial Environment during any phase of the Project are rated not significant, and are not considered further in the assessment.

5.3.3.1 Assessment of Project-Related Environmental Effects

A summary of the environmental effects assessment and prediction of residual environmental effects resulting from interactions ranked as 2 on the Terrestrial Environment is provided in Table 5.4.3.

Table 5.3.5 Summary of Residual Project-Related Environmental Effects on the Vegetation and Wetland Resources

Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics						Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects?	Recommended Follow-up or Monitoring
			Direction	Magnitude	Geographic Extent	Duration and Frequency	Reversibility	Ecological/Socio-economic Context					
Change in Terrestrial Populations	Construction: • Site preparation; • Physical construction of the facility structures and installation of equipment; and • Construction of infrastructure for feedstock harvesting	• Avoid known locations of plant and wildlife SAR and SOCC, where feasible. • Include any SAR or SOCC found within or adjacent to the PDA in post-construction monitoring and follow-up plans. • Conduct clearing activities at the plant location in fall and/or winter, outside the breeding season of migratory birds and calving season. • If active nests are discovered during tree clearing at the plant site, a vegetated buffer zone around the nest will be established and activities will be minimized in the immediate area until nesting is complete and chicks have fledged and left the area. • Flag any vascular plant SAR or SOCC found within 30 m of the PDA, and minimize Construction adjacent to the plants whenever feasible. • Keep litter and garbage contained to limit wildlife encounters. • Use designated roadways and access roads.	A	L	S	ST/ O	R	U/D	N	M	L	N	Follow-up to include field study of the selected plant site and potentially feedstock harvesting infrastructure areas (if not previously evaluated).

		contained to limit wildlife encounters. • Field engineering, design, and construction of new roads will follow the Timber Harvest Planning and Operating Guidebook.											

KEY

Direction:
- P Positive.
- A Adverse.

Magnitude:
- L Low: Change of plant populations that do not affect the sustainability or biodiversity of populations within the RAA; no change in wetland function.
- M Moderate: Change in populations that affect the sustainability of populations or biodiversity within the RAA; change in wetland function after the application of mitigation and compensation.
- H High: Change in populations that affect the sustainability of populations or biodiversity within the region; non-compensated loss of wetland function.

Geographic Extent:
- S Site-specific: Within the PDA.
- L Local: Within the region.

Duration:
- ST Short term: Occurs and lasts for short periods (*e.g.,* days/weeks/months).
- MT Medium term: Occurs and lasts for extended periods of time (*e.g.*, years).
- LT Long term: Occurs during Construction and/or Operation and lasts for the life of Project.
- P Permanent: Occurs during Construction and Operation and beyond.

Frequency:
- O Occurs once.
- S Occurs sporadically at irregular intervals.
- R Occurs on a regular basis and at regular intervals.
- C Continuous.

Reversibility:
- R Reversible.
- I Irreversible.

Ecological/Socio-economic Context:
- U Undisturbed: Area relatively or not adversely affected by human activity.
- D Developed: Area has been substantially previously disturbed by human development or human development is still present.
- N/A Not Applicable.

Significance:
- S Significant.
- N Not Significant.

Prediction Confidence:
Based on scientific information, statistical analysis, professional judgment, and/or effectiveness of mitigation.
- L Low level of confidence.
- M Moderate level of confidence.
- H High level of confidence.

Likelihood:
Based on professional judgment:
- L Low probability of occurrence.
- M Medium probability of occurrence.
- H High probability of occurrence.

5.3.3.2 Potential Project Environmental Effect Mechanisms

The following Project activities and physical works associated with Construction and Operation that were ranked as 2 will interact with the Terrestrial Environment and have potential to result in significant adverse residual environmental effects, and will thus be considered in more detail in this EA:

- site preparation (change in terrestrial populations only);
- physical construction of the facility structures and installation of equipment (change in terrestrial populations only);
- construction of infrastructure for feedstock harvesting (change in terrestrial populations only); and
- feedstock harvesting (change in terrestrial populations only).

The interactions between these Project activities and the Terrestrial Environment are discussed in the context of the measurable parameters for the potential environmental effects.

The activities associated with Construction (*i.e*., site preparation and installation of structures) have potential to result in a change in terrestrial populations through habitat loss and degradation, loss of individuals of plant and wildlife SAR and SOCC, and mortality to migratory birds. Field studies will be conducted once the plant site is selected to determine the potential for changes in terrestrial populations.

Construction activities within the PDA will result in the permanent loss of habitat for some plant and wildlife species, and the creation of edge habitat along the PDA, through vegetation removal and grubbing of the site. Clearing of the PDA will result in the direct habitat loss of forest. At this time the amount of clearing required for the plant site has not been determined. Only three species of trees grown in the village of Haines Junction, including, white spruce, trembling aspen, and balsam poplar. These species are typically found in previously disturbed sites such as roadsides and forest edges, and are commonly found in the Yukon.

Further discussion will be included regarding the feedstock harvesting site once details are available. When available the following details will be included, where applicable:

- habitat types within the LAA;
- discussion of old growth forest;
- loss and degradation of habitat;
- habitat fragmentation;
- discussion of plant SAR and/or SOCC;
- migration routes;

- trapping activities in the vicinity of the PDA;
- identification of forest resource management zones (*i.e.*, high wildlife value areas and fuel abatement areas) in the vicinity of the PDA;
- identification of traditional use plants;
- loss of wetland area and the resultant loss of wetland function (including hydrological function).

5.3.3.3 Mitigation Measures

The mitigation measures that will be implemented during the Project are listed in Table 5.4.3. The key mitigation measures to reduce environmental effects of the Project on the Terrestrial Environment are listed below. These mitigation measures will be implemented wherever technically and economically feasible to minimize potential environmental effects of the Project on the Terrestrial Environment:

- avoid known locations of plant and wildlife SAR and SOCC, and established nest sites of migratory birds;
- limit Project-related activity outside of the PDA;
- clean construction machinery prior to entering and leaving the worksite to reduce the spread of potential invasive species from one area to another;
- flag off environmentally sensitive areas prior to Construction;
- conduct clearing activities in fall and/or winter, outside the breeding season of migratory birds (May 1 to August 31). If any clearing during migratory bird breeding season is required, surveys will be conducted to determine if migratory bird nesting activity is taking place. If nesting activity is taking place that clearing will be delayed until bird young of the year have fledged and left the nest;
- conduct clearing activities in fall and/or winter, outside of calving season;
- establish buffers and protect active migratory bird nests until fledging, upon their discovery in work areas;
- keep litter and garbage contained to reduce wildlife encounters;
- use designated roadways and access roads;
- follow conditions of any Project environmental permits; and
- field engineering, design, and construction of new roads will follow the Timber Harvest Planning and Operating Guidebook.

Due to the unknown location of feedstock harvesting, additional mitigation may be required, including but not limited to:

- Employ standard erosion and sediment control measures, including:
  - erosion control fencing;
  - check dams;
  - sedimentation control ponds where appropriate;
  - construction sequencing to minimize soil exposure;
  - retaining existing vegetation as long as possible;
  - re-vegetating and mulching of denuded areas;
  - diverting run-off away from denuded areas;
  - optimizing length and steepness of slope;
  - keeping surface water run-off velocities low;
  - proper sizing and protecting of drainage ways and outlets;
  - intercepting of sediments on site; and
  - inspecting and maintaining the above-mentioned control measures.
- Minimize channeling near wetlands.
- Clean construction machinery prior to entering and leaving wetlands to reduce the spread of potential invasive species from one wetland to another.

The mitigation sequence of avoidance, minimization, and compensation, as applied to the Project, are presented here in the form of mitigation to avoid wetlands where possible, minimize the loss and potential environmental effects, and ultimately compensate for any residual losses.

5.3.3.4 Characterization of Residual Effects

If not carefully carried out or suitably mitigated, the Project could affect the Terrestrial Environment due to a change in terrestrial populations. The loss of individuals of SAR or SOCC would constitute a residual environmental effect. At the plant site there are no anticipated occurrences of SAR or SOCC, however, if they were present it is anticipated that the individuals of each species outside of the PDA will ensure that the local populations persist. Effective Project planning, design, avoidance, and the application of known and proven mitigation measures will reduce the environmental effects of the Project on changes to Terrestrial Populations so that they are not significant. The application of the same standard mitigation to avoid or reduce potential environmental effects on migratory birds will be

implemented. This includes clearing outside the breeding season when nests and/or nestlings are not present.

Residual effects related to feedstock harvesting will be evaluated once the harvesting area has been selected. If the selected areas are in the vicinity of a wetland, effective Project planning, design, avoidance, and the application of known and proven mitigation measures will reduce the environmental effects of the Project on changes to wetlands so that they are not significant. Where avoidance is not possible, mitigation measures that will be established for work with regard to wetlands will include implementation of well-established and proven erosion and sedimentation control measures. With mitigation, potentially including compensation, the Project will result in no net loss of wetland function and area.

With the proposed mitigation (*e.g.*, no loss of protected or rare species, mitigation for protection of migratory birds) the residual environmental effects of a change in terrestrial populations during all phases of the Project are rated not significant. This conclusion has been determined with a moderate level of confidence in consideration of the planned implementation of proposed proven mitigation measures described above and current lack of site specific data.

5.3.4 Assessment of Cumulative Effects

In addition to the Project environmental effects discussed above, an assessment of the potential cumulative environmental effects was conducted for other projects and activities that have potential to cause environmental effects that overlap with those of the Project, as identified in Table 1.2.3. Table 5.4.4 below presents the potential cumulative environmental effects to the Terrestrial Environment, and ranks each interaction with other projects as 0, 1, or 2 with respect to the nature and degree to which important Project-related environmental effects overlap with those of other projects and activities.

Table 5.3.6 Potential Cumulative Environmental Effects to the Terrestrial Environment

Other Projects and Activities With Potential for Cumulative Environmental Effects	Potential Cumulative Environmental Effects	
	Change in Terrestrial Populations	Change in Wetlands
Upgrades to Municipal Water Treatment System	0	0
Land Use	1	1

Notes:
Cumulative environmental effects were ranked as follows:
0 = Project environmental effects do not act cumulatively with those of other Projects and Activities.
1 = Project environmental effects act cumulatively with those of other Project and Activities, but are unlikely to result in significant cumulative environmental effects OR Project environmental effects act cumulatively with existing significant levels of cumulative environmental effects but will not measurably change the state of the VEC.
2 = Project environmental effects act cumulatively with those of other project and activities, and may result in significant cumulative environmental effects OR Project environmental effects act cumulatively with existing significant levels of cumulative environmental effects and may measurably change the state of the VEC.

Interactions between the Project and upgrades to the municipal water treatment system in Haines Junction have ranked as a 0 in Table 5.23. The upgrades are currently complete and increased the villages capacity for municipal water use, including that for industry. Any additional future upgrades to the water treatment system would only serve to further improve water quality and quantity in Haines Junction and would not result in adverse cumulative environmental effects.

Potential Project-related effects on terrestrial populations and wetlands could overlap with current land use within the RAA and therefore result in a cumulative change in terrestrial populations and change in wetlands. Historical and current use of land for recreational purposes includes recreational hunting, fishing, trail development, and use of land for hiking, all-terrain vehicles, or snowmobiling as well as industrial and forest resource harvesting activities. Past and present terrestrial population effects and change in wetlands associated with land use in the RAA have potential to interact cumulatively with the Project to adversely affect terrestrial populations and wetlands.

Existing recreational land use in the RAA has potential to encroach on lands and waters that support terrestrial populations, and result in changes in wetland area and function. These potential effects could be amplified due to overlap with similar effects associated with Project-related activities and infrastructure. Trails intended for recreational land use support ATV and other traffic that can also disturb wetlands, and other wildlife habitat important to terrestrial populations and can overlap cumulatively with other projects affecting these habitats.

Resource land use in the RAA, including forestry and mining activities, has potential to interact cumulatively with the Project to affect terrestrial populations and wetlands through removal, destruction, or disturbance of SOCC individuals and habitats, including wetlands. Potential forestry-related cumulative effects on SOCC will be mitigated by the compliance with territorial forestry guidelines, where applicable and by the natural regeneration of forestry resources.

The contribution of the Project to cumulative environmental effects is not expected to be substantive in the LAA, and likely not in the RAA.

Cumulative effects will be re-evaluated once the location of feedstock harvesting is determined and final plant siting has been completed.

5.3.5 Determination of Significance

5.3.5.1 Residual Cumulative Environmental Effects

The potential environmental effects of the Project on a Change in Terrestrial Populations and Change in Wetlands are not significant, but will overlap with the environmental effects of other projects and activities that have been or will be carried out. The principal activities of concern are forest resource harvesting, mining, and recreational land use resulting in the loss of terrestrial habitat, including wetlands. The residual cumulative environmental effects of a Change in Terrestrial Populations and Change in Wetlands, as a result of past, present, and reasonably foreseeable projects or activities that have been or will be carried out, in combination with the environmental effects of the Project, during all phases are rated not significant. This determination has been made with a moderate level of confidence as the specific areas are currently undefined.

5.3.6 Summary Consultation Influence on the Assessment

At the time of writing, consultations in the community are on-going. A summary of the consultations as they apply to Terrestrial Environment will be provided following the completion of the consultations for the Project.

5.3.7 Effects Monitoring and Adaptive Management

Baseline terrestrial field studies of the PDA will be completed prior to Construction. Studies typically include breeding bird surveys and rare plant surveys, with incidental occurrences of other wildlife species being recorded in conjunction with these activities. Studies are developed in consultation with regulatory authorities (*e.g.*, Yukon Environment, Environment Canada, *etc*.)

In the event that the feedstock harvesting areas are located in the vicinity of a wetland, wetland monitoring is recommended for any wetlands (mapped or unmapped) within the PDA or a 15 m buffer, in order to assess potential change in function. A wetland monitoring plan will be developed prior to construction. Monitoring (as per Section 79 of the *SARA*) may be warranted if SAR are likely to be affected by the Project (to be determined by targeted field studies). No other follow-up or monitoring is required to verify the predictions of the environmental effects assessment on the Terrestrial Environment, or to verify the effectiveness of mitigation.

5.4 FRESHWATER RESOURCES

Freshwater Resources consists of watercourses (rivers and streams) that provide habitat for fish and other freshwater aquatic species. The Freshwater Resources VC includes fish and fish habitat and surface water quality as indicators of the overall health of the ecosystem. Fish habitat includes physical (*e.g.*, substrate, temperature, flow velocity and volumes, water depth), chemical (*e.g.*, dissolved oxygen, pH, nutrients), and biological (*e.g.*, fish, benthic invertebrates, aquatic plants) attributes of the environment that are required by fish to carry out life cycles processes (*e.g.*, spawning, rearing, feeding, overwintering, migration). Biomass plant activities are not anticipated to have significant environmental effects on the Freshwater Environment as the plant is not located in the immediate vicinity of any freshwater source. Once the locations of feedstock harvesting have been selected, further information will be included with respect to the selected areas and the VC scope of assessment would be revised as required.

5.4.1 Scope of the Assessment

This section defines the scope of the environmental assessment of Freshwater Resources in consideration of the nature of the regulatory setting, issues identified during public and First Nations engagement activities, potential Project-VEC interactions, and existing knowledge.

5.4.2 Existing Conditions

The Yukon Territory is drained by three major river systems. The Yukon drainage basin, the Alsek/Tatshenshini drainage basin, and the Peel and Liard sub-basins of MacKenzie River (Fisheries and Oceans Canada 2011). These rivers and streams have 38 recorded species of freshwater fishes. A list of these species and their status ranks can be found in Table 4.1.3. Please note that the last CESCC assessment that included an assessment for fish was in 2005 report; no current fish ranking data is available in the 2010 report.

Notes:

S1 = Critically Imperiled—Critically imperiled in the jurisdiction because of extreme rarity or because of some factor(s) such as very steep declines making it especially vulnerable to extirpation from the jurisdiction.

S2 = Imperiled—Imperiled in the jurisdiction because of rarity due to very restricted range, very few populations, steep declines, or other factors making it very vulnerable to extirpation from jurisdiction.

S3 = Vulnerable—Vulnerable in the jurisdiction due to a restricted range, relatively few populations, recent and widespread declines, or other factors making it vulnerable to extirpation.

S4 = Apparently Secure—Uncommon but not rare; some cause for long-term concern due to declines or other factors.

S5 = Secure—Common, widespread, and abundant in the jurisdiction.

S#S# = Range Rank — A numeric range rank (*e.g.*, S2S3 or S1S3) is used to indicate any range of uncertainty about the status of the species or ecosystem. Ranges cannot skip more than two ranks (*e.g.*, SU is used rather than S1S4).

B = Breeding—Conservation status refers to the breeding population of the species in the nation or state/province.

SU = Unrankable—Currently unrankable due to lack of information or due to substantially conflicting information about status or trends.

SNA = Not Applicable —A conservation status rank is not applicable because the species or ecosystem is not a suitable target for conservation activities.

Wild Species: The General Status of Wild Species in Canada

At Risk: Species for which a formal, detailed risk assessment (COSEWIC status assessment or provincial or territorial equivalent) has been completed and that have been determined to be at risk of extirpation or extinction (*i.e.* Endangered or Threatened). A COSEWIC designation of Endangered or Threatened automatically results in a Canada General Status Rank (Canada rank) of At Risk. Where a provincial or territorial formal risk assessment finds a species to be Endangered or Threatened in that particular region, then, under the general status program, the species automatically receives a provincial or territorial general status rank of At Risk.

May Be At Risk: Species that may be at risk of extirpation or extinction and are therefore candidates for a detailed risk assessment by COSEWIC, or provincial or territorial equivalents.

Sensitive: Species that are not believed to be at risk of immediate extirpation or extinction but may require special attention or protection to prevent them from becoming at risk

Secure: Species that are not believed to belong in the categories Extinct, Extirpated, At Risk, May Be At Risk, Sensitive, Accidental or Exotic. This category includes some species that show a trend of decline in numbers in Canada but remain relatively widespread or abundant.

Exotic: Species that have been moved beyond their natural range as a result of human activity. In this report, Exotic species have been purposefully excluded from all other categories.

The closest river to the anticipated Project site is an unnamed tributary of the Dezadeash River. The tributary flows west and is located approximately 800 m to the north of the village, within the municipal boundary. The main branch of Dezadeash River flows west and is located adjacent to the south of the village. Dezadeash River empties into Alsek River and is located within the boundaries of the Alsek River watershed. Fish species found within the Alsek River basin are listed in Table 4.1.5 below.

The location of feedstock harvesting has not yet been determined. Once the location is selected information on freshwater resources in these areas will be included in this report.

5.4.3 Regulatory/Policy Setting

For the purposes of this report, the current interpretation of the federal *Fisheries Act* has been applied. Changes to the Act will come into effect in 2013. Planned mitigation with respect to Freshwater Resources will not be affected by any changes to the Act. The federal *Fisheries Act* defines "fish" to mean all fish, shellfish, crustaceans, marine animals and any parts of shellfish, crustaceans, or marine animals, and the eggs, sperm, spawn, larvae, spat, and juvenile stages of fish, shellfish, crustaceans, and marine animals. The federal *Fisheries Act* defines "fish habitat" as spawning grounds and any other areas including, nursery, rearing, food supply, and migration areas on which fish directly or indirectly depend on. Fish habitat includes physical (*e.g.*, substrate, temperature, flow velocity and volumes, water depth), chemical (*e.g.*, dissolved oxygen, pH, nutrients), and biological (*e.g.*, fish, benthic invertebrates, plankton, aquatic plants) attributes of the environment that are required by fish to carry out life cycles processes (*e.g.*, spawning, rearing, feeding, overwintering, migration).

Fish and fish habitat are protected through federal and provincial legislation. Currently, fish habitat is protected under the *Fisheries Act*, as per the DFO's Policy for the Management of Fish Habitat (DFO 1986). This policy applies to all projects and activities in or near water. The guiding principle of this

policy is to achieve no-net-loss of the productive capacity of fish habitats. Fish and fish habitat are regulated by Sections 20, 21, 22, 30, 32, 35, 36, 37, 40, and 43 of the *Fisheries Act* which is administered by DFO, as follows.

- Sections 20, 21, and 22 relate to the obstruction of fish passage, and state that where fish passage is obstructed, a fish pass or passage must be provided, and sufficient water must flow to allow for fish migration and movement past the obstruction.
- Section 30 requires that if deemed necessary by the Minister of Fisheries, screens will be placed on artificially created ditches to prevent fish from entering.
- Section 32 prohibits the killing of fish from means other than fishing.
- Section 35 prohibits the harmful alteration, disruption or destruction (HADD) of fish habitat by any persons unless authorized by the Minister of Fisheries.
- Section 36 prohibits the release of deleterious substances into any river or harbour or in any water where fishing is carried on.
- Section 37 states that anyone undertaking work that may cause HADD must submit their works for review by the Minister. The Minister can then refuse the works, grant permission for the works providing changes are made, or grant permission for the works to take place.
- Section 40 outlines the consequences of contravening section 35 of the *Fisheries Act*.
- Section 43 outlines the regulations for carrying out the purposes and provisions of the *Fisheries Act*.

A number of Boards and Councils have been established under the Umbrella Final Agreement (UFA) and Yukon First Nation Final Agreements which have advisory and management responsibilities related to fish and fish habitat Yukon-wide, and within specific First Nation Traditional Territories. These include the Yukon Fish and Wildlife Management Board which make recommendations to the Yukon and First Nation governments on issues related to fisheries management, legislation, research, policies and programs; and the Mayo District Renewable Resource Council (MDRRC), which is responsible for making recommendations on fish and wildlife management; policies and proposed development activities in the Na-cho Nyäk Dun Traditional Territory. The Salmon Sub-Committee, also established under the UFA, is mandated with providing advice and recommendations to governments specific to the management of salmon and salmon habitat in the territory.

Surface water quality is managed through federal guidelines. The CCME maintains guidelines for the protection of aquatic life for many water quality parameters. These guidelines are generally accepted as best practice in environmental assessment to mitigate Project activities such that the CCME guidelines are not exceeded, where it is considered technically and economically feasible to do so.

Aquatic SAR are protected federally under *SARA*. While there are no current publicly available provincial ranks for fish species of special concern, fish are included in the 2005 CESCC ranking list and they have a YCDC rank within the province.

5.4.4 Key Issues and Identification of Effects

Freshwater Resources has been selected as a VC due to its importance in supporting aquatic life. Freshwater Resources are valued as biological and natural resources by the public and by federal and territorial regulatory authorities.

There have been no interactions identified between Freshwater Resources and the proposed plant site (FEED site location) or throughout the majority of Haines Junction (with the exception of the southern part of the village). At this time the location of feedstock harvesting is unknown and could potentially be in the vicinity of a river, lake, pond, or stream.

Potential effects to Freshwater Resources resulting from harvesting activities could include effects to freshwater resulting in changes to fish populations, disruption, destruction or alteration to fish habitat, and/or impacts to water quality.

5.4.5 Mitigation Measures

The application of known and proven mitigation measures will be implemented as part of the Project to avoid or minimize the environmental effects on Freshwater Resources, in the event any part of the Project will be conducted in the vicinity of a freshwater source. The following mitigation measures will be employed along with other mitigation, as appropriate.

- implementation of well-established and proven erosion and sedimentation control measures, including silt fences, mulching, and hydroseeding;
- all barren soil will be stabilized for over-wintering;
- proper storage and use of hazardous materials;
- The Proponent will consult with DFO to ensure that Project activities (if determined to interact with freshwater resources) will be conducted, where possible, outside of biologically sensitive life stages of resident fish species. If activities are required in waters during these periods, DFO may require additional mitigation;
- visual monitoring in the vicinity of the Project to ensure that turbidity in waterways is limited;
- removal of any construction debris or other material that enters the freshwater environment; and
- compensation for HADD in accordance with the DFO Policy for the Management of Fish Habitat, if required.

5.4.6 Summary Consultation Influence on the Assessment

This section will be completed following planned consultations.

5.4.7 Effects Monitoring and Adaptive Management

Depending on the harvesting areas, baseline field surveys may be required, and would include fish and fish habitat studies.

Continued monitoring of sediment controls is suggested during all Project activities that have potential to affect freshwater resources. Water quality monitoring may be conducted if determined necessary during Project planning. The Canadian Water Quality Guidelines for Protection of Aquatic Life (for TSS) should be consulted for guidance in this event. If required, monitoring of the HADD compensation project will be conducted after the Project is implemented.

5.5 HERITAGE RESOURCES

The proposed biomass gasification power plant (the Project) by the Champagne and Aishihik First Nations (CAFN) and the Yukon Energy Corporation (YEC) will be located within the village of Haines Junction, Yukon, on Settlement Lands belonging to the CAFN. The Project is comprised of two parts:

- the biomass energy plant (the Plant); and
- biomass feedstock timber harvesting (Feedstock).

The Plant will operate as a power and heat source for buildings within Haines Junction and the Feedstock will be the fuel source for the Plant. At the time of the writing of this document, the areas to be harvested for Feedstock are unknown; however, future development of Feedstock is anticipated to take place on Settlement and non-Settlement Lands within the Champagne and Aishihik Traditional Territory (CATT).

5.5.1 Scope of the Assessment

This section defines the scope of the environmental assessment for Heritage Resources valued component in consideration of the nature of the regulatory setting, issues identified during public and First Nations engagement activities, potential Project-VC interactions, and existing knowledge.

At the time of the writing of this document, public and First Nations engagement activities have not all taken place. An introductory open house was held in Haines Junction and input from that engagement is included in Section 2.0 (Consultation). This assessment will be updated prior to submission to YESAA to incorporate engagement issues as warranted.

5.5.1.1 Key Issues and Identification of Potential Effects

Potential interactions between the Project and Heritage Resources are presented below and those aspects of the Project that may cause environmental effects, either positive or adverse, are identified. The Project may interact with Heritage Resources in the following ways:

- the Construction and Operation phases of the Plant will result in ground disturbing operations, potentially impacting unidentified subsurface heritage resources; and

- the Construction and Operation phases of the Feedstock will result in site-alteration (removal of vegetation from forested areas), potentially affecting built or subsurface heritage resources.

The potential environmental effects to be assessed are associated with Project-related ground disturbing or site-altering activities that may have an effect on Heritage Resources.

5.5.1.2 Regulatory/Policy Setting

Heritage Resources in the Yukon Territory are protected and managed under multiple sets of legislation; the *Historic Resources Act*, the *Umbrella Final Agreement,* the Champagne and *Aishihik First Nations Final* Agreement, and the Yukon *Environmental and Socio-Economic Assessment Act* (*YESAA*).

5.5.1.2.1 Definition of Heritage Resources

Heritage Resources, as defined in the *Historic Resources Act* include *"…(a) a historic site, (b) a historic object, and (c) any work or assembly of works of nature or of human endeavour that is of value for its archaeological, palaeontological, pre-historic, historic, scientific, or aesthetic features*…" (Government of Yukon 2002b:5).

Heritage Resources, as defined in the *Umbrella Final Agreement* (Government of Canada 1993a:4–5), include:

- **Moveable Heritage Resources:** Moveable non-documentary works or assemblies of works of people or of nature that are of scientific or cultural value for their archaeological, palaeontological, ethnological, prehistoric, historic or aesthetic features, including moveable structures and objects;

- **Heritage Sites:** An area of land which contains Moveable Heritage Resources, or which is of value for aesthetic or cultural reasons;

- **Documentary Heritage Resources**: Public Records or Non- Public Records, regardless of physical form or characteristics, that are of heritage significance, including correspondence, memoranda, books, plans, maps, drawings, diagrams, pictorial or graphic works, photographs, films, microforms, sound recordings, videotapes, machine-readable records, and any copy thereof.

The definition of a Heritage Resource under *YESAA* mirrors the definition outlined in the *Umbrella Final Agreement*, but also includes "…*an area of land that contains a work or assembly of works…or an area that is of aesthetic or cultural value, including a human burial site outside a recognized cemetery…*" (YESAB 2011).

Any object, whether archaeological, historic, ethnographic or palaeontological in nature, abandoned, and more than 45 years old can be deemed a historic object by the Government of Yukon's Minister of Tourism and Culture (the Minister). The Minister may, with appropriate criteria, designate a site as a historic site, whether or not historic objects are associated with it. The only exception is when the site in question is located on Yukon First Nation settlement land. In this case, the Minister may designate a

site with consent from the Yukon First Nation which governs the settlement land, in this case, CAFN (Government of Yukon 2002b).

Historic sites are generally classified as being associated with the historic period, and are typically associated with built heritage structures (Gotthardt and Thomas 2007). It should be noted that while the historic period is, by convention, associated with appearance of documentary written records, within CATT the historic period commences in the early-mid 19th century, and coincides with the arrival of the Hudson's Bay Company in the Yukon Territory (Thomas 2006:13). Archaeological sites are generally associated with human evidence pre-dating European contact, or, the prehistoric period and are usually associated with sub-surface deposits or remains (Gotthardt and Thomas 2007).

5.5.1.2.2 Legislation

The *Historic Resources Act* (Government of Yukon 2002b), is administered by representatives in the Historic Sites Unit and Heritage Resources Unit (HRU) (Archaeology, Palaeontology, and Geographic Place Names Programs), Cultural Services Branch, in the Yukon Department of Tourism and Culture.

- The Historic Sites Unit "provides for the research, preservation, management, development and interpretation of Yukon's historic sites and routes" (Government of Yukon 2012b). This includes the administration of the *Historic Resources Act* and meeting the Government of Yukon heritage obligations under the *Umbrella Final Agreement* and individual First Nation final agreements.

- The Heritage Resources Unit "is responsible for the management, conservation, research and interpretation of land-based heritage resources" (Government of Yukon 2012c). This includes licencing for scientific research under the *Scientists and Explorers Act* (Government of Yukon 2002c) and permitting for archaeological research under a Yukon Archaeological Sites Regulation Permit.

The *Umbrella Final Agreement* (Government of Canada 1993a) signed between the Government of the Yukon, The Government of Canada, and The Council for Yukon Indians, allows for self-governance and management of all aspects of heritage pertaining to individual Yukon First Nations traditional territories and Settlement Lands, in this case the CAFN. CAFN has developed a framework for Heritage Resources, outlined in *Chapter 13 – Heritage of the Champagne and Aishihik First Nations Final Agreement* (Government of Canada 1993b).

YESAA guidelines state that socio-economic effects include that any effects on Heritage Resources must be taken into consideration by all parties involved in a proposed development.

5.5.1.2.3 Heritage Resources Assessments

The implementation of a Heritage Resource Assessment (HRA) in the Yukon Territory is dependent on two factors:

- the level of impact a development may have; and,

- the type of lands on which the proposed development is taking place (*i.e.,* Settlement vs. non-Settlement lands).

As a result of the need for disposition of lands for the Project, an HRA, mandated under *Operational Policy 2011-01 – Heritage Resources Information Requirements for Land Application Proposals Policy* (YESAB 2011) of *YESAA* is required. HRAs are comprised of two stages. The first stage, the "overview assessment", includes a description of known heritage resources in the Project area, an evaluation of potential to encounter unknown heritage resources, the effects the Project may have on existing or unidentified/potential heritage resources, and, if necessary, appropriate mitigation measures. The overview assessment takes place at a desktop level, and provides baseline information. Following the "overview assessment", if it is determined that further investigation of potential effects of the Project on existing or unidentified/potential Heritage Resources is warranted, then the second stage, a "site assessment" must take place within the Project Development Area (PDA).

Known heritage resources may be identified prior to design and construction of a project. Archaeologists use these known resources, along with generalisations about the movement of past humans across the landscape and environmental factors (*e.g.,* distance to water, slope of terrain) to suggest the potential for encountering previously unrecorded heritage resources. This is not an exact process, and the factors that archaeologists consider when determining the "heritage resource potential" of an area can vary significantly depending on the region or sub-region. Furthermore, the criteria employed by archaeologists for assessing heritage resource potential often do not include consideration for intangible heritage resources. The cultural, ethnographic, or spiritual connection and the special relationship between First Nations and their environments is not an easily quantified value. Documentary and ethnographic accounts, oral histories, community consultation, and traditional use studies are all essential elements for understanding this relationship.

As this Project will have the potential to interact with Heritage Resources due to ground disturbing activities, both for the Plant and Feedstock elements, an HRA is required.

On non-Settlement lands, or lands administered by the Government of Yukon, an HRA follows policies and guidelines established by the Cultural Services Branch. The *Position Statement – Historic Resources Impact Assessment and Mitigation Requirements Related to Land Altering Developments* (the Position Statement) (Government of Yukon 2003) and processes outlined in the *British Columbia Archaeological Impact Assessment Guidelines* (the Guidelines) (Government of British Columbia 1998) provide guidance and methodology for conducting an HRA.

Particularly relevant for the Feedstock component of the Project is the implementation plan for forestry-related HRAs conducted within CATT (Section 3.8 of the *Integrated Landscape Plan for the Champagne and Aishihik Traditional Territory* (the ILP)) (EMR 2006). The ILP was developed by CAFN and the Yukon Department of Energy, Mines and Resources as a means to address concerns about management of Heritage Resources with the development of a forestry industry in the Yukon. Furthermore, Energy, Mines and Resources has developed *Forest Resources Regulation – Historic and Archaeological Resources Standards and Guidelines* (EMR 2011) to assist with the protection and management of Heritage Resources.

As outlined in *Chapter 13 – Heritage* of the *Champagne and Aishihik First Nations Final Agreement*, CAFN will develop independent heritage management policies for Settlement Lands. *CAFN Heritage Resources specialists are currently developing an assessment process to ensure the protection of Heritage Resources. In consultation with Stantec, CAFN have indicated they envisage this process as operating independent of, but parallel to, territorial impact assessments.*

5.5.1.3 Selection of Measureable Parameters

The environmental assessment of Heritage Resources is focused on the following environmental effect:

- Change in Heritage Resources within the PDA.

The environmental effect has been selected as a result of the need for disposition of lands for the Project and the requirement to conduct an HRA. The requirement to protect any known or unknown/undocumented heritage resources is also outlined under the *Historic Resources Act* and Chapter 13 of the *Champagne and Aishihik First Nations Final Agreement*. The manner in which these effects are mitigated is described in the Guidelines and appropriate mitigation to be developed in consultation with CAFN.

The measurable parameters used for the assessment of potential environmental effects presented above and the rationale for their selection is provided in Table 5.7.1.

Table 5.5.1 Measurable Parameters for Heritage Resources, Traditional Activities and Culture

Environmental Effect	Measurable Parameter	Rationale for Selection of the Measurable Parameter
Change in Heritage Resources	Presence/absence of a heritage resource	• The Position Statement (Government of Yukon 2003) and the Guidelines (Government of British Columbia 1998) establish the process for determining presence/absence of heritage resources (*e.g.,* overview assessment (documentary research, direct consultation and preliminary field reconnaissance), and archaeological impact assessment (survey, evaluative testing, assessment, impact management)) on non-Settlement Lands. Presence confirms an environmental effect; absence indicates that any discovery (unplanned) of a Heritage Resource would be an Accident. • *CAFN Heritage Resources specialists are currently developing an assessment process to ensure the protection of Heritage Resources. In consultation with Stantec, CAFN have indicated they envisage this process as operating independent of, but parallel to, territorial impact assessments.* • The *Historic Resources Act* and *Chapter 13 – Champagne and Aishihik First Nations Final Agreement* protect all Heritage Resources, including built heritage, prehistoric and historic sites and objects, archaeological, palaeontological, ethnological, or aesthetic features, moveable structures and objects, documentary resources and human burial sites.

5.5.1.4 Spatial Boundaries

The spatial boundaries for the environmental effects assessment of the Heritage Resources, Traditional Activities and Culture are defined below.

Project Development Area (PDA): The PDA is the most basic and immediate area of the Project. The PDA is limited to the area of physical ground disturbance associated with the Project, and consists of an area that includes the area of physical disturbance associated with the biomass plant and associated facilities as well as the area associated with biomass feedstock harvesting (including forest roads). The PDA is the area represented by the physical Project footprint as defined in Chapter 3.1.2 above.

Local Assessment Area (LAA): The LAA is the maximum area within which Project-related environmental effects can be predicted or measured with a reasonable degree of accuracy and confidence. The LAA includes the PDA, Haines Junction, and any adjacent areas where Project-related environmental effects may reasonably be expected to occur. Since the potential environmental effects on Heritage Resources are limited to the area where ground disturbing or site-altering activities will take place, for this VC, the LAA is essentially the same as the PDA. At this time, there are no anticipated environmental effects that will occur outside of the PDA for Heritage Resources.

Regional Assessment Area (RAA): The RAA is limited to and includes the Yukon Territory. The RAA is the area within which the Project's environmental effects may overlap or accumulate with the environmental effects of other projects or activities that have been or will be carried out. The extent to which cumulative environmental effects for Heritage Resources may occur depend on physical and biological conditions and the type and location of other past, present, and reasonably foreseeable future projects or activities that have been or will be carried out, as defined within the RAA. For Heritage Resources, the RAA may be considered lands within the Champagne and Aishihik Traditional Territory (CATT), and the southwest region of the Yukon Territory.

5.5.1.5 Temporal Boundaries

The temporal boundaries for the assessment of the potential environmental effects of the Project on Heritage Resources include the phases of Construction, Operation, and Decommissioning.

5.5.1.6 Residual Effects Significance Criteria

A *significant adverse residual environmental effect* on Heritage Resources is defined as one that results in a permanent Project-related disturbance to, or destruction of, all or part of a Heritage Resource (including Historic sites and objects, and all moveable and documentary Heritage Resources) considered by CAFN and the Government of Yukon to be of major importance due to factors such as rarity, undisturbed condition, spiritual or cultural importance, or research importance, and that cannot be mitigated or remedied by way of compensation.

5.5.2 VC Existing Conditions

The Project PDA will be located within the limits of the village of Haines Junction, in southwest Yukon. The preliminary PDA of the proposed biomass plant is located just east of the intersection between Willow Acres Road and the Alaska Highway (to be confirmed prior to detailed design). As the site location has not been finalized, the greater area of the village of Haines Junction was included in the evaluation of existing information.

At the time of the writing of this report, specific Feedstock areas are undefined. It is anticipated that feedstock timber harvesting will take place within the CATT, which encompasses an estimated 1,959,000 HA of southwest Yukon, according to the ILP (EMR 2006) (Figure 5.5.1). However, planning and development for the forest industry will occur only in the Forest Resource Management Zone (93,700 HA in the ILP) (EMR 2006). The areas that would potentially be harvested for Feedstock are likely to be predominantly located within 50-70 km of Haines Junction over the life of the Project, delimited by the boundaries of the Forest Resource Management Zone (Damecour, pers. comm. 2012).

Typically, there are two methods for determining the existing conditions of Heritage Resources within the PDA. These include:

- **evaluation of existing information,** gathering data of known heritage resources provided by documented archaeological and historic sites, territorial and museum records, First Nations (*i.e.*, CAFN), local historical societies, community historians; and

- **field investigation,** consists of a field assessment for those resources that might exist within the PDA but of which we currently do not have knowledge.

5.5.2.1 Evaluation of Existing Information – Heritage Resources

Representatives from CAFN and the Cultural Services Branch, Government of Yukon, provided information on known or recorded heritage resources for Haines Junction. Various documentary resources were consulted for background information and history of the PDA and the general Project area. The results are presented below.

Haines Junction is a small village located along the Alaska Highway, and named after the point where the Alaska and Haines Highways meet. The village was established in the 1940s during construction of the Alaska Highway, but has been home to the Southern Tutchone people and their ancestors for over 5,000 years. Prior to its 1940's naming, Haines Junction was known as "Dakwakada", or "high cache" for the type of food caches used in that area throughout the year (VOHJ 2012). The region surrounding Haines Junction is well known for its dynamic landscape; located in the foothills of the St. Elias Mountains, close to glaciers, and immediately east of the boundary of Kluane National Park and Reserve. Kluane Park, along with adjoining parks in British Columbia and Alaska are designated as a UNESCO World Heritage Site (Figure 5.5.1).

Human History and Prehistory

The known period of human occupation in the southwest Yukon extends back over 12,000 years since the receding of the Cordilleran Glaciers and has been well documented relative to other regions even within the Yukon (Clark 1991; Thomas 2006). The prehistory of this region is generally divided up chronologically into five periods based on technological changes visible in the archaeological record and known assemblages (Thomas 2006). This sequence begins with the Palaeo-Indian period (ca. 12,000–8000 BP) and the Northern Cordilleran tradition (ca. 8000–7000 BP) (Clark 1991), followed by the Little Arm Phase (ca. 7000-5000 BP), Taye Lake Phase (ca. 5000-1250 BP) and culminates in the Aishihik Phase (ca. 1250-200 BP) (Workman 1978; Thomas 2006).

Stratigraphic dating of late prehistoric sites (associated with the Aishihik Phase) in the southwest of Yukon and eastern Alaska is made easier by the presence of the White River Ash layer, or White River tephra. This pale-coloured ash layer is the result of a volcanic eruption originating at Mount Bona, Alaska just over 1200 years ago in AD 803 (Clague et al. 1995). Although its thickness and coverage depends on distance from the original eruption, the tephra can be 20 cm thick almost 300 km from the source (Clark 1991), and covers an area of approximately 540,000 km^2 (Robinson 2001). It is speculated that while this eruption certainly caused immediate disruption and displacement of the Southern Tutchone people living there at the time, they returned to the area shortly after the eruption event (Clark 1991).

Figure 5.5.1 Champagne and Aishihik First Nations Traditional Territory

The Southern Tutchone are a group of peoples linked by a common language family, Athabaskan (McClellan 1975), or Athapaskan (Clark 1991; Workman 1978). The six regional groups that constitute the Southern Tutchone occupy an area including most of the southwest Yukon Territory and into northern British Columbia and parts of Alaska (McClellan 1975; Thomas 2006). Four of these groups occupy the Alsek River drainage system, and comprise the modern-day Champagne and Aishihik First Nations (CAFN 2012b; Thomas 2006). These groups are:

- the Champagne Band, formerly centred at the village of Champagne (approximately 65 km east of Haines Junction) and originally lived near *Shäwshe*-Dalton Post;
- the Hutshi Band, previously located east of Hutshi Lake (northeast of Haines Junction) and exploited territory in the headwaters of the Nordenskiold River;
- the Aishihik Band and village were in the past situated at the head of Aishihik Lake (north-northeast of Haines Junction); they shared common territory with Champagne and exploited territory as far east as Kluane Lake; and
- the Kloo Lake Band resided near a trading post located on Kloo Lake, northwest of Haines Junction (McClellan 1975; Thomas 2006:11).

Up until the early 1900s the most recent ancestors of modern-day Champagne and Aishihik First Nations were subsistence hunter-fisher-gatherers, exploiting the land and resources surrounding them. Summers were usually spent gathering berries and fishing salmon, including Sockeye, coho and chinook on the Tatshenshini River although fish resources in the lakes and rivers within traditionally exploited territories were year-round food sources (CAFN 2013; Thomas 2006). Late summer hunting of moose, caribou, Dall's sheep, mountain goat, gophers and other small mammals was essential both for food and for trade with other groups in the region, particularly the Pacific Coast Tlingit groups (CAFN 2013; McClellan 1975; Thomas 2006). During the winter, the Southern Tutchone would use caches of dried fish and meat for subsistence (McClellan 1975; Thomas 2006). Winter was also the period of time when trapping was most prevalent, a practice that took place primarily in and around the lakes where much of the population lived (McClellan 1975; Thomas 2006).

Trapping and trade of furs was always an essential part of the CAFN economy, and after the arrival of the Europeans this practice intensified and increased in importance (Thomas 2006). The Chilkat people, a sub-group of the Pacific Coast Tlingit and neighbours of the Southern Tutchone, moved inland to southwest Yukon during the early European Contact period (Thomas 2006). This migration lead to an increase in trapping and trade with Europeans, but also allowed for greater trade, exchange and sharing of culture between the Chilkat and Southern Tutchone peoples (CAFN 2013; McClellan 1975). Trapping continues to be actively pursued in modern times by members of CAFN on both a full- and part-time basis (CAFN 2013).

Prior to the arrival of European goods and technology (*e.g.*, steel implements, outboard motors for boats), the Southern Tutchone employed resources readily available to them from the land for crafting tools. Implements made of bone, antler and stone were used for cutting down trees, preparing hides, and processing meat (McClellan 1975). Native copper was a resource available to the Southern Tutchone due to its availability in nugget form. It is speculated that prior to European contact, native

copper have been sourced at the upper White River/Klutlan glacier area approximately 185 km west-northwest of Haines Junction (Workman 1978).

The first Europeans explored southwest Yukon in the late 1800s, entering over the Chilkat Pass, a boundary between the Coast and St. Elias mountain ranges southwest of Haines Junction, following the Chilkat (now Dalton) Trail (Thomas 2006; VHJ 2012). European-led expeditions to the area occurred from 1882-1896; however, it was the Klondike gold rush that brought the Canadian Government to the region. The Northwest Mounted Police established Dalton Post in 1898, and legal surveys demarcating the national and territorial boundaries along the Tatshenshini-Alsek drainage were established the same year (Thomas 2006). The discovery of gold in the creeks east of Kluane Lake in 1903 created an influx of over a thousand miners to the area, a rush that continued sporadically in the region until the late 1920s (Thomas 2006; VHJ 2012). The completion of the Haines Road/Alaska Highway in 1942 saw the establishment of Village of Haines Junction at this crossroads, Historic Mile 1016 on the Alaska Highway (Government of Yukon 2012d).

Environment

The Champagne and Aishihik Traditional Territory (CATT) encompasses six ecoregions including the Klondike Plateau, Ruby Ranges, Saint Elias Mountains, Yukon Plateau-Central, Yukon Southern Lakes and the Yukon-Stikine Highlands (EMR 2006). The only two ecoregions within the CATT that may be affected by the Project are the Ruby Ranges Ecoregion and a small portion of the Yukon Southern Lakes Ecoregion (EMR 2006; Smith et al. 2007). However, of equal importance is the Yukon Stikine Highlands Ecoregion, due to the presence of the Tatshenshini River which lies within its boundaries. The Tatshenshini River is a traditionally significant river for CAFN peoples, as described in *Chapter 13 – Schedule B* of the CAFNFA and a designated Canadian Heritage River (CHRS 2013; Government of Canada 1993b).

Major waterbodies and watercourses in the Ruby Ranges are located in the Aishihik Basin east of the St. Elias Mountains where Haines Junction and the CATT are situated. These include the Dezadeash, Aishihik, Kathleen, Donjek and Kluane Rivers. The Alsek and Kaskawulsh Rivers form the south boundary of the Ruby Ranges Ecoregion, and Nisling River the north (YEWG 2004). The largest lake entirely within the Yukon, Kluane Lake, is also located in the Ruby Ranges (YEWG 2004). Significant watercourses in the Yukon Southern Lakes include the Teslin, upper Yukon, and Takhini Rivers, and smaller rivers including Nisutlin, Wolf and M'Clintock Rivers. Major waterbodies include Teslin, Wolf, Marsh and Laberge Lakes, and the Nisultin River Delta wetland complex (YEWG 2004).

The glacial history of the valley where Haines Junction is located, created by the Shakwak Trench, is fairly complex. Margins of three Pleistocene glaciers, all originating in the St. Elias Mountains to the west, are visible in various places in the Ruby Ranges ecoregion (YEWG 2004). Approximately 90% of this ecoregion was glaciated during the pre-Reid glaciation (2.9 million years ago to ca. 400,000 years ago), 60% during the Reid glaciation (ca. 300,000 to 230,000 years ago) and 50% during the McConnell glaciation (ca. 28,000 to 15,000 years ago) (YEWG 2004). The Yukon Southern Lakes ecoregion was covered in glacial ice between ca. 26,000 and 9000 years ago (YEWG 2004).

The close proximity of existing glaciers to the Haines Junction area, and the advance and retreat of various ice-sheets has resulted in an area that has been flooded repeatedly over the last 12,000 years. Glacial- and Neoglacial Lake Alsek formed as a result of the built-up of water from glacial ice blocking

the Alsek River drainage, southwest of Haines Junction (Duk-Rodkin 2004; YEWG 2004). Most recently, the Shakwak valley was submerged under Neoglacial Lake Alsek from 1725–1850, caused by the advance of the Lowell Glacier (YGS 2012). While the period between 1725–1850 is the most recent, Neoglacial Lake Alsek had formed three times in the period known as the "Little Ice Age", a global cooling period extending for approximately 500 years between the years 1350–1850 (YGS 2012).

Champagne and Aishihik Heritage Routes

The Champagne and Aishihik Heritage Routes were identified in the *Champagne and Aishihik First Nations Final Agreement* as having a particular cultural and heritage significance to CAFN and consist of:

- The Shakat Trail that follows from Aishihik Village to Nisling River, Onion Creek, Tincup Lake, Talbot Creek, Albert Creek and back to Aishihik Village;
- The Isaac Creek Trail that follows from Aishihik Village to Tetchal Mun (Sekulmun Lake), Isaac Creek, Gladstone Creek, Kluane Lake, Talbot Arm (Kluane Lake), Talbot Creek, and then meets with the Shakat Trail;
- The Hutshi Trail that follows from Hutshi to Giltana Lake, Tetchal Mun (Sekulmun Lake), Aishihik Village, Nisling River and Carmacks;
- The Kloo Lake to Aishihik Village Trail that follows from Kloo Lake to Dry Pass, Bear Lakes, Tetchal Mun (Sekulmun Lake) and Aishihik Village; and
- The Selkirk Trail that follows from Kusawa Lake (west side) to Takhini River, Klusha Creek, Nordenskiold River, Yukon River and Fort Selkirk, with a branch west from Kusawa Lake to Klukshu.

These routes are outlined in *Chapter 13 – Schedule A* and depicted in *Appendix B – Maps* in the *Champagne and Aishihik First Nations Final Agreement*.

The PDA of the Plant will not impact any of the recorded Champagne and Aishihik Heritage Routes. At the time that this report was written, Feedstock areas were undefined. It is recommended that prior to development of Feedstock areas, Champagne and Aishihik Heritage Routes be taken into consideration as areas of avoidance and special concern to ensure the protection of these heritage resources.

Recorded Archaeological Sites in the Yukon Archaeological Sites Data Base

<u>Pre-Contact Resources</u>

Biomass Energy Plant

A review of the general Project boundaries for the preliminary Plant PDA, which included all CAFN Settlement Lands and all non-Settlement Lands located within the community of Haines Junction, was conducted by HRU, Cultural Services Branch of the Government of Yukon. This review found that no

documented archaeological sites are located inside the preliminary PDA of the Plant or within the limits of the village of Haines Junction (Gotthardt, pers. comm. 2012).

Feedstock Harvesting

At the time that this report was written, feedstock areas were undefined and no formal review was conducted. Upon receiving Feedstock PDAs, the HRU and Heritage Resources specialists with CAFN will be contacted and consulted prior to any ground disturbing or site-altering activities to determine presence/absence of recorded Pre-Contact archaeological sites in the Yukon Archaeological Sites Data Base.

Historic Resources

Biomass Plant

Upon reviewing the Yukon Register of Historic Places and the Canadian Register of Historic Places, there were no identified Historic Places located in the preliminary Plant PDA, or within the limits of the village of Haines Junction (CRHP 2012; YRHP 2012). The Yukon Sites Inventory Program provided information on six documented Historic Sites/Structures within the LAA for the Plant (*i.e.,* Haines Junction). Exact locations were provided for all six structures (Figure 5.5.2) and after reviewing, no Historic Sites/Structures will be impacted by the Plant component of the Project.

Feedstock Harvesting

At the time that this report was written, Feedstock areas were undefined and no formal review was conducted. Upon receiving Feedstock PDAs, the Government of Yukon Historic Sites Registrar, the Yukon Register of Historic Places and the Canadian Register of Historic Places will be contacted and consulted prior to any ground disturbing or site-altering activities to determine presence/absence of known Historic Resources.

Palaeontological Resources

Biomass Energy Plant

Representatives from HRU, Palaeontology Program, were contacted regarding the potential to encounter palaeontological resources within the Plant PDA. The area in and around Haines Junction was completely glaciated during the late Wisconsinan period (13,000–14,000 years before present), thus the preservation of Pleistocene-aged fossils is unlikely (Hare pers. comm. 2012; Smith et al. 2007). Holocene-aged fossils have been recovered from the mountainous areas surrounding Haines Junction; however, none within the Plant PDA or LAA (Farnell et al. 2004; Hare pers. comm. 2012).

The closest recorded palaeontological resource was found at Pine Lake, approximately 10 km northeast of Haines Junction (Figure 5.5.1), and was a Pleistocene elk (*Cervus elaphus*) mandible collected from glacial outwash deposits located near the lake. The discovery of this fossil suggests that other late Pleistocene vertebrate remains may be located in glacial sediments (glaciofluvial outwash) in the areas surrounding Haines Junction (Zazula pers. comm. 2013).

Figure 5.5.2 Historic Sites and Structures

Feedstock Harvesting

At the time that this report was written, Feedstock areas were undefined and no formal review was conducted. Upon receiving Feedstock PDAs, the HRU, Palaeontology Program will be contacted prior to any ground disturbing or site-altering activities to determine the potential for encountering palaeontological resources. However, due to the level of ground-disturbance involved in forest harvesting, the likelihood for interaction with palaeontological resources is not high.

5.5.2.2 Field Investigation

Field investigation was not completed at the time of the writing of this report. This section will be updated upon completion of a Heritage Resource Assessment for the Project.

5.5.3 Potential Project VC Interactions

5.5.3.1 Project Effects Mechanisms

Table 5.7.2 below lists each activity and physical work for the Project, and ranks each interaction as 0, 1, or 2 based on the level of interaction each activity or physical work will have with the Heritage Resources.

Table 5.5.2 Potential Project Environmental Effects to the Heritage Resources

Project Activities and Physical Works	Potential Environmental Effects Change in Heritage Resources
Construction	
Site preparation	2
Physical construction of the Facility Structures	2
Installation of Equipment	0
Commissioning	0
Construction of Infrastructure for Feedstock Harvesting	2
Operation	
Operation and Maintenance of Plant Site	0
Feedstock Harvesting	2
Decommissioning, Reclamation and Closure	
Plant Site	0
Harvested Areas	1

Project-Related Environmental Effects

Notes:

Project-Related Environmental Effects were ranked as follows:

0 = No interaction. The environmental effects are rated not significant and are not considered further in this report.

1 = Interaction will occur. However, based on past experience and professional judgment, the interaction would not result in a significant environmental effect, even without mitigation, or the interaction would clearly not be significant due to application of codified practices and/or permit conditions. The environmental effects are rated not significant and are not considered further in this report.

2 = Interaction may, even with codified mitigation and/or permit conditions, result in a potentially significant environmental effect and/or is important to regulatory and/or public interest. Potential environmental effects are considered further and in more detail in the EA.

5.5.3.2 Construction

Activities ranked as 0 for the Construction Phase in Table 5.7.2 include: Installation of Equipment and Commissioning. Installation of the Equipment and Commissioning does not involve ground disturbance and therefore there will be no interaction with these activities and Heritage Resources. As a result, the potential environmental effects of Installation of the Equipment and Commissioning activities on a change in Heritage Resources are ranked as 0.

There are no Construction activities ranked as 1 in Table 5.7.2.

5.5.3.3 Operation

Activities ranked as 0 for the Operation Phase in Table 5.7.2 include: Operation and Maintenance of Plant Site. Operation and Maintenance of the Plant Site does not involve ground disturbance and therefore there will be no interaction with these activities and Heritage Resources. As a result, the potential environmental effects of Operation and Maintenance of Plant Site on a change in Heritage Resources are ranked as 0.

There are no activities ranked as 1 in Table 5.7.2.

5.5.3.4 Decommissioning, Reclamation and Closure

Activities ranked as 0 for the Decommissioning, Reclamation and Closure Phase in Table 5.7.2 include: Plant Site. No ground disturbance beyond that already completed during the Construction is anticipated for this phase of the Project. As a result, the potential environmental effects of Plant Site activities on a change in Heritage Resources are ranked as 0.

Activities ranked as 1 in Table 5.7.2 include: Harvested Areas. Ground disturbance is not expected to take place at this stage, in which case the result will be no further environmental effects to Heritage Resources during the Decommissioning, Reclamation and Closure – Harvested Areas activity. However, in the event that post-harvest scarification or mechanical ground preparation activities take place during the Decommissioning, Reclamation and Closure – Harvested Areas activity, the implementation of a Heritage Resource Assessment (HRA) (described below in Section 5.5.3.6), protection of sites, and establishment of buffer zones prior to the Construction and Operation phases will prevent any significant environmental effect to Heritage Resources.

Thus, in consideration of the nature of the interactions and the planned implementation of known and proven mitigation, the potential environmental effects of all Project activities and physical works that were ranked as 0 or 1 in Table 5.7.2 on Heritage Resources during any phase of the Project are rated not significant, and are not considered further in the assessment.

5.5.3.5 Assessment of Environmental Effects

A summary of the environmental effects assessment and prediction of residual environmental effects resulting from interactions ranked as 2 on Heritage Resources is provided in Table 5.7.3.

Table 5.5.3 Summary of Residual Project-Related Environmental Effects on the Heritage Resources, Traditional Activities and Culture

Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics						Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects?	Recommended Follow-up or Monitoring
			Direction	Magnitude	Geographic Extent	Duration and Frequency	Reversibility	Ecological/Socio-economic Context					
Change in Heritage Resources • Unauthorized disturbance or destruction of Heritage Resources of significance.	Construction (includes: Site Preparation, Physical Construction of the Facility Structure, and Construction of Infrastructure for Feedstock Harvesting)	• Complete a confirmatory Heritage Resource Assessment within the PDA. • Report results of HRA to the Government of Yukon Heritage Resources Unit and CAFN. • If approved, implement mitigation for any heritage resources encountered during field investigation. • Development of an archaeological response protocol should there be any accidental discovery of heritage resources during Project activities.	A	L	S	P/O	I	U/D	N	H	L	N	To be determined following completion of Heritage Resource Assessment.
	Operation (Feedstock Harvesting)	• Development of a strategic plan for the assessment, inventory, mitigation and/or protection of heritage resources in Feedstock areas. • Complete a confirmatory Heritage Resource Assessment within the PDA(s) for Feedstock. • Report results of HRA to the Government of Yukon Heritage Resources Unit and CAFN. • If approved, implement mitigation for any heritage resources encountered during field investigation.	A	L	S	P/O	I	U/D	N	H	L	N	To be determined following determination of potential Feedstock harvesting areas and completion of subsequent Heritage Resource Assessment.

Table 5.5.3 Summary of Residual Project-Related Environmental Effects on the Heritage Resources, Traditional Activities and Culture

Table 5.5.3 Summary of Residual Project-Related Environmental Effects on the Heritage Resources, Traditional Activities and Culture

Potential Residual Project-Related Environmental Effects	Project Phases, Activities, and Physical Works	Proposed Mitigation / Compensation Measures	Residual Environmental Effects Characteristics: Direction	Magnitude	Geographic Extent	Duration and Frequency	Reversibility	Ecological/Socio-economic Context	Significance	Prediction Confidence	Likelihood	Cumulative Environmental Effects?	Recommended Follow-up or Monitoring

KEY

Direction
- P Positive.
- A Adverse.

Magnitude
- L Low: Minor impairments to heritage resources or recent built feature (*e.g.*, loss of individual artifact, movement of hunting blind, trap line)
- M Medium: Loss of heritage resources in a previously disturbed context (*e.g.*, some artifacts disturbed/lost, features remain intact), or in a deteriorated state (*e.g.*, wooden structures such as an abandoned cabin, brush camp or cache)
- H High: Destruction or loss of a significant portion of intact heritage resources, including sites, structures, and subsurface heritage resources in a stable and undisturbed condition.

Geographic Extent
- S Site-specific: Within the PDA.
- L Local: Within the LAA.
- R Regional: Within the RAA.

Duration
- ST Short term: Occurs and lasts for short periods (*e.g.,* days/weeks).
- MT Medium term: Occurs and lasts for extended periods of time (*e.g.,* years).
- LT Long term: Occurs during Construction and/or Operation and lasts for the life of Project.
- P Permanent: Occurs during Construction and Operation and beyond.

Frequency
- O Occurs once.
- S Occurs sporadically at irregular intervals.
- R Occurs on a regular basis and at regular intervals.
- C Continuous.

Reversibility
- R Reversible.
- I Irreversible.

Ecological/Socio-economic Context
- U Undisturbed: Area relatively or not adversely affected by human activity.
- D Developed: Area has been substantially previously disturbed by human development or human development is still present.
- N/A Not Applicable.

Significance
- S Significant.
- N Not Significant.

Prediction Confidence

Confidence in the significance prediction, based on scientific information and statistical analysis, professional judgment and known effectiveness of mitigation:
- L Low level of confidence.
- M Moderate level of confidence.
- H High level of confidence.

Likelihood

Likelihood of a significant environmental effect occurring, based on professional judgment:
- L Low probability of occurrence.
- M Medium probability of occurrence.
- H High probability of occurrence.

Cumulative Environmental Effects?
- Y Potential for environmental effect to interact with the environmental effects of other past, present or foreseeable projects or activities in RAA.
- N Environmental effect will not or is not likely to interact with the environmental effects of other past, present or foreseeable projects or activities in RAA.

5.5.3.6 Mitigation Measures

The following mitigation measures, through careful design and planning, will be employed to avoid or reduce the environmental effects of the Project on Heritage Resources potentially resulting from the environmental effects mechanisms described above:

Construction Phase

The HRA will include a visual assessment of the PDA for the Plant and infrastructure for Feedstock where ground disturbing activities are planned. This HRA will seek to confirm presence/absence of heritage resources within those PDAs. The methodology for the HRA will be developed as part of a strategic Heritage Resources management plan in consultation with the Government of Yukon Heritage Resources Unit and Forest Management Branch and representatives from CAFN.

Results of the HRA will be reported to Government of Yukon Heritage Resources Unit and CAFN. Following consultation with HRU and CAFN, additional investigation and/or mitigation of any identified heritage resources discovered in the PDAs may be necessary.

In the event that heritage resources not identified during the HRA are encountered, an archaeological response protocol will be developed. This will include, at a minimum, the immediate cessation of all ground-disturbing activities and require contacting representatives with CAFN or the HRU.

Operation Phase (in relation to Feedstock only)

The following mitigating measures have been defined to avoid significant effects on Heritage Resources, in general consideration of the Feedstock activities and will be refined as the extent of the activities become known.

A strategic plan for the assessment, inventory, mitigation and/or protection of Heritage Resources will be developed in consultation with CAFN and the Government of Yukon Heritage Resources Unit and Forest Management Branch. This plan will be implemented prior to any ground disturbance and/or site-altering activities where appropriate.

The HRA will include a visual assessment of the PDAs for Feedstock harvesting where ground disturbing and/or site-altering activities are planned. This HRA will seek to confirm presence/absence of heritage resources within the PDA(s). The methodology for the HRA will be developed as part of a strategic Heritage Resources management plan in consultation with the Government of Yukon Heritage Resources Unit and Forest Management Branch and representatives from CAFN. Areas will be assessed on a case by case basis as Feedstock areas are developed.

Results of the HRA will be reported to Government of Yukon Heritage Resources Unit and CAFN. Following consultation with HRU and CAFN, additional investigation and/or mitigation of any identified heritage resources discovered in the PDAs may be necessary.

In the event that heritage resources not identified during the HRA are encountered, an archaeological response protocol will be developed. This will include, at a minimum, the immediate cessation of all ground-disturbing activities and require contacting representatives with CAFN or the HRU.

Should heritage resources, including places of cultural or spiritual importance to CAFN citizens, be identified in Feedstock areas, buffer zones using flagging and/or fencing will be established to minimize the potentially affected area. Forest Resource Regulations, for example, stipulate that 100 m "no disturbance" buffer zones may be established in areas with known heritage resources. Furthermore, if following the HRA it is determined that heritage resources are solely subsurface deposits, winter logging on snow-covered ground is recommended. Forest harvesting on snow covered grounds can minimize ground disturbance and any potential effects to Heritage Resources.

Post-harvest HRAs may be recommended as a research and monitoring requirement, as outlined in Section 3.8 of the ILP.

Field investigations have not been completed at the time of the writing of this report. Information pertaining to the results of the HRA, including the identification of heritage resources and any required mitigation, will be discussed in detail here when complete.

5.5.3.7 Characterization of Residual Effects

At this time, no field investigation or HRA has been conducted for the Plant or Feedstock. It is recommended that the Characterization of Residual Effects be revised following the completion of the field investigation and HRA.

The potential for an adverse environmental effect on Heritage Resources present in the PDA has the highest probability of occurring during Construction (Site Preparation, Physical Construction of the Facility Structures) of the Plant component and Construction and Operation of the Feedstock component of the Project when ground breaking activities will take place. The majority of ground disturbing, earth moving, and site-altering (*e.g.*, tree-felling) activities will take place during these phases. With appropriate mitigation measures in place, the potential destruction or alteration of all or part of a Heritage Resource, including those Heritage Resources identified by CAFN as pertaining to a special relationship their people have with the natural environment, should be avoidable.

The Plant component is located within Haines Junction village limits, is a small footprint, and while it will most likely be located in an undeveloped block (preliminary PDA is undeveloped), the area surrounding the Plant PDA has witnessed development extending back to the original development of the Alaska Highway. Background research and consultation with the Government of Yukon HRU and Palaeontology Program (Gotthardt pers. comm. 2013; Hare pers. comm. 2012; Zazula pers. comm. 2013) and representatives with CAFN (Brown pers. comm. 2013) indicate that the potential for encountering heritage resources in the immediate preliminary Plant PDA or within the village of Haines Junction is considered low.

Many of the proposed Feedstock harvesting areas within the CATT are undeveloped and located in areas where past overland travel routes, past and present hunting, trapping and fishing, and short-term habitation may have taken place. Some of the most sensitive areas, *Conservation Forest Management Zones,* have been previously accounted for and protected from future timber harvesting under the ILP (EMR 2006). The potential for encountering heritage resources within Feedstock harvesting areas could range from low to high, depending on the locations. However, the implementation of mitigation measures, including Heritage Resource Assessments, "no disturbance" buffer zones, and winter

logging where warranted will reduce the likelihood of a significant adverse effect on Heritage Resources.

Consultation with regulatory bodies (*i.e.*, the Government of Yukon HRU and CAFN) will take place following the determination of Feedstock harvesting areas. No ground disturbing or site-altering activities will proceed prior to this consultation and/or the implementation of an HRA for the Feedstock PDAs.

Potential adverse environmental effects are anticipated to be low in magnitude for all phases of the Plant component as the likelihood of encountering heritage resources is low within the village of Haines Junction. Potential for adverse environmental effects are anticipated to be low in magnitude for all phases of the Feedstock as the assessment and mitigation measures in place will allow for the protection and/or avoidance and/or excavation of heritage resources identified in the PDAs. The geographic extent of the environmental effect is limited to the specific area within the PDA where potential heritage resources are located and thus mitigation measures are achievable. The duration of any potential adverse environmental effects on Heritage Resources for the Project would be permanent and irreversible. Heritage Resources are non-renewable, and cannot be reclaimed or reconstituted. Disturbance of an intact Heritage Resource occurs only once, either through mitigation or accident, and is permanently altered thereafter. Mitigation would be conducted in a controlled, professional, and sensitive manner with the input and participation of CAFN, regulatory bodies and all Project stakeholders. Due to these measures, the potential adverse environmental effects to Heritage Resources are not anticipated. The ecological context of the preliminary Plant PDA is relatively undisturbed, but the LAA (the village of Haines Junction) is a developed area. Potential Feedstock PDAs will be located in an area within the CATT that is both undeveloped and undisturbed apart from low-level forest operations.

An HRA will be conducted, including a visual assessment of areas within the Plant PDA. At the time that this report was written, Feedstock areas were undefined; however, it is anticipated that an HRA will be conducted on a case by case basis as areas are defined. Implementation of mitigation measures established in consultation between CAFN, the Government of Yukon HRU and Forest Management Branch and any party involved in conducting the HRA will also take place at this time. Procedures and protocols outlined in the Position Statement and the Guidelines will be followed. CAFN is currently developing a process to ensure the protection of Heritage Resources. This process will act as an independent and parallel assessment to those outlined in the Position Statement and Guidelines.

A significant adverse environmental effect on Heritage Resources during the Construction and Operation of the Plant and Feedstock components of the Project is not anticipated. A significant adverse environmental effect may be avoided through the implementation of mitigation where by all areas with known heritage resources, or the potential to encounter heritage resources, including areas of cultural or spiritual importance, are investigated prior to any ground disturbing or site-altering activities.

5.5.4 Assessment of Cumulative Effects

At the time of the writing of this report, there is insufficient information to conduct an assessment of Cumulative Effects or Statement of Significance for Heritage Resources. This will be revised upon the determination of final Plant and Feedstock PDA locations.

5.6 TRADITIONAL ACTIVITIES AND CULTURE

The proposed biomass gasification power plant (the Project) by the Champagne and Aishihik First Nations (CAFN) and the Yukon Energy Corporation (YEC) will be located within the village of Haines Junction, Yukon on Settlement Lands belonging to the CAFN. The Project is comprised of two parts:

- the biomass plant (the Plant); and
- biomass feedstock timber harvesting (Feedstock).

The Plant will operate as a power and heat source for buildings within Haines Junction and the Feedstock will be the fuel source for the Plant. At the time of the writing of this document, the PDA(s) of the Feedstock are unknown; however, future development of Feedstock is anticipated to take place on non-Settlement Lands within the Champagne and Aishihik Traditional Territory (CATT).

Traditional Activities and Culture is recognized as a VC for this EIA due to the potential impacts with those activities identified in consultation with CAFN as being of traditional or cultural importance to the community and citizens at large. These activities may include hunting, fishing, or trapping but may also include social and community gatherings, cultural or spiritual ceremonies. This assessment of Traditional Activities and Culture is preliminary and will be further refined through consultation with the CAFN community members as details of feedstock harvesting are defined.

5.6.1 Scope of the Assessment

This section defines the scope of the environmental assessment of Traditional Activities and Culture in consideration of the nature of the regulatory setting, issues identified during public and First Nations engagement activities, potential Project-VEC interactions, and existing knowledge.

At the time of the writing of this document, public and First Nations engagement activities have not all taken place. An introductory open house was held in Haines Junction and input from that engagement is included in Section 2.0 (Consultation). This assessment will be updated prior to submission to YESAA to incorporate engagement issues as warranted.

5.6.1.1 Key Issues and Identification of Potential Effects

Potential interactions between the Project and Traditional Activities and Culture are highlighted and those aspects of the Project that may cause environmental effects, either positive or adverse, are identified. The Project may interact with Traditional Activities and Culture in the following ways:

- Construction and Operation of the Plant will result in ground disturbing and site-altering activities (alternative use of the land during Operation), potentially impacting the ability to conduct Traditional or Cultural Activities within the Plant PDA and on adjacent lands; and
- Construction and Operation of the Feedstock will result in site-alteration (removal of vegetation from forested areas), potentially impacting the ability to conduct Traditional or Cultural Activities taking place within the greater CATT.

5.6.1.2 Regulatory/Policy Setting

The *Traditional Activities and Protection Act* (the Act) (CAFN 1998) was established:

> *"(a) to ensure the wise management of Settlement Land and resources of Champagne and Aishihik people on behalf of present and future generations; (b) to ensure comprehensive and integrated decision making respecting the use and management of Settlement Land and resources, including the full consideration of environmental, cultural, historic and socio-economic factors in that decision making; and (c) to protect the culture, traditions, health and lifestyle of Champagne and Aishihik people and to ensure that information pertaining to these things is used respectfully and wisely in decisions made by the Champagne and Aishihik First Nations."* (CAFN 1998:3)

Any development project taking place on CAFN Settlement Lands is required to obtain a permit for, and is responsible for protection of, those Settlement Lands under the Act. The Act and permits issued under it are enforced by the administrator of the act (the Director) and officers appointed by the CAFN Council.

The protection of Traditional Activities and Culture on non-Settlement Lands in the CATT is afforded through *Section 3.8 – Heritage and Culture Guidelines* of the *Integrated Landscape Plan for the Champagne and Aishihik Traditional Territory* (the ILP) (EMR 2006). Section 3.8 of the ILP outlines a process by which qualified representatives on behalf of CAFN and the Government of Yukon Heritage Resources will assess the cultural and heritage values of each proposed forest development on a site by site basis.

5.6.1.3 Selection of Measureable Parameters

The environmental assessment of Traditional Activities and Culture is focused on the following environmental effect:

- Change in Traditional Activities and Culture within the PDA

This environmental effect has been selected as a result of the need for disposition of lands for the Project and protection afforded to Traditional Activities and Culture under *YESAA* and the Act.

The measurable parameters used for the assessment of the environmental effect presented above and the rationale for their selection is provided in Table 5.8.1.

Table 5.6.1 Measurable Parameters for Traditional Activities and Culture

Environmental Effect	Measurable Parameter	Rationale for Selection of the Measurable Parameter
Change in Traditional Activities and Culture	Ability to conduct Traditional or Cultural Activities within the PDA	• Traditional Activities and Culture are afforded protection under CAFN legislation, the *Traditional Activities Protection Act.* • Land- and Site-altering (*e.g.*, tree-felling) activities, and noise and dust during construction, within the PDA has the potential to impact traditional and/ or cultural activities that may take place within the PDA (*e.g.*, subsistence harvesting, cultural or spiritual ceremonies, social gatherings)

5.6.1.4 Spatial Boundaries

The spatial boundaries for the environmental effects assessment of Traditional Activities and Culture are defined below.

Project Development Area (PDA): The PDA is the most basic and immediate area of the Project. The PDA is limited to the area of physical ground disturbance associated with the Project, and consists of an area that includes the area of physical disturbance associated with the biomass plant and associated facilities as well as the area associated with biomass feedstock harvesting (including forest roads). The PDA is the area represented by the physical Project footprint as defined in Chapter 3.1.2 above.

Local Assessment Area (LAA): The LAA is the maximum area within which Project-related environmental effects can be predicted or measured with a reasonable degree of accuracy and confidence. The LAA includes the PDA, Haines Junction, and any adjacent areas where Project-related environmental effects may reasonably be expected to occur. Since the potential environmental effects on Traditional Activities and Culture may extend beyond the PDA (*e.g.*, the disruption of key migration routes for hunting, trap-line concessions), the LAA must include

Regional Assessment Area (RAA): The RAA is limited to and includes the Yukon Territory. The RAA is the area within which the Project's environmental effects may overlap or accumulate with the environmental effects of other projects or activities that have been or will be carried out. The extent to which cumulative environmental effects for Traditional Activities and Culture may occur depend on physical and biological conditions and the type and location of other past, present, and reasonably foreseeable future projects or activities that have been or will be carried out, as defined within the RAA. For Traditional Activities and Culture, the RAA may be considered lands within the CATT, and the southwest region of the Yukon Territory.

5.6.1.5 Temporal Boundaries

The temporal boundaries for the assessment of the potential environmental effects of the Project on Traditional Activities and Culture include the phases of Construction, Operation, and Decommissioning.

5.6.1.6 Residual Effects Significance Criteria

A *significant adverse residual environmental effect* on Traditional Activities and Culture is defined as one that results in a permanent Project-related change in ability to conduct a Traditional or Cultural Activity including, but not limited to, those activities conducted by CAFN citizens and outlined as "traditional activities" in the Act *"…for food, subsistence or ceremonial purposes to strengthen and enhance social, spiritual and cultural relationships and values…*" (CAFN 1998:2) and that cannot be mitigated or compensated for.

5.6.2 VC Existing Conditions

The Project PDA will be located within the limits of the village of Haines Junction, in southwest Yukon. The preliminary PDA of the biomass energy plant is located just east of the intersection between Willow Acres Road and the Alaska Highway. This assessment will be updated as required following final siting.

At the time of the writing of this report, specific Feedstock areas are undefined. It is anticipated that feedstock timber harvesting will take place within the CATT, which encompasses an estimated 1,959,000 HA of southwest Yukon, according to the ILP (EMR 2006) (Figure 5.5.1). However, planning and development for the forest industry will occur only in the Forest Resource Management Zone (93,700 HA in the ILP) (EMR 2006). The areas that would potentially be harvested for Feedstock are likely to be predominantly located within 50-70 km of Haines Junction over the life of the project, delimited by the boundaries of the Forest Resource Management Zone (Damecour, pers. comm. 2012).

Methods for determining the existing conditions of Traditional Activities and Culture within the Project PDA rely on communication with the population who currently occupy that land, or have knowledge of recent use and activities conducted therein. At the time of the writing of this report, documentary sources remain the primary resource for Traditional Activities and Culture. Consultation with CAFN citizens, non-aboriginal Yukon citizens living in the area, and traditional use studies for the Project, including the Plant and Feedstock PDAs will be conducted and/or consulted prior to any Project-related ground disturbance or site-altering activities.

5.6.2.1 Evaluation of Existing Information

Information contained in the Heritage Resources VC (Section 5.5) describes the general human setting of the recent past with a particular focus on the Southern Tutchone people, direct ancestors to the modern-day Champagne and Aishihik First Nations. Section 5.5 discusses traditional hunting-fishing-gathering practices and a brief overview of the Southern Tutchone seasonal round based on information available in documentary sources. Further descriptions of more recent (*i.e*., present-day) use of the land and resources, community, spiritual, and cultural activities practiced by CAFN and non-aboriginal Yukon citizens in the Project area will be gathered through consultation during the detailed Feedstock assessment.

5.6.3 Potential Project VC Interactions

5.6.3.1 Project Effects Mechanisms

Table 5.8.2 below lists each Project activity and physical work for the Project, and ranks each interaction as 0, 1, or 2 based on the level of interaction each activity or physical work will have with the Traditional Activities and Culture.

Table 5.6.2 Potential Project Environmental Effects to Traditional Activities and Culture

Project Activities and Physical Works	Potential Environmental Effects
	Change in Traditional Activities and Culture
Construction	
Site preparation	1
Physical construction of the Facility Structures	1
Installation of Equipment	0
Commissioning	0
Construction of infrastructure for Feedstock Harvesting	2
Operation	
Operation and Maintenance of Plant Site	0
Feedstock Harvesting	2
Decommissioning, Reclamation and Closure	

Table 5.6.2 Potential Project Environmental Effects to Traditional Activities and Culture

Project Activities and Physical Works	Potential Environmental Effects
	Change in Traditional Activities and Culture
Plant Site	0
Harvested Areas	0

Project-Related Environmental Effects
Notes:
Project-Related Environmental Effects were ranked as follows:
0 = No interaction. The environmental effects are rated not significant and are not considered further in this report.
1 = Interaction will occur. However, based on past experience and professional judgment, the interaction would not result in a significant environmental effect, even without mitigation, or the interaction would clearly not be significant due to application of codified practices and/or permit conditions. The environmental effects are rated not significant and are not considered further in this report.
2 = Interaction may, even with codified mitigation and/or permit conditions, result in a potentially significant environmental effect and/or is important to regulatory and/or public interest. Potential environmental effects are considered further and in more detail in the EA.

5.6.3.2 Construction

Activities ranked as 0 for the Construction Phase in Table 5.8.2 include: Installation of Equipment and Commissioning. Final Plant site selection will take into account key areas for Traditional Activities and Culture, and Installation of the Equipment and Commissioning does not involve land- or site-altering activities, therefore will not interact with any Traditional or Cultural Activities. As a result, the potential environmental effects of Installation of the Equipment and Commissioning activities on a change in Traditional Activities and Culture are ranked as 0.

Activities ranked as 1 for the Construction Phase in Table 5.8.2 include: Site Preparation and Physical Construction of the Facility Structures. While both activities ranked as 1 in the table will result in land- or site-altering activities, site selection of the Plant will take into consideration, and be located to minimize, interaction with Traditional Activities and Culture. As a result, it is anticipated that no significant environmental effect, due to the application of codified practices and permit conditions, would occur to Traditional Activities and Culture.

Operation

Activities ranked as 0 for the Operation Phase in Table 5.8.2 include: Operation and Maintenance of Plant Site. The biomass energy Plant will be located to avoid key areas for Traditional Activities and Culture, and the Operation and Maintenance of Plant Site activity does not involve land- or site-altering activities, therefore will not interact with any Traditional or Cultural Activities. As a result, the potential environmental effects of Operation and Maintenance of Plant Site activities on a change in Traditional Activities and Culture are ranked as 0.

There are no activities ranked as 1 during the Operation phase in Table 5.8.2.

5.6.3.3 Decommissioning, Reclamation and Closure

Activities ranked as 0 for the Decommissioning, Reclamation and Closure Phase in Table 5.8.2 include: Plant Site and Harvested Areas. No land- or site-alteration beyond that already completed during the Construction and Operation Phases are anticipated for this phase of the Project. As a result, the potential environmental effects of Plant Site and Harvested Areas activities on a change in Traditional Activities and Culture are ranked as 0. The ranking of 0 for Plant Site and Harvested Areas activities

assumes that the Plant PDA will remain unchanged and that the Feedstock PDA(s) will be re-forested and returned to natural growth.

There are no activities ranked as 2 for Traditional Activities and Culture in the Decommissioning, Reclamation and Closure phase.

Thus, in consideration of the nature of the interactions and the planned implementation of known and proven mitigation, the potential environmental effects of all Project activities and physical works that were ranked as 0 or 1 in Table 5.8.2, including cumulative environmental effects, on Traditional Activities and Culture during any phase of the Project are rated not significant, and are not considered further in the assessment.

5.6.3.4 Assessment of Environmental Effects

The only interactions ranked as a 2 and thus requiring further assessment are related to Feedstock harvesting which is not being assessed in detail in this draft assessment. At the time of the writing of this report, there is insufficient information to conduct a further assessment of Environmental Effects on Traditional Activities and Culture. Mitigation measures, Residual and/or Cumulative effects will be revised upon the determination of final Plant and Feedstock PDA locations. No land- or site-altering activities or disruption of Traditional or Cultural Activities (*e.g.*, subsistence hunting, trapping, spiritual or cultural ceremonies, social and community gatherings) will take place for the Project prior to consultation with CAFN citizens and non-aboriginal Yukon citizens living on and/or using lands that may potentially be impacted by the Project.

6.0 ASSESSMENT OF EFFECTS OF ACCIDENTS AND MALFUNCTIONS

Accidents and malfunctions are unplanned, adverse events affecting the Project during Construction and Operation. Three potential sources of accidents and malfunctions are considered in this assessment: process upsets, fires, and vehicle collisions.

Process upsets will be minimized to the extent possible by conducting the appropriate preventative and routine maintenance of mechanical components of the Project, as well as the control of the process operation by an installed system. In the event of a process upset, operators would respond to the event by manually adjusting the relevant process parameters to resolve the issue as quickly as possible. For mechanical breakdowns, operators would be dispatched as soon as possible to conduct the required maintenance or repairs of the affected equipment. In the case of major process upsets, if the issue cannot be resolved internally in a timely fashion, the process would be shut down in a controlled manner to conduct the required repairs.

Fires at the Project site could result from an accident, from spontaneous combustion of biomass, or from potential fires within the equipment (*e.g.*, gas cleaning). The immediate concern for a fire would be for human health and safety. Local air quality conditions may be influenced by emissions from a fire and other adjacent infrastructure could be at risk of damage or loss as well.

The emissions from a fire would likely consist mainly of smoke (particulate matter) and CO_2 but could also include CO, NO_X, SO_2, VOCs, and other products of incomplete combustion. A large fire could create particulate matter levels greater than the ambient air quality standard over distances of several kilometres, but such situations would be of short duration and are not expected to occur.

The facility will be equipped with several fire hydrants, and personnel will be adequately trained in fire-fighting procedures, to respond to any fire that may result from spontaneous combustion of biomass or other means. However, since limited quantities of biomass will be stored on-site, and since their storage will be for a relatively short period of time, the risk of spontaneous combustion is low.

The potential for vehicle accidents exists for all phases of the Project. In addition to the employee-related traffic to and from the site, the operation of heavy equipment on-site during Construction as well as the operation of heavy trucks for equipment and biomass deliveries has the potential to result in vehicle accidents during Operation.

The Project is anticipated to be located near the Alaska Highway, which is a main roadway. The Project will result in an increase of 3 to 15 trucks per week in during Operation. This increased truck traffic associated with Operation of the Project equates to a small increase in overall traffic volumes in the area. Further to this, the Project-related traffic is expected to be confined to existing truck routes. Therefore, the increase in traffic is not expected to result in a substantive increase in the potential for vehicles accidents.

7.0 EFFECTS OF THE ENVIRONMENT ON THE PROJECT

The effects of the environment on the Project are associated with risks of natural hazards and influences of nature on the Project, during all phases. These environmental effects are defined in Section 2(1) of the *Canadian Environmental Assessment Act* as *"…any change to the project that may be caused by the environment…whether any such change or effect occurs within or outside Canada*." Typically, potential effects of the environment on any project are a function of project or infrastructure design and how these may be affected by nature. These effects may arise from physical conditions, land forms, and site characteristics which may act on the Project such that the Project components, schedule and/or costs could be substantively and adversely changed.

Good engineering design involves the consideration of environmental effects and loadings or stresses (from the environment) on the Project. The planning and engineering design for this Project are no exception. Equipment and materials will be used that are able to withstand severe weather, and other influences. Environmental stressors, such as those that could arise as a result of climate change, severe weather, and other factors, would be addressed by engineering design, materials selection, and best practices.

Mitigation strategies for minimizing the likelihood of a significant effect of the environment on the Project are inherent in the planning process, the engineering design codes and standards, and the construction practices. As such, and in consideration of the best management practices that will be applied throughout the design, Construction and Operation of the Project, as demonstrated in the following sections, the effects of the environment on the Project during all phases of the Project will be managed through responsible design and thus have been rated not significant.

7.1.1 Influence of Consultation on the Assessment

At the time of writing, consultations in the community are on-going. A summary of the consultations as they apply to effects of the environment on the Project will be provided following the completion of the consultations.

7.1.2 Potential Effects on the Project

The environmental attributes that were considered to have a potential effect on the Project were based on a review of the known past and existing conditions, and knowledge gained through projections of potential future conditions (*e.g.*, potential effects of climate change). Based on the issues and concerns identified, the environmental attributes selected for consideration include:

Severe weather, including:

- wind;
- precipitation; and
- electrical storms.

Climate change, including:

- changes in mean temperature; and
- changes in precipitation amounts, frequency, and type (rain).

As a result of climate change, the Haines Junction area may be subject to melting permafrost and increased risk of forest fires resulting from causes other than the Project.

Climate conditions and climate change are presently the focus of much concern globally. "*With global attention now focused on climate change, government agencies, non-profit organizations, the private sector, and individual citizens are gearing up to face climate-related challenges*" (NOAA 2010). The people of the Yukon have already begun addressing climate change by holding two conferences, titled *Climate Change in Our Backyard*, in 2006 and 2009. The conferences brought together local experts in the Champagne and Aishihik First Nations Traditional Territory (CATT) and researchers to discuss the observed changes in the CATT, what changes might be expected, and what adaptive strategies may be employed.

7.1.3 Extreme Weather Events

Extreme weather events may be characterized as events of heavy precipitation or strong winds.

There are climate normals data available from the Whitehorse meteorological station (Environment Canada 2012d) . The most extreme daily rainfall event in Whitehorse was recorded on June 27, 1985 to be 44.9 mm, and the most extreme daily snowfall event was recorded on March 8, 1967 to be 27.2 cm. The maximum hourly wind speed was recorded on January 9, 1962 to be 72 km/hour, and a maximum gust speed of 106 km/hour was recorded on February 19, 1964.

With respect to effects on the Project, extreme weather events may affect the harvesting and transportation of wood through temporarily reduced access to wood and transportation infrastructure. In addition, the storage of wood chips on site may be compromised if the biomass storage building fails. These effects may be mitigated by considering extreme weather events in the design and operation of the Project activities and infrastructure.

7.1.4 Forest Fire

Between 1950 and 2006, a total of 6,294 fires have occurred in the Yukon. Forest fires may be caused by lightning strikes or human activities. The average annual area burned is 1,495 km^2 (149,515 hectares) (Government of Yukon 2011b). Haines Junction has a volunteer fire department.

In the event that Haines Junction is evacuated due to a forest fire, the Project can be safely and quickly shut down. The immediate area surrounding the site will be cleared of vegetation. No other effects on the Project due to forest fires are anticipated.

7.1.5 Climate Change

"Climate" is defined as the statistical average (mean and variability) of weather conditions over a substantial period of time (typically 30 years), accounting for the variability of weather during that period (Catto 2006). The relevant parameters used to characterize climate are most often surface variables such as temperature, precipitation, and wind, among others.

"Climate change" is an acknowledged change in climate that has been documented over two or more periods, each with a minimum of 30 years (Catto 2006). The Intergovernmental Panel on Climate Change (IPCC) defines climate change as a change in the state of the climate that can be identified (*e.g.*, by using statistical tests) by changes in the mean and/or the variability of its properties and that persists for an extended period, typically decades or longer. Climate change may be due to natural internal processes or external forcings, or to persistent anthropogenic changes in the composition of the atmosphere or in land use (IPCC 2007). The United Nations Framework Convention on Climate Change (UNFCCC) makes a distinction between climate change attributed to human activities and climate variability attributable to natural causes, by defining climate change as a change of climate which is attributed directly or indirectly to human activity that alters the composition of the global atmosphere and which is in addition to natural climate variability observed over comparable time periods (IPCC 2007).

The definition of climate change dictates the context in which the effects of those changes are discussed. While it is appropriate to examine the effects of projected climate change on Operation over the next 50 to 100 years, it is not fitting to consider the effects of climate change projections on Construction which will take place over a relatively short period of time (6 to 8 years) in the near future. Construction will occur over the first year of the Project, and as such it is more appropriate to consider the effects of recent climatological conditions, especially the potential adverse effects of weather variability and weather extremes (*e.g.*, change in precipitation) on Construction.

To assess the environmental effects of climate on the Project, current climate and climate change must both be considered. Current climate conditions are established by compiling relevant historical data and establishing a climatological background for the Haines Junction area. Climate change effects projected over the life of the Project (approximately 20 years) are determined through a review of the two Climate Change in Our Backyard conference reports (CAFN 2006; CAFN 2009b). The 2009 report indicates that the annual mean temperature of southern Yukon is projected to be 2.6°C warmer and that precipitation is projected to increase by 10 to 45% in the next 50 years. As a result, changes to water resources, biodiversity, transportation infrastructure, health, and local economies are anticipated. Nevertheless, given the lifetime of the Project (approximately 20 years), the effects of Climate Change are not likely to cause adverse effects on the Operation of the Project.

8.0 SUMMARY OF SIGNIFICANCE

The assessment of potential effects provided in the sections above has been completed based on desktop literature and information review and in consideration of initial consultation with First Nations and the public on their interests and values. Preliminary findings for each VC have been developed in consideration of the Project activities as understood from the FEED study and may require updates once the Project location and infrastructure are finalized. Updates may also include a more detailed assessment of feedstock harvesting activities.

In consideration of existing ambient air quality conditions and estimated Project emissions of air contaminants, ambient air quality is expected to remain well below regulatory objectives during operation of the plant. Annoyance from noise is not expected to be caused by the plant if it is located at least 500 m from residences (to avoid sleep disturbance). If the plant is located in a building this distance could be less. The chipping operation will likely need to be located 500 to 1,000 m from residences and sensitive receptors (such as the school or other areas of frequent land use) to avoid annoyance.

Minimal influence on water resources is expected as the plant will use little to no water (depending on vendor) and should be located at least 30 m away from surface water sources. Feedstock (in chip form) will be stored indoors to avoid siltation to surface water run-off.

Significant environmental effects on vegetation and wildlife are not expected based on the species documented in Haines Junction.

Additional consultation is required in relation to traditional ecological knowledge and traditional activities and culture to confirm any constraints that should be considered. Based on the consultation conducted to date, no concerns have been raised that are expected to hinder development of the Project in a way that will not significantly effect these values.

Known and documented heritage resources have been confirmed and will be avoided in locating the plant.

Transportation infrastructure is not expected to be noticeably influenced as a result of the Project. Truck traffic is estimated at 3 to 15 trucks per week to supply feedstock during Operation. Similar or less traffic is expected during Construction.

The Project will require resources for construction and operation, therefore a positive effect on labour and economy is expected. Planning of forest harvesting will include consideration of existing land users to ensure that other land users such as existing harvesters, trappers, outfitters and wilderness tourism are not negatively affected.

Human health and well-being should not be affected by the Project. The plant would be operated within applicable regulations which have been developed to protect human health and well-being.

The risk of accidents related to the Project will be minimized through the design and procedures during Operation.

1 BACKGROUND

1.1 Introduction

The primary objective of this Front End Engineering Design (FEED) Study is to confirm the viability of electricity generation in Yukon using small-scale gasification technology fuelled from local forest biomass feedstock. The project will require either a Yukon Environmental and Socio-economic Assessment Board (YESAB) District Office or Executive Office level effects assessment for the biomass facility. Baseline work on feedstock harvesting is outside the scope of this project.

Also outside of the scope of this project is the waste heat study that will be led by Champagne and Aishihik First Nations' Renewable Energy Committee. The waste heat study will identify possible uses of the waste heat from the biomass plant, will be carried out at the same time as the FEED study, and will be completed by Clean Technology Community Gateway (CTCG).

This engagement plan sets out how the project team will meaningfully engage with First Nations, stakeholders, regulators, decision-makers and the general public. It provides a working list of stakeholders and potentially interested First Nations, a description of communication timelines, and describes how engagement will be carried out. It is based, in part, on information provided in the draft communications plan provided to Stantec by the project team.

For the purposes of this document, the Project Partners/Project Sponsors are the following:

- Yukon Energy (YEC)
- Champagne Aishihik First Nations (CAFN)
- Dakwakada Development Corporation (DDC)
- Cold Climate Innovation (CCI)
- Village of Haines Junction (VHJ)

The Project Steering Committee is made up of the following individuals:

- Michael Brandt, YEC – Co-Chair
- Ray Wells, YEC – Co-Chair
- Roger Brown, CAFN
- Hector Campbell, YEC
- Stephen Mooney, CCI

The Project Management Team and Project Contributors are those individuals shown in Figure 2.1.

1.2 Communications Approach

Strong stakeholder engagement is required to build community support for the use of biomass energy generation in Haines Junction. As several organizations are sponsoring the project, the project team will ensure the views of each Project Partner are contained in engagement and communication materials, as appropriate. The outputs from project engagement will be shared with the Project Partners and Steering Committee members at key decision points and at the end of the project.

1.3 Public Engagement Principles

The project will involve stakeholder and relationship-building over a number of different phases and possibly over a number of years. The following principles will guide this engagement:

Communication

- Communicate regularly on the project's progress
- Wherever practical, maximise opportunities for stakeholders to provide feedback
- Clearly communicate feedback mechanisms to foster two-way communication

Transparency

- Clearly explain the decision-making process and define the intended outcomes of any engagement activities
- Where and as appropriate, communicate to stakeholders what they can and cannot influence in the consultation process
- Inform stakeholders about how their input will be used
- Where appropriate, document decisions or outcomes of meetings with stakeholders

Inclusiveness

- Identify stakeholders and, wherever possible, involve them in any consultation at an early stage
- Seek to understand stakeholder issues or concerns
- Facilitate stakeholder engagement as appropriate

1.4 Communications Aim

The overarching communications aim for the project is to generate stakeholder awareness, understanding and support and to communicate the following to project audiences:

- CAFN, DDC, YEC, CCIC, and VHJ are working together to investigate the possibility of locating a biomass electricity generation plant in the Haines Junction area

- If the project proceeds, it could mean additional renewable energy and, potentially, a source of district heat, creation of local jobs, and economic opportunities/growth for local businesses and corporations
- The project may serve as a demonstration project for biomass power generation in other similar northern and rural communities in Canada

1.5 Key Messages

The steering committee and project team have worked to develop the following key messages. These key messages will be used when communicating with stakeholders, regulators and the general public. These messages may be amended and added to as the project progresses.

Table 1.1: Key Messages

Question	Detailed Key Messages
Who are the Project Partners?	▪ The Champagne and Aishihik First Nations, the Dakwakada Development Corporation, Yukon Energy, Cold Climate Innovation at the Yukon Research Centre, and the Village of Haines Junction
What's the project all about?	▪ The partners are exploring a potential opportunity to produce renewable energy in the Haines Junction area using biomass gasification technology ▪ The plant concept envisions the building of a small scale gasification plant that will generate between 0.5 and 2 megawatts of renewable electricity, helping to develop a sustainable and secure energy future for the Haines Junction community and the Yukon. ▪ The partners are looking at producing electricity using a power plant fueled by beetle-killed trees, sawmill waste, and other sources of renewable wood fiber harvested from the Haines Junction area. The partners are also exploring whether heat energy produced by the power plant could potentially be provided to local facilities.
What stage is the project at?	▪ We are in the early stages of exploring this opportunity and we are investigating different technologies and project scales. ▪ Our initial work includes informing and discussing the concept with First Nations, stakeholders and the public while conducting a detailed feasibility study to see if operating a biomass gasification power plant in Haines Junction is technologically, environmentally and financially a good choice. ▪ Based on preliminary work that demonstrated the possible viability of a biomass gasification facility in Haines Junction, Stantec has been engaged to conduct a detailed feasibility study funded by each of the project partners and Natural Resources Canada, Canadian Northern Economic Development Agency and the Government of Yukon. The results of that technology study are expected in 2013. ▪ Once the results of Stantec's feasibility study are known, the project partners will share that information and seek feedback. They will then decide whether to continue with further studies and how best to move forward. Future work will involve exploring in greater detail the source and sustainable supply of wood fiber fuel for the proposed biomass facility. If the overall concept is feasible, the biomass project will then undergo community, environmental, socio-economic, and regulatory reviews before a decision is finally made to proceed with construction and operations.
Why is the project unique?	▪ This is the first time that the project partners have combined forces to collaborate on a potential renewable energy project. The technology is innovative and has been successfully used in other parts of Canada, in the United States, and in Europe and

Question	Detailed Key Messages
	Asia. If built, the power plant would be the first biomass electricity production facility in the Yukon and has the potential to act as a demonstration project for other small rural and northern communities.
What are the potential benefits of the project?	▪ A biomass power plant could generate at least 0.5 megawatts of much-needed renewable electricity, contributing to a sustainable and secure energy future for the Haines Junction community and the Yukon. ▪ The project could create local jobs and offer long-term economic opportunities for local businesses to grow. ▪ Waste heat from the facility could potentially be used to heat existing or new facilities (such as a community greenhouse).
What are the potential challenges?	▪ Cost ▪ Wood fiber availability ▪ Ensuring sustainable wood fiber harvesting and sustainable operation of the power plant ▪ Potential noise and other effects from increased traffic, construction, and industrial activity ▪ Possible air emissions
What are key questions that the Project Partners still need to answer?	▪ Given existing technology and potential fuel sources, is a biomass power project in the Haines Junction area technically and economically feasible? ▪ Is there an acceptable location for the biomass power plant? ▪ Can a biomass power plant be developed and operated in an environmentally and socially responsible way? ▪ Is there enough renewable wood fiber available to fuel the proposed power plant for the long-term? ▪ Where would the wood fiber be harvested and can it be sustainably harvested? ▪ What are the likely positive and negative effects on the environment and on local residents? ▪ Would there be any significant negative effects? ▪ Could any significant negative effects be satisfactorily avoided or mitigated?

1.6 Communications Goals and Objectives

- Create and maintain awareness and understanding of the project among the general public, decision-makers, key stakeholders, and interested First Nations, including its potential costs and benefits, and proposed engagement processes
- Identify stakeholders and potentially interested First Nations, build and maintain strong relationships, ensure that engagement occurs at the right level, at the right time, in the right way
- Identify, document and monitor issues and concerns that arise during the engagement process
- Identify needed planning, design and management measures to avoid, mitigate or resolve issues

- Encourage the sharing of traditional land use and traditional knowledge information by interested and potentially affected First Nations
- Provide early notification of the project and adequate opportunities for public input
- Ensure the steering committee, project partners and the project team communicate with 'one voice' to the public, stakeholders and regulators
- Identify and manage communications issues to minimize their potential adverse impact on the project

2 PROJECT TEAM

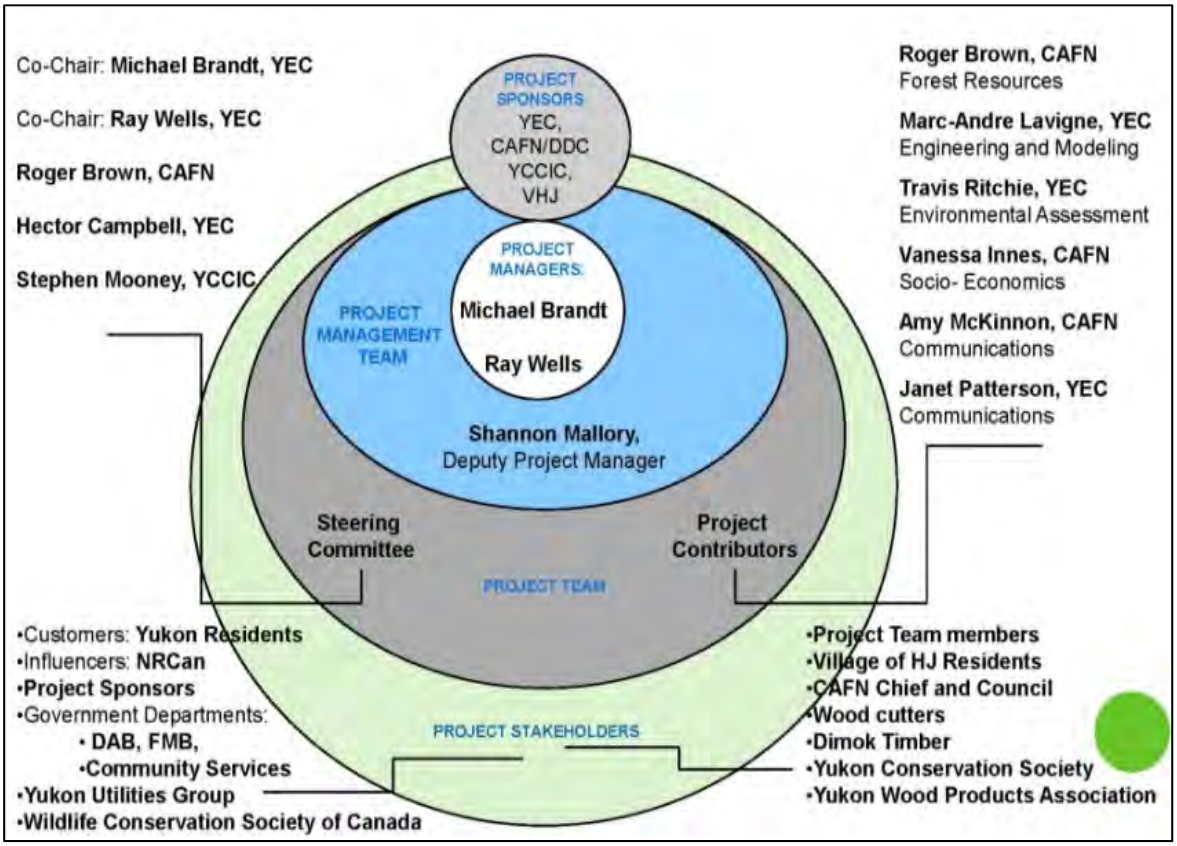
2.1 Structure

The project team is shown in Figure 1.1 below. The project team is comprised of technical staff from YEC, DDC and CAFN. Team members will be given tasks that are relevant to their knowledge area by the steering committee, co-project managers or deputy project manager.

To support the project management team and project consultants, the Steering Committee has been established that has technical representation from at least two of the Project Partners. A number of sub-committees may be formed to deal with specific issues throughout the project. The Steering Committee will:

- Have overall guidance and direction of the Project
- Direct actions to the deputy project manager and the co-project managers as well as the project team

Figure 2.1: Project Team



2.2 Roles and Responsibilties

To ensure that project communications are clear, consistent and coordinated, the roles and responsibilities of the Project Partners, Steering Committee, project management team, and Project Contributors must be clearly described. The following roles and responsibilities have been recommended by the Steering Committee:

Table 2.1: Communications Roles and Responsibilities

Partner	Role/Responsibility
Project Sponsors/Project Partners	The Project Sponsors will: • Defer all public/media communications regarding the project to their Communications representatives
Project Steering Committee	The Steering Committee will: ▪ Have overall guidance and direction of the Project ▪ Direct actions to the deputy project manager and the co-project managers as well as to the project team ▪ Act as project points of contact and decision makers for their organizations as members of the Project Steering Committee ▪ Approve the communications and stakeholder engagement strategy ▪ Approve all media releases and media interviews ▪ Approve all engagements and communications with assessment, resource management and regulatory agencies (e.g., YG Forest Management Branch, YESAB), beyond sharing information that is already in the public domain ▪ The Project Steering Committee with the Project Sponsors, Project Management Team and Project Contributors will be involved in the the development of the key messages to ensure consistency and content accuracy of communication
Project Management Team	The Project Management Team will: ▪ Defer all public communications regarding the project to communications representatives ▪ Act as a key contact point for stakeholders in cooperation with the deputy project manager ▪ Have overarching responsibility for preparation of communications and engagement materials and events ▪ Have overarching responsibility for assessment and regulatory agency communications and engagement ▪ Identify and manage issues ▪ Approve all communications as authority may be designated to it in writing by the steering committee
Deputy Project Manager / Designate (e.g. Project Consultants)	The Deputy Project Manager/Designate will: ▪ develop draft materials for Project Sponsor, Project Steering Committee, Project Management Team and Project Contributor review ▪ provide information to Communications Representatives for website materials ▪ maintain the contact database ▪ prepare papers and advice to the Project Management Team, the Steering Committee, and Project Contributors ▪ communicate with Stantec regarding Steering Committee direction on engagement and communications activities
Project Contributors	The Project Contributors will play a supporting role in communications and stakeholder engagement for the project. Working with the Steering Committee, the Project Contributors may assist with: • managing communications and engagement activities

Partner	Role/Responsibility
	• identifying and managing issues • assisting with media activities as required • monitoring media coverage and the external environment for impacts on the project • providing strategic communications advice to the Project Management Team and Steering Committee as needed
Communications Representatives	Will draft the following: • summaries of media coverage and external opinion/discussions relating to the Project • communication responses to manage reactive media activities • information for newsletters The Communications Representatives will update the engagement plan as needed

3 COMMUNICATION PROTOCOLS

3.1 Confidentiality

Project-related documents are considered confidential and are only to be shared with the internal project team unless specific approval is given for their release by the steering committee.

3.2 Communications With Regulators

Any communications and engagement regarding the project with assessment and regulatory agencies/personnel requires prior notification and approval by the steering committee. Improptu conversations may occur, but shall not go beyond sharing information currently available to the public and hearing what the other party may want to share.

3.3 Media Relations

The following rules should govern all project-related communications with the media:

- Media releases are to be signed off by the Steering Committee before being sent out
- All planned contact with media will be coordinated through the project management team
- All media releases and media engagements (e.g., interviews) will be pre-approved by the Steering Committee
- *** NRCan requires three weeks notice of any news releases

- Before doing media interviews, the spokesperson should notify all project parties by email. Following the interview, the spokesperson should send another email to the Project parties providing a summary of the conversation
- Communications representatives will be the initial point of contact for all reactive media enquiries (see table below for details)

Table 3.1: Project Media Contacts

Project Partner	Communications Representatives
Yukon Energy	David Morrison / Janet Patterson
CAFN	Chief James Allen
DDC	Murray Arsenault
Village of Haines Junction	Mayor George Nassiopoulos
Cold Climate Innovation Research Centre	Tanis Davey

3.4 Communications with Steering Committee

Project communications with the Steering Committee will be governed by the following rules:

- Steering Committee meetings will be sent out with an outlook meeting request with a link and phone number for GoTo Meeting
- Project status reports will be sent to the Steering Committee by email as they are received from the consultant

3.5 Monitoring

The project management team will continuously identify emerging issues by monitoring the following:

- Media coverage
- Blogs and other social media (Facebook/Twitter/Google +)
- Policy environment
- Stakeholder feedback (formal and informal)

4 ENGAGEMENT WITH STAKEHOLDERS

4.1 Project Stakeholders

Potential project stakeholders are listed below (this list will be added to and amended over time):

Table 4.1: Stakeholder List

Industry and Industry Associations Arctic Inland Building Products Dimok Timber Ltd. Tourism Industry Association Yukon Wilderness Tourism Association Yukon Outfitters Association Yukon Wood Products Association	**Project Team, Sponsors and Contributors** CAFN Dakwakada Development Corporation Yukon Energy Centre Cold Climate Innovation Village of Haines Junction
Research and Academic Yukon College, Northern Research Institute	**Regulators and Decisionmakers** YESAB YUB Yukon Executive Council Office
Local Government and Local Government Associations Village of Haines Junction (Mayor and Council) Association of Yukon Communities	**Potentially affected land users and representative organizations** Trappers Guide Outfitters Hunters Recreational/Commercial Fishermen
Nongovernmental Organizations Wildlife Conservation Society of Canada Council of Canadians Yukon Conservation Society Canadian Parks and Wilderness Society	**Yukon Government** Environment Yukon Yukon Highways and Public Works Yukon Economic Development Yukon Energy, Mines and Resources Yukon Government Climate Change Secretariat Yukon Health and Social Services Yukon Land Use Planning Council
Government of Canada Environment Canada Canadian Northern Economic Development Agency (CanNor) Natural Resources Canada	**Other Interested or Influential Groups** Local Residents of Village of Haines Junction and surrounding area Alsek Renewable Resource Council General Public Media MLAs MPs

4.2 YESAA Stakeholder Consultation Requirements and Processes

Section 50(3) of the *Yukon Environmental and Socio-Economic Assessment Act* ("YESAA") states the following with respect to both First Nations and stakeholder consultation requirements:

> Before submitting a proposal to the Executive Committee, the proponent of a project shall consult any first nation in whose territory, or the residents of any community in which, the project will be located or might have significant environmental or social economic effects.

Section 3 of YESAA states:

> Where, in relation to any matter, a reference is made in this Act to consultation, the duty to consult shall be exercised
>
> (a) by providing, to the party to be consulted,
>
> (i) notice of the matter in sufficient form and detail to allow the party to prepare its views on the matter,
>
> (ii) a reasonable period for the party to prepare its views, and
>
> (iii) an opportunity to present its views to the party having the duty to consult; and
>
> (b) by considering, fully and fairly, any views so presented.

Under YESAA, the amount of public participation and engagement required varies significantly depending on the type of assessment. Public participation is significantly greater in an Executive Committee screening scenario when compared to the level of participation required for a Designated Office evaluation. Scale of the project, the environmental sensitivity to the type of development, and level of public concerns also may dictate the degree of public participation required.

When reviewing the project proposal, the Yukon Environmental and Socio-economic Assessment Board (YESAB), will be most concerned that :

- Adequate consultation was conducted with all stakeholders
- The project team listened, fully and fairly considered, and responded to the issues raised during the consultation
- The project team made adjustments to the planning process or the project proposal as a result of the consultation where appropriate

Following submission of the Project Proposal, YESAB will conduct their formal First Nation and public consultation review process. During that process, the project team may be asked to respond to queries or concerns. The project team will continue meetings with all stakeholders and First Nation groups on ongoing issues as appropriate and public meetings may be held to provide further opportunities for participation.

5 ENGAGEMENT WITH FIRST NATIONS

The project will be located entirely within the traditional territory of the CAFN and they are the primary First Nations that will be engaged with regard to the Project. As they are a project partner it is likely that engagement with the CAFN community and leadership will take place in an ongoing fashion, with regular meetings and information updates to assess ongoing CAFN community support and to deepen the understanding of potential CAFN concerns. Dedicated presentations for CAFN members only (possibly in the various CAFN communities outside of Haines Junction) may also be held to encourage feedback and to ensure support.

While it is unlikely that the project will have an effect on the traditional territories of other First Nations, there is potential that the following First Nations and First Nations associations may express some interest in the Project and may request information:

- Carcross/Tagish First Nation
- Council of Yukon First Nations – Natural Resources and Environment
- Kluane First Nation
- Kwanlin Dun First Nation
- Little Salmon Carmacks First Nation
- Ta'an Kwäch'än Council
- White River First Nation

Letters introducing the project and project partners may be sent to those First Nations that express interest (or are likely to have an interest) in the Project. Meetings and/or follow-up phone calls may be necessary. A record of all communications and communication attempts will be maintained. The majority of communication with interested First Nations groups should be by letter or, alternatively, the details of verbal communications should be confirmed by letter to maintain an accurate record.

5.1 YESAA First Nations Consultation Requirements

YESAA, Section 50(3) states the following with respect to First Nations consultation:

> Before submitting a proposal to the Executive Committee, the proponent of a project shall consult any first nation in whose territory, or the residents of any community in which, the project will be located or might have significant environmental or social economic effects.

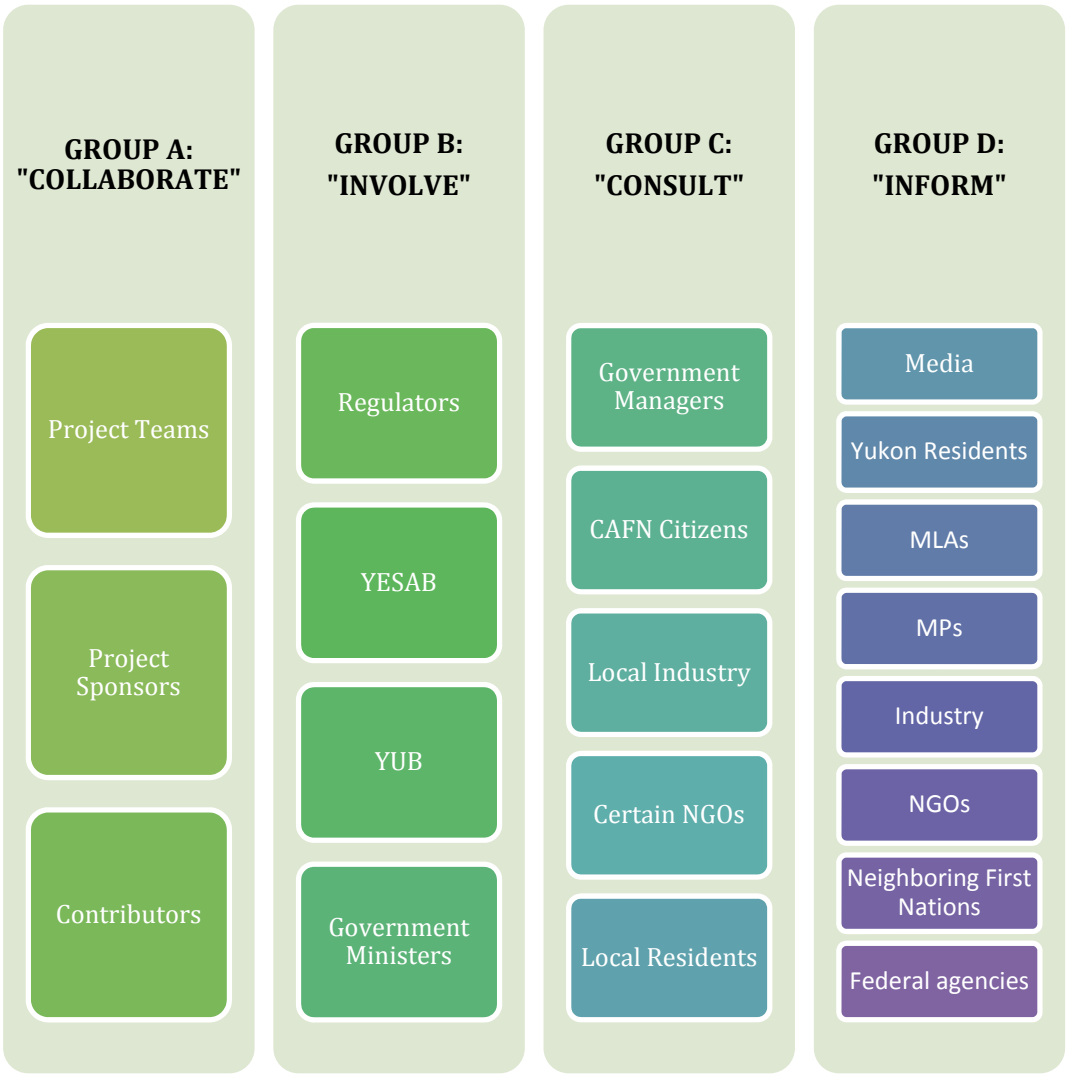
Under YESAA the knowledge and views of Yukon First Nations and their citizens will be sought out by regulators. Notification will be sent to all First Nations whose territory the project may be located on or where the project might have significant environmental or socio-economic effects. Renewable Resource Councils, Yukon Fish and Wildife Management Board and Salmon Sub-Committee will be notified if the Project may have environmental or socio-economic effects on areas or wildlife within their mandate. First Nations will have the opportunity to participate and share their views and information during the comment period for the assessment. YESAA also provides opportunities for

incorporation of traditional knowledge into the assessment of the Project and that traditional knowledge is a factor that must be considered and incorporated into the assessment.

6 LEVEL OF ENGAGEMENT AND PARTICIPATION

The level of engagement and participation in the Project by First Nations communities and stakeholders can be grouped as follows:

Figure 6.1: Engagement and Participation Levels



The following table describes the different stakeholder audiences, their projected engagement level, potential methods of engagement (this table will be updated and amended as needed)

Table 6.1: Audiences and Engagement Levels

Group	Engagement Level	Description	Audiences				
A	COLLABORATE	Stakeholders that are responsible for driving the Project (e.g. Project Sponsors, Project Management, Deputy Project Manager, Project Steering Committee, Project Contributors)	CAFN Dakwakada Development Corporation Yukon Energy Yukon Research Centre Cold Climate Innovation Village of Haines Junction				
B	INVOLVE	Stakeholders who have a high-level of engagement with the Project and are involved in the decision-making process	YESAB YUB Yukon Executive Council Office First Nation regulatory agencies(?) Government Ministers? Natural Resources Canada				
C	CONSULT	Stakeholders who need to have a good understanding of the Project and will be invited to provide input at critical points (e.g. Federal, Territorial, and FN Resource Management Agencies, FN citizens and local residents, industry, land users and owners, planning groups and committees, NGOs, ENGO)	CAFN citizens CAFN Resource Management Agencies Local Residents of Village of Haines Junction and surrounding area Potentially affected local land users and representative organizations Trappers Guide Outfitters Hunters (?) Nongovernmental Organizations Yukon Conservation Society		Territorial Government Resource Management Agencies Environment Yukon Yukon Highways and Public Works Yukon Energy, Mines and Resources Government of Canada Resource Management Agencies Canadian Northern Economic Development Agency (CanNor) Alsek Renewable Resource Council		
D	INFORM	Stakeholders who require a broad level of awareness of the project Stakeholders who may be influential or important	Yukon Residents Media MLAs MPs Research and Academic Yukon College, Northern Research Institute	Industry and Industry Associations Arctic Inland Building Products Dimok Timber Ltd. 7 ENGAGEMENT PROCESSES AND TIMELINES

The following table provides a list of key dates, events, techniques and audiences:

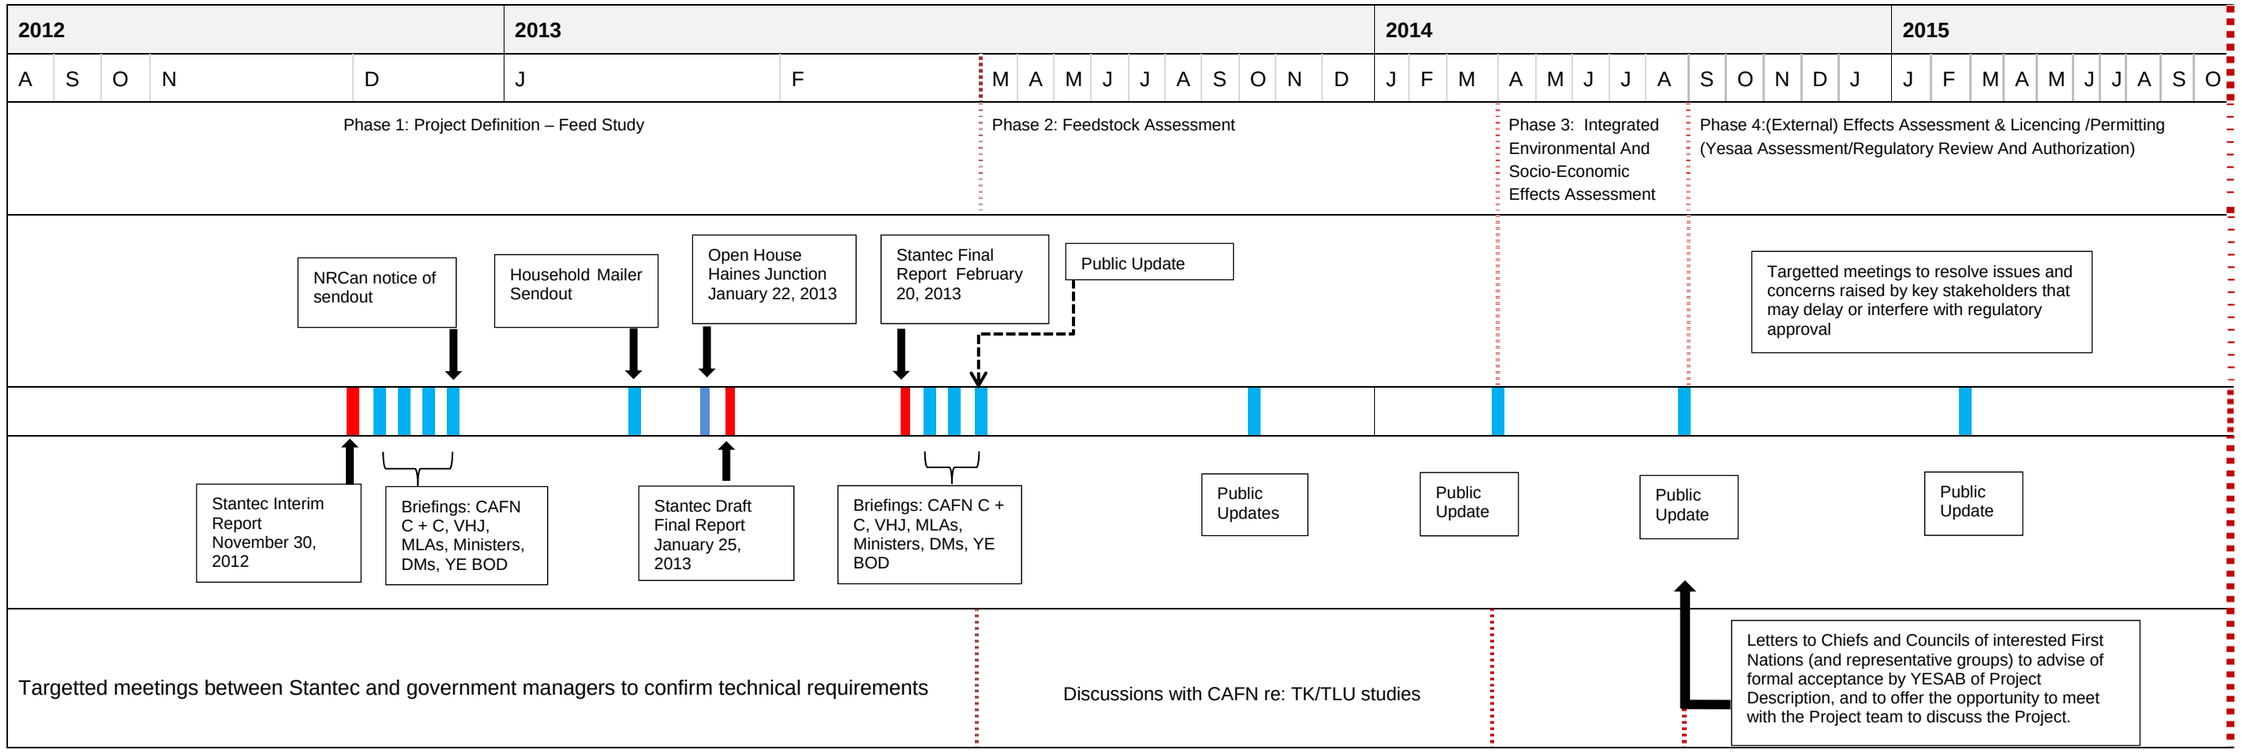
Table 7.1: Key Dates, Events and Audiences

Phase	Date	Event and Techniques	Key Audiences
PHASE 1	**AUGUST 2012 – MARCH 2013 BIOMASS TECHNOLOGY RESEARCH AND FEASIBILITY STUDY**		
	November 30, 2012 Stantec - Final Interim Report		
	Late November – December 2012	Briefings on Project Progress • Face to face meetings and targetted correspondence • Targetted meetings between government managers and Stantec to confirm technical requirements such as code requirements	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors Government managers
	November 30, 2012	• Newsletter Complete	All
	December 13, 2012	• Final proofs to Aasman for design and printing	n/a
	Mid-January 2013	• Newsletter mailout sent to Haines Junction area residents. Information also posted on various websites. Key Messages: • Project is in early stages – here's what is happening • Build awareness of Project and progress • Project Team is looking for input on how stakeholders want to be consulted moving forward and their issues and concerns	CAFN citizens, Haines Junction area residents, Stakeholders, General public
	January 25, 2013 Stantec Submits Draft of Final Report		
	January 22, 2013 5:30 p.m Da Ku Cultural Centre Haines Junction	Open House in Haines Junction • Build awareness and support for Project • Confirm/add to list of those interested in participating in engagement opportunities and receiving information • Confirm location preferences among stakeholders and community	CAFN citizens, Haines Junction area residents, Interested stakeholders, General public Key regulatory agencies should also be notified of the open houses via email, and invited to attend.
	February 20, 2013 ***** Stantec Submits Final Report *********		
	Late February 2013	Briefings on Project Progress and Final Report results • Face to face meetings and targetted correspondence	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors
**** DECISION POINT ****			
	Spring 2013	Communication update to key stakeholders and the public • Email/targeted correspondence Provide updated information on Project progress (on website etc.) • Methods of communication and messages can be determined based on final report (i.e. is this project a go or no go at this point).	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
PHASE 2	**2013/2014 FEEDSTOCK ASSESSMENT**		
	Fall 2013	Communication update to key stakeholders and the public • Email/targeted correspondence Provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public

Section 7: Engagement Processes and Timelines

**** DECISION POINT ****			
PHASE 3	**2014 INTEGRATED ENVIRONMENTAL AND SOCIO-ECONOMIC EFFECTS ASSESSMENT**		
	Spring 2014	Communication with CAFN regarding traditional knowledge and traditional land use studies + capacity support. Communication update to key stakeholders and the public (email/targeted correspondence, provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
**** DECISION POINT ****			
PHASE 4	**2014 – 2016 (EXTERNAL) EFFECTS ASSESSMENT & LICENCING /PERMITTING (YESAA ASSESSMENT/REGULATORY REVIEW AND AUTHORIZATION)**		
	Fall 2014	Communication update to key stakeholders and the public. • email/targeted correspondence and provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
	Spring 2015	Communication update to key stakeholders and the public • email/targeted correspondence and provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
	Fall 2015	• Communication update to key stakeholders and the public • Email/targeted correspondence • Face to face meetings or written correspondence to address specific issues and respond to queries and concerns that resut from the formal review process • Public meetings as required • Updated information on Project progress on website etc.	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
PHASE 5	**2016 DETAILED DESIGN AND TENDERING**		
	Spring 2016	Communication update to key stakeholders and the public • Email/targeted correspondence • Provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
**** DECISION POINT ****			
PHASE 6	**2016+ CONSTRUCTION**		
	Fall 2016	Communication update to key stakeholders and public • email/targeted correspondence, provide updated information on Project progress	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
	Spring 2017	Communication update to key stakeholders and public • email/targeted correspondence and provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
PHASE 7	**2016 + OPERATIONS**		
	Fall 2017	Communication update to key stakeholders and public • email/targeted correspondence and provide updated information on Project progress (on website etc.)	CAFN Chief and Council, Village of Haines Junction Mayor and Council, Kluane MLA, Ministers and DMs of Energy, Mines & Resources and Economic Development, Yukon Energy Board of Directors, CAFN citizens, Haines Junction area residents, General public
PHASE 8	**DECOMMISSIONING**		

Figure 7.1: Engagement Timelines



8 ENGAGEMENT METHODS

The following are techniques that may be used by the Project team to engage First Nations, stakeholders and the general public:

- Letters and email correspondence
- Face to face meetings
- Workshops and open houses
- Project information sheets and posters (distribute to local government offices, libraries, local recreational centres, community bulletin boards, schools, First Nation band offices
- Radio and television advertisements
- Media interviews
- Website and social media
- Advertisements in community newspapers

To cultivate relationships with First Nations and key stakeholders that have an active interest in the Project, meetings will be held to provide updates on the Project, discuss planned work, listen to concerns and assess areas of interest. The Project Team may also choose, where appropriate, to engage with particular First Nations and stakeholder groups in planning and conducting specific Project tasks.

8.1 Recording Communications

All feedback from First Nations and stakeholders will be tracked in a shared information management system (“Smartsheet”). Where follow-up communication is required, the responsibility for that communication will be clearly assigned to an individual and the name of the person who followed up will be recorded, along with when the communication happened, how it happened (e.g. email, telephone), and a brief description of the content of conversation/communication. Speeches and presentations will be documented in a similar manner; the identities of those who attended the event and the nature of feedback received will be documented. Where follow-up communication is required after the presentation or speech then the details of that communication will be documented and tracked.

Information on communications activities will be available on demand and the data will be regularly updated. Stantec recommendeds that a communications log modelled on the template found in Appendix B be used when documenting communications with First Nations, key stakeholders and the general public. The communications log should be accessible either by all members of the Project team so they are able to add their own data as they carry out engagement activities, or alternatively, by selected team members with responsibility for adding the information. Note that regular backing up and protection of engagement log contents from accidental deletion is essential. Stantec has agreed that it will be responsible for maintaining the log until January 30, 2013.

A “Record of Contact” form may also be used by team members to standardize recording of communications. A template for that form is attached as Appendix B.

8.2 Documenting Issues and Concerns

Issues may be recorded using a table similar to the following (new columns can be added where appropriate):

Table 8.1: Example Issue Log

Primary Issue	Potential Responses/Mitigations

8.3 Scheduled Meetings

Scheduled/completed meetings for the project are as follows (to be completed as dates are known):

Table 8.2: Meetings

Location	Date	Venue	Address

DRAFT

8.4 Open Houses

8.4.1 Timing

An introductory open house will be held in Haines Junction on January30, 2013 to introduce the Project, generate interest and inform First Nations citizens (particularly CAFN citizens), stakeholders and the general public. The following table will be revised as venues and dates are confirmed:

Table 8.3: Open Houses

Location	Date	Venue	Address
Haines Junction	January 22, 2013 (date moved to January 23, 2012 due to death of CAFN elder)	Da Ku Cultural Centre	280 Alaska Highway Haines Junction

8.4.2 Format and Materials

Project open houses will be staffed by members of the Project team, and potentially by representatives of the Project partners and Project consultants. Project representatives will be on hand to speak with attendees, present information, and answer questions from attendees.

Team members staffing the open house should discretely record comments, questions, and concerns from those in attendance on simple notepads when it is convenient. That information can then be transcribed into a more standardized record of contact form (see Appendix B for a record of contact form template) at a later date. We recommend that Team members not fill out forms while actually speaking to attendees.

Poster boards laid out within the venue can provide key information on aspects of the Project and Project Partners, preferred locations, preliminary designs, regulatory processes, potential interactions with the environment, key studies to be carried out and next steps.

The structure of the open houses should allow members of the public in attendance to speak with project representatives with expertise in particular subject areas of interest. Attending project team members should represent a wide range of technical expertise so that detailed and/or technical questions can be answered in person, wherever possible. This will reduce the need for follow-up communications and increase the likelihood that the open house will lead to greater understanding of the Project and spread of reliable and correct information throughout the community by attendees.

Materials required will include:

- Project information sheets
- Sign-up sheets
- Comments cards

Stantec recommends the use of draw prizes or other incentives at open houses. Prizes can enhance interest, boost attendance, encourage attendees to provide contact information, and increase the likelihood that attendees will stay longer and provide more comments and questions.

8.4.3 Recording Attendance

A “welcome” table will be placed inside the entrance of each open house and will be staffed by Project team members who are responsible for tracking attendance. Attendees will be asked to sign in and provide email addresses or other contact information (so that they can be added to Project newsletter, information mailing list etc.). Signing in should not be required, however. Project team members should also maintain an overall head count of all attendees and keep a record of total attendance.

DRAFT

9 ENGAGEMENT PERFORMANCE MEASURES

The Project's engagement processes should be evaluated using both objective and subjective measures. Relevant measures include the following:

- Number of specific meetings, open houses and other engagement sessions with interested First Nations, key stakeholders and representative local organizations (e.g. non-profit organizations, advocacy groups)
- Website traffic statistics (e.g. number of visits, frequency, duration, etc.)
- Quantity and quality of dialogue generated (letters, comments, discussion on project website and external discussions)
- Number of public events held and attendance level at those events, presentations or workshops provided, inquiries received concerning the Project, brochures/flyers distributed, subscribers to website and/or newsletter, articles or columns in local newspapers, radio/tv spots, and radio/tv interviews

These statistics should be tabulated and included in the Project reporting, along with other indicators as part of the summary of engagement necessary for any future project proposal for assessment pursuant to YESAA

The material herein reflects Stantec's professional judgment given the information available to Stantec at the time of preparation.

ASSUMPTIONS - OPTION 1 (0.5 MW)

INPUT IN SHADED CELLS ONLY yellow cells indicate awaiting final numbers from engineering

CAPITAL:

District heating, installed cost		*not included*
Biomass plant, installed cost	$6,307,949	
Total plant etc.	$6,307,949	*see 'Capital Costs' worksheet*
ORC	$194,235	
Feedstock yard		
Land	$0	*see 'Capital Costs' worksheet*
Buildings	$2,983,204	*see 'Capital Costs' worksheet*
Equipment	$2,278,988	*see 'Capital Costs' worksheet*
Total capital requirement	$11,764,376	
Capital renewal - annual rate		
Plant	4.0%	*% of original capex, starting in year 4 - assume 25 year life*
Buildings	2.0%	*% of original capex, starting in year 4 - assume 50 year life*
Equipment	6.0%	*% of original capex, starting in year 4 - assume 15 year life*

OPERATING:

Revenues

Total annual sales - kWh	3,504,000	*500kWe, 80% availability*
Electricity selling price - $/kWh	$0.200	per CAFN (Ray)
ORC Electricity sales - kWh	258361	*@ 8% of remaining heat*
District heat annual sales - kWh	1,283,645	*Revised DE Network*
Heat selling price - $/kWh	$0.185	*per CTCG*
Government subsidies - $/kWh	$0.00	

Expenses

O&M expenses - plant - $ / kWh		
O&M expenses - yard - $ / kWh		
O&M expenses - district heat - $	$37,000	*per CTCG*
O&M ORC	$5,938	*per CTCG*
O&M Plant	$242,000	*per FEED report*
Feedstock - $/tonne	$50.40	*per FEED report*

Production factor - tonnes/kWh	0.00086		*1 kg (.001 tonne) per hour = 1 kWh*
Fuel cost per kWh	$0.04		
Amortization (CCA) - annual rate			
Plant	50.0%		*Accelerated CCA class 43.2, see below*
Buildings	4.0%		*CCA class 1*
Equipment	30.0%		*CCA class 43*
Income tax - combined rate	35.0%		
FINANCIAL:			
Grant money	67%	$7,882,132	
Capitalization			
Debt %	70%	$2,717,571	per CAFN (Ray)
Equity %	30%	$1,164,673	per CAFN (Ray)
Total capital funding		$11,764,376	ok
Ownership			
CAFN	60%	$698,804	per CAFN (Ray)
Yukon Energy	30%	$349,402	per CAFN (Ray)
Village of Haines Junction	10%	$116,467	per CAFN (Ray)
	100%	$1,164,673	
Long term debt			
Interest rate	5.0%		
Debt term, in years	20		
ROI requirements - after tax			
CAFN	15%		per CAFN (Ray)
Yukon Energy	15%		per CAFN (Ray)
Village of Haines Junction	15%		per CAFN (Ray)
WACC - after tax	8.00%		
Annual inflation rate	3.0%		*assumes same rate for both operating and capital expenditures*
Terminal (perpetuity) value multiple	20.0		*Terminal Value = FCF (yr 20)/(WACC – growth rate) : assumes growth rate = inflation rate*
Feedstock inflation rate	1%

Accelerated CCA for Clean Energy Generation

Class 43.2 was introduced in 2005 and is currently available for assets acquired on or after February 23, 2005 and before 2020. For assets acquired before February 23, 2005, accelerated CCA is provided under Class 43.1 (30 per cent). The eligibility criteria for these two classes are generally the same, except that cogeneration systems that use fossil fuels must meet a higher efficiency standard for Class 43.2 than for Class 43.1. Systems that only meet the lower efficiency standard are eligible for Class 43.1.

Class 43.2 includes a variety of stationary clean energy generation or conservation equipment that is used to produce electricity or thermal energy, or used to produce certain fuels from waste that are in turn used to produce electricity or thermal energy. Subject to detailed rules in the regulations, eligible equipment includes:

ELECTRICITY

- High efficiency cogeneration equipment;
- Wind turbines;
- Small hydroelectric facilities;
- Fuel cells;
- Photovoltaic equipment;
- Wave and tidal power equipment;
- Equipment that generates electricity using geothermal energy; and
- Equipment that generates electricity using an eligible waste fuel.

THERMAL ENERGY

- Active solar equipment;
- Ground source heat pump equipment;
- District energy equipment that distributes thermal energy from cogeneration;
- Equipment that generates heat for an industrial process or a greenhouse using an eligible waste fuel; and
- Heat recovery equipment used in electricity generation and industrial processes.

FUELS FROM WASTE

- Equipment that recovers landfill gas or digester gas;
- Equipment used to convert biomass into bio-oil; and
- Equipment used to produce biogas through anaerobic digestion.

If the majority of tangible property in a project is eligible for inclusion in Class 43.2, then certain intangible project start-up expenses (for example, engineering and design work and feasibility studies) are treated as Canadian Renewable and Conservation Expenses. These expenses may be deducted in full in the year incurred, carried forward indefinitely for use in future years, or transferred to investors using flow-through shares.

Budget 2010 proposes to expand Class 43.2 to include: (a) heat recovery equipment used i a broader range of applications; and (b) distribution equipment used in district energy systems that rely primarily on ground source heat pumps, active solar systems or heat recovery equipment.

Accelerated CCA for Clean Energy Generation

Class 43.2 was introduced in 2005 and is currently available for assets acquired on or after February 23, 2005 and before 2020. For assets acquired before February 23, 2005, accelerated CCA is provided under Class 43.1 (30 per cent). The eligibility criteria for these two classes are generally the same, except that cogeneration systems that use fossil fuels must meet a higher efficiency standard for Class 43.2 than for Class 43.1. Systems that only meet the lower efficiency standard are eligible for Class 43.1.

Class 43.2 includes a variety of stationary clean energy generation or conservation equipment that is used to produce electricity or thermal energy, or used to produce certain fuels from waste that are in turn used to produce electricity or thermal energy. Subject to detailed rules in the regulations, eligible equipment includes:

ELECTRICITY

- High efficiency cogeneration equipment;
- Wind turbines;
- Small hydroelectric facilities;
- Fuel cells;
- Photovoltaic equipment;
- Wave and tidal power equipment;
- Equipment that generates electricity using geothermal energy; and
- Equipment that generates electricity using an eligible waste fuel.

THERMAL ENERGY

- Active solar equipment;
- Ground source heat pump equipment;
- District energy equipment that distributes thermal energy from cogeneration;
- Equipment that generates heat for an industrial process or a greenhouse using an eligible waste fuel; and
- Heat recovery equipment used in electricity generation and industrial processes.

FUELS FROM WASTE

- Equipment that recovers landfill gas or digester gas;
- Equipment used to convert biomass into bio-oil; and
- Equipment used to produce biogas through anaerobic digestion.

If the majority of tangible property in a project is eligible for inclusion in Class 43.2, then certain intangible project start-up expenses (for example, engineering and design work and feasibility studies) are treated as Canadian Renewable and Conservation Expenses. These expenses may be deducted in full in the year incurred, carried forward indefinitely for use in future years, or transferred to investors using flow-through shares.

Budget 2010 proposes to expand Class 43.2 to include: (a) heat recovery equipment used i a broader range of applications; and (b) distribution equipment used in district energy systems that rely primarily on ground source heat pumps, active solar systems or heat recovery equipment.

Accelerated CCA for Clean Energy Generation

Class 43.2 was introduced in 2005 and is currently available for assets acquired on or after February 23, 2005 and before 2020. For assets acquired before February 23, 2005, accelerated CCA is provided under Class 43.1 (30 per cent). The eligibility criteria for these two classes are generally the same, except that cogeneration systems that use fossil fuels must meet a higher efficiency standard for Class 43.2 than for Class 43.1. Systems that only meet the lower efficiency standard are eligible for Class 43.1.

Class 43.2 includes a variety of stationary clean energy generation or conservation equipment that is used to produce electricity or thermal energy, or used to produce certain fuels from waste that are in turn used to produce electricity or thermal energy. Subject to detailed rules in the regulations, eligible equipment includes:

ELECTRICITY

- High efficiency cogeneration equipment;
- Wind turbines;
- Small hydroelectric facilities;
- Fuel cells;
- Photovoltaic equipment;
- Wave and tidal power equipment;
- Equipment that generates electricity using geothermal energy; and
- Equipment that generates electricity using an eligible waste fuel.

THERMAL ENERGY

- Active solar equipment;
- Ground source heat pump equipment;
- District energy equipment that distributes thermal energy from cogeneration;
- Equipment that generates heat for an industrial process or a greenhouse using an eligible waste fuel; and
- Heat recovery equipment used in electricity generation and industrial processes.

FUELS FROM WASTE

- Equipment that recovers landfill gas or digester gas;
- Equipment used to convert biomass into bio-oil; and
- Equipment used to produce biogas through anaerobic digestion.

If the majority of tangible property in a project is eligible for inclusion in Class 43.2, then certain intangible project start-up expenses (for example, engineering and design work and feasibility studies) are treated as Canadian Renewable and Conservation Expenses. These expenses may be deducted in full in the year incurred, carried forward indefinitely for use in future years, or transferred to investors using flow-through shares.

Budget 2010 proposes to expand Class 43.2 to include: (a) heat recovery equipment used i a broader range of applications; and (b) distribution equipment used in district energy systems that rely primarily on ground source heat pumps, active solar systems or heat recovery equipment.

Corporate income tax rates (for December 31, 2012 year ends)

General (non M&P)	M&P	CCPC		
		Active business income to $500,000		Investment income
		Non-M&P	M&P	
15 **30**	2.5 **17.5**	4 **15**	2.5 **13.5**	15 **49.67**

Figures in **bold** are combined federal/territorial rates.

Other 2012 rates

Capital tax	None
Payroll tax	
Sales tax	

Additional highlights

No additional significant corporate tax changes were announced.

Accelerated CCA for Clean Energy Generation

Class 43.2 was introduced in 2005 and is currently available for assets acquired on or after February 23, 2005 and before 2020. For assets acquired before February 23, 2005, accelerated CCA is provided under Class 43.1 (30 per cent). The eligibility criteria for these two classes are generally the same, except that cogeneration systems that use fossil fuels must meet a higher efficiency standard for Class 43.2 than for Class 43.1. Systems that only meet the lower efficiency standard are eligible for Class 43.1.

Class 43.2 includes a variety of stationary clean energy generation or conservation equipment that is used to produce electricity or thermal energy, or used to produce certain fuels from waste that are in turn used to produce electricity or thermal energy. Subject to detailed rules in the regulations, eligible equipment includes:

ELECTRICITY

- High efficiency cogeneration equipment;
- Wind turbines;
- Small hydroelectric facilities;
- Fuel cells;
- Photovoltaic equipment;
- Wave and tidal power equipment;
- Equipment that generates electricity using geothermal energy; and
- Equipment that generates electricity using an eligible waste fuel.

THERMAL ENERGY

- Active solar equipment;
- Ground source heat pump equipment;
- District energy equipment that distributes thermal energy from cogeneration;
- Equipment that generates heat for an industrial process or a greenhouse using an eligible waste fuel; and
- Heat recovery equipment used in electricity generation and industrial processes.

FUELS FROM WASTE

- Equipment that recovers landfill gas or digester gas;
- Equipment used to convert biomass into bio-oil; and
- Equipment used to produce biogas through anaerobic digestion.

If the majority of tangible property in a project is eligible for inclusion in Class 43.2, then certain intangible project start-up expenses (for example, engineering and design work and feasibility studies) are treated as Canadian Renewable and Conservation Expenses. These expenses may be deducted in full in the year incurred, carried forward indefinitely for use in future years, or transferred to investors using flow-through shares.

Budget 2010 proposes to expand Class 43.2 to include: (a) heat recovery equipment used i a broader range of applications; and (b) distribution equipment used in district energy systems that rely primarily on ground source heat pumps, active solar systems or heat recovery equipment.

ASSUMPTIONS - OPTION 9 (0.5 MW)

INPUT IN SHADED CELLS ONLY yellow cells indicate awaiting final numbers from engineering

CAPITAL:

District heating, installed cost		*not included*
Biomass plant, installed cost	$2,836,094	
Total plant etc.	$2,836,094	*see 'Capital Costs' worksheet*
ORC	$194,235	
Feedstock yard		
Land	$0	*see 'Capital Costs' worksheet*
Buildings	$2,128,742	*see 'Capital Costs' worksheet*
Equipment	$2,299,974	*see 'Capital Costs' worksheet*
Total capital requirement	$7,459,045	
Capital renewal - annual rate		
Plant	4.0%	*% of original capex, starting in year 4 - assume 25 year life*
Buildings	2.0%	*% of original capex, starting in year 4 - assume 50 year life*
Equipment	6.0%	*% of original capex, starting in year 4 - assume 15 year life*

OPERATING:

Revenues

Total annual sales - kWh	4,051,500	*500kWe, 92.5% availability*
Electricity selling price - $/kWh	$0.200	*per CAFN (Ray)*
ORC Electricity sales - kWh	329036	*@ 8% of remaining heat*
District heat annual sales - kWh	1,283,645	*Revised DE Network*
Heat selling price - $/kWh	$0.185	*per CTCG*
Government subsidies - $/kWh	$0.00	

Expenses

O&M expenses - plant - $ / kWh		
O&M expenses - yard - $ / kWh		
O&M expenses - district heat - $	$37,000	*per CTCG*
O&M ORC	$6,468	*per CTCG*
O&M plant	$242,000	*per FEED report*
Feedstock - $/tonne	$50.40	*per FEED report*

Production factor - tonnes/kWh	0.00086		*1 kg (.001 tonne) per hour = 1 kWh*	
Fuel cost per kWh	$0.04			
Amortization (CCA) - annual rate				
Plant	50.0%		*Accelerated CCA class 43.2, see below*	
Buildings	4.0%		*CCA class 1*	
Equipment	30.0%		*CCA class 43*	
Income tax - combined rate	35.0%			
FINANCIAL:				
Grant money	67%	$4,997,560		
Capitalization				
Debt %	70%	$1,723,039	per CAFN (Ray)	
Equity %	30%	$738,445	per CAFN (Ray)	
Total capital funding		$7,459,045	ok	
Ownership				
CAFN	60%	$443,067	per CAFN (Ray)	
Yukon Energy	30%	$221,534	per CAFN (Ray)	
Village of Haines Junction	10%	$73,845	per CAFN (Ray)	
	100%	$738,445		
Long term debt				
Interest rate	5.0%			
Debt term, in years	20			
ROI requirements - after tax				
CAFN	15%		per CAFN (Ray)	
Yukon Energy	15%		per CAFN (Ray)	
Village of Haines Junction	15%		per CAFN (Ray)	
WACC - after tax	8.00%			
Annual inflation rate	3.0%		*assumes same rate for both operating and capital expenditures*	
Terminal (perpetuity) value multiple	20.0		*Terminal Value = FCF (yr 20)/(WACC – growth rate) : assumes growth rate = inflation rate*	
Feedstock inflation rate	1%

EXECUTIVE SUMMARY

Yukon Energy Corporation (YEC) is studying the viability of developing a biogas plant to treat Whitehorse residential and commercial source separated organic (SSO) waste and utilize the biogas to produce power and/or heat. Biogas production is placed in the context of a large effort to expand electrical generation capacity in Yukon. Anaerobic digestion is a process to convert organic waste into a gas for the production of clean energy.

YEC hired Electrigaz/WSP to prepare a preliminary design of a biogas plant for Whitehorse organic waste and to assess its economic viability. The design is based on Whitehorse data and previous reports but also on analysis results that Electrigaz/WSP obtained from a sampling campaign conducted in May, September and October 2015.

Whitehorse residential organic waste has been collected and composted for several years. The following curve shows the seasonality of organic waste and municipal solid waste (MSW) being collected from 2000 to 2013.

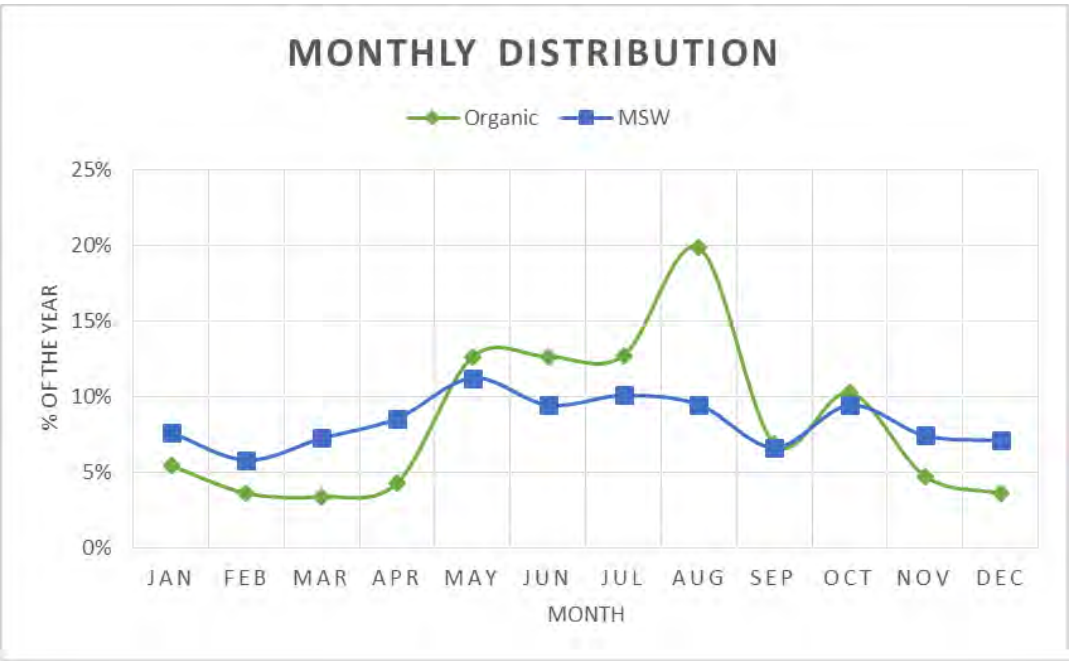

Figure 1 Monthly variation of waste quantities collected

Commercial organic waste collection has been initiated recently in Whitehorse and is being expanded to include additional local businesses. The municipality is also expecting an increase in the quantity of material collected by residential and commercial clients over the next few years. The following curve shows the expected organic waste amounts collected for the next 20 years.

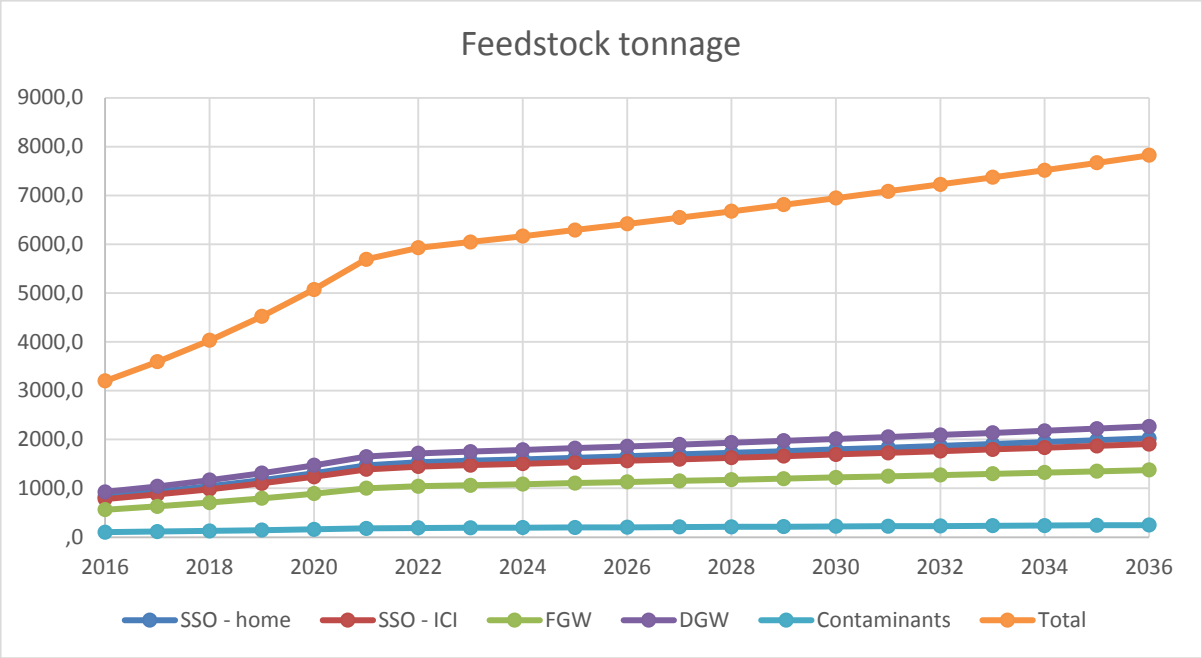

Figure 2 Amount of organic waste collected (2016-2036)

Because of waste volumes and the existing composting platform/equipment, a dry (high solids) garage style anaerobic digester is recommended because it is simple to operate, affordable, uses or discharges virtually no water and requires no front-end contaminant removal (performed by compost sieving) at the Whitehorse compost facility. To reduce unnecessary investment, operational cost and to avoid noise and odor nuisance to neighbouring properties, the proposed plant would be located at the landfill next to the existing composting site.

The proposed biogas plant rated at approximately 150 kW(e) would be composed mainly of a building that includes four anaerobic digestion tunnels and a reception/mixing hall. The combined heat and power (CHP) unit, flare, biofilter and percolate tank are to be placed adjacent to the building. The operation of the plant would be based on a 28-day schedule and the material will be received and stored inside a receiving hall 7 days before entering a garage. In a garage-style digester the material is moved with a front-end loader and each week the operator empties part of the garage before filling with fresh material. The digestate is then sent to the compost facility. The biogas is temporally stored in a 599 m3 biogas holder that is placed on top of the percolate tank. The biogas is then sent to two (2) 100 kW(e) CHP units for production of renewable power and hot water. Two smaller generators are necessary to match significant seasonal biogas production variations, a larger unit could not accommodate these significant "turndowns".

The scenario for production and sale of heat, in the form of hot water, generated by a 500 HP biogas boiler is not recommended because of the cost of deploying a district heating network over to the nearest client for minimum of three (3) kilometers and the heat production being "out of phase" with heating needs (peaking in winter) and biogas production (peaking in summer).

For a "heat only" project to be viable it would have to significantly raise the organic treatment gate fee, gather important capital subsidies and sell 100% of the heat produced during winter and summer months. The following table shows the levelized cost of energy (heat) for different organic treatment gates fees and capital subsidy support.

Table 1 Boiler scenario: financial analysis

Gate fees $/ton	Subsidy % of CAPEX	Lcoe (real) $/ kWh(th)	Lcoe (real) $/GJ
38	0%	0.227	62.996
38	70%	0.085	23.488
45	0%	0.203	56.405
45	60%	0.081	22.541
50	0%	0.186	51.697
50	40%	0.105	29.121

This scenario, estimated at approximately $6.1M, is unlikely to attract industrial clients (green houses, industrial thermal processes, etc.) because energy prices are not discounted significantly. The utilization of biogas in CHP units is better adapted to this location since it allows selling of energy in the summer and during power demand peaks. The deployment of CHP units would be phased in with one 100 kW unit installed initially and a second 100 kW unit (or more if landfill gas is exploited) 5 years later. It is assumed that the heat generated by the CHP would be used entirely at the composting building to heat the facility and potentially dry further the compost before bagging it.

The CHP project is estimated to require a total capital investment of approximately C$7.1M and to cost over $255,000 per year to operate.

The revenue from the biogas plant will come from gate fees, electricity and heat sales. With a current market pricing of $0.21/kWh for the electricity sold to the grid, a $38/t gate fee, and savings of $12/GJ for heat, the project is not economically viable. With these market conditions the project would require significant capital subsidies. The following table shows the levelized cost of energy (electricity) for different organic treatment gates fees and capital subsidy support:

Table 2 CHP scenario: financial analysis

Gate fees $/ton	Heat sales $/GJ	Subsidy % of Capex	LCOE ($/kWh(e))
38	12	0%	$0.638
38	12	70%	$0.206
45	12	0%	$0.576
45	12	50%	$0.267
50	12	0%	$0.531
50	12	40%	$0.284

Biogas captured from the landfill could potentially help boost electrical production and provide better project economics. Further study of this scenario would be needed.

Nevertheless, it is clear that this project will require organic treatment gate fee adjustment and capital investment in form of subsidies because the revenues generated by the project are insufficient to warrant the high capital investment.

Based on the current market conditions it is unlikely that the project would attract independent project developers. The project would probably have to be developed by Yukon Energy Corporation and/or the City of Whitehorse with the support of capital grants.

1 INTRODUCTION

Yukon Energy Corporation (YEC) is studying the viability of developing a biogas plant to treat Whitehorse residential and commercial source separated organic (SSO) waste and utilize the biogas to produce power and/or heat. The biogas production is placed in a large effort from YEC to expand electrical generation capacity in Yukon.

1.1 PROJECT DRIVERS

1.1.1 POLICIES

The 2009 Energy Strategy for Yukon identifies the increased use and supply of renewable energy as a priority for the Yukon government: it seeks to expand the supply of renewable energy by 20 per cent by 2020 and to update and develop a policy framework for electricity that emphasizes efficiency, conservation and renewable energy. The Strategy aims at being self-sufficient in terms of energy, using local resources, which would include biomass. On the other hand, when the Strategy refers to biomass it means wood, and does not mention biogas as an opportunity in Yukon. It gives priority to renewable energy development in diesel-powered communities, yet also mentions the hydro grid may reach its capacity in the near future. Indigenous gas (LNG) resources could, however, be used to make up for any shortfall. Yukon released a draft policy for independent power production earlier this year.

The Strategy complements the Yukon government's 2009 Climate Change Strategy and Action Plan. It mentions waste management as a specific priority and states that "the Yukon government is undertaking a study to review the administration and operations of territorial solid waste sites to assist the government with determining sustainable management practices." This study, however, although put out per RFP, was never commissioned [YG 2015c]. Although landfill emissions are identified as a major GHG emission source, it is not clear how the biogas initiative fits into the Plan, which mainly focuses on the territorial government's own emissions, as well as industrial emissions. It does have a target to reduce electricity use by demand-side management programs by 5 GWh by 2016, yet electricity production projects, as the one under consideration, are usually not seen as elements of demand management.

The Yukon government provides a number of programs to help Yukon residents, businesses, First Nations, and municipalities reduce their energy consumption and replace fossil fuels with local renewable energy resources. None of these seem applicable to the proposed project.

Yukon Energy Corporation: As a renewable energy company, YEC is exploring all potential renewable energy options. YEC is interested in harnessing biogas as an energy source and has conducted testing on organic material to assess its biogas potential in 2014 [YEC 2015]. This present report is the next step of this project, by presenting a feasibility analysis in order to determine whether the biogas project in Whitehorse could move forward.

City of Whitehorse: The city's Sustainability Plan aims at increased renewable energy, reducing GHG emissions, and operational cost savings – all reflected in the scope of the biogas project. Waste diversion and composting are mentioned as goals, but no connection is made between energy and waste. "Work with private businesses on innovative ideas in waste management" is one of the ideas mentioned as an appendix to the Plan.

Solid waste management is identified as a key element of the current 2013-2015 Council priorities on the city's website. With a goal of Zero Waste by 2040, the City's Solid Waste Action Plan sets an initial target of a 50% reduction in the amount of waste sent to landfill by 2015. Sixty two percent (62%) of the waste

landfilled comes from the institutional, commercial, and industrial sectors. In year 2015, landfill disposal rates for businesses are [CoW 2015]:

- Unsorted waste: $ 250/ton (food service businesses only)
- Sorted waste free of organics: $ 94/ton
- Organic waste (separated): $ 36/ton

On June 1st, 2015, the City of Whitehorse enacted the first phase of the commercial organic waste management bylaw, which bans organic waste (food scraps, compostable paper and packaging, food soiled cardboard and waxed cardboard) from disposal as garbage from Food Service Businesses. These businesses now have to pay a much higher disposal rate for unsorted waste containing organics. The city's Sewer and Storm Bylaw requires all commercial, industrial and institutional food facilities to dispose of fats, oils and grease properly and to install and maintain a proper grease interceptor (grease trap) to appropriate plumbing fixtures. Such fat would be a valuable ingredient for a digester. The City's commercial organic waste diversion efforts have diverted 96 tonnes of organics in 2013/14 and also target other commercial, institutional, and multi-family buildings. At that time, 5,700 residential homes were participating in bi-weekly organics collections [CoW 2015b].

1.1.2 ECONOMIC CONTEXT

Microgeneration Program: This program is administered by the Energy Solutions Centre and offers $0.21 per kWh of electricity fed into the grid in the Whitehorse area. It is mainly aimed at residential customers, with an upper capacity limit of 50 kW. As such, it is not suitable for the proposed project.

Carbon credits: Emission reduction projects, which reduce after-project emissions to below current baseline emission levels, can leverage the sale of carbon credits to part-finance the project. In this case, however, carbon credits are an unlikely source for financing because:

- The project is small. This means few credits would be generated and their monetization is then not cost-effective. To certify credits for sale, it is necessary to engage two consultants for emission quantification and verification. This annual process can cost more than $10,000 and is usually only employed for larger projects.
- Emission reductions will be small. The waste heat produced will likely be used on-site with a large portion being consumed to heat the digester (fermentation usually occurs at temperatures around 35°C, which requires heating). The electricity produced will also partly be used internally to operate the digester, and the amount exported to the local grid will mainly displace hydro or in the future, LNG, given that Whitehorse's electricity comes from the hydro-based Yukon Integrated System.
- Selling carbon credits means that any carbon emission reductions achieved by the project are lost to the purchaser: it is as if the credit purchaser had created these emission reductions himself and they can then no longer be claimed for the city's internal reduction targets.

IPP Policy: The draft (May 2015) independent power producer (IPP) policy identifies the proposed project as a "Tier 1" project, since it is less than 2 MW in size and would be connected to the Yukon Integrated System. A Standing Offer Program is expected to be operational by the end of 2015. Biomass (potentially including municipal SSO) is explicitly included as an eligible energy source. The proposed IPP rate for projects on the Integrated System is 21 ¢/kWh, which is the avoided cost of generations of YEC (rates will be updated every three years and posted publicly to reflect changes in the avoided cost of new generations).

Heat: Some of the waste heat produced by the biogas engines will be required to heat the digester. Surplus heat is likely too little to warrant a hot water pipeline to customers off the landfill premises. The landfill's own buildings could, however, be heated. They are currently heated with electricity and some propane for peaking purposes in the winter, as well as for backup. The forced air heating system (as opposed to replacing baseboard heaters) would simplify the use of waste heat to supplement or replace the current heating fuels. General electricity service costs (on a monthly basis) for municipal clients on the Integrated System are [YHC 2012]:

- 11.36 ¢/kWh for the first 2,000 kWh;
- 14.59 ¢/kWh for the next block up to 15,000 kWh;
- 17.72 ¢/kWh for over 15,000 up to 20,000 kWh;
- A demand charge of $8.26/kWp also applies (this could be reduced if electric heating is replaced);
- A monthly base fee of $41.28 is charged to municipal customers (not affected by project).

Although no electricity bill from the landfill was available, compiled billing data suggests the landfill consumes between 1,000 and 4,000 kWh of electricity per month [CoW 2015c], placing it into the 14.59 ¢/kWh class for its marginal electricity cost. This would then be the cost to be paid for any extra grid electricity required to operate the digester. Since the municipal government and non-governmental service rates are almost identical, no material economic impact would result if the digester would be operated by a private entity required to pay its own electricity bills.

Cooking oil: MacDonald's (and possibly, other businesses) are currently shipping used cooking oil to Alberta for processing. This occurs at considerable cost [YN 2013] and a digester could reduce this cost while producing a large amount of biogas from the material. Smaller amounts of used oil from other sources are currently either landfilled or mixed in with composting material. Some smaller operations use their own used oil to operate vehicles converted for using filtered cooking oil, or for heating [ibid.].

Financing: The Yukon Government has no particular program to provide financial incentives for renewable energy projects; their support is based on the IPP policy outlined above. Some federal programs exist that could fund or co-fund the biogas project (see Table 1). For example, the ecoENERGY program for aboriginal and northern communities offers financial support for heat and power production in northern Canada (the potential amount available is unknown since program rules are currently under revision). Note that funding programs are often not accessible to private project proponents (such as IPPs) but only to municipal or aboriginal groups.

Table 3 Support Programs for Renewable Energy Projects

Program Name	Program Authority	Eligibility
ecoENERGY for Aboriginal and Northern Communities	Aboriginal Affairs and Northern Development Canada	First Nations Municipalities
EcoAction	Environment Canada	Non-profit community groups only
Green Municipal Fund	Federation of Canadian Municipalities	Municipalities (energy projects must displace at least 40% of current energy use)
Philantropic project funding	Bullfrog Power	Contact Bullfrog for details; typical funding amount is $10,000 per project

1.2 PROJECT HISTORY

Over the years, several studies have been conducted to assess the technical feasibility of an organic waste treatment plant in Whitehorse. The first major study specific to biogas was conducted by Aecom Canada Ltd. in 2010 and the conclusion was that renewable biofuel production will help the reduction of greenhouse gas (GHG) emissions, will enhance local energy security and displace fossil fuel usage. The second major study was conducted by Morrison Hershfield in 2012; the conclusion was that the value of the electricity produced would have to be between $0.21 and $0.66 per kWh. Both studies mention the technical feasibility of the future plant and the need of a feasibility study that would evaluate the real cost.

In 2014, YEC conducted an RFI to measure market interest for supplying equipment and/or project development for this project. The RFI was for 4,000 tons per year of organic material. YEC received four complete proposals from Bio-en Power, Bioferm, Himark and Gicon. They also received two CHP proposals from 2G Cenergy and AB Energy,in 2015. The proposals can be resumed as follows:

- The Bio-en power system costs $2,608,277 +/- 20%, with a 100 kW(e) CHP unit.
- The Himark system costs $2,264,821, with a 132 kW(e) CHP unit
- The Bioferm system costs $4,037,000 USD, with two 100 kW(e) CHP units
- The Gicon system costs $7,440,727,with a 125 kW(e) CHP unit

The RFI process also provided information on:

- Modular approach to manage increases in amounts of biowaste collected
- Digester performance for each company
- Input characterization requirements
- Operation of each system
- Operation and maintenance cost

1.2.1 COMPOST MARKETS

There are two markets for the compost currently produced at the landfill: retail to residential and commercial clients, and wholesale to local farmers. The latter market is currently not yet active but could be developed in the near future. The City of Whitehorse believes that "organic" certification for the compost – expected to be achieved soon – would open up the farming market for its product, for any amounts produced that cannot be sold to the retail market.

The retail market has a volume of about 400 tons per year, with an increasing trend. The compost is well liked by local customers and so, sales have been growing over the past years. According to the city, retail sales occur at the rates and volumes shown in Table 2.

Table 4 2015 Compost Sales and Revenue

Sales Unit	Price	Annual Volume	Total Sales
20 litre bags	$5 each	1,810 bags (≈36 yd^3)	$9,065
1-9 cubic yards	$45/$yd^3$	113 yd^3	$5,085
10+ cubic yards	$25/$yd^3$	758 yd^3	$18,950
Agricultural (bulk)	$25/$yd^3$	Not yet developed	$0
TOTAL		400+ tons*	$33,100

Source: CoW 2015b
Note: Sales from January 1 through September 30. Sales end in early October.
* Assuming a bulk density of 1000 lb/yd3 [NCSU 2015

If the farming market were to take up any incremental volumes, the compost would likely be sold at the same $25/$yd^3$ price that is currently in use for larger bulk customers [CoW 2015b]. In 2014, the amount of food waste accepted for composting was 2,225 tons. This resulted in about 500 tons of compost produced. Much of the weight loss is due to lost moisture but another 500 tons are used at the landfill as cover material since the material is too contaminated with rocks, plastics, etc. to be sold [ibid.].

1.3 OBJECTIVES OF THIS STUDY

YEC hired Electrigaz/WSP to prepare a preliminary design of a biogas plant for Whitehorse organic waste and to assess the economic viability of such a project. The design is based on Whitehorse data and previous reports but also on analysis results that Electrigaz/WSP has obtained from a sampling campaign in September and October 2015.

1.4 DATA PROVIDED BY THE CLIENT

1.4.1 PROBABLE SITE

The AD system is proposed to be constructed on the Whitehorse Municipal Landfill near the actual composting site. Figure 1 is a sky view of Whitehorse and the red box is the landfill location (Figure 2).

Figure 3 Whitehorse, YK

Figure 4 Whitehorse municipal landfill (in red) and composting site (in green)

1.4.2 WHITEHORSE ORGANIC WASTE COLLECTION

The City of Whitehorse has been collecting residential and commercial SSO for several years and is currently composting this material at their composting platform located at the municipal landfill site. There are two types of collection: residential and commercial.

1.4.3 RESIDENTIAL SSO

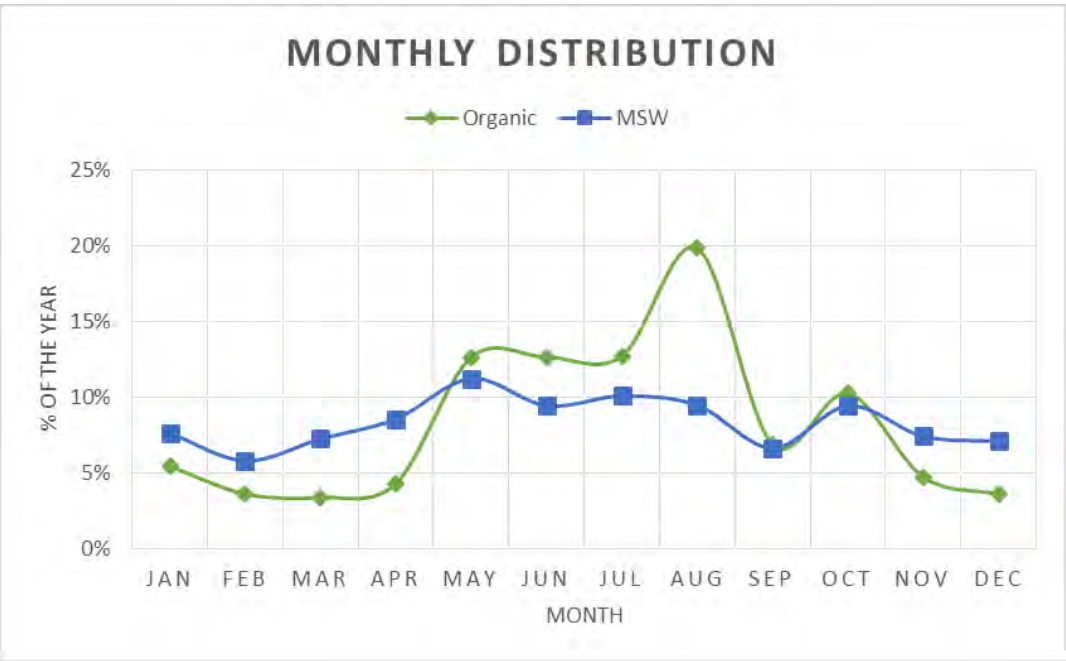
The first organic collection (residential) started in 2000 and the number of participants is growing each year. The collected amounts for organic and total waste from 2000 to 2013 are presented in Table 3. The total organic represents both the residential curbside collection and the ICI collection.

Table 5 Tons of waste collected (2000-2013)

Tons/Year	2000	2001	2002	2003	2004	2005	2006	2007	2008	2009	2010	2011	2012	2013
Total Organic	203	388	852	943	1 005	1 041	977	1 131	1 314	1 828	2 149	2 569	2 117	2 267
Total MSW	10 578	11 455	11 145	11 348	12 232	13 120	13 205	14 615	14 431	14 140	15 870	14 742	14 974	14 093
% organic/MSW	2%	3%	8%	8%	8%	8%	7%	8%	9%	13%	14%	17%	14%	16%

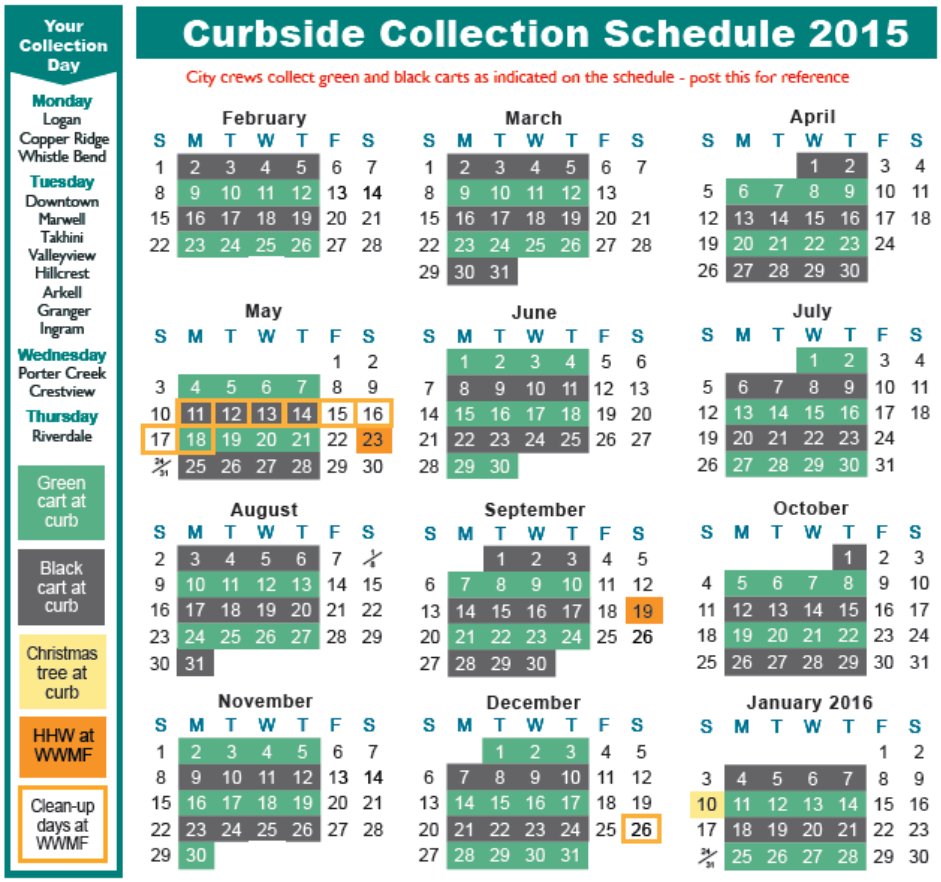
The amounts shown in Table 3 are shown on a monthly basis in the figure below, based on Whitehorse previous reports. This figure demonstrates the variation of amounts collected throughout the year, with a peak in August.

Figure 5 Monthly variation of waste quantities collected



SSO regroups all organic waste separately collected from residential sources. In Whitehorse, residential SSO has been collected for more than 10 years and the number of participants is growing each year. The SSO is collected in green bins on curbsides every two weeks (see Figure 4 for details on curbside collection).

Figure 6 Curbside Collection Schedule 2015



The SSO includes food waste like meat, fish and any dairy product but also garden waste and food soiled paper. Electrigaz/WSP separated the SSO into four different fractions to determine the gas production potential of the material in an AD:

1. Food waste (SSO)
2. Green yard waste (GYW)
3. Dry yard waste (DYW)
4. Contaminants (rocks, sand, plastic, non-organic materials)

Prior to this report, a sampling and analysis campaign was undertaken to determine the percentages of each fraction. The sampling and analysis procedure can be found in Appendix A.

1.4.4 COMMERCIAL SSO

ICI includes multi-family residential, restaurant and grocery food waste, as well as materials collected from the hospital and the correctional centre. Collections recover material from large bins near each facility and arrive each Friday.

Like residential organics, ICI is also separated into four fractions (SSO, GYW, DYW, contaminants)

1.5 APPLICABLE TECHNOLOGIES

1.5.1 REVIEW OF RFI PROPOSALS RECEIVED FOR THE PROPOSED BIOGAS SYSTEM

YEC has received replies from five suppliers to its request for information; Himark, Viessmann/BIOFerm (BIOFerm), Bio-en Power, Wildstone/Gicon (Wildstone), and Enerpedia. The suppliers propose different technology solutions, which have been reviewed in order to give a recommendation on a preferable technology. More in-depth information on each supplier is presented in Annex 7.3 Technology review.

Which technology to use, in this particular project is a function of the feedstock characteristics (the substrate) as well as the specific conditions, on-site. The substrate is predominantly source sorted organic waste collected by City of Whitehorse's municipal organics collection system. It consists mainly of food waste with some yard clippings in the spring, summer and fall. The substrate is considered dry, i.e. containing relatively high solids. The design of the biogas production system also needs to consider the large variations in the amount of waste as well as changes to the composition of the waste throughout the year.

There are some site conditions to specifically take into consideration; the cold climate, the scarcity of water supply at the site and the fact that the facility does not provide room for additional composting beyond 2,200 tons per year.

1.5.1.1 DRY VS WET DIGESTION TECHNOLOGY

Anaerobic digestion systems can be divided into dry and wet technologies. The dry technologies are used for substrates with a high concentration of total solids (TS), i.e. over 25 % TS. According to the feedstock characteristics determined by the feedstock samples, TS is never less than 24 %. This indicates that a dry technology is preferable. An additional argument for using a dry digestion technology is the scarcity of water at the site. Dry digestion technologies use only a fraction of the water used by wet technologies. Therefore, a dry (high solids) digester technology is recommended. Such systems are also in use at other municipal organic waste processing facilities, such as the Harvest Power system in Richmond, BC.

1.5.1.2 MESOPHILIC VS THERMOPHILIC ANAEROBIC DIGESTION

The anaerobic digestion process can function over a wide range of temperatures. From psychrophilic temperatures at around 10°C, to mesophilic temperatures at around 35°C and thermophilic temperatures at around 55°C. Mesophilic and thermophilic digesters are most commonly used, given the higher gas production from those systems.

Thermophilic conditions offer a higher biogas yield by reactor volume, but require a higher energy input for heating. In a mesophilic reactor, the digestive process is more stable and less subject to process inhibition.

Since every supplier has a preferable temperature range, this parameter will be determined by the type of system and supplier chosen. At this point, there is no recommendation as to which temperature range is preferable.

1.5.1.3 RECOMMENDATIONS

Since the water supply is a concern for the project, a wet digestion technology is not preferable. Bio-en power proposes a biogas facility using wet digestion, which according to the RFIs uses, approximately,

twice as much water as the dry technologies. Therefore, the proposal from Bio-en power is not recommended.

Even though the proposal from Enerpedia includes a dry digestion technology, it is not designed for this specific project. It is therefore hard to say whether the proposal meets the requirements for this site or not. One concern is whether the design, which was originally prepared for the market in France, is resilient enough for the much colder climatic conditions in Yukon.

Himark's, BIOFerm's, Wildstone's and Bekon's proposals are based on essentially the same technology, even though they present it in different terminologies. The proposed designs operate in different temperature ranges. As mentioned earlier, a recommendation as to the preferable temperature range cannot be given at this stage of the project. To make an adequate choice of supplier, more specific and detailed information is required.

Since the proposals are designed for different capacities and feedstocks, the figures are hard to compare. It may not be accurate enough to simply convert the figures to a certain feedstock amount since other elements of the plant design and setup may change as a result. Instead, the numbers are presented per ton input. Comparisons between the numbers should be performed with caution. The heat and electricity output as well as the water usage are especially hard to compare, since not all suppliers present data or use different units.

The following table shows a preliminary ranking of each supplier. The values are based on the original amounts of feedstock used in each proposal.

Table 6 Ranking of recommended suppliers: (++++) Highest score, (-) No score

Supplier	Cost estimate	Biogas production	Chp output	Water usage
Himark	Total cost based on 4000 tons input: C$ 3,005,694* C$ 751/ton input (+++)	Total based of 4000 tons input: 806,285 m^3/year 201.6 m^3/ton input (++++)	Gross power output: 134 kW_e Net power output: 121 kW_e Thermal output: 265 kW_{th} Process heat input: 173 kW_{th} (-)	Total based on 4000 tons input: 504 tons/year 0.126 tons/ ton input (++++)
BIOFerm	Total cost based on 3,202 tons input: C$ 5,211,191* C$ 1,627/ton input (++)	Total based of 3,202 tons input: 266,316 m^3/year 83.2 m^3/ton input (+)	Gross power output: 583 MWh_e/year Gross thermal output: 817 MWh/year (++++)	(-)
Wildstone	Total cost based on 2,334 tons input: C$7,440,727 C$ 3,188/ton input (+)	Total based on 2,334 tons input: 232,403 Nm^3/year 100.4 m^3/ton input (++)	Gross power output: 472 MWh_e/year Net power output: 245 MWh_e/year Gross thermal output: 609 MWh_{th}/year Net thermal output: 477 MWh_{th}/year (+++)	Total based on 2,334 tons input: 467 tons/year 0.2 tons/ton input (+++)
Bekon	Total cost based on 4,500 tons input: C$ 3,085,000 C$ 685.5/ton input (++++)	Total based on 4,500 tons input: 512,820 m^3/year 113.9 m^3/ton input (+++)	(-)	Total based on 4500 tons input: 2500 tons/year 0.56 tons/ ton input (++)

* Exchange rate 1.326903, 2015-11-19

Himark made the lowest cost estimate and projects the highest biogas output. However, Himark's biogas output per ton input seems overrated since the figure is about double compared to BIOFerm, Bekon and Wildstone. The project cost estimate seems very low compared to the other proposals. Bekon's proposal also estimated a very low cost but that is explained by not including the CHP unit.

BIOFerm has excluded some items from the budgetary costs. For example, engineering design, earthworks, odor control system, fire suppress system design and installation, front end loader, biofilter, composting equipment, etc. Wildstone on the other hand has, in addition to the engineering, equipment, installation, commissioning and support connected to the process, also included engineering, civil, structural, mechanical and electrical costs connected to the building. This might explain why Wildstone's budgetary costs are higher than the others.

Himark, Bekon and Wildstone have provided figures for the water usage. Himark uses the lowest amount of water per ton input. Bekon's water usage estimation represents more than two times the water

consumption of the other suppliers. This higher water consumption may be explained by using water for cleaning the fermenter doors and drains.

Regarding the electricity and heat output, the figures cannot be meaningfully compared since Himark only presents the capacity rating of the CHP, BIOFerm does not present net outputs and Bekon presents no output at all. For the economic analysis of the project, the heat and electricity net output provided to the market is of crucial importance.

To conduct a proper ranking, more information is needed and the different categories would have to be weighted. It is recommended to ask for more specific information from Himark, BIOFerm, Wildstone and Bekon regarding annual fresh water usage, annual heat and electricity net output, biogas production, and estimated costs.

2 FEEDSTOCK

2.1 QUANTITY

The organic waste volume was monitored from the year 2000 to 2013 (Table 3). Electrigaz/WSP estimated the volume of organic waste for the lifetime of the future biogas plant (2016 to 2036).

Hypothesis

- 44% of the total waste is organic (source: Recyc-Quebec)
- 2% increase of total waste generated per year
- 10% increase of organic waste diverted per year
- 80% maximum collection efficiency for the separated organic fraction
- 30% of the total organic waste is from the ICI sector

The historical amounts are shown in Table 3 and the future estimate is shown in Section 2.4 below. The amount of organic waste collected in 2016 should be around 3,200 tons and after 20 years of operation, the plant should be operating at around 7,800 tons per year. The tonnage will grow rapidly in the first five years to reach around 6,000 tons per year as more residential and commercial clients get involved and are educated in the process. The assumed growth in waste generation comes from the City of Whitehorse expected organic diversion resident's participation. All others assumptions come from the consultant experience and extrapolation of previous studies.

2.2 COMPOSITION

A sampling and testing campaign was performed to assess SSO composition and overall quality of the feedstock for biogas production.

2.2.1 SAMPLING AND TESTING PROCEDURE

The sampling campaign took place in May, September and October 2015 and was followed by lab analyses. The objectives of this campaign were to estimate the nature and proportion of contaminants and to estimate the monthly tonnage and characterize the variation of its composition throughout the year. The principal results are in Tables 5 and 6. For detailed results, see the sampling report in Appendix B. The sample procedure and the on-site assessment are described in the sampling report appendix.

The principal on-site observation is the low content of contaminants (less than 5% of weight) and the very high content of green and dry yard waste in summer and fall for residential collections. The contaminants are mostly plastic bags but cardboard, recyclable material, styrofoam, bottles, wood and landfill material are also found.

Samples were analyzed for total solid, volatile solid and NPK contents. WSP/Electrigaz decided not to perform a biochemical methane potential (BMP) test because the nature of the materials found is common to AD projects and the high cost of a BMP test was not justified, given reliable estimates can be made based on feedstock composition and literature values.

2.3 FEEDSTOCK TESTING RESULTS AND ASSUMPTIONS

Table 5 represents the quality hypothesis used to calculate biogas production. The hypothesis is based on consultant expertise combined with sampling campaign results from three different months. The organic waste from ICI and residential sources was sampled in May, September and October 2015. Samples were analyzed on a mass basis to evaluate the percentage of each waste fraction.

All samples reveal less than 5% of contaminants. Organics from the ICI sector were generally less contaminated than those collected from the residential sector.

ICI waste is mainly composed of SSO through the year, with a peak of yard waste in September. Residential waste is mainly composed of SSO from November to April. During the rest of the year, yard waste can make up for more than 80% of the mass.

Table 7 Monthly SSO composition results and assumptions

Period	Ici				Residential			
	SSO	Green Yard Waste	Dry yard waste	Contaminants	SSO	Green Yard Waste	Dry Yard waste	Contaminants
Jan	93,0%	0,5%	3,0%	3,5%	91,0%	0,5%	5,0%	3,5%
Feb	95,0%	0,5%	1,0%	3,5%	95,0%	0,5%	1,0%	3,5%

Three samples from May, September and October were sent to the Environmental Research and Innovation Center of the University of Wisconsin for further analysis. The sampling and analysis protocols described in appendix A were designed to provide the most accurate picture of organic waste seasonal volumes and composition. The principal information that was necessary for the present report was the total solid (%TS) and the volatile solids (%VS). Both results are shown in Table 6. The lab also analyzed total nitrogen, phosphorus and potassium content (NPK) to see if there may be potential for inhibition during the digestion process. The tolerance to inhibitors will depend on the AD process but should not be a concern at this point regarding the result in the lab.

Table 8 Feedstock characteristics

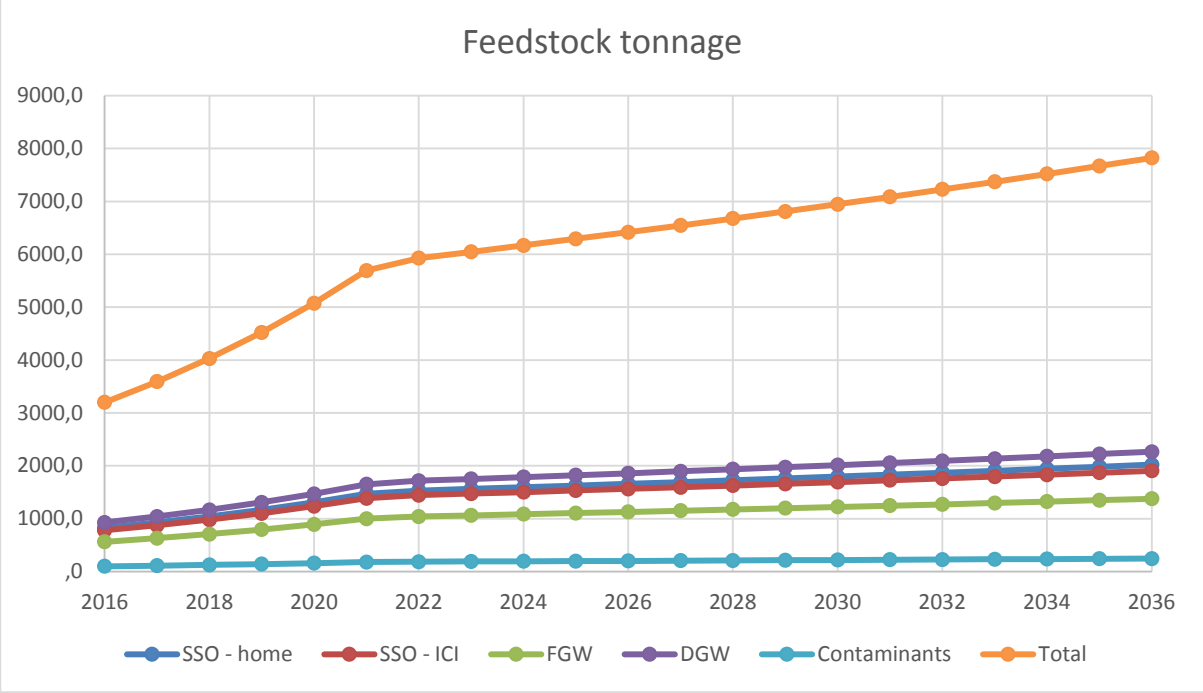
Feedstocks	%TS	%VS	M³ Biogas/T VS	Density (KG/L)	Methane (%CH_4)
SSO from residential collection	36%	82%	600	0,9	60%
Green yard waste	31%	81%	380	0,8	55%
Dry yard waste	44%	86%	100	0,8	55%
SSO from ICI	23%	83%	600	0,9	60%

Note: %TS and %VS come from Wisconsin laboratory results and the other parameters come from the consultant's database.

2.4 FEEDSTOCK DESIGN CURVE

The figure below shows the amount of each organic waste fraction collected and the total amount of organic waste expected to be collected from 2016 to 2036. To produce those curves we applied the hypothesis in section 2.1 to Tables 3 and 5. Based on the City of Whitehorse's organic program forecast, the first five years show the learning and adaption curves as the collection is expanded to include more and more of the existing buildings, and after the first five years, the amount is growing as the waste amount is growing with demographics (2%/year). The feedstock is separated in different SSO fractions including fresh garden waste (FGW) and death garden waste (DGW).

Figure 7 Amount of organic waste collected (2016-2036)



3 PROCESS

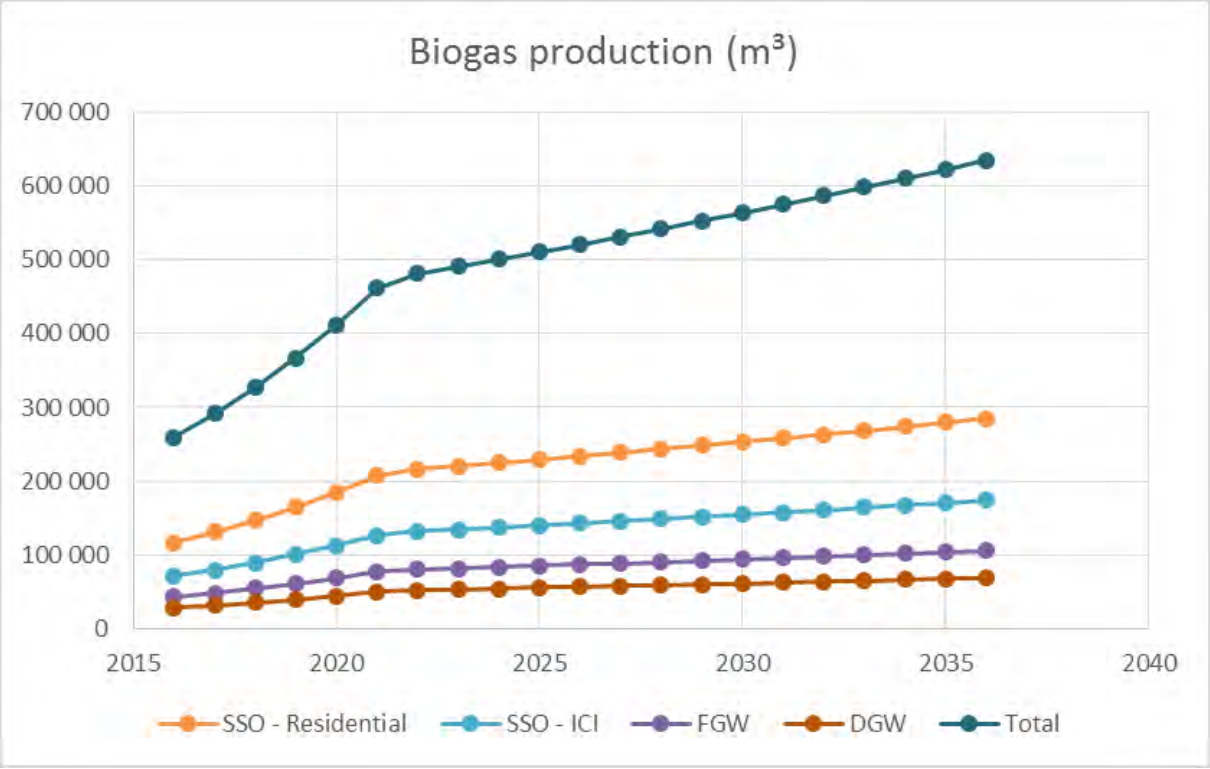
3.1 PROCESS SELECTION

Because of waste volumes and existing composting platform/equipment, a dry garage-style anaerobic digester is recommended since it is simple to operate, affordable, uses or discharges little water and requires no front-end contaminant removal. To reduce capital costs and to avoid odour or noise nuisance to neighbouring properties, the proposed plant would be located at the landfill, next to the existing composting site.

3.2 BIOGAS CALCULATIONS

The figure below shows the biogas production per year from all organic fractions from 2016 to 2036. The biogas production calculation is using the tonnage, the quality and the methane potential of each organic waste fraction. Each SSO fraction has different composition leading to specific biogas production.

Figure 8 Annual biogas production by fraction (2016-2036)



The biogas production will vary in quality and quantity through the year but will average 5.63 kWh thermal per normal cubic meter. The potential production of biogas (Figure 7) is close to 15.000 m³/month in April and near 65 000 m³/month in August. This variation can be expressed in m³/hr, as shown in Figure 8. Note that the biogas storage capacity can only allow biogas storage for hours (3 to 10 hours) and therefore cannot store summer biogas production for usage in the winter.

Figure 9 2016 monthly biogas production

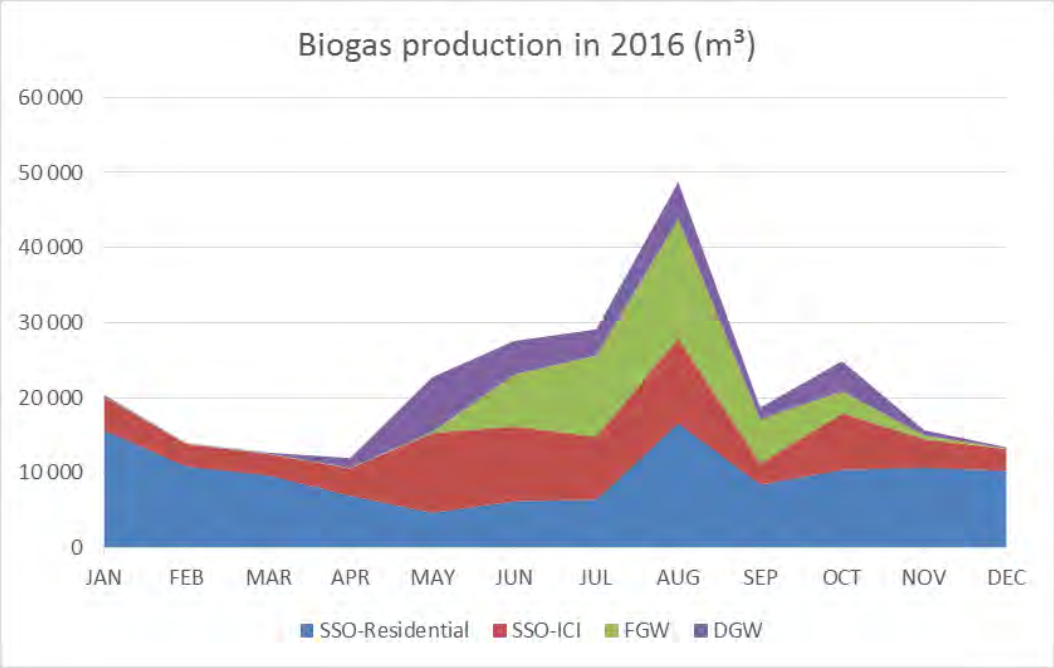


Figure 10 Monthly biogas production. 2016-2036

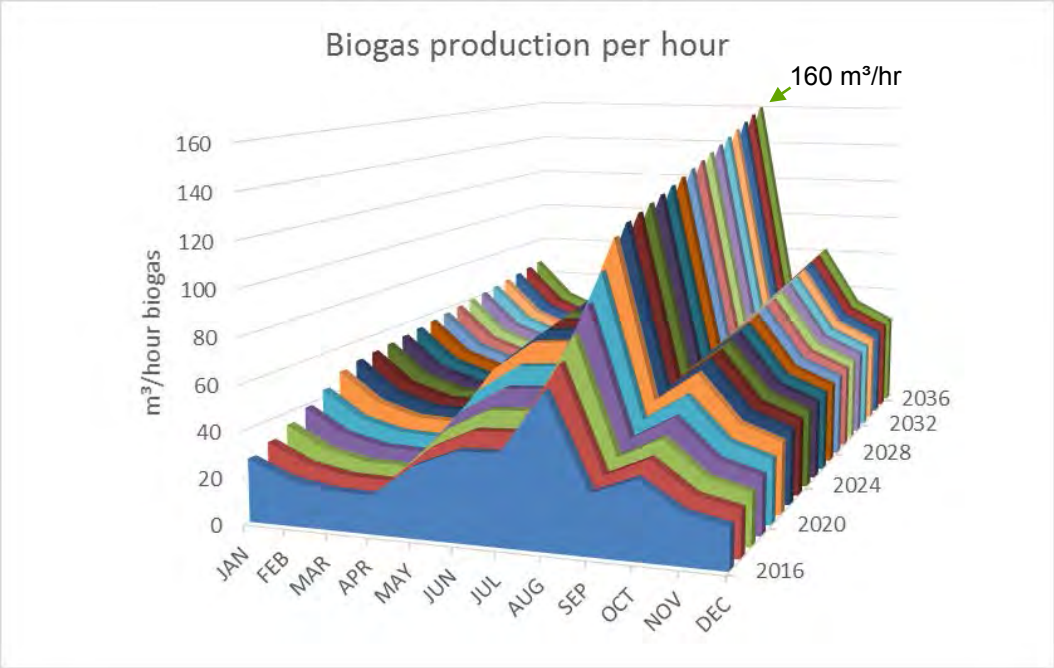
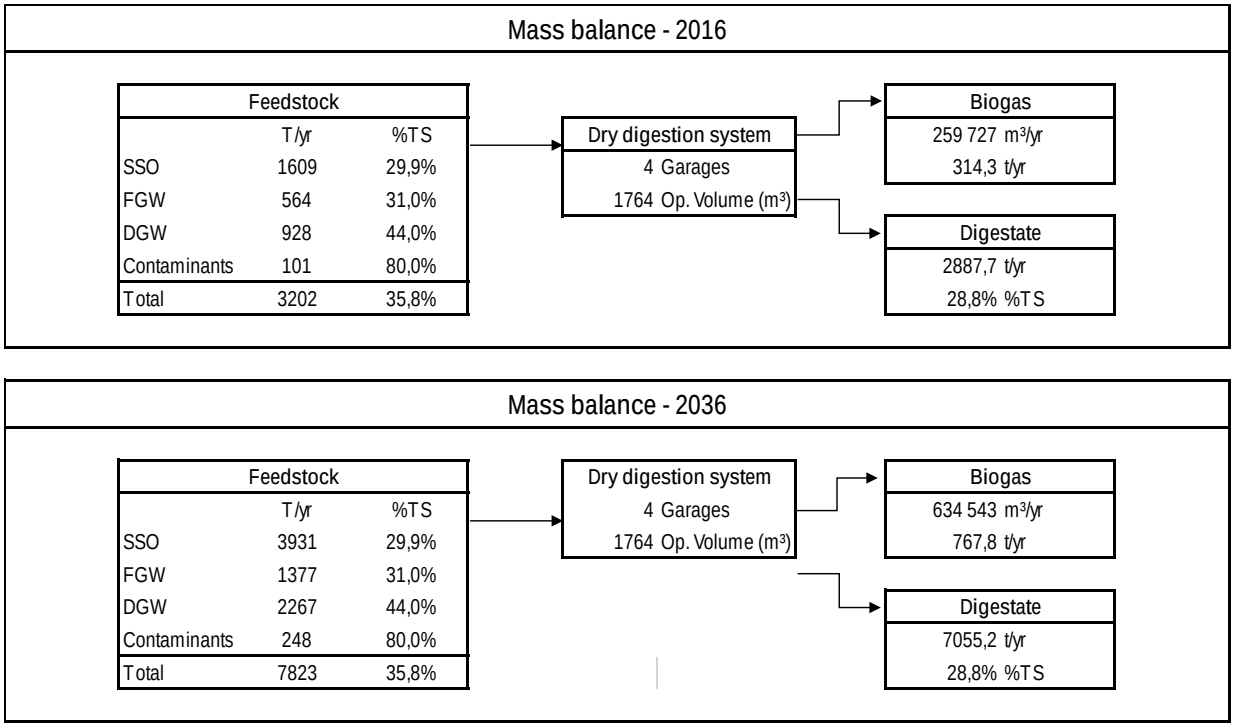


3.3 MASS BALANCE

The next figure shows the mass balance of a dry digestion batch system for 2016 and 2036. The mass balance represents a typical system; the final mass balance for the Whitehorse site should be provided by the technology supplier. The addition of water and operational parameters will impact the final mass balance. The facility processing capacity is flexible, allowing to process 2016 tonnage as well as 2036. The process elasticity is possible by adjusting chambers retention time and filling levels.

Figure 11 Mass balance



3.4 ENERGY BALANCE

3.4.1 BIOGAS UTILISATION

Biogas utilisation was analyzed for two cases. The first case is the utilisation of a boiler to produce heat (hot water) and the second case is the use of a combined heat and power (CHP) system to produce electricity and heat (hot water).

For the boiler scenario, it has been estimated that all biogas will be injected to a boiler with a thermal efficiency of 90%.

For the CHP scenario, the use of two 100 kW(e) CHP provides more flexibility to the operator, producing electricity for sale and heat for self-consumption. Section 4.5 contains more details on the potential utilisation of thermal heat for both cases.

WSP/Electrigaz recommends a phased acquisition of the CHP system by installing only one 100 kW CHP unit at project start and adding the other one after about five years. Phased construction will increase the use factor of each CHP unit and will lead to a steadier electricity output curve.

Normally a 100 kW(e) CHP unit can be used at a 50 to 100 kW(e) output. The electric efficiency of these units is between 30 to 39% and the thermal efficiency is between 40 to 49%. To model the CHP unit for the economic analysis, 35% was used as the average electric efficiency and 40% for thermal efficiency.

The project will have an average electricity output capacity of 56 kW(e) in 2016, dropping to 33 kW(e) in April and reaching the full 100 kW(e) in August. In 2036, the average output level will be 132 kW(e), dropping to 80 kW(e) in April and reaching 200 kW(e) in August. During the winter months, when the biogas production is low, the CHP system cannot run 24/24h because the minimum range of the CHP is 50 kW. In this case, the biogas holder will help utilize biogas during peak hours.

The average thermal output level will be around 64 kW in 2016, with 37 kW in April and 114 kW in August. In 2036, the average thermal output level will be around 151 kW, with 91 kW in April and 229 kW in August. The energy balance can also be estimated in percentage as shown in table 9.

Table 9 Energy balance for 2016

	Boiler Scenario	CHP Scenario
Total biogas energy	100.0%	100.0%
Electricity production	0.0%	35.0%
Heat production	78.7%	28.7%
Internal heat use	11.3%	11.3%
Energy loss	10.0%	25.0%

The electricity production represents the percentage of energy used to produce the electricity with the CHP. The heat production percentage represents the heat output amount after the internal heat use (heating of feedstock and digesters). The internal heat use represents the percentage of energy production used for internal heat load.

The energy loss is based on the efficiency of the equipment for each scenario. In the CHP scenario the electricity production has an efficiency of 35% and the heat production of 40%, this means that there's a loss of 25%. For the boiler scenario the efficiency is 90%.

3.4.2 PROCESS HEAT LOAD

The process heat load is based on the need of heat to bring the feedstock to 37°C from its original temperature (assuming a mesophilic system) during each month of the year and the heat that is necessary for maintaining the complete system at 37°C.

The next equation was used to determine the heat needed to bring the feedstock to the operation temperature.

$$Q=M*Cp*\Delta T$$

Where:

- Q = Amount of thermal energy transferred (kJ)
- M = Mass of feedstock (kg)

→ Cp = 4.19 kJ / kg * K

→ ΔT = Temperature differential (K)

The ΔT used in this report was based on average temperature in Whitehorse and the differential is presented in the next table.

Table 10 Temperature differential in Whitehorse

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
ΔT	55.7	50.1	44.2	36.7	30.4	25.4	23.0	24.7	29.7	36.3	47.0	52.9

The heat necessary to maintain the system at 37°C was calculated by using the percentage of the thermal energy that was needed to heat the feedstock. In this study, WSP/Electrigaz estimated 11.3% of the energy produced used to heat the process. The total heat load is presented in the next table in gigajoule.

Table 11 Internal heat load to maintain digester at 37°C

3.4.3 ESTIMATED EXPORTABLE ELECTRICITY

The power that can be exported to the grid is shown in the next table, using a simplified approach based on an average kW(e) per month output level and continuous operation. This calculation represents 100% of the system's gross power output and does not deduct internal power use to operate the digester (assumed to be provided from the grid at the landfill's current electricity rate).

Table 12 Gross power production (kW(e))

KW(E)	2016	2020	2024	2028	2032	2036
Jan	54	86	104	113	122	132
Feb	39	63	76	82	89	96
Mar	34	53	65	70	76	82

Nov	43	68	83	89	97	105
Dec	35	56	68	74	80	87

These gross power production figures can also be represented has the potential of electricity production each hour of the day (capacity factor already factored in)

3.4.4 ESTIMATED EXPORTABLE THERMAL ENERGY

3.4.4.1 HEAT UTILIZATION SCENARIO EVALUATION

Waste heat utilization scenarios have already been evaluated in a previous study. Two surplus heat utilization scenarios were analyzed:

- District energy system
- Greenhouse heating

For the district energy system the study targeted some main buildings that could be powered by an energy generation unit. Some public buildings in the Whitehorse area include the correctional center and Yukon College, situated approximately 3 km from the composting site. However, even this distance is considered too far to be economically viable primarily because of the capital cost of such a heat

transportation grid[1]. There is also the possibility to sell heat to nearby industrial facilities or composting sites. The scenario has been assumed in the present study for economic analysis.

The other possibility analyzed in a previous study is greenhouse heating. The study analyzed different scenarios considering the market demand on typical vegetables such as tomatoes, cucumbers and lettuce. The study established different footprint areas required to respond to market demand. These scenarios have been taken to estimate energy requirements for different greenhouse footprints. Note that these values have only been taken to analyze if such scenarios would be feasible in the present analyzed project. In the previous study, vegetable market demands for Haines Junction community and Whitehorse were analyzed. Three different scenarios were established. The first one was to respond to 100% of Haines Junction's demand which would represent approximately 2% of the Whitehorse demand. This scenario would require a greenhouse of 486 m^2. This is the smallest scenario considered by the study as the two other scenarios required a footprint of 5,338 and 5,824 m^2 to respectively respond to 25% of Whitehorse's demand and 27% of Whitehorse's demand. From these footprints, the study established energy demand peaks presented in the following table.

Table 13 Expected heating demand for three production scenarios

Heating Demand	Whitehorse (2%)	Whitehorse (25%)	Whitehorse (27%))
Greenhouse footprint area required (m^2)	486	5,338	5,824
Maximum heating energy required (kW_{th})	167	1,829	1,995
Total capital/construction & Durable goods cost	$ 167,625.70	$ 1,539,359.82	$ 1,436,720.50
Yearly O&M costs	$ 79,485.26	$ 883,065.32	$ 963,446.89

Haines Junction Bioenergy Project – Evaluation of waste heat potential, Clean Technology Community Gateway, 2012.

The previous table also shows the capital investment that would be needed to build these greenhouses as well as the operational cost for each scenario.

However, it must be noted that these values represent peak energy demand and were calculated considering an outdoor temperature of -54ºC. This extreme temperature is not expected on a regular basis.

The following section will analyze the feasibility of such scenarios, considering the thermal energy availability from the proposed AD plant.

The highest energy availability from an AD plant occurs during the summer months. Two main reasons explain this fact. First, the input tonnages are higher in summer, which leads to higher biogas production. At the same time, in the summer months, internal energy consumption is lower due to higher outdoor temperatures. These two facts combined lead to much higher energy availability in the summer when heat energy demand is at its lowest. Greenhouse heat demand is not different from any other energy consumers, i.e. it needs more energy in winter. This means there is an imbalance between energy production and energy demand in this kind of project.

The following table presents the estimated monthly usable waste heat production from the AD project, using a CHP unit for three targeted years. The analyzed years have been targeted considering the CHP

[1] Haines Junction Community study assumed a cost of $944/m for distribution pipe (typical for Canadian provinces; may be a low estimate for Yukon). A 3 km pipe would then cost $2.8M.

purchase phases of the project (a second CHP unit would be installed in 2020) and to illustrate the impact of increased organic waste collection rates throughout the years.

Table 14 Estimated monthly exportable heat and maximum thermal power production from CHP scenario

Maximum KW_{TH} And GJ Exportable With CHP	2016		2020		2036	
	Total GJ	Maximum kW_{th}	Total GJ	Maximum kW_{th}	Total GJ	Maximum kW_{th}
Jan	110	41	175	65	269	100
Feb	80	33	127	52	196	81
Mar	76	28	120	45	185	69
Apr	68	26	108	42	167	64
May	114	43	181	68	279	104
Jun	165	64	262	101	403	156
Jul	183	68	290	108	446	167
Aug	217	81	471	176	395	148
Sep	114	44	181	70	279	108
Oct	134	50	212	79	328	122
Nov	87	33	137	53	211	82
Dec	74	28	117	44	181	68
Total	**1,423**	**n/a**	**2,381**	**n/a**	**3,340**	**n/a**

This table shows that only a small amount of heat could be exported - especially in the winter months.

If greenhouse scenarios are analyzed thoroughly, only the smallest scenario (representing 2% of Whitehorse vegetable demand) could possibly be fed with heat as its maximum heat demand is reached in July 2036 (167 kWth). However, this heat generation peak is reached only after 20 years and is in July, when there is little heat demand from a greenhouse. The heat demand peak will be in winter months when the exportable heat is expected to be very low due to internal plant consumption.

Note that for this scenario and for the purpose of the economic analysis of this study, it has been estimated that all heat would be sold to nearby composting site.

However, biogas could also be directly directed to a 500 HP boiler and only generate heat that could be used the same way. This option would produce no electricity but could generate approximately twice the amount of heat to be gained from the CHP unit's waste heat. The following table shows heat generation values with a boiler scenario.

Table 15 Estimated monthly exportable heat and maximum thermal power production from boiler scenario

Maximum KW_{TH} And GJ Exportable With Boiler	2016		2020		2036	
	Total GJ	Maximum kW_{th}	Total GJ	Maximum kW_{th}	Total GJ	Maximum kW_{th}
Jan	317	118	502	187	774	289

Jul	477	178	757	283	1 167	436
Aug	799	298	1 267	473	1 953	729
Sep	304	117	481	186	742	286
Oct	386	144	612	228	943	352
Nov	245	95	389	150	599	231
Dec	210	78	333	124	513	191
Total	**4,141**	**n/a**	**6,563**	**n/a**	**10,118**	**n/a**

The winter heat demand peak would be reached in January 2020 but not in December or February - two months that have the same energy demand peaks. However, the January heat availability means that it could be possible to fill heat demand even in the winter months. Therefore, an auxiliary heating system could be used when extreme conditions occur, whereas the biogas could generate enough energy to maintain the temperature of a 486 m^2 greenhouse.

Previous study found that to be economically viable, a greenhouse project will have to be highly subsidized and similarly so would a greenhouse at the Whitehorse compost facility using biogas waste heat. In fact, all scenarios analyzed were generating high annual losses. It must be noted that this study assumed waste heat would be provided free of charge. This means that with any price of energy, these scenarios would be even less viable.

Note that for this scenario (thermal power production from boiler scenario) and for the purpose of the economic analysis of this study, it has been estimated that all heat would be sold to nearby composting site and any other industrial company that could be situated in a radius of approximately 700 m from the site. At the moment, KBL is actually present in a radius of 700 m but its heat consumption would probably be "out of phase" with biogas production (peaking in summer). Moreover, actual yearly heat consumption only adds up to 8 550$[2], which would not be enough for the present estimated heat production.

[2] Value extracted from Doug Dawley email received on the 7th of December 2015

Also note that because no greenhouse scenario proved to be viable in the previous report and because of the imbalance of energy production and consumption, no greenhouse scenario has been analyzed further in this report. The economic analysis in section 5 shows both boiler and CHP scenarios would need subsidies or higher gate fees to be viable and, considering the capital investment and operational cost of greenhouses, the addition of one of any size to these projects would only bring down their economic viability.

4 PLANT PRELIMINARY DESIGN

4.1 GENERAL PLANT DESCRIPTION

The plant is composed mainly of a building (garage) that houses four anaerobic digestion tunnels and a reception/mixing hall (Figure 10). The CHP unit, flare, biofilter and percolate tank are located outside the building. The operation of the plant is based on a 28-day schedule and the material is stored outside for seven days before entering the garage. In a garage-style digester the material is moved with a front-end loader and each week the operator empties part of the garage before filling the tunnels with fresh material. The digestate is then sent to the compost facility.

Before the opening of the garage, air is injected to reach a safe atmosphere. The air in the garage is always monitored to assure safety. Batch operation forces the operator to leave at least 40% of the digestate in the garage to accelerate the digestion process of the new material. A biolfiter is used to treat the air inside the building.

The percolate and the process water are sent to the percolate tank and recirculated in the garage to humidify and inoculate the fresh material. The biogas is stored in a 599 m³ biogas holder that is placed above the percolate tank. The biogas is then sent to the CHP unit or a boiler. Typically these systems come equipped with health and safety systems to detect biogas leaks and other hazards.

Figure 12 Oshkosh garage-style biogas plant

4.1.1 EQUIPMENT LIST WITH DESCRIPTIONS

- 4 x Dry digester (garage style) : 21 m L x 7 m W x 5 m H
- 2 x Biogas blower
- 1 x Biogas holder (600 m3) and percolate tank (1000 m3)
- 1 x Biogas H2S removal and water trap with one pump
- 2 x CHP unit (gas engine) with exhaust gas heat recovery
- 3 x Percolate pumps
- 1 x Open flare

- 1 x Biofilter
- 1 x Air blower
- 1 x Heat exchanger with one pump
- Biogas piping
- Percolate piping
- Air piping
- Hydraulic system
- Control (SCADA, PLC)
- Instrumentation (flow meter, thermocouple, LEL/HEL sensors, biogas analyzer, etc.)

A process schematic is presented in section 4.1.2 below.

Reception and composting area

A designated area within the building is reserved for feedstock mixing. This area will have sufficient space to receive feedstock for a minimum of seven days and to allow proper mixing of the incoming feedstock with up to 40% of the actual digestate used as an inoculum. The feedstock mass is transported with a front-end loader to the digester building, then directly to the feedstock mixing/staging area. The mixed substrates are then transported to the respective digester, again using a front-end loader.

As discussed in section 2.3, the incoming feedstock contains less than 5% contaminants. Throughout the year, the yard waste portion of ICI and residential organic waste will vary. ICI waste will have its yard waste peak in September, while residential waste will contain 80% of its mass in yard waste from May through October. Depending on the technology that will be used, part of the yard waste can be diverted directly to composting, if needed.

Whitehorse Composting Facility

The Whitehorse Composting Facility has been optimized recently (2014) to operate more consistently throughout the year (particularly during the winter), to reduce the space required for composting, to reduce operation and maintenance cost, and to reduce issues associated with plastics films. The production of compost from SSO and yard waste is achieved using outdoor highly aerated windrows. The windrows' dimensions are 30 ft wide by 14 ft high. Note that the City of Whitehorse is planning future upgrades to the current composting facility that include perforated concrete pads to aerate the composting windrows as well as computer-controlled aeration and temperature monitoring using wireless temperature probes.

Whitehorse's SSO and yard waste are delivered to the composting facility via the city's waste collection program. The feedstock is dropped by the organic waste trucks at the designated reception area onto the compost pad. Each load is inspected in order to manually remove coarse contaminants. The bags (compostable or plastic) containing the different feedstock materials and the bulking agents are taken to a mixer with a front-end loader. The bulking agent may be a combination of yard waste and separated compost overs. The equipment, a twin vertical screw-mixer that can process approximately six tons of a blend of composting material at a time, is used mainly to break open bags, to shred food waste, and to prepare a homogeneous blend. The mixer is powered by a 120 horsepower farm tractor. The screws in the mixer have very sharp knives rotating at 40 rpm. The cutting action of the mixer knives allows breaking open the plastic bags without shredding them to small pieces, which can be very difficult to screen afterwards. The plastic bits are small enough that they do not hinder the composting process.

The blended material is then discharged from the mixer and piled up, forming aerated windrows to begin the composting process. The composted material reaches temperatures up to 80°C and is turned at least once during the composting process to allow all the material to be exposed to the temperatures required for potential pathogen elimination. The total composting process residence time can vary from four months to a year, depending on operational parameters (i.e.: temperature, air flow, humidity, etc.) After the compost is cured, it is screened to ¼ of an inch diameter using a trommel screener with a stainless steel mesh. The resulting compost is a clean high organic material that is sought after by the community.

High Solids Digestion – Garage style digester

The proposed garage style digester system operates on a sequential batch basis, where four garage boxes / chambers are deployed in the dedicated digester building. Each of these chambers accommodates 7 days' worth of feedstock. The process involved in the sequential batch operation cycle is described below:

1. Feed mixing & preparation
2. Loading
3. Percolation and fermentation – anaerobic system
4. Purging and ventilation
5. Unloading

The four rectangular digesters are of carbon steel construction with epoxy coating, and stainless steel lining in the headspace. They are sealed, gas-tight, in order to contain the biogas produced and minimize heat loss. Their key design features are as follows:

1. Dimensions: 21 m Long x 7 m Wide x 5 m High, with at least 0.6 m of free head space
2. Door arrangement: hydraulically operated gas-proof gates with inflatable sealing lip placed on the gate frame for sealing. The door can open horizontally as well as vertically, depending on design.
3. Drainage to be provided on the floor periphery and mid-line to channel the percolate/percolation flow towards a below-grade collection sump with a passive screening system to prevent collection of larger solid particles.
4. Fine mesh grating covering the drainage trough on the periphery and in the center of the floor. The entire floor is to be used as the loading surface for the feedstock stack (the material inside each digester tunnel). This surface will be slightly inclined to direct the liquid flow towards the troughs.
5. Nozzle spray system (i.e.: 6 rows of 12 percolation sprinklers) that allows the percolate reuse to further expose the material to micro-organisms for material decomposition and methane production. This system ensures effective distribution of the percolate stream over the feedstock.
6. The garage digesters are completely sealed with alarms to indicate loss of pressure. All doors are sealed with a system for detecting seal failure as well as sensors capable of sensing liquid levels, pressure, and gas composition in digesters and gas and liquid flow from digesters on a continuous basis.

Percolate recycling and fermentation

The percolate storage is designed to serve as a reservoir for heat and anaerobic cultures and provides buffering capacity against acids generated at batch start-up. The percolate that filters through the feedstock is collected and stored in a continuous stirred tank reactor (CSTR) located close to the garage digesters. The CSTR tank has a membrane roof system that temporarily acts as gas storage. This keeps the biogas at constant pressure and houses incoming gas from the four digestion chambers. In order to conserve heat and protect the digester membrane from the climate, it is recommended to include an additional hard shell roof. The biogas captured from each garage digester is routed through a piped ventilation system to the dual membrane CSTR tank. The tank is usually operated at mesophilic temperature and includes paddle mixers. The mixers are controlled via variable frequency drives and the drive motor of the mixer is mounted onto the outside wall of the tank.

The key functions of the percolation system are:

1. Inoculation of the feedstock with a stream that contains fine particles and is a biologically active substrate
2. Maintaining adequate moisture content in the feedstock stack
3. Initial soaking and heating to thermophilic temperatures of the freshly loaded feedstock, with higher percolation flow rates.
4. Tempered low-source heating of feedstock
5. Hydrolysis of the feedstock stack material, and carry-over of dissolved solids in the stream
6. Generation of biogas from the percolation tank

The key elements of the percolation system are:

1. Percolation tank; Carbon steel tank, used for storage of the percolate stream as well as production of biogas from the percolation stream. The percolation tank is furnished with a heating loop to maintain its operating temperature constant. The head space of the tank is epoxy power coated to prevent corrosion from H2S. The membrane roof system temporarily acts as gas storage
2. Percolation Tank Supply pump/s (2): centrifugal pump(s) with interconnected piping that transfer percolate collected flow from the garage digesters to the percolation tank
3. Percolation feed pump/s: centrifugal pump(s) with interconnected piping that transfer percolate stream from the tank to the spray nozzles in the fermenters.

Biogas Treatment

The biogas is driven from the garage digester and the percolation tank by blowers. It is then sent to a gas conditioning system to ensure acceptable gas parameters (i.e.: temperature, humidity, contaminant levels). The water in the biogas is removed by reducing the gas temperature to condense and remove surplus moisture. Corrosive compounds, such as H2S, are also removed via a carbon filter and/or iron sponge before leaving the gas conditioning unit. The biogas is then ready for use in the CHP unit or it will be combusted in the process flare.

The following step in the biogas polishing process is to remove the remaining moisture from the gas. This is achieved when it passes through a condenser where chilled water is used to decrease the temperature of the biogas. A diaphragm pump delivers the condensate to the percolate tank as make-up water, thereby minimizing offsite disposal. The pressure of the biogas is adjusted by modifying the blower power to ensure that it is delivered at the correct pressure.

Biogas Flare

A biogas flare is incorporated into the proposed biogas plant concept. The flare is used to burn off spec gas during start-up of each digester, and in instances when more biogas is being produced than can be utilized by the CHP system.

CHP System

The biogas generated via the fermentation process in the digesters at the Whitehorse Facility will be utilized as a fuel source in 2 X 100 kW(e) CHP biogas engines. The biogas produced should have a suitable methane concentration to be used as fuel for a gas engine. In a CHP plant, the gas will be combusted in the engine and converted to mechanical and thermal energy for the process and/or electric energy for the community.

The CHP system is supplied with its own control system, which communicates with the digester control system (DCS) for the rest of the plant. Waste heat from the CHP system's exhaust gas is captured in a water/glycol stream and then utilized in the biogas plant.

Ventilation and purge system

Prior to digester loading/unloading (digester exchange), a purge system will safely dilute methane to below flammable levels, using air. At the time of digester exchange, air composition inside the chamber will continuously be monitored and stored. This data will be used to evaluate production levels and biogas quality, as well as to ensure safety when performing operations inside the chambers. The values will be communicated to the security system controlling the chamber doors, which cannot be opened until all methane is completely removed from the chamber and safe atmospheric levels of CO2 and H2S are reached. During a normal purging sequence, air will be brought in to dilute the fermenter chamber, resulting in a very small period of time and range at which the fermenter will pass through the explosive zone. Hence, the potential explosion risks will be avoided. The purging of a garage digester, through the biofilter, can take from 3 to 6 hours. The rate of air changes is set at a minimum of 12 changes per hour. The key components of the purging system are:

1. Forced air blower/s
2. Fibreglass reinforced plastic piping from the blower up the garage digester, and to the exhaust system
3. Explosivity (lower/higher explosive limit) Sensor (1 per digester)
4. Gas chromatograph inlet in the common Air/Biogas exhaust line

Odor control

The building and process air from the reception and mixing area, digestate processing area, and the digester purge gas will be treated to minimize the odor. An odor control system, in this case a biofilter, will remove the odors from the air stream. The complete air system will be controlled and monitored by software and will operate optimally to reduce water and energy consumption. An acid wet-scrubber will be installed upstream to the fans under negative pressure and will send the scrubbed air to the biofilter. To facilitate the operation, the biofilter can be designed for 120 to 150% of the required capacity. The air-to-surface ratio of the biofilter will allow a residence time greater than 60 seconds.

The key components of the odor control system are:

1. Corrosion resistant duct system
2. Corrosion resistant fan

3. Biofilter, complete with watering and water circulation system

During the cold season, the process water will be heated to prevent the piping freezing and to increase the temperature of the air stream going to the biofilter.

Wastewater reuse

The water used in the air scrubber is continuously recirculated and only a fraction (blow-down) requires disposal to the CSTR tank. The precipitate from the process is a desirable nutrient-rich additive to the compost product.

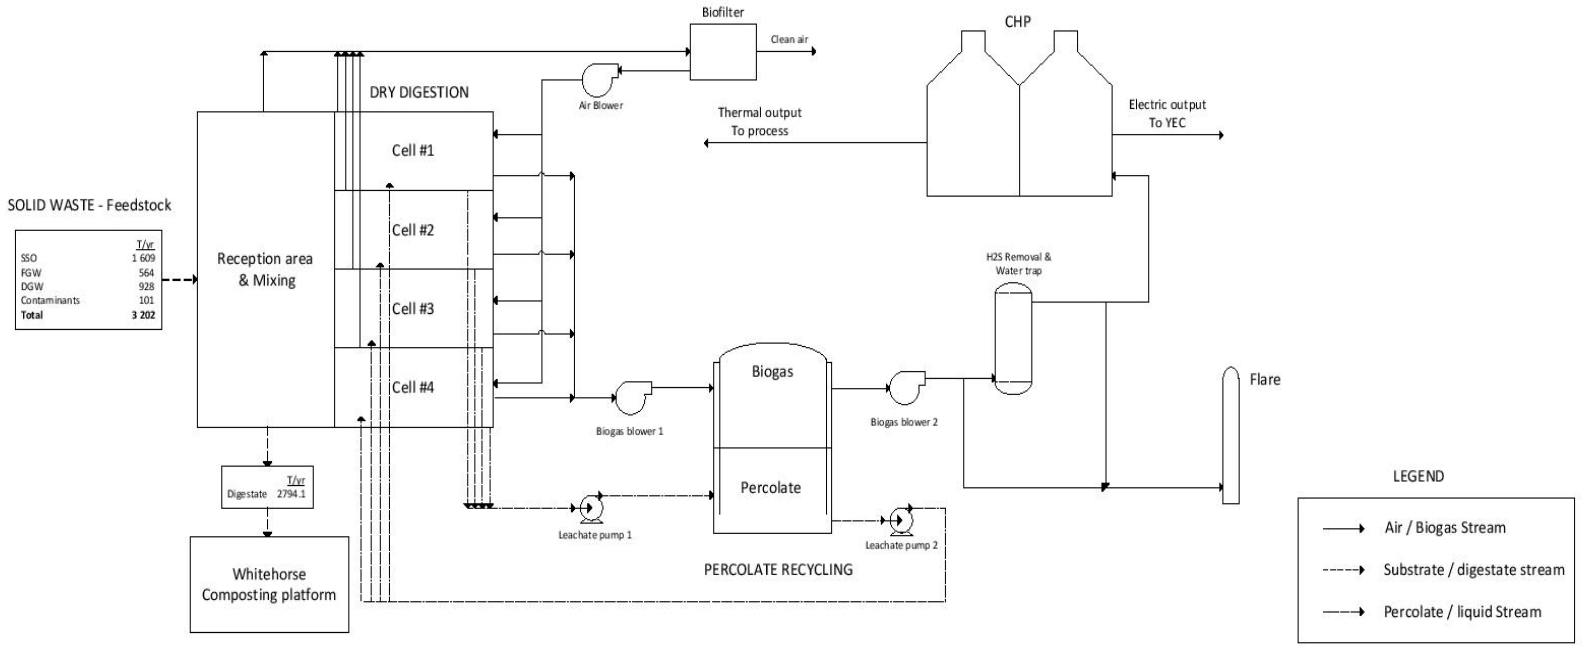
The percolate of the biofilter is filtered and recirculated on the biofilter surface for maintaining an adequate moisture level in the filter bed. Any excess water due to precipitation is collected and captured in the CSTR tank.

Plant Instrumentation, Control and Analysis

The proposed biogas plant is fully automated by a supervisory control and data acquisition (SCADA) system. The SCADA system monitors and controls the various unit processes and the operation of the mechanical equipment that comprise the digestion and biogas processing systems. The SCADA system consists of sensors, indicators, actuators, final control elements, interface equipment, and accessories connected to distributed programmable controllers operating in a multi-user, multitasking environment. The SCADA system is designed to allow trending of process information and notification of plant alarms. Programmable Logic Controllers (PLC) provide for distributed control of the digestion and biogas processing systems. Both discrete and analog interfaces are used for the field devices, such as motors, valves, switches, thermocouples, and transmitters. The fermentation system's instrumentation and control system will provide data to the operations personnel required to monitor the digestion and biogas system process instrumentation. The corporate personnel would also be able to view the performance of, and make changes to the processes remotely over the Internet if needed.

4.1.2 P&ID

Figure 13 P&ID

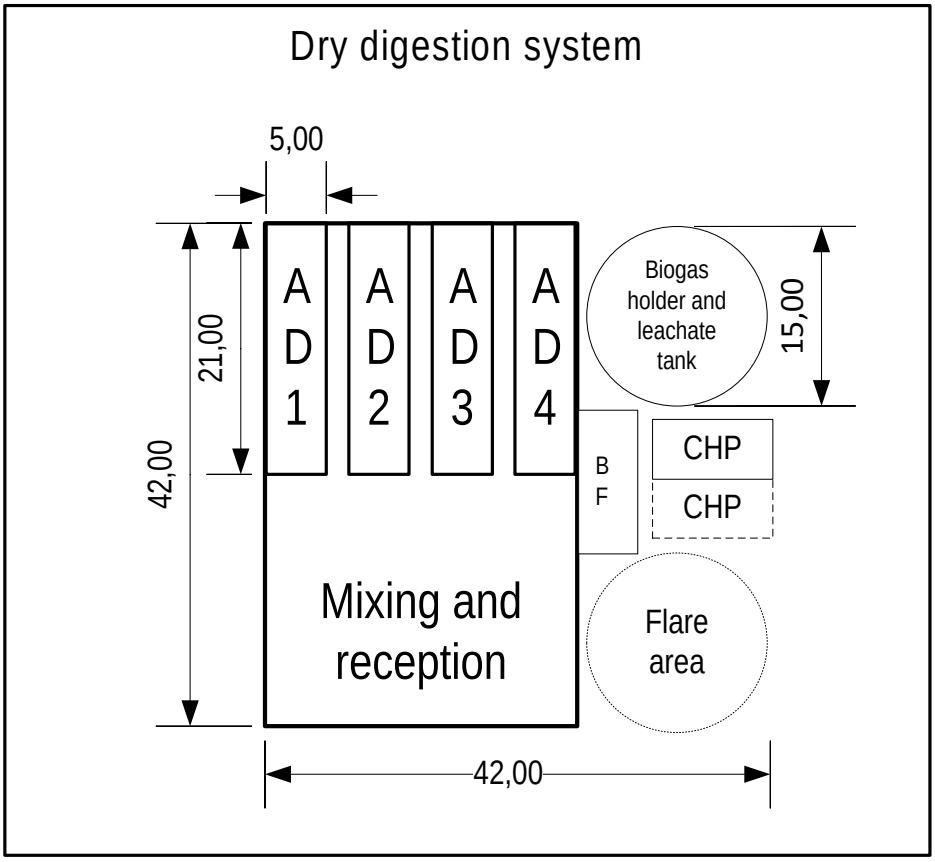


4.2 PLANT LAYOUT

The next two figures show the onsite location and the plant layout. The footprint for the plant is around 1,800 m2. The Plant layout includes all equipment that will be installed. In this project, there will be one 100 kW(e) CHP unit installed at the beginning and the other will be installed few years after. The description of the plant and the equipment list are in section 4.1 above.

Figure 14 Biogas plant localisation

Figure 15 Biogas plant layout



*BF is the Biofilter

4.3 PLANT UTILITIES

The plant requires the connections to water and electricity utilities. The need for water comes from the mixing and reception hall where water can be added to feedstock and where water is also used for cleaning. The percolate, the captured storm water and any other process water are collected in the percolate tank and recirculated to the AD tunnels. There is no need for a wastewater treatment plant because the percolate can be directly sent to the landfill percolate treatment plant if needed. The percolate tank should be filled up in the commissioning phase.

The electricity connection is mainly for the safety equipment and the air treatment, as well as for percolate mixers. Dry digestion requires less electricity than conventional wet digestion because there are less pumps and mixing equipment. The feedstock stack in each tunnel remains unmoved until a digester exchange, when new material is inserted at one end of the tunnel and old, digested material is removed at the other using a front loader.

4.4 POTENTIAL SUPPLIERS

Considering the solid content of the waste, the digestion technology should be a dry (high solids) digestion. Many suppliers offer turnkey systems for dry digestion, including:

- OWS – Dranco
- Valorga
- Bio-En power*
- Kompogas
- Bioferm*
- Bekon
- Gicon*
- Himark*

*Suppliers present for the RFI in 2014

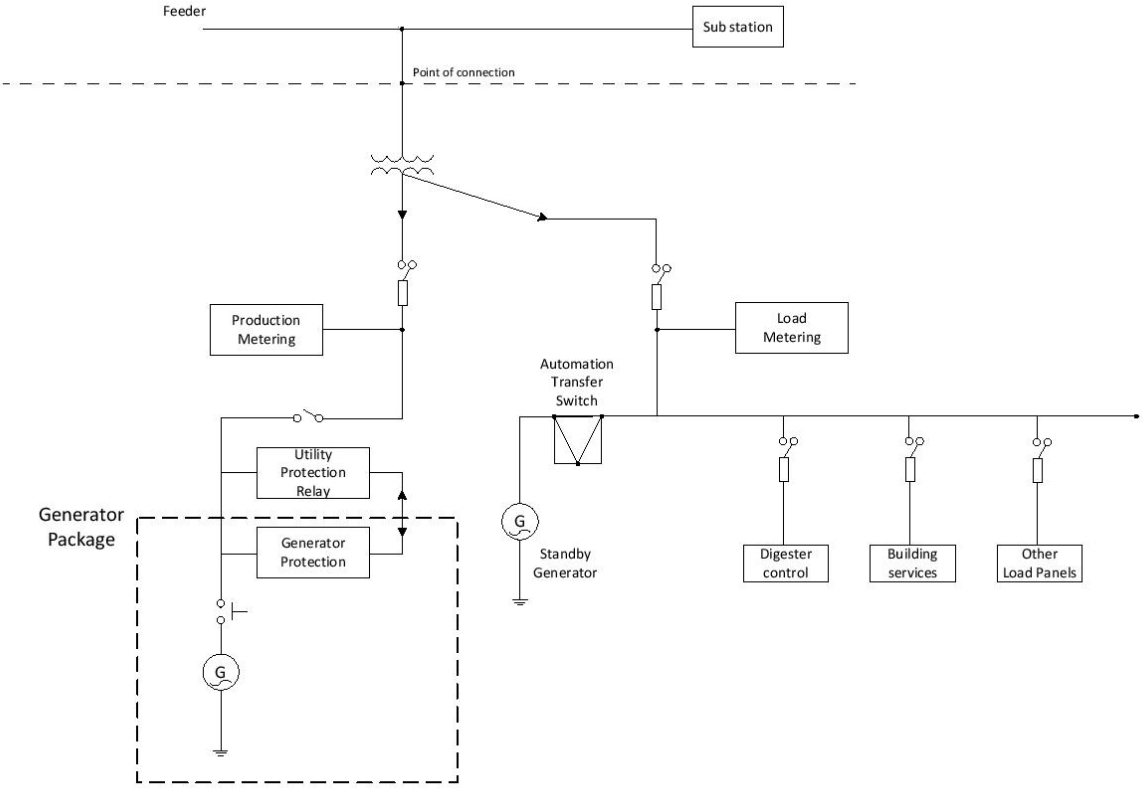
The system will be different in terms of:

- Temperature (mesophilic or thermophilic)
- Operation (batch or continuous)
- Digester shape (horizontal or vertical)
- Retention time (2 to 5 weeks)

4.5 PRELIMINARY ELECTRICAL SLD

The information provided by the previously mentioned suppliers allowed Electrigaz/WSP to prepare preliminary electrical schematics – a Single Line Diagram (SLD) – for the Whitehorse organic waste biogas plant. It is important to mention that the proposed concept will be subject to future modifications, as the engineering process will progress.

Figure 16 Electrical SLD



From this SLD, a preliminary motor and generator list can be generated:

- Percolate pump motors
- CHP Generator
- Blowers (2)
- Biogas H2S removal water pump motor
- Heat exchange pump motors

5 BUSINESS CASE EVALUATION

This section develops the financial parameters for both the CHP and Boiler scenarios and draws conclusions as to their economic viability.

5.1 CHP SCENARIO

In this scenario, several technical and economic assumptions have been made. The most essential parameters used are shown below:

Table 16 CHP scenario: economic assumptions

Economic Assumptions			
Inflation	2.00%	Life cycle/amortization (yrs)	20
Interest on loan	3.58%	Operating supervision	5%
Equity	40%	Plant overhead	3%
Debt	60%	Admin cost	2%
Electrical efficiency	35%	Boiler efficiency	90%
Heat recovery efficiency	40%	Electricity rate ($/MWh)	$210.00
Capacity factor	95%	CND$-USD$	1.30
NPV rate	3.38%	Property tax	-
Real discount rate	3.38%	Return on equity	8.25%
Contaminant disposal ($/t)	$94.00	Insurance	0.3%
Loader operation (hrs/d)	8	Wastewater disposal ($/t)	-
Global loader cost ($/hr)	130	Compost disposal ($/t)	-
Plant technician (hrs/d)	2	Maintenance & repair (%capex)	0.50%
Plant technician cost ($/hr)	40	CHP maintenance ($/kWh)	0.015

The equipment and material portion of the capital cost was increased by 7% to factor in typical additional costs for the Whitehorse remote/northern market. These assumptions, as well as the 4.5% lending rate, are on the optimistic side. A private project developer will probably have to work under less advantageous conditions.

5.1.1 CAPITAL COST

The capital cost estimation has been made considering RFI received as well as experience from WSP/Electrigaz group.

The following tables provide Class 4 cost details of capital expenses necessary to realize this project.

Table 17 CHP scenario: capital costs

Equipment List (Anaerobic Digestion) +/- 20%

Categories	Items	Total Including Installation
Civil		$350,000
	Site preparation	
	Ground structuring	
	Utility services	
AD process		$2,405,000
	Process building	
	Reception/mixing hall	
	Dry digestion (4 tunnels)	
	Percolate tank	
	Piping (percolate/biogas)	
	Automation system	
Ancillary process building systems		$198,000
	Ventilation equipment	
	Fire suppression system	
	Offices	
Odour management		$193,000
	Acid scrubber + facilities	
	Biofilter + facilities	
Heating equipment		$245,000
	Heat exchanger	
	Biogas boiler	
	Hot water pump	
Biogas management equipment		$164,000
	Biogas storage (percolate tank roof)	
	Flare	
	Gas blower	
Indirect costs		$967,000
	Permiting, Engineering, supervision, project management	
	Legal expenses	
	Start-up, commissioning	
	Temporary services (trailers, utilities, etc.)	
Contractor profit (EPC construction)		$533,000
Contingency		$533,000
Total cost		**$5,588,000**

Equipment List (Biogas CHP) +/- 20%

Categories	Items	Total Including Installation
CHP		$955,000
	H2S scrubber	
	CHP (2x 100 kWe)	
	Heat pipes	
	Interconnection to grid	
Indirect costs		$151,000
	Permiting, Engineering, supervision, project management	
	Legal expenses	
	Start-up, commissioning	
	Temporary services (trailers, utilities, etc.)	
Contractor profit (EPC construction)		$143,000
Contingency		$143,000
Total cost		**$1,392,000**

As it is stated in the previous sections, the capital costs in the RFI responses received were ranged between $685 and $3,188 per ton of annual treatment capacity.

Since, in the first year of the project, the plant input is estimated at 3202 tons per year, the present capital cost estimation fit in this range at $2,180 /tons (considering AD and CHP equipment). It must also be noted however that the plant is sized to process incoming substrate until 2036 which is estimated at 7,823 tons. With this annual tonnage the capital costs per tonnage is $892 which also fits in the range.

5.1.2 OPERATIONAL COSTS

The following tables provide Class 4 operational cost details for the first 20 years of operation.

Table 18 CHP scenario: operational costs (for year 1 to 9)

Operational Costs +/- 20%	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026
AD/Biogas technician	$29,200	$29,784	$30,380	$30,987	$31,607	$32,239	$32,884	$33,542	$34,212	$34,897
Loader operation (machinery/fuel/labour)	$116,800	$119,136	$121,519	$123,949	$126,428	$128,957	$131,536	$134,166	$136,850	$139,587
Operating supervision	$1,460	$1,489	$1,519	$1,549	$1,580	$1,612	$1,644	$1,677	$1,711	$1,745
Process Water	$-	$-	$-	$-	$-	$-	$-	$-	$-	$-
Electricity	$13,888	$15,632	$17,622	$19,556	$24,773	$27,782	$29,312	$30,400	$31,529	$32,702
Waste water disposal costs	$-	$-	$-	$-	$-	$-	$-	$-	$-	$-
Solid digestate disposal costs	$-	$-	$-	$-	$-	$-	$-	$-	$-	$-

5.1.3 FINANCIAL ANALYSIS

Capital cost was adjusted to take into consideration phased capital investment (5th year CHP) and interest during construction (IDC).

Table 20 CHP scenario: Capital costs breakdown

Capex Breakdown (+/- 20%)	
AD process	$5,588,000
CHP (Yr 0)	$892,000
CHP (Yr 5)	$500,000
Total	$6,980,000
Interest during construction (IDC)	$69,923
Subsidy	----
Fixed capital investment (Yr 0)	$6,549,923
Fixed capital investment (Yr 5)	$500,000
Capital outlay (Yr 0)	$2,619,969
Capital outlay (Yr 5)	$200,000
Loan (Yr 0)	$3,929,954
Loan (Yr 5)	$300,000

Repeated financial analyses were performed for several price points to determine the levelized cost of energy (LCOE). Exportable heat is assumed to be sold entirely at the price of $12/GJ or $43/MWh (th)

Table 21 CHP scenario: financial analysis

Gate Fees $/ton	**Heat Sales** $/GJ	**Subsidy** % of Capex	**LCOE ($/KWH(E))** Real
38	12	0%	$0.638
38	12	70%	$0.206
45	12	0%	$0.576
45	12	50%	$0.267
50	12	0%	$0.531
50	12	40%	$0.284

The following financial results are presented for a gate fee of $38/ton (2016 rate) and $0.21/kWh, which are market financial parameters currently in force for the proposed project (see Section 1.1.1).

Table 22 CHP scenario: financial results (for years 0 to 9)

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026

5.2 BOILER SCENARIO

In this scenario the biogas is used to generate hot water to be sold, entirely, to existing and hypothetical heat clients located at less than 700 m of the biogas plant.

Key technical and economic assumptions made for this scenario are summarized below:

Table 24 Boiler scenario: economic assumptions

Economic Assumptions			
Inflation	2.00%	Plant depreciation (yrs)	20
Interest on loan	3.58%	Operating supervision	5%
Equity	40%	Plant overhead	3%
Debt	60%	Admin cost	2%
Electrical efficiency	35%	Boiler efficiency	90%
Heat recovery efficiency	40%	Electricity rate ($/MWh)	$210.00
Capacity factor	95%	CND$-USD$	1.3
NPV rate	3.38%	Property tax	-
Real discount rate	3.38%	Return on equity	8.25%
Contaminant disposal ($/t)	$94.00	Insurance	0.3%
Loader operation (hrs/d)	8	Wastewater disposal ($/t)	-
Global loader cost ($/hr)	130	Compost disposal ($/t)	-
Plant technician (hrs/d)	2	Maintenance & repair (%capex)	0.50%
Plant technician cost ($/hr)	40	CHP maintenance ($/kWh)	0.015

The equipment and material portion of the capital cost was augmented by 7% to factor in additional costs typical for the Whitehorse remote/northern market.

5.2.1 CAPITAL COSTS

The capital cost estimation has been made considering RFI received as well as experience from WSP/Electrigaz group.

The following tables provide Class 4 cost details of capital expenses necessary to realize this project.

Table 25 Boiler scenario: capital costs

Equipment List (Anaerobic Digestion) +/- 20%

Categories	Items	Total Including Installation
Civil		$350,000
	Site preparation	
	Ground structuring	
	Utility services	
AD process		$2,405,000
	Process building	
	Reception/mixing hall	
	Dry digestion (4 tunnels)	
	Percolate tank	
	Piping (percolate/biogas)	
	Automation system	
Ancillary process building systems		$198,000
	Ventilation equipment	
	Fire suppression system	
	Offices	
Odour management		$193,000
	Acid scrubber + facilities	
	Biofilter + facilities	
Heating equipment		$65,000
	Heat exchanger	
	Hot water pump	
Biogas management equipment		$164,000
	Biogas storage (percolate tank roof)	
	Flare	
	Gas blower	
Indirect costs		$918,000
	Permiting, Engineering, supervision, project management	
	Legal expenses	
	Start-up, commissioning	
	Temporary services (trailers, utilities, etc.)	
Contractor profit (EPC construction)		$506,000
Contingency		$506,000
Total cost		**$5,305,000**

Equipment List (Heat Network) +/- 20%

Categories	Items	Total Including Installation
Heat network		$519,000
	Biogas boiler	
	Heat pipes	
	Heat network water pump	
	Delivery heat exchanger	
Indirect costs		$42,000
	Permiting, Engineering, supervision, project management	
	Legal expenses	
	Start-up, commissioning	
	Temporary services (trailers, utilities, etc.)	
Contractor profit (EPC construction)		$78,000
Contingency		$78,000
Total cost		$717,000

The only differences between the capital cost estimation from CHP scenario and boiler scenario are the heat network cost and the CHP unit cost. In the CHP scenario, it is assumed that heat is sold across the street to the composting building (minimal heat network). In the boiler scenario, the CHP unit is replaced by a boiler which cost less but also embeds the cost of deployment of a heat network to existing KBL and/other hypothetical proximity clients.

For this scenario, it has been estimated that a heat consumer would be in a 700 m radius from site.

5.2.2 OPERATIONAL COSTS

The following tables provide (+/-20%) operational cost details for the first 20 years of operation:

Table 26 Boiler scenario: operational costs (for years 1 to 9)

Operational Costs +/- 20%	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026
AD/Biogas technician	$29,200	$29,784	$30,380	$30,987	$31,607	$32,239	$32,884	$33,542	$34,212	$34,897
Loader operation (machinery/fuel/labor)	$116,800	$119,136	$121,519	$123,949	$126,428	$128,957	$131,536	$134,166	$136,850	$139,587

5.2.3 FINANCIAL ANALYSES

The capital cost was adjusted to take into consideration interest during construction (IDC).

Table 28 Boiler scenario: Capital costs breakdown

Capex Breakdown	
AD process	$5,305,000
Heat network	$717,000
Total	$6,022,000
Interest during construction (IDC)	$64,981
Subsidy	$-
Fixed capital investment	$6,086,981
Capital outlay	$2,434,792
Loan	$3,652,189

Repeated financial analyses were performed for several price points to determine the levelized cost of energy (LCOE).

Table 29 Boiler scenario: financial analysis

Gate Fees $/ton	Subsidy % of CAPEX	LCOE (REAL) $/KWh(th)	LCOE (REAL) $/GJ
38	0%	0.227	62.996
38	70%	0.085	23.488
45	0%	0.203	56.405
45	60%	0.081	22.541
50	0%	0.186	51.697
50	40%	0.105	29.121

The analyses show that without significant subsidies the heat only project has difficulty competing with other heat sources.

The following financial results are presented for a gate fee of $38/ton (2016 rate) and heat at $15/GJ. Note that it has been assumed that all generated heat will be sold to a client situated in a 700 m radius.

Table 30 Boiler scenario: financial results (for years 0 to 9)

	2016	2017	2018	2019	2020	2021	2022	2023	2024	2025	2026

6 CONCLUSION

The proposed CHP and heat only biogas projects at the current composting site, with a respective capital investment of $7.1M and $6.1M, were found to be uneconomic without a subsidy based on the current cost and revenue parameters determined above.

The scenario of production and sale of heat, in the form of hot water, generated by a 500 HP biogas boiler is not recommended because of the cost of deploying a district heating network over to the nearest client. At the moment, KBL is actually present in a radius of 700 m but its actual yearly heat consumption only adds up to $8,550 of propane, which would not be enough revenue to warrant such an investment. Moreover, its heat consumption is "out of phase" with and biogas production (peaking in summer).

For a "heat only" project to be viable it would have to significantly raise the organic treatment gate fee, gather important capital subsidies and sell 100% of the heat produced during winter and summer months. The following table shows the levelized cost of energy (heat) for different organic treatment gates fees and capital subsidy support

Table 32 Boiler scenario: financial analysis

Gate Fees $/ton	Subsidy % of CAPEX	LCOE (REAL) $/KWh(th)	LCOE (REAL) $/GJ
38	0%	0.227	62.996
38	70%	0.085	23.488
45	0%	0.203	56.405
45	60%	0.081	22.541
50	0%	0.186	51.697
50	40%	0.105	29.121

This scenario, estimated at $6.1M, is unlikely to attract industrial clients (green houses, industrial thermal processes, etc.) because energy prices are not discounted significantly.

The utilization of biogas in CHP units is better adapted to this location since it allows selling of heat and electricity in the summer and during power demand peaks. The deployment of CHP units would be phased in with one 100 kW unit installed initially and a second 100 kW unit (or more if landfill gas is exploited) 5 years later. The heat generated by the CHP would be used entirely at the composting building to heat the facility and potentially dry further the compost before bagging it.

The project is estimated to require a total capital investment of approximately C$7.1M and to cost over $255,000 per year to operate.

The revenue from the biogas plant will come from gate fees, electricity and heat sales. With a current market pricing of $0.21/kWh for the electricity sold to the grid, a $38/t gate fee (2016 rate), and savings of $12/GJ for heat, the project is not economically viable. With these market conditions the project would require significant capital subsidies. The following table shows the levelized cost of energy (electricity) for different organic treatment gates fees and capital subsidy support:

Table 33 CHP scenario: financial analysis

Gate Fees $/ton	Heat Sales $/Gj	Subsidy % of CAPEX	LCOE ($/KWh(E)) REAL
38	12	0%	$0.638
38	12	70%	$0.206

45	12	50%	$0.267
50	12	0%	$0.531
50	12	40%	$0.284

Biogas captured from the landfill could potentially help boost electrical production and provide better project economics. Further study of this scenario would be needed.

Nevertheless, it is clear that this project will require organic treatment gate fee adjustment and capital investment in form of subsidies because the revenues generated by the project are insufficient to warrant the high capital investment.

Based on the current market conditions it is unlikely that the project would attract independent project developers. The project would probably have to be developed by Yukon Energy Corporation and/or the City of Whitehorse with the support of capital grants.

1 INTRODUCTION

Electrigaz/WSP are assessing the composition of the residential and ICI organic waste collected in Whitehorse in order to perform a feasibility study of an anaerobic digestion plant processing this material.

2 FEEDSTOCK

The sampling and analysis campaign will be specific to organic waste from the two (2) following streams:

- → Household curbside
- → ICI collection

The sampling and analysis campaign will focus on finding the proportions and digestibility of the following feedstock:

1. Source sorted organic (SSO)
   - Fruit and vegetable
   - Meat
   - Bread and cereal
   - Egg
   - Paper
   - All other food waste
2. Fresh garden waste (FGW)
   - Grass
   - Leave
   - Plants and flower
3. Dead garden waste (DGW)
   - All garden waste that have lost is original color (ex: brown grass)
   - Wood branches, wood chips
4. Contaminants
   - All none organic waste
     - Plastic, metal, glass, rock, sand, Styrofoam, mirror
   - Some organic that are hardly biodegradable

A lot of research studies are already available regarding the biomethane production potential of each of these four categories. Considering this available data, it appears necessary to focus on the proportions of each of them into the feedstock to assess the seasonality of the biomethane production potential of the global feedstock.

3 PROPOSED APPROACH

Electrigaz/WSP are proposing to perform 2 different types of assessments:

3.1 WASTE SAMPLING AND ANALYSIS

Two (2) sampling events (Aug and Oct) would occur where material would be manually separated into the four (4) fractions described above and weighted. The operation will be documented with notes and pictures.

The material sampled would be analysed for total solids, volatile solids, NPK only.

3.2 CONTINUOUS ON SITE VISUAL ASSESSMENT

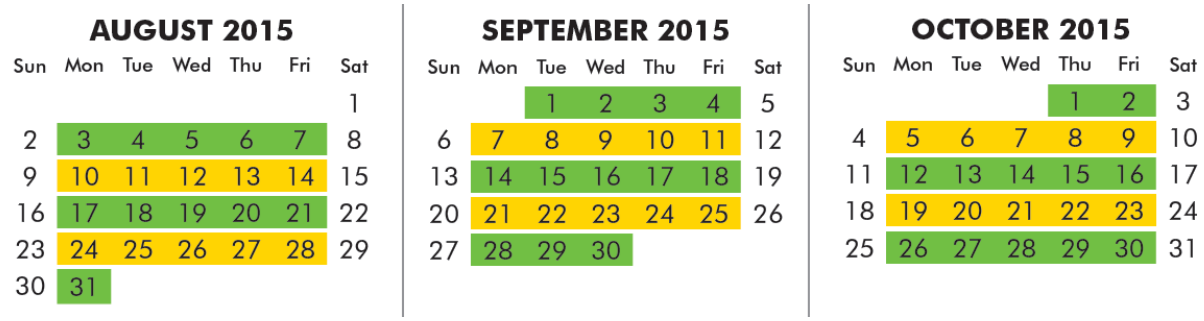
Every other week from August 31st to October 30th, a technician (student) would perform visual assessment (notes + photos) of the material being received on the composting site to assess feedstock composition trends in time.

4 VISUAL ASSESSMENT METHODOLOGY

The technician (student) will have to take multiple pictures and fill a description sheet for all truck loads received at the Whitehorse composting facility. The data sheet is at the end of this report.

This job will be from august 31st to October 30th 2015 and will follow the organic collection of the municipality (visual assessment every other week).

Figure 1 Whitehorse 2015 collection (yellow for recycling and green for garden and organic)



5 WASTE SAMPLING METHODOLOGY

The technician should be on site for 2 period of 2 days.

- August 31 to September 2, 2015
- October 14 to 16, 2015

For each load received on these days the composting site operator will take a representative bucket of the organic waste and put it on the side, in a defined and safe area, to facilitate the technician job. At the end of the day, the composting site operator can process the organics that was put on the side.

Each day on site, the technician should weight and separate all fractions from portions (set aside by loader) for all truck loads.

5.1 SAMPLING METHOD

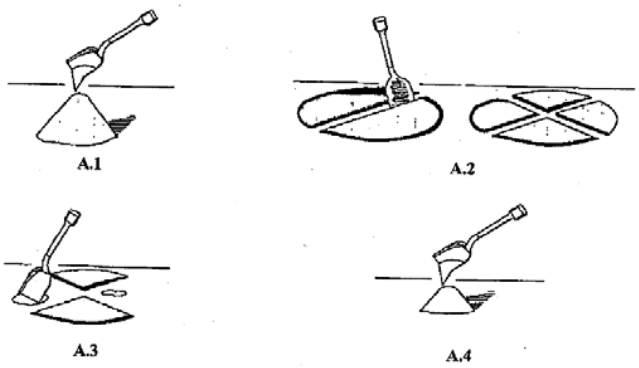
- On each organic reception take a 4.5 gallons sampling
- Remove 30 centimeters of material from point 1
- Take 1,5 gallons from point 1
- Remove 30 centimeters of material from point 2
- Take 1,5 gallons from point 2
- Remove 30 centimeters of material from point 3
- Take 1,5 gallons from point 3

5.2 WEIGH ANALYSIS

- Proceed to one Quarter division method (see next section)
- Weigh the sample
- Separate by hand all fraction
- Weigh all sub-fractions (4)
- Fill the report

5.3 QUARTERS DIVISION METHOD

- **A.1** : Put the sample on a concrete slab or on a tarp. Give the sample a cone shape
- **A.2** : Flatten the top of the cone and split the sample into four piles along two perpendicular diameters with respect to each other.
- **A.3** : Remove and discard two diametrically opposite quarters , leaving a clean surface in this space freed
- **A.4** : Mix the remaining districts and repeat operations A.1 to A.3 until the required amount of the sample for analysis



6 PERFORMED LAB ANALYSIS

For each sampling event (3 days), from the various piles analysed, the technician will create a representative sample of:

- ICI: SSO
- ICI: FGW
- ICI: DGW
- Residential: SSO
- Residential: FGW
- Residential: DGW

These samples will be kept at 4 °C and sent at the end of the sampling week to a local lab for Total Solids (%TS) and Volatile Solids (%VS).

The technician will also perform a separation of the frozen material collected in April by the client to be sent for the same lab analysis

A total of 18 lab tests will be performed.

7 REQUIRED TECHNICIAN EQUIPMENT

- Camera
- Notebook
- Laboratory and/or work gloves
- Steel toe shoes
- Mask (optional)
- Safety helmet and vest
- Disposable coverall
- Shovel and/or fork and several (3-5) 20 liters buckets
- Portable weigh scale
- Tarp and large plastic bag (Ziploc)
- Support from composting site operator (loader)

8 DATA SHEETS

The next two pages present report data sheets that technicians will use to collection site information.

After filling the report technician and student can allow the organic waste operator to process the material. After each day, clean all material.

APPENDICES

APPENDIX A LAB TEST RESULTS

APPENDIX B SAMPLING PROCEDURE

1 INTRODUCTION

A sampling and analysis campaign has been performed to estimate input tonnage and quality to a possible AD plant that would treat organic waste from Whitehorse ICI and residential.

Objectives of this campaign were the following:

- Estimate contaminant nature and proportion
- Estimate possible monthly and seasonal tonnage and characterization variation throughout the years.

Results would mainly focus on characterizing contaminant nature and composition as well as determining proportion of three main feedstock categories (SSO, DGW, and FGW).

SSO stands for source sorted organics and mostly represents food waste or kitchen waste like fruit or vegetable peels and trimmings. FGW is fresh garden waste which is typically fresh cut grass or garden trimmings. DGW stands for death garden waste which is mainly fallen leaves or tree trimmings.

This information will enable WSP/Electrigaz to properly estimate AD system requirements as well as biogas production.

2 SAMPLING PROCEDURE

A sampling procedure has been generated and accepted by both the client and WSP/Electrigaz. The procedure is available in the appendix B.

This procedure has been followed by the technician on site to assure representativeness of the sampling results. The sampling procedure also included a visual assessment campaign performed by a local student.

3 VISUAL ASSESSMENT RESULTS

A visual assessment is the first step to the characterization of the input material. This step offers the possibility to physically evaluate the input and to testify some unpredictable contaminant scenarios. Electrigaz/ WSP consider this evaluation primordial to establish contaminant removal and input handling strategies. Visual assessments may be, in some cases, the only way to establish worst case scenarios or to verify if these scenarios are plausible. It gives the opportunity to evaluate the possibility a plant will receive in logs, gas canisters or any other cumbersome or unusual contaminant during operation.

Visual assessments were made to establish a preliminary estimation of feedstock available for an AD process. The main objective of these assessments is to provide a rough estimation of main components present in feedstock (SSO, DGW, FGW and contaminants) and seasonal variations of these components.

A total of 20 visits have been made on site to visually inspect feedstock. These visits were made from August 28th until the 22nd of October 2015. This period of time spreads over 2 seasons and represents a typical sample from which it will be possible to derive a yearly average. On each visit, the technician was asked to note input composition and nature of contaminants found in daily loads brought on site.

Note that this visual estimation will also be used to compare lab result characterizations made afterward

3.1 OBSERVATION LOG

The following table sums up the contaminant observations made on each visit.

Table 1 Visual Assessment Log

3.3 COMPOSITION ESTIMATION

The following estimations have been made from visual assessments.

SEASON	SSO (%)	FGW (%)	DGW (%)	CONTAMINANT
				(%)
Summer	19%	37%	41%	3%
Fall	5%	10%	83%	2%

This composition estimation has been made considering tonnage of loads fed on compost platforms when the technician was on site and a rough proportion analysis based only on visual analysis.

It can be noted that SSO and FGW seem much higher in summer compared to fall in which a high amount of DGW is observed. As expected, this is mainly due to leaf input that represents the main organic waste in fall.

Also note that contaminant proportion seems quite constant from summer to fall and is relatively low. The main contaminants noted are non-compostable plastic bags. From these conclusions it seems population has already been well educated. Implementation of an AD plant would not change their habits and it is reasonable to estimate that contaminant proportion would not drastically change.

4 LAB ANALYSIS

4.1 RATIONALE

It is important to mention that the analysis and process estimation approach privileged by Electrigaz/WSP differs slightly from YEC requests. YEC requested biochemical methane potential (BMP) tests on the inputs fed to the composting facility but at this point of the project Electrigaz/ WSP estimate it would be premature and unrepresentative to conduct such analyses.

In our experience, the challenge of BMP testing is the representativeness of the samples. Since SSO substrate quality varies on every load received, it is almost impossible to generate a homogeneous sample that would be representative of the total input.

Moreover, in such small projects biogas yield precision is considered secondary since costs associated to material handling and contaminants removal will deeply influence the economics and viability of the project as well as the produced energy price. This is why general composition of the inputs is more a concern than the actual biogas production.

More specifically ratios between food waste, fresh garden waste, dead garden waste and contaminants and how they may vary in volume and ratios over the seasons are all crucial information to estimate operation strategy and timeline.

It has to be noted that Electrigaz/ WSP and its partner Krieg und Fischer (Germany) cumulates over 30 years of specialized biogas engineering. The consortium has charts for biochemical methane potential (BMP) for every typically processed substrate. This chart presents CH4 yield per kg of organic dry matter. Organic dry matter represents the digestible part of dry matter in a substrate. It is then possible, from substrate characterization, to accurately evaluate biogas production.

By knowing CH4 volume produced from every kg of organic dry matter, the exact degradation of the substrate is calculated and biogas volume production is known as well as mass balance of the entire plant. Therefore, the newly adopted protocol is not focused on biogas production only but focused on composition through sorting protocols and testing for basic parameters such as dry matter and organic dry matter composition and NPK which are the main values considered to design an AD plant.

By experience the consortium only does BMP on exotic and poorly documented substrates. As North American SSO is well documented it has been recommend that lab analyses mainly focus on dry matter and organic dry matter content.

4.2 RESULTS

Lab analyses have been made on representative samples taken on site to support the visual assessments and to precisely define substrate composition and characteristics.

Each sample has been primarily separated in waste type, as defined in the previous sections, SSO, FGW and DGW. It is known that each type of substrate will degrade differently in an AD process and this is why it is important to separate them before proceeding to lab characterization. This separation will enable to precisely define the feedstock seasonality and its impact on AD biogas production, mass balance and equipment sizing.

Each separated sample was analysed to determine the following

- Dry matter,
- Organic dry matter,
- NPK

These results will enable WSP/ Electrigaz to develop process designs. The following table presents the results of the analysis.

Note that sample details (sampling date, sample mass) are available in the appendix

TECHNOLOGY REVIEW

Appendix Technology review

Proposed systems in RFIs

In this appendix, each of the five proposed biogas systems is summarized. The information provided in the proposals varies greatly.

Himark Biogas Inc.

Himark Biogas Inc. proposes a biogas system using a dry digestion technology. The design includes four dry fermentation chambers, a percolate recirculation system, a biogas polishing system and a cogeneration system. The proposed facility has a capacity of 4000 tons per year, but the capacity can be increased by installing additional fermentation chambers.

The dry fermentation system operates on a sequential batch basis. Each of the four chambers has a volume of 306 m^3 and can accommodate seven days' worth of feedstock (assumingly based on average annual substrate). Before loading the fermentation chambers, the substrate is prepared by mixing it with a bulking agent, potentially dehydrated digestate. Himark however mention that bulking agent addition might not be necessary in this case. The mixing is performed within the digester building, which can accommodate for eight days' worth of feedstock and up to 90 tons of recalcitrant digestate. The fermentation chambers are heated by an internal glycol heating system, with heat provided by the cogeneration system.

Complete pathogen destruction is achieved by operating the fermenter at a temperature of 55 °C, i.e. thermophilic temperature range. According to the supplier, the fermentation chambers can reach the thermophilic operating conditions without external energy requirements due to internal heat generation at the beginning of the digestion process. Typically this lasts for 10 to 16 hours from the beginning of the cycle. Thereafter the fermentation chambers are heated by the internal glycol heating system.

The fermentation chambers are connected to a percolation sprinkler system. It is used to spray the feed with percolate in order to accelerate the anaerobic fermentation process. The percolate is biologically active and contains microorganisms that will enhance the digestion process. The excess percolate from the fermenters drains to a percolation sump where it is fed to a separate percolate tank. In the tank the percolate recharges with the thermophilic organisms required for digestion. The percolate tank is heated to a temperature of 55 C° with internal glycol heating loops. The percolate stream is sprayed on top of the substrate at a temperature of about 62 °C.

The percolate tank is a significant generator of biogas and will approximately produce 25-40 % of the total amount of biogas. The percolate tank is equipped with pumps transporting the percolate drained from the fermenters to the tank as well as from the tank and to the sprinkler nozzles. The percolate tank is equipped with Blown down and Make up water systems to prevent salts from cycling up in the percolation stream.

The proposal includes a cogeneration system containing internal combustion engines, which drives generators to produce electricity. The waste heat is captured in a stream of glycol and utilized in the anaerobic digestion plant. In order to utilize the biogas in the cogeneration system, the gas needs to be pretreated in a scrubbing and polishing process. Contamination of H_2S needs to be removed to prevent oxidation of cogeneration system equipment. Before the biogas can be utilized the moisture content needs to be decreased and the gas must be delivered within specified

temperature and pressure ranges (not specified in the proposal). The proposal includes a biogas scrubbing system using ferric chloride injections into the percolate stream.

Table 1: Proposal specifics Himark Biogas

Mass and energy balances summary	Total project estimate	Used technology and major components for biogas production
Biogas production: 806,285 m^3/year (Based on a 4000 ton feedstock) Cogeneration system: Gross power: 134 kW_e Net power 121 kW_e Thermal output: 265 kW_{th} Water use: 504 tonnes/year Liquid waste: 504 tonnes/year Sludge: 3.1 tonnes/year (% TS of around 34 %)	$ 2,264,821 USD	Biogas is produced in dry fermentation chambers and a percolate tank. Major components: ◦ Fermentation chambers ◦ Percolate tank and recirculation system ◦ Purge and ventilation system ◦ Biogas scrubber and polishing system ◦ Cogeneration unit ◦ Biogas storage ◦ Biogas flare

Himark has experience on biogas production from source sorted organic waste (SSO). It has conducted the detailed design for a biogas plant in Hairy Hill, Alberta, Canada where the hot and extreme cold climates needed to be taken into consideration. Himark has also conducted three integrated anaerobic digestion and fertilizer projects with SSO as feedstock in Hampshire, USA.

Viessmann/BIOFerm

BIOFerm, a part of the Viessmann group, propose a biogas system that includes a combined anaerobic digestion and compost facility. The design includes four dry fermentation chambers, a percolate storage tank, a biogas treatment system, gas storage, a CHP plant and an odor control system. The proposed sizing of the fermentation chambers allows for potential increase of feedstock quantity from 3,202 tons per year to 7,823 tons per year. The design enables this expansion by increasing the loading height in the fermentation chambers. While running below maximum capacity, the amount of recycled digestate can be increased to lengthen the retention time and utilize more digester space.

The substrate is fed in batches to the four dry fermentation chambers where biogas, digestate and percolate are produced. At the start-up of the plant, each fermenter will be staggered in start-up by one week, which allows the waste to be received and stored no longer than 7 days prior to entering into a fermenter unit. When a fermentation chamber is at the end of a single digestion cycle, typically 28 days, the digested material is removed. A portion of the digestate is mixed with the fresh material and reloaded to a fermenter to begin a new cycle. At full capacity, 40 % of the digestate will be recycled. The digestate that was not mixed and reloaded into the fermentation chamber is then ready for composting or to be used as landfill cover. The fermentation chambers are connected to an in-floor heating system keeping the substrate at a constant temperature of 40 °C, i.e. optimum condition for mesophilic anaerobic digestion. Heat is provided from the CHP system. BIOFerm argues that mesophilic conditions are preferable because the majority of methane producing bacteria thrives in mesophilic temperature ranges and has higher growth rates than the minority existing in the thermophilic temperature ranges. This has been demonstrated to increase the resistance to toxic impacts and variations in the feedstock characteristics. However, digestion in the thermophilic range has been noted for a higher pathogen destruction rate. BIOFerm further argues that the possible gains in gas production with thermophilic conditions are offset by the increased costs.

The substrate stored in the fermentation chambers is sprayed with percolate containing microorganisms to optimize the digestion process. The percolate drained from the fermentation chambers is collected into a percolate storage tank, a continuously stirred-tank reactor. The BIOFerm dry fermentation process is distinguished by pairing a wet fermenter to the process, which enables handling of liquid feedstock in addition to dry waste. Biogas is captured by a gas blower from both the fermenters and the percolate storage tank. The percolate storage tank is operated at 38-44 °C temperature range.

The biogas is treated by removing water and toxic compounds such as H2S or siloxanes. The water condensate by decreasing the gas temperature and toxic compounds are removed via a carbon filter and/or an iron sponge. A biological desulfurization is integrated into the roof structure of the gas storage. The gas can now be used in a CHP or be upgraded to vehicle fuel. The design include two 100 kW CHP biogas engines utilizing the produced biogas.

The BIOFerm system includes an odor control using a biofilter. The odor control system uses water that is recirculated. Only a fraction of the water is sent to the percolation tank.

Viessmann anticipate that no wastewater will be generated for offsite disposal due to the high solids nature of the feedstock. Additional liquid will be required to ensure the anaerobic digestion facility runs efficiently. The amount may vary du to potential of liquid collected from source separated organic material.

Table 2: Proposal specifics Viessmann/BIOFerm

Mass and energy balances summary	Total project estimate	Used technology and major components for biogas production
Biogas production: 266,316 m^3/year (Based on a 3,202 tons feedstock) 650,652 m^3/year (Based on a 7,823 tons feedstock) CHP output: 3,202 tons feedstock Gross power: 583 MWh_e/year Gross thermal output: 2,790 MMBTU/year 7,823 tones feedstock Gross power: 1,499 MWh_e/year Gross thermal output: 6,329 MMBTU/year Water use: Required. (Amount dependent on feedstock) Liquid waste: 0 tons/year Digestate: 4,072 tons/year (Based on a 3,202 tons feedstock) 9,950 tons/year (Based on a 7,823 tons feedstock)	$ 3,927,270 USD	Biogas is produced in dry fermentation chambers and a percolate tank. Major components: ◦ Mixing hall with compost boxers and digesters ◦ COCCUS 1000 Percolate tank ◦ Exhaust system with biofilter ◦ Gas dome ◦ Substrate storage ◦ CHP (2x100 kW)

BIOFerm describes three reference facilities in Europe that utilize municipal organic waste, food waste and materials from landscape conservation. It also presents a case study from an industry-scale dry fermentation anaerobic digester at the University of Wisconsin-Oshkosh, which uses 8000 tons of food waste, yard waste and crop residuals annually.

Bio-en power Inc.

Bio-en power proposes a facility with a wet digestion technology that will eliminate the need for the current composting system. The design include one 1,590 m^3 insulated anaerobic digestion fermentation tank, two 100 m^3 pasteurization tanks and a CHP. The system can handle 4000 tons of feedstock per year, with monthly fluctuations.

The incoming waste will be preprocessed by chopping and mixing in the preprocessing pit. It will then be fed to the pasteurization tanks before fed into the main fermenter via a pump station. The dry substrates are stored in a driving silo and then fed as required to the main fermenter via the dry loading unit. The substrate is fermented in the fermenter at a temperature between 35°C and 55°C. The digesters will eliminate pathogens and weeds and therefore no additional composting is required. The digestate is separated into a solid fraction and a liquid residue. The digestate can be used as a fertilizer.

Table 3: Proposal specifics Bio-en power Inc.

Mass and energy balances summary	Total project estimate	Used technology and major components for biogas production
(Based on 2,220 tons feedstock) Biogas production: 306,600 m^3/year CHP output: Power output: 560 MWh_e/year Thermal output: 720 MWh_{th}/year Water use: 1,000 tons/year Solid waste: 1,825 tons/year Liquid waste: 1,095 tons/year	$ 2,608,277 CAD	Biogas is produced by using wet anaerobic digestion technology. Major components: ◦ Insulated anaerobic digestion fermentation tank ◦ Pasteurization tanks ◦ Preprocessing pit ◦ Gas storage ◦ Driving silo ◦ CHP

According to the references in the RFI, Bio-en has no experience from SSO feedstock. From the references, all located in Europe, it seems Bio-en instead has experience of feedstock such as corn silage, rye, cattle dung, slaughter waste, blood and biogenic wastes.

Wildstone/Gicon

Gicon proposes a biogas facility using the patented GICON® Process consist of a two-stage, dry-wet anaerobic digestion process. The design includes a pretreatment area, ten percolation tunnels, two methane digesters, a percolate buffer tank, a digestate storage tank, gas storage, an emergency flare and a CHP.

The process begins with feedstock pretreatment by shredding and mixing. The feedstock is then loaded into percolation tunnels, for an initial hydrolysis stage, where it remains for a retention time of 14-20 days. In the percolation tunnels the substrate is irrigated with process water and liquid digestate resulting in an organically-laden liquid. This liquid substrate in then pumped to a buffer tank which continuously feeds the methane digesters (fixed bed reactors), where the methanogenesis stage begins. The two methane digesters operate at 38 °C, i.e. mesophilic conditions, and produce the majority of the biogas. The remaining solid residuals are composed mainly of difficult-to-degrade material and can subsequently be treated under aerobic conditions by means of composting.

Table 4: Proposal specifics Wildstone/Gicon

Mass and energy balances summary	Total project estimate	Used technology and major components for biogas production
(Based on a 2,334 tons feedstock) Biogas production: 232,403 Nm^3/year CHP output: Gross power output: 472 MWh_e/year Net power output: 245 MWh_e/year Gross thermal output: 609 MWh/year Net thermal output: 477 MWh/year Water use: 467 tons/year for the anaerobic digestion process 36-108 tons/year for biological desulfurization Liquid waste: 1500 tons/year Contaminant materials: 120 tons/year Final compost: 474 tons/year	$ 7,440,727 CAD	Biogas is produced by using a two-stage, dry-wet anaerobic digestion technology. Major components: ◦ Pretreatment area ◦ Percolation tunnels ◦ Methane digesters ◦ Percolate buffer tank ◦ Digestate storage tank ◦ Process water tanks ◦ Gas storage ◦ Emergency flare ◦ Building ventilation system ◦ CHP

Gicon has delivered more than 60 biogas facilities worldwide. The patented GICON® process has been implemented at Harvest Power's Richmond Energy Garden biogas plant near Vancouver. 40,000 tons of residential/commercial SSO and lawn/garden waste is processed in the facility annually.

Enerpedia

Enerpedia presents a number of case studies for small-scale anaerobic digestion facilities in Western Europe. Enerpedia does not provide a specific proposal for the Whitehorse project. However, one case that can be interesting is a dry pocket digester facility installed on the horse farm of Thierry de Pas in France.

The digester's biomass input on a yearly basis consists of 650 tons of litter and 850 tons of communal bio-organic waste and other biomass. Biogas is produced by mesophilic dry digestion and then utilized in a 50 kW_e CHP. The system included of six modular digestion containers of a standard size of 30 m^3 with a residence time of 25-30 days. Percolate from the anaerobic digestion is recirculated to maintain a favorable microbial community in each of the containers.

The biogas is captured and stored in a gas balloon before it is utilized in the CHP. The digestate is spread out on proprietary grassland and cropland.

Table 5: Case study of dry type pocket digester in France.

Mass and energy balances summary	Total project estimate	Used technology and major components for biogas production
(Based on 1500 tons feedstock) CHP output: Gross power output: 253 MWh_e/year Heat use: 425 MWh_{th}/year	684,000 €	Biogas produced by using a two-stage, dry-wet anaerobic digestion technology. Major components: ◦ Digestion containers ◦ Heating network ◦ "Gas balloon" storage ◦ CHP

Enerpedia has only collected information from different case studies and installations across Western Europe. The only case operating with a dry fermentation technology uses litter, communal bio-organic waste and other biomass as feedstock.

Whitehorse, Yukon Y1A 6S7

Attention: Shannon Mallory, Environmental Coordinator

Dear Shannon:

Re: 5160120 - Review of Waste to Energy Business Case Analysis

Introduction

Morrison Hershfield completed a business case analysis for Yukon Energy Corporation (YEC) in 2012 exploring the feasibility of developing a Waste to Energy facility in Whitehorse ("Waste to Energy Updated Design Basis and Business Case Analysis", April 24, 2012). The primary purpose of the proposed facility was to increase firm electrical generation capacity in Yukon (1.6 MW capacity; 9,975 MWh generated annually).

We understand that YEC may be including "Waste to Energy" among the options to be considered in an updated Resource Plan and would like to determine if the results of Morrison Hershfield's 2012 business case analysis ("MH 2012") require revisions or updating. This memo includes a brief discussion of the key business case variables and provides an assessment of whether the business case results remain applicable for YEC's current planning initiative.

Review of Key Business Case Variables:

A brief discussion of the key business case variables determined in MH 2012 is provided below:

Feedstock Availability

The design basis for the 2012 business case was predicated on optimizing the use of available City of Whitehorse Municipal Solid Waste (MSW) feedstock and augmenting the MSW with higher cost biomass (wood) feedstock during the winter period when waste volumes decrease. The business case analysis assumed that available MSW volumes would decrease significantly by 2015 coinciding with the City's policy direction of achieving a 50% waste diversion target by 2015. The business case also included a number of sensitivity analyses that examined alternative waste diversion scenarios.

We understand the City of Whitehorse has not yet achieved its 50% diversion target and higher volumes of MSW are currently being disposed in landfill than predicted in the business case analysis. However, since the City is continuing to implement their Zero Waste programs outlined in the Solid Waste Action Plan (City of Whitehorse, 2013) the assumption of reduced future MSW volumes (used in the business case analysis) remains valid.

It was assumed that biomass (to augment the MSW feedstock) would be obtained from a variety of sources including spruce beetle-killed wood, local brushing and clearing, and Construction & Demolition waste. We are not aware of any significant changes in either the availability or competitive end uses for these biomass sources.

Technology and Conversion Efficiency

In the RFI process used to support the 2012 business case, seven vendors provided technical and price information. Some of these vendors are no longer active in the marketplace. However, one vendor, namely EcoWaste Solutions, has been expanding its operations and added additional capabilities. Since this was also one of the highest rated vendors in our assessment, we can confirm that the standard module size originally chosen is still valid.

There have been no new technologies for energy from waste that have reached maturity in this size range to the best of our knowledge in the past 4 years. From other recent projects and technology reviews we can confirm that controlled-air two-stage technology is still the most appropriate technology for this size range, fuel type and location.

The conversion efficiency of waste into heat and power depends on the heating value of the feedstock and the efficiency of the technology. Since neither have changed, the conversion efficiency will also not have changed.

Capital Cost Estimates

The major variables in the capital cost estimates are:

- Chute to stack combustion and energy recovery technology
- Site costs
- Installation and commissioning costs
- Interest rates

Given that the technology assumptions have not changed, the facility size is the same, and inflation has been minimal we estimate that the original cost used in the financial analysis is still valid.

Since it is premature to select a site for this facility (at this planning stage) there is no basis for updating estimated site costs.

Inflation rates have been low (or even negative) in Yukon over the past few years indicating that there is no basis for updating installation and commissioning costs.

Interest rates have actually dropped since the business case analysis was conducted, but only minimally. Since they are expected to rise again, we suggest that the 5.5% annual rate used in the business case analysis is still valid.

In summary, capital costs can be expected to be in the same range as projected in the original financial analysis.

Operating Costs

The most significant operating costs accounted for in the 2012 business case analysis were labour, variable O&M costs, and cost of biomass (wood) supply. Similar to the discussion of capital cost estimates (above), it is assumed that labour and variable O&M costs have not changed significantly as a result of low inflation experienced in Yukon (Whitehorse). We are also not aware of any reason that costs for procuring local biomass (wood) will have changed significantly over the past 4 years.

Revenues

The 2012 business case analysis is highly dependent on revenues from both MSW tipping fees and the sale of heat to a future District Energy System (DES) in Whitehorse. The business case analysis assumed a tipping fee rate of $108 per tonne of MSW received. Since the current (2015) City of Whitehorse Landfill tipping fees range between $94/tonne for sorted waste to $250 for unsorted waste, the estimate used in the business case analysis is still considered reasonable.

Estimated revenue from heat sales to a future DES were based on heating loads and district energy system capital and operating costs derived from a recent DES study completed for YEC in 2013 ("Whitehorse Community Energy Project: Community Energy System Feasibility Study Report", FVB Energy Inc). This is currently the best available information for assessing District heating opportunities and costs in downtown Whitehorse.

Conclusion

Based on the discussion provided in this letter, the Waste to Energy business case analysis results completed for YEC in 2012 are suitable for the purpose of YEC's current high-level resource options assessment.

Yours truly,
Morrison Hershfield Limited

Yukon Energy Corporation
2 Miles Canyon Road
Whitehorse, Yukon Y1A 6S7

Attention: David Morrison, President and CEO

Dear Mr. Morrison:

Re: Waste to Energy Updated Design Basis and Business Case Analysis

Morrison Hershfield is pleased to submit this final report to Yukon Energy Corporation to assist the Corporation in their evaluation of waste to energy opportunities in Whitehorse.

We look forward to continuing to support the Corporation in the evaluation and implementation of future energy opportunities in the territory.

Yours truly,

Morrison Hershfield Limited

Don McCallum, MASc., P.Eng.
Director, Environmental Services

M:\PROJ\5104045\02\REPORTING\FINAL REPORT\510404502 WTE PRE_DESIGN APRIL 24 FINAL.DOCX

EXECUTIVE SUMMARY

Yukon Energy is considering increasing firm electrical generation capacity in Yukon using municipal solid waste (MSW) as a fuel source in a waste to energy (WTE) process. A preliminary business case analysis completed by Morrison Hershfield in 2011 indicated that WTE could provide firm, dependable electricity at significantly lower cost than diesel-generated electricity, provided waste heat from the process could be utilized and sold in a District Energy System (DES). This report updates the WTE business case analysis incorporating feedback received from key stakeholders, updated facility design, performance and cost information, preliminary District Energy System feasibility results, and a preliminary analysis of siting, environmental and approval considerations.

Several meetings and discussions have been held between Yukon Energy, their consultant team, and key stakeholders including City of Whitehorse, Government of Yukon Community Services Department, Raven Recycling, P&M Recycling, and the Yukon Conservation Society. Issues identified during these meetings included potential impact on City landfill operations and costs, air emissions, ash management, and concerns that WTE would harm and limit recycling opportunities. Yukon Energy organized a half-day workshop and public meeting on October 18, 2011 for the purpose of identifying issues and opportunities and outlining a plan for moving forward. A key theme identified at the workshop and public meeting was support for locally derived energy sources. There was a strong desire expressed to ensure that WTE is part of an integrated waste management system and does not compete with recycling. There was also strong support for increased diversion of materials away from the landfill and future WTE, with discussion of the territory and City potentially establishing a 50% waste diversion target.

The WTE facility design capacity was decreased to 25,000 tonnes per year from 30,000 tonnes per year in response to the desire of the City of Whitehorse to establish and achieve a 50% waste diversion goal. Approximately 7,700 tonnes per year of wood biomass would be required initially to ensure the WTE facility operates at full utilization, assuming the waste diversion target was achieved at plant startup. The amount of wood biomass required would decrease over time based on continued population and waste growth and maintaining a 50% waste diversion target.

A call for Expressions of Interest (EOI) yielded technical responses from seven vendors potentially interested in providing a WTE process. The response confirmed the technical basis of the business case analysis (conventional combustion utilizing either a small mass burn system or different forms of close-coupled gasification), provided expected energy recovery efficiencies, and outlined capital and operating cost estimates.

A preliminary siting assessment, informed by the results obtained from a separate Whitehorse District Energy feasibility study, identified potential site locations in the Marwell Industrial area and along Robert Service Way south of the downtown area. While a more detailed siting assessment and consultation will be required prior to final site selection, the business case analysis assumes siting in the Marwell area because of proximity to potential heat customers, access to municipal services and compatibility with adjacent land uses.

Air emissions have been estimated for a WTE facility and compared to emissions from diesel combustion in electrical generators and furnace oil combustion in space heating applications. Assuming the electricity produced from WTE displaces diesel-generated

electricity, and waste heat is utilized in a DES displacing furnace oil, WTE is expected to result in a net reduction of nitrogen oxide, particulate matter and carbon monoxide emissions and a net increase in sulphur dioxide emissions.

The estimated cost to produce 10,000 MWh per year of electricity from MSW and biomass in the "base case" is $0.31 per kWh. This estimate is similar to the cost of diesel-generated electricity and does not provide a clear incentive to pursue a WTE project. This cost estimate is higher than reported in the September 2011 preliminary business case analysis ($0.16 per kWh) largely as a result of two key factors: (1) requirements for additional biomass (higher cost) feedstock during initial operations, assuming that the waste diversion target of 50% is achieved in 2015; and (2) reduced electricity generation efficiencies reported by vendors when operating in a combined heat and power mode, while meeting the heat quality requirements specified in the initial results of the FVB Energy Whitehorse district energy study.

A sensitivity analysis identified two key areas of uncertainty that have the ability to significantly affect business case viability, as follows:

- An application for federal grant funding has been made under the NRCan ECO II program. If this funding request is successful, the electricity production costs could be reduced to $0.21/kWh.

- The base case analysis assumes an almost immediate drop (by 2015) in residual waste volumes to meet a 50% diversion target. The actual implementation schedule for achieving the diversion target is not yet known. If the diversion target was achieved in seven years (instead of two), the cost to produce electricity using WTE is $0.21 per kWh in 2015.

Based on the study results, it is recommended to determine if project feasibility can be improved through further examination of two key project uncertainties: capital funding grant availability and confirmation of waste diversion strategy implementation.

1. INTRODUCTION

1.1 Overview

Yukon Energy is assessing a range of potential alternatives for increasing firm electrical generation capacity in Yukon. This report examines the social, environmental, technical and economic considerations associated with the development of a waste to energy (WTE) facility located in Whitehorse utilizing municipal solid waste (MSW) as the primary fuel source.

A preliminary WTE business case analysis completed in 2011 (Morrison Hershfield 2011) examined three facility scenarios, with capacities ranging between 20,000 and 30,000 tonnes per year and electricity generation between 14,000 and 17,000 MWh per year. The analysis examined the impact of utilizing wood biomass to augment MSW feedstock during periods of lower waste generation rates and the impact of utilizing low-grade waste heat in a potential District Energy System (DES). Utilizing preliminary facility cost and revenue assumptions, the estimated cost of electricity production ranged between $0.16 and $0.18 per kWh which increased to over $0.27 per kWh if no district energy revenue was available. The most cost-effective and flexible facility scenario incorporated wood biomass as a supplementary feedstock source. The preliminary business case analysis incorporated a number of recommendations for proceeding with the project evaluation including:

- Confirm feedstock (MSW and wood biomass) quantity, quality and costs;
- Refine facility cost estimates;
- Undertake detailed feasibility study of a Whitehorse DES;
- Secure agreements for feedstock supply;
- Select a site for the WTE facility
- Confirm facility permitting and approval requirements
- Prepare a request for proposal (RFP) for the design and construction of a WTE facility.

The specific objectives and study scope addressed in this report is outlined in the following section.

1.2 Study Scope and Objective

The objective of this report is to refine the WTE business case analysis, allowing Yukon Energy and key project stakeholders to determine whether to proceed into more detailed siting, engineering and approval investigations and activities. The study scope incorporates the following elements:

1. *Incorporate stakeholder and public input*

   A one-day WTE stakeholder workshop, public meeting and focused stakeholder meetings have been undertaken for the purpose of communicating preliminary results and obtaining input into the future project direction. The results of these

activities are documented and have been used to update the facility design basis and environmental considerations.

2. *Refine assessment of heat utilization opportunities*

   Since the completion of the preliminary business case analysis, a Whitehorse DES feasibility study conducted by FVB Energy has been initiated by Yukon Energy in partnership with the City of Whitehorse, Yukon Cold Climate Innovation Centre, and Yukon Government. The preliminary results of this separate study are incorporated into this report to determine the potential heat utilization opportunities of a WTE facility.

3. *Update design basis*

   The WTE facility design basis has been updated to incorporate more detailed assessments of feedstock and plant. The MSW feedstock assessment is revised to incorporate stakeholder input on future diversion targets and strategies for addressing seasonal waste generation variability. Sources and volumes of local wood biomass have been assessed for use as supplementary feedstock.

   A call for Expressions of Interest (EOI) provides a basis for updated facility process details, Combined Heat and Power (CHP) efficiencies and facility costs.

4. *Assess siting, environmental and approval considerations*

   Two siting potential areas for siting are identified and described incorporating considerations for waste utilization, transportation impacts, environmental considerations, land availability and compatibility with adjacent land uses. Potential environmental issues, described in the earlier Morrison Hershfield (2011) report are updated, and the project approval process outlined.

5. *Refine WTE business case analysis*

   The WTE business case analysis incorporates updated analyses of facility costs and revenues to determine an estimated cost of electricity production. Key financial inputs include:

   - Potential MSW tipping fee revenue based on an assessment of Whitehorse Landfill life cycle costs;
   - Wood biomass costs based on local supply assessment;
   - Facility capital and operating costs informed by industry responses to the call for EOI;
   - Allowance for land, servicing, and electrical tie-in costs;
   - Heat revenue using results of preliminary Whitehorse DES feasibility study.

   A sensitivity analysis illustrates the impacts to the business case if a capital funding grant is obtained (application has been filed) or if key assumptions are varied for critical project variables.

2. ENERGY DEMAND

2.1 Electricity

Yukon Energy is the primary generator of electricity in Yukon, with the capacity to generate electricity from both hydro and diesel combustion sources. At present almost all of the territory's electricity is generated from hydro sources[1].

The demand for electricity has been steadily rising since 2000 as a result of commercial and residential growth. More recently, increased mining activity in the territory has resulted in an additional industrial load, which is forecasted to continue to grow in the near-term. The result of this forecasted growth in electricity demand is that there is expected to be a shortfall in the supply of clean energy to the grid by 2014 (Yukon Energy, 2011).

Until new electricity generation capacity is installed on Yukon Energy's grid, the shortfall of clean energy, relative to electricity demand, will be met through the combustion of diesel in existing generators. The cost of diesel generation is high (approximately $0.30 per kWh at current fuel prices) compared to the rates charged to Yukon customers in the past decade: $0.13 - $0.14 per kWh for residential customers and $0.15 - $0.16 per kWh for commercial customers (Yukon Energy, 2011). Waste to Energy provides the potential to generate electricity at a lower cost, emitting fewer greenhouse gas emissions, when compared to diesel generation.

2.2 Heat

2.2.1 Whitehorse DES Feasibility Study

Yukon Energy in partnership with the Yukon Government, the City of Whitehorse, and the Yukon Cold Climate Innovation Centre at Yukon College is leading a study aimed at providing an assessment of the technical and economic viability of establishing a DES in the City of Whitehorse. FVB Energy has been retained to conduct the study which is expected to be completed in May 2012.

The scope of this district energy study includes the assessment of a range of alternative system concepts, development of a recommended system and design basis, and definition of a business model. The final deliverables of the work are expected to provide a comprehensive evaluation of technical and business case viability, and a strong foundation for proceeding into more detailed engineering and design if the concept proves feasible.

Key outcomes include:

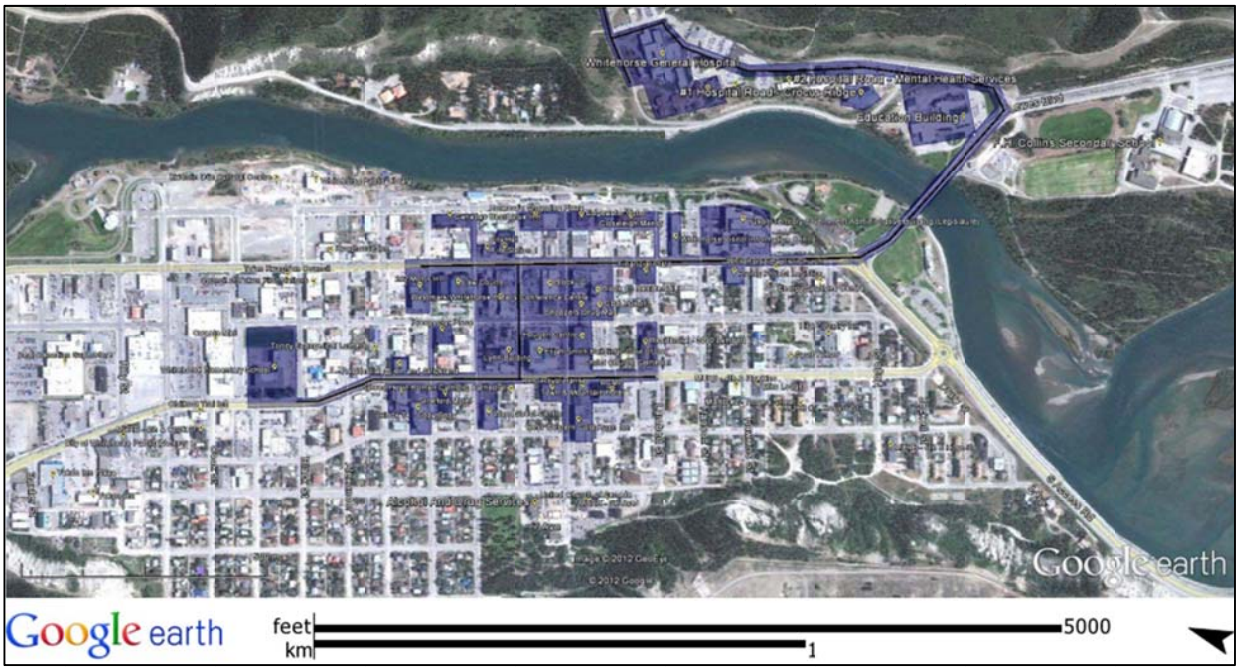
- A review of previous pre-feasibility work (Stantec, 2010), independently reassessing the district energy potential and developing business case scenarios of several alternative heating zones throughout the city.

[1] 94% Hydro in 2009, as reported at the Yukon Energy Charrette in March, 2011

- Development of a DES Business concept and owner/operator models.
- Engagement with potential DES customers.
- Development of a technical concept.
- Development of a memorandum of understanding (MOU) and energy service agreements (ESA) with potential customers.
- Preparation of design basis document (DBD) that includes project definition and business plan.

Currently the project is at its midway point. FVB Energy has completed a high level technical and business case evaluation of seven district energy zones in nine separate scenarios. At this point in the assessment, the scenario including the hospital district and the downtown core area provides the highest heating demand and net revenues and the lowest payback period among the evaluated scenarios. As a result, this scenario has been recommended by FVB for further development and is adopted for the WTE business case. Figure 1 illustrates the potential layout for the Downtown and Hospital district energy scenario.

Figure 1: Potential Whitehorse DES distribution lines servicing the Downtown and Hospital area.



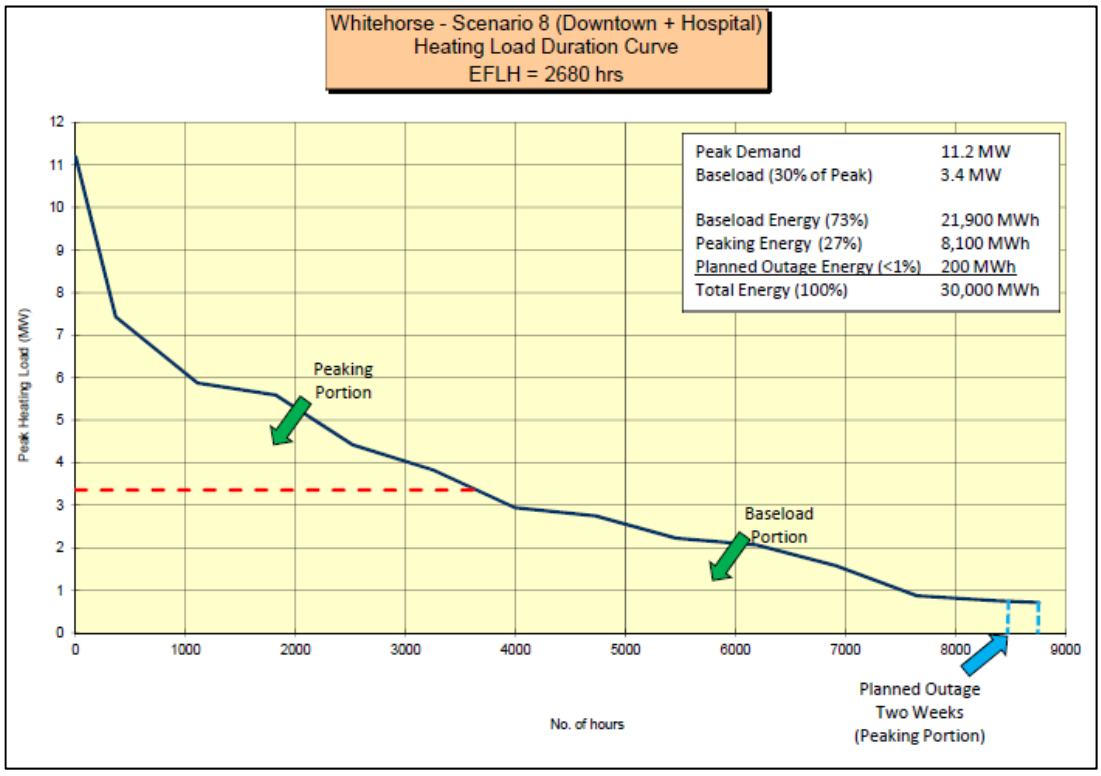
Source: FVB Energy Pre-Screening Scenarios Jan 25, 2012.

2.2.2 Heat Utilization Opportunities

Utilizing waste heat produced in the WTE facility in a future DES will significantly increase the overall energy efficiency of the WTE facility while also providing an additional revenue stream.

Based on the preliminary results of the district energy business case analysis by FVB, a feasible business case exists for implementing a DES in Whitehorse. Assuming a DES is constructed to service the hospital and downtown district (Scenario 8 as described in the FVB study), the DES would distribute 30,000 MWh of heating energy a year. Figure 2 illustrates the heat load-duration relationship for the hospital and downtown district, assuming a central DES biomass heating plant provides a base load heating supply with 3.4 MW capacity (73% of total annual heating demand). The remaining heating demand would be met through peaking boilers.

Figure 2: Heating load-duration curve for Whitehorse Downtown and Hospital District (FVB Energy, 2012)



A WTE plant constructed in Whitehorse would eliminate the need for a central biomass heating plant to service the DES. Assuming a design capacity of 25,000 tonnes per year, the WTE facility could generate up to 4 MW of usable heat energy (in addition to electrical power) that would meet 79% (23,700 MWh) of the total annual DES heating demand.

Total WTE facility energy efficiency increases dramatically if heat is utilized in addition to electrical power production. However, based on the expected heat quality required in a Whitehorse DES, heat utilization will result in some reduced electricity production, compared to an electricity-only process. Further discussion of CHP considerations in the WTE design basis is provided in Section 4.

3. PUBLIC ENGAGEMENT

A public meeting, one-day workshop, and a series of stakeholder meetings have been organized by Yukon Energy since the WTE project was initiated in 2010. The purpose of the public engagement has been to share information and identify the opportunities and issues.

Several meetings and discussions have been held between the Yukon Energy project team and City of Whitehorse senior staff for the purpose of understanding the City's waste management challenges and opportunities and potential impacts of a WTE facility on the City's landfill operations. The project team has made presentations to City Council at Council and Senior Management (CASM) meetings on June 9, 2010, May 18, 2011 and August 3, 2011. The purpose of these presentations has been to communicate project progress, understand City waste issues and priorities, identify joint opportunities, and hear project concerns.

Early in the project development, a project meeting was held on the evening of November 30, 2010 with representatives from Raven Recycling, P&M Recycling, Yukon Conservation Society and Government of Yukon Community Services. A follow-up meeting was held with representatives from the same organizations on August 9, 2011 to discuss the draft results of the Preliminary Business Case Analysis (Morrison Hershfield 2011). Key issues raised at these meetings included air emissions, ash management, and concerns that a WTE facility would harm and limit recycling efforts. Interest was also expressed for utilizing waste heat to increase the overall energy efficiency and displace fossil fuels used in space heating.

Waste to Energy was one of the potential energy sources discussed at the Yukon Energy Charrette in March 2011. Following up from the Charrette, Yukon Energy organized a half-day workshop and evening public meeting focused on WTE on October 18, 2011 (full workshop report included in ***Appendix A***). Over 70 invited participants attended the workshop session and 68 people attended the evening public meeting. Presentations were made by Yukon Energy and their consultant, a representative of Raven Recycling and P&M Recycling, and the City of Whitehorse. Following the presentations, workshop participants were organized into facilitated groups and asked to consider the following:

- Identify the opportunities and the challenges/issues around Waste to Energy
- Can the issues become opportunities? How?
- What does Yukon Energy need to make this project work?
- What does Raven Recycling and P&M Recycling need to make this work?
- What does the City of Whitehorse need to make this work?

A key theme identified during the workshop and public meeting was support for locally derived energy sources. However, there was a strong desire to ensure that WTE was part of an integrated waste management system and did not compete with recycling. There was also strong support for increased diversion of materials away from landfill and future WTE (50% by 2015 identified as a potential target) and strict air emission regulations.

4. UPDATED DESIGN BASIS

4.1 System Capacity

A system capacity of 30,000 tonnes per year was initially studied and used in the preliminary WTE business case analysis (Morrison Hershfield, 2011). This capacity was based on the known waste quantities with current recycling and composting activities in Whitehorse, plus waste coming to the Whitehorse landfill from outside communities.

Internal City of Whitehorse planning plus a Yukon Territorial Government study into waste diversion has resulted in more ambitious recycling goals in the community, with a target of 50% total diversion by 2015 currently being considered. In meetings with the City and local recycling groups, these figures were acknowledged as the new target that would henceforth be used for the planning basis of any energy recovery from residual, non-recycled waste.

As a first step it was necessary to get a thorough understanding of the waste volumes that would be generated with the new recycling targets, and how these might affect a WTE facility. City of Whitehorse Landfill Cost Assessment study was initiated to review the waste disposal situation at the Son of War Eagle landfill (Morrison Hershfield, 2012). The purpose of this study was two-fold: to estimate the future generation of waste that would need to be disposed at the landfill under a recycling only scenario as well as a recycling plus WTE scenario, and what would be the life cycle costs under each scenario. The residual waste volumes would help to determine a WTE facility size and also determine the life expectancy of the current landfill design under the 2002 Solid Waste Management Plan (Gartner Lee, 2003). The life cycle costs would determine unit costs for disposal of residuals and in the case of WTE, of ash and non-combustible residuals. The results of this study, completed as a landfill full cost accounting report is included as ***Appendix B***.

The landfill full cost accounting report was prepared in close consultation and cooperation with the City of Whitehorse. All available data and reports and projections available from the City were used and City staff were interviewed extensively. The study is based on the existing landfill plan from 2003 updated with current fill volumes and projections. The study examines the true cost of landfilling, focusing specifically on the disposal to landfill of the residues that are not recycled, composted or used for energy. The study does not include the cost of collection, recycling or composting in the calculations. These are separate items that need to be dealt with through an integrated zero waste management planning process led by the City of Whitehorse.

4.1.1 Waste Trends

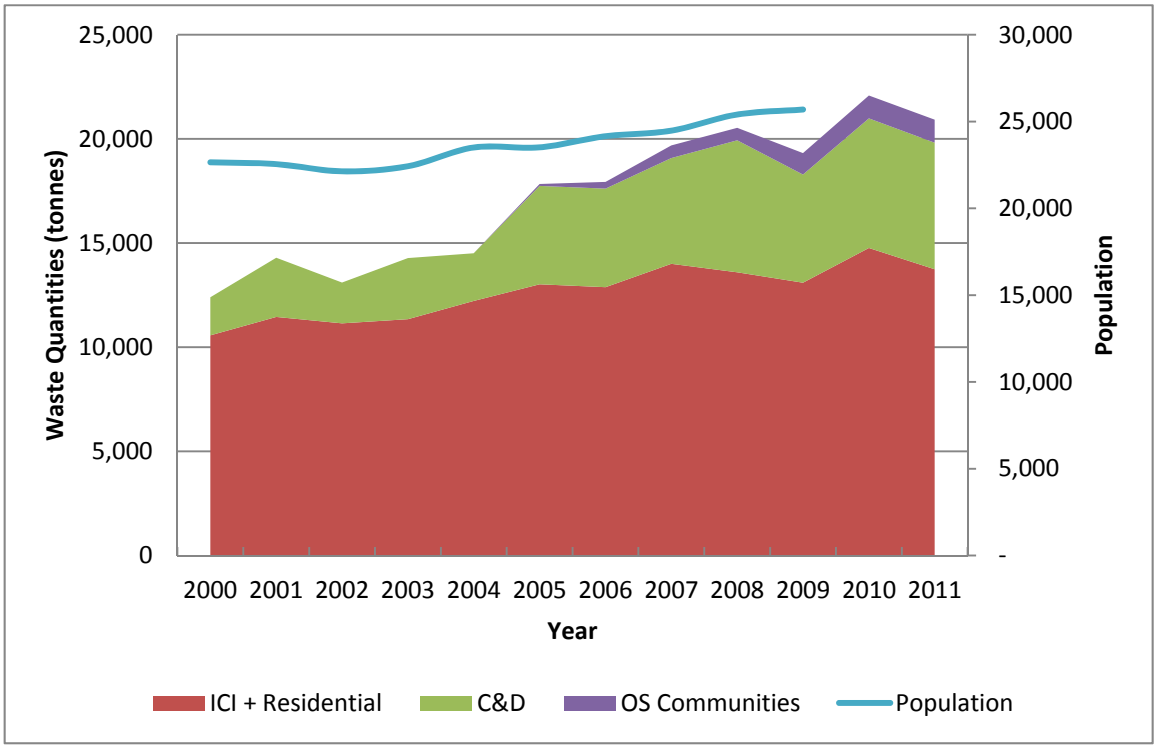
Waste generation quantities were forecast into the future based on historical tipping data obtained from the City for the years 2000 to the end of 2011. Only waste that is permanently disposed of in the landfill cells was included in the analysis. This comprised domestic curbside collected residential waste (RES); Industrial, Commercial, Institutional (ICI) waste including multi-family residential waste; waste from Outside Communities (OS); and, Construction and Demolition (C & D) waste. Excluded from the analysis were tires, white goods, grubbing, etc. which are not permanently disposed of in the landfill cells.

Figure 3 illustrates the quantities of waste managed at the city landfill over the last 11 years along with population statistics[2] over the same time period. It is apparent from this figure that waste growth rates have exceeded the rate of population growth.

Domestic waste (residential and IC&I) has consistently been the largest contributor of waste disposed at the landfill, although C & D waste has shown the largest increase in waste volumes over the past 11 years. In particular, C & D waste volumes exhibited a significant jump between 2004 and 2005 from 2,290 tonnes in 2004 to 4,723 tonnes in 2005.

Residential curbside waste is a relatively small portion (10-12%) of total domestic waste.

Figure 3: Recent Waste Growth in Whitehorse



The cause of the high rates of waste growth over the past decade and the volatility in waste volumes from year to year is likely related to a range of economic factors. Gross Domestic Product (GDP) in Yukon rose over 60% during this time period (6.2% per year on average) while by comparison Canada's GDP rose just 42% (Statistics Canada, 2010).

[2] Source: Population statistics obtained from the Yukon Bureau of Statistics 2009 Population Report

4.1.2 Disposal Quantities with Enhanced Diversion

This analysis provides an estimate of the amount of waste that would need to be disposed of at the Son of War Eagle Landfill assuming enhanced diversion, projected to 2060. It assumes for simplicity that 50% of waste would be diverted from landfill by 2015 and that this diversion rate could be maintained in spite of waste growth through increased population growth and economic activity. Wastes are broken down by domestic waste (residential, commercial and institutional sources), C&D waste (construction and demolition sources and generally of a different nature than domestic waste), and waste coming from outside communities, which is assumed to be only domestic.

Waste projections are shown in Figure 4 and Table 1. As can be seen from the figure, there is a sharp decrease of waste in 2015 when aggressive diversion programs are assumed to be implemented. After that time, volumes continue to increase in step with population growth. In reality, the transition will likely be more gradual and waste diversion is ultimately expected to exceed 50% as higher local awareness sets in and higher levels of government implement more rigorous product stewardship programs. Since these cannot be predicted at this time, the simplified model has been used for this study. However, a sensitivity analysis has been incorporated into the business case analysis assuming implementation of the diversion target is phased in between 2013 and 2020.

Figure 4: Projected landfill quantities under enhanced diversion

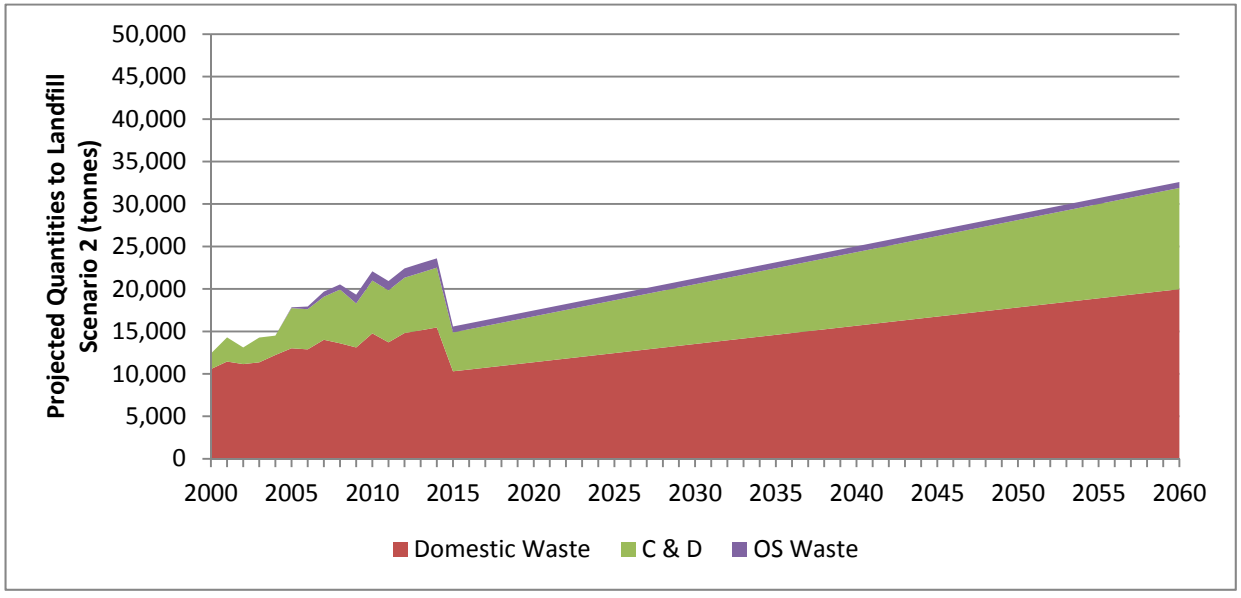


Table 1: Waste quantity projections based on enhanced diversion rate (tonnes)

	2010	2015	2020	2025	2030	2035	2040	2045	2050	2055	2060

4.1.3 Waste to Energy Facility Sizing

The residual feedstock available for waste to energy is calculated based on a 50% waste diversion target from the landfill being initiated in 2013 and achieved by 2015. This is a very aggressive schedule and as a sensitivity calculation, a more gradual phase-in of diversion programs from 2013 to 2020 was also considered (in the sensitivity analysis).

It is known from previous studies that there is a large variation in waste generation between summer (high) and winter (low) and that the peak summer monthly generation rate can be more than double of the monthly average for the year. Sizing of the WTE facility attempts to make the greatest use of the resource, while providing constant power and heat output. This is the rationale for choosing to supplement MSW with biomass when required: to capture as much of the MSW energy as reasonably possible.

Based on the enhanced diversion rate, the monthly average waste available in 2015 would be about 1,300 tonnes per year. For capacity selection, this has been increased by 50% to capture the higher waste volumes available in the summer months, without catering to the peak monthly generation (which is 100% higher than the average). During those months (e.g. in the winter) when there is insufficient MSW, biomass will be used to keep the facility operating at capacity.

For this analysis, a nominal design capacity WTE facility of 25,000 tonnes per year has been chosen. The actual annual throughput would be 95% of the total design capacity or 23,750 tonnes year. The projected loading of the WTE plant over time is shown in Figure 5 and Table 2. The biomass portion that needs to be used as fuel diminishes as MSW increases due to population and economic activity increases (while achieving 50% diversion). By 2035 the WTE facility would be using only MSW as feedstock.

Figure 5: Waste to Energy Feedstock Quantities

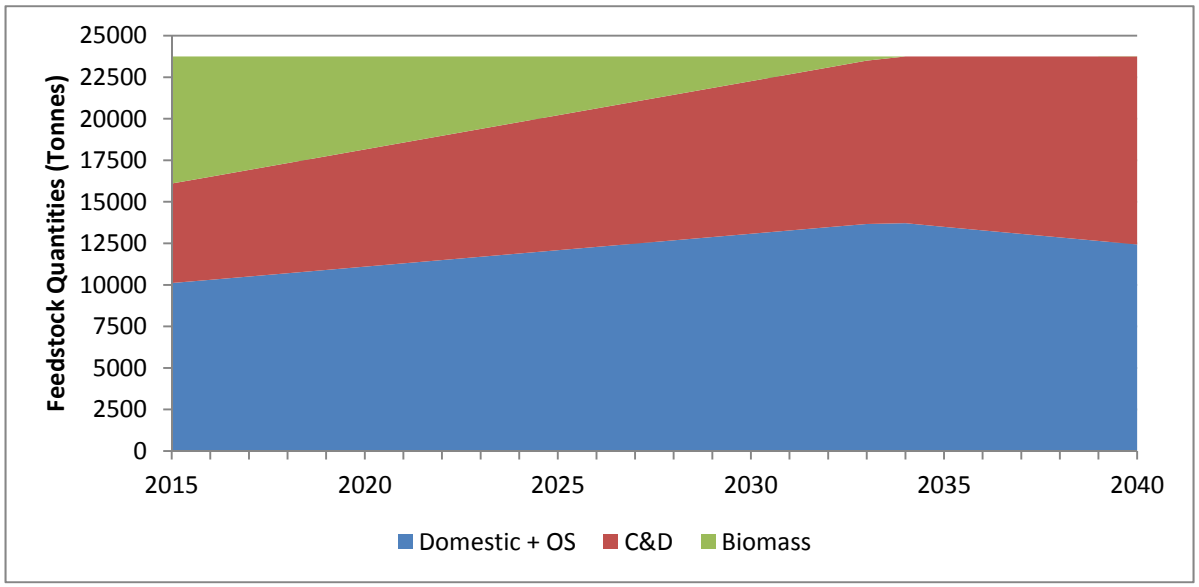

Table 2: Total Feedstock Quantities and Biomass Requirements (Tonnes)

	2015	2020	2025	2030	2035	2040
Domestic + OS	10,110	11,098	12,087	13,075	13,284	12,431
C&D	5,988	7,054	8,121	9,187	10,466	11,319
Biomass	7,652	5,598	3,543	1,488	0	0

4.1.4 Impact on Landfill with Enhanced Diversion and WTE

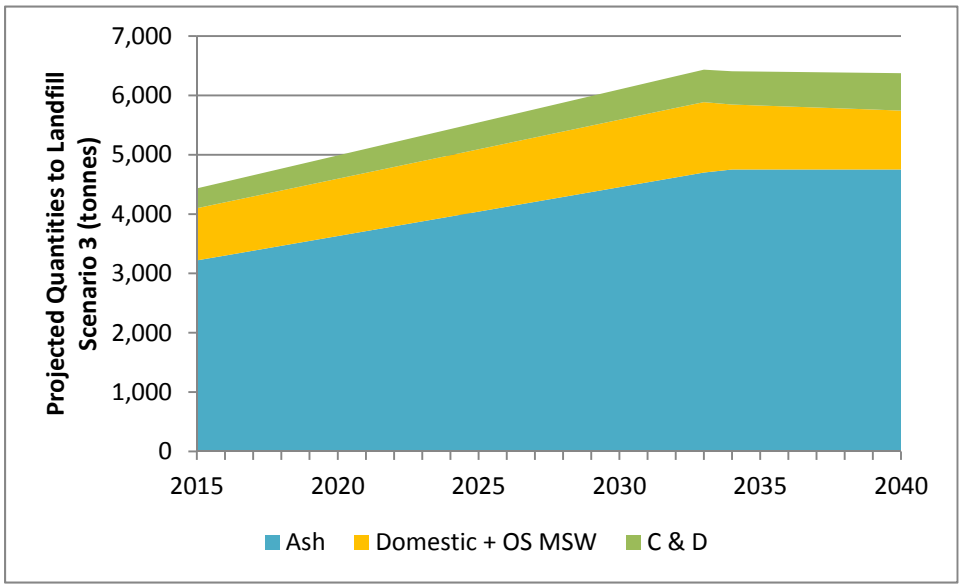
This analysis assumes that a Waste to Energy facility is constructed and commissioned by 2015. The design basis of the WTE facility maximizes utilization of remaining municipal solid waste after waste diversion (recycling and composting). It is assumed that the City achieves an enhanced waste diversion target of 50% by 2015. This is a simplification, as described above, but is used for modeling purposes.

It is assumed that solid waste growth beyond the WTE plant's capacity (which could use all of the MSW by 2035) would be accommodated through additional diversion programs. Using this assumption and projected waste growth rates, a total waste diversion rate of 57% would be required by 2040

The operating life of the WTE facility is assumed to be 25 years (to year 2040). It is likely that the WTE facility will operate longer (if there is waste still available), and the landfill will continue to accept waste/ash past 2040. Projecting waste quantities to the end of the landfill life is not considered practical for this analysis, since a WTE facility would extend the life of the current landfill well into the next century.

Projected waste and ash quantities going to the landfill until 2040 (25 year life of WTE plant) are shown in Figure 6. Wastes directed to landfill under this scenario would be primarily non-hazardous and stabilized ash resulting from the WTE process, plus some non-combustible C&D waste plus domestic waste when the WTE plant is undergoing maintenance.

Figure 6: Waste and Ash to Landfill



4.1.5 Biomass

As proposed in the preliminary business case analysis (Morrison Hershfield 2011), biomass, or wood waste, would be used as a supplementary fuel for the WTE facility if and when there is insufficient municipal waste available (e.g. during winter when waste generation rates are lower). Wood biomass therefore provides the flexibility to operate the facility at 100% capacity regardless of the available amounts of MSW.

Estimated annual biomass requirements are shown in Table 2. Initially, approximately 7,650 tonnes would be required with demand decreasing with waste growth.

The WTE facility could accept wood from multiple sources, which are discussed below. The cost of an on-site chipper and covered storage are incorporated in the facility cost estimates.

Potential sources investigated are:

1. Wood waste from mill residues;
2. Harvested spruce beetle kill and fire kill timber from Haines Junction;
3. Clearing and grubbing waste from construction activity within Whitehorse;

4. FireSmart wildfire management program;
5. Chipped wood waste from communities outside of Whitehorse;
6. Yukon Energy Right Of Way clearing; and,
7. Woody biomass from Yukon Highway maintenance.

4.1.5.1 Wood waste from mill residues

The closest source of mill residues to Whitehorse is the Dimok Timber mill in Haines Junction. Discussions with Dimok Timber determined that the estimated annual available mill residue is approximately 3000 oven dried tonnes (ODT) or approximately 3,500 green tonnes. Currently, there are no uses for the residues which are stockpiled and burned. Dimok Tiber provided Morrison Hershfield a quote for the delivered cost of the mill residues of $124/green tonne based on a maximum moisture content of 20% (Clunies-Ross, 2011). The quote includes costs for equipment to process, handle, store, and deliver biomass fuel. The most significant investment is a walking floor trailer which allows for self-unloading of the wood chips. Walking floor trailers are available in capacities ranging between 18 and 27 tonnes of biomass. This would result in between 111 and 167 loads annually depending on the trailer used.

According to Dimok Timber, the relatively low quantities provide a relatively low economy of scale and potential reductions in biomass volume requirements reduces the period in which capital costs can be amortized. The additional capital cost of the processing and handling equipment, and walking floor trailer over shipping raw logs means that utilization of mill residues results in no cost savings over using harvested timber.

4.1.5.2 Harvested spruce beetle kill and fire kill timber from Haines Junction

Spruce beetle killed wood is currently being harvested in the Haines Junction area, some of which is being shipped to Whitehorse primarily for use as firewood. Approximately 25,000 m3 of wood is currently allocated for firewood and forestry mill operations annually. The current annual allowable cut (ACC) is 100,000 m^3 or 45,000 tonnes per year, which could potentially yield a biomass supply that significantly exceeds the requirement for the WTE facility. The current price for delivered raw beetle kill logs from Haines Junction to Whitehorse at a commercial scale is approximately $115 per green tonne ($135 per ODT)[3].

[3] Based on $140 per cord of beetle kill spruce delivered to Whitehorse on a commercial scale, personal communication Clunie-Ross, Dimok Timber.

4.1.5.3 Clearing and grubbing waste from construction activity within Whitehorse

Historically, a significant portion of wood waste from land clearing for land development in Whitehorse was sent to the Son of War Eagle Landfill. In most cases this consists of non-merchantable timber, slashing, branches, and roots with intermingled topsoil.

Figure 7 indicates annual volumes between the year 2000 and 2005 were between 1,127 and 2,980 tonnes. The generation rates of clearing and grubbing waste is tied to land development activity in Whitehorse resulting in significant fluctuations over the years. In 2006 tipping fees for clearing and grubbing waste increased to $150 per tonne resulting in a sharp and sustained reduction in the volumes being sent to the landfill. As a result, clearing and grubbing waste over the last five years has been diverted primarily to landfill areas at MacLean Lake Road, near Copper Ridge subdivision off of Sandpiper Drive, and in smaller quantities on private lots that are close to job sites.

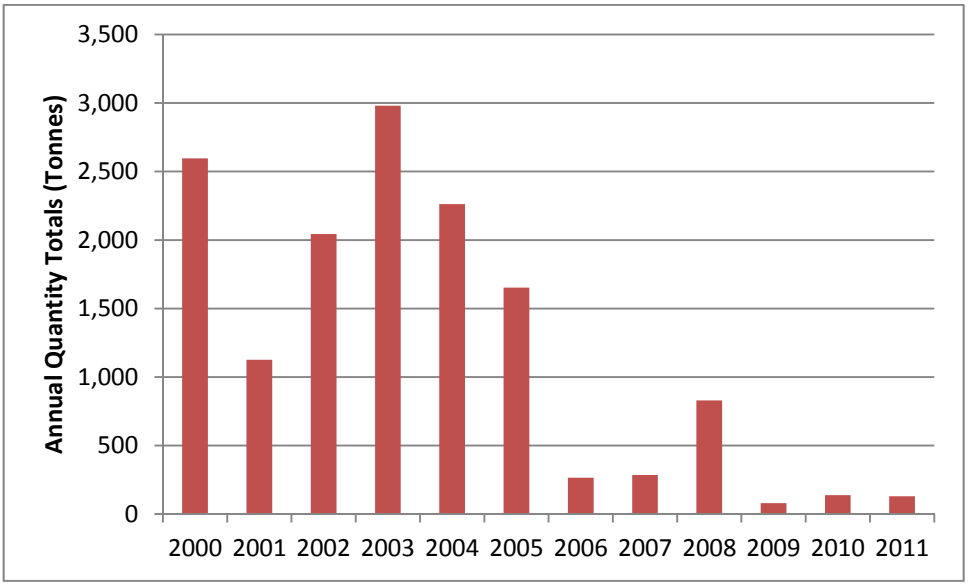
In absence of records of volumes that are currently being sent to site it is difficult to determine how much material exists in the stockpiles. Furthermore, loading and transportation costs and the likely contamination with topsoil and rocks would make extracting from existing stockpiles uneconomical.

The MacLean Lake Road site is an active site that is managed by the Yukon Contractors Association. Currently there is no charge to send waste to the site; however, introducing a $20 – $30 per load fee is currently being contemplated.

The hauling and disposal of clearing and grubbing waste is currently an onerous cost for contractors. This provides an opportunity for the WTE facility to obtain a potentially free to low cost biomass source provided careful loading and sorting of clearing and grubbing waste is undertaken to reduce soil contamination.

Based on the historical information available, it is difficult to predict what future clearing and grubbing biomass generation rates and what proportion of total material generated in Whitehorse could be obtained by a WTE facility. However, for preliminary estimation purposes, an assumption of 1000 tonnes is used. A modest financial incentive (such as $25) per tonne could be provided to capture a greater share of available clearing and grubbing waste and to encourage more careful separation of wood waste from contaminants such as soil and rocks in the waste brought to site. Separation would provide more efficient processing, reduce wear on the equipment and reduce the quantity of contaminants that would eventually have to be landfilled.

Figure 7: Historical Landfill Clearing and Grubbing Quantities disposed at City landfill



4.1.5.4 FireSmart Wildfire Management Program

The FireSmart program in the Yukon clears the equivalent of approximately 120 ha of land per year to reduce the wildfire exposure risk for Yukon Communities (pers comm. Jan, 2012 Fred Jennings, FireSmart Manager, YTG). Approximately half of the FireSmart work occurs in the Southern Lakes region which would result in a total volume of approximately 820 tonnes (680 ODT) of biomass annually[4]. Currently, most of the wood from the FireSmart program is taken by local people for firewood as costs are too high and volumes are too low to justify loading and hauling the material from a commercial perspective.

According to the FireSmart manager, there is the potential for a larger 1000 ha of fuel control work required in the Whitehorse area; however, no budget or timeframe has been established to implement such a program.

Based on the above information, current FireSmart volumes do not appear to be able to provide an economically significant and reliable supply of biomass.

4.1.5.5 Chipped wood waste from communities outside of Whitehorse

Wood construction and brush waste from outside communities is currently being chipped primarily in the spring to fall months at four sites located in Carcross, Tagish,

[4] 120 ha per season, approximately 25m^3 of wood available per ha, 2.2 m^3 per oven-dried tonne, assuming 20% moisture content.

Marsh Lake and Deep Creek. On average, there are 8 – 10 small gravel truckloads of wood chips being chipped at each site monthly for approximately 5 months of the year (pers. Comm. Jan 2012, Wes Wirth, Director, Operations and Programs Community Services Government of Yukon and Brian Buchannan, Contractor to YTG.) [5] As a result, it is estimated that approximately 650 tonnes of wood chips could be available per year from all four sites. With the cost of dump trucks between $120 and $130 per hour, the delivered cost of wood chips to Whitehorse is assumed to be approximately $25 per tonne.

4.1.5.6 Yukon Energy Right Of Way clearing

Power line right of way clearing is generally conducted by mowing with one hydro axe and a crew of two hand brushers. The material generally consists of poplar and willow and is left in the right of way. Encroachment of larger tree species such as spruce is generally not an issue in the right of way. However, where significant overgrowth exists it is typically in areas that are difficult to access and therefore would be difficult to export. Merchantable wood from new ROW development is used by the forestry sector while non-merchantable wood is left for salvage as firewood. There are no new major transmission lines planned in the near term.

Yukon Energy completed a vegetation audit in 2010 which provides an indication of the timing of when brush clearing is required to maintain right of ways. The schedule shows that between 140 and 240 ha per year would need to be maintained over the next ten years. The location of the clearing activities within a particular year would determine the feasibility of collecting and shipping the biomass to Whitehorse.

Biomass from power line right of way clearing cannot be relied upon as a reliable source of biomass; however, should vegetation control near Whitehorse be collected, it could potentially provide a supplemental source of biomass to costlier sources.

4.1.5.7 Woody biomass from Yukon Highway maintenance

Information from Yukon Government's Vegetation Control Program from 2008 to 2011 was provided from the Yukon Government Transportation Maintenance branch. Currently highway vegetation control consists of three types of clearing:

1. Type A: ROW full width brushing covers the area from shoulder to old growth is between 10 and 30 m and primarily used to improve sightlines. This type of material could include trees and brush. Significant Type A work has occurred near Whitehorse in the past few years (between Teslin and Haines Junction has already been thinned) and new areas generally being worked on are increasingly further from Whitehorse (beyond Stewart Crossing.) Between 2008 and 2011, 60 to 300 km were covered. In 2011, 200 piles approximately 10 m wide by 3 m high were generated and burned.

[5] Assumed density of woodchips to be 400 kg/m3, volume of truck load 12 cubic yards or 9.17m^3 resulting in 3.6 t per truck.

2. Type B: Shoulder brushing / mowing covers the area of up to 5 – 6 m from edge of shoulder and generally consists of patchy areas of willows and small brush which provide marginal heating value. Areas are maintained every 6 to 8 years. Historically, the distance covered annually for shoulder brushing has been between 168 and 500 km.
3. Type C: Shoulder mowing usually covers a distance of 2.5 – 4 m from edge of shoulder and generally consists of willow, clover and grass which provide very low heating value. Between 250 and 300 km are mowed annually.

Based on the above information it appears that the only suitable sources of biomass would be from Type A maintenance activities; however, no new major maintenance works are planned for the Whitehorse area which makes availability to this source cost-prohibitive.

4.1.5.1 Wood biomass source summary

Numerous potential sources of biomass exist, although consistent availability and accessibility of many of those sources is difficult to predict and rely upon. For a source to provide a significant and sustained supply of biomass, both collection and delivery costs must be more competitive than alternatives such as spruce beetle kill wood from Haines Junction.

Table 3 summarizes potential biomass sources along with their estimated present and future costs.

Based on the above discussion, the main reliable sources of biomass could be from mill residues, spruce beetle kill wood from Haines Junction, and clearing and grubbing waste from land development within Whitehorse. Other minor sources such as wood waste from outside communities, FireSmart, and ROW clearing could be accepted as is at the WTE facility site at a modest financial incentive such as $25 per green tonne.

Table 3: Biomass Sources, Anticipated Annual Availability and Delivered Cost.

Source	Quantity (green t)	Cost ($ per tonne)[6]				
		2012 $	2015 $	2020 $	2025 $	2030 $
Mill Residues	3,500 tonnes	$124	$136	$157	$182	$211
Beetle Kill Wood Delivered from Haines Junction	10,000+ tonnes	$115	$126	$146	$169	$196
Clearing and Grubbing Waste from Whitehorse	1000 tonnes	-	$25	$29	$34	$39
Wood chips from outside communities	650 tonnes	$25	$29	$34	$39	$45
Other (ROW Clearing, FireSmart, Other)	Minor and variable	-	$25	$29	$34	$39

Whole logs delivered from Haines Junction appear to be more cost-effective for the relatively small scale biomass demand than mill residues because mill residues require the purchase of a wood chipper in Haines Junction and vehicles such as a walking floor trailer to transport the wood chips. On-site chipping, handling and processing facilities are accounted for in the WTE facility cost estimates. It is anticipated that as biomass requirements decrease, reliance would be shifted toward less expensive sources.

Table 4 shows the blended average biomass price including inflation[7] based on the quantity requirements. Initially, the average biomass cost is estimated at $104 per tonne with the majority of biomass sources from beetle kill wood from Haines Junction.

[6] Annual costs are escalated assuming 3% inflation to account for higher escalation transportation fuel costs.
[7] Inflation for delivered biomass costs is assumed to increase at a higher rate than the actual inflation rate due to reliance and to reflect a greater escalation in fuel costs. Thus, a 3% annual inflation rate is assumed.

Table 4: Annual Biomass Feedstock Requirements and Average Price

	2015	2020	2025	2030
Annual Biomass Requirements	7,600	5,600	3,500	1,500
Source Quantities (green tonnes)				
Beetle Kill Wood from Haines Junction	5,950 @ $126	3,950 @ $146	1,850 @ $169	0
Clearing and Grubbing Waste from Whitehorse	1,000 @ $25	1,000 @ $29	1,000 @ $34	1,000 @ $39
Wood Chips from Outside Communities	650 @ $29	650 @ $34	650 @ $39	500 @ $45
COST				
Average Biomass Price ($ / green tonne)	$104	$112	$106	$34

4.1.6 Capacity Summary

- A WTE design capacity of 25,000 tonnes per year has been selected for the updated business case analysis. The facility will be capable of burning biomass (waste wood) as well as MSW, so that any shortfall in waste feedstock can be made up with biomass.
- It is estimated that the WTE plant will be burning MSW without need for biomass by 2035 based on current projections (assuming 50% waste diversion is maintained from 2015 onwards). This is for calculation and comparative analysis only. The actual ratio of waste to biomass will be dictated by the amount of recycling and diversion that can be achieved and the actual rate of MSW growth.
- A WTE life of 25 years is projected, after which time a decision will have to be made on whether to upgrade the facility and continue operations or to decommission the facility for lack of feedstock or because newer, more effective technologies are available to replace it.
- The current lifespan of the Son of War Eagle landfill based on the existing Landfill Management Plan (Gartner Lee, 2003), is until 2057 based on 50% waste diversion implemented in 2015. If waste diversion and WTE are in place, the capacity of the landfill would extend well into the next century. According to the City of Whitehorse, there is additional land available at the landfill for future expansion, if needed.
- Biomass is available from a variety of sources. There is adequate biomass available from reliable sources at a cost of $115 to $124 per green tonne delivered. Additional sources of biomass are less reliable but can help to

offset the cost of biomass whenever these sources are available. The cost of biomass from other sources is low, since there is a saving in disposal costs and usually only transportation and some handling expenses need to be covered.

4.2 Process Technology

In the preliminary business case analysis (Morrison Hershfield Ltd. 2011), it was determined that controlled air conventional combustion, close coupled gasification and small scale mass burn met the necessary criteria for implementation at this time. The criteria for technology selection included ability to handle the small volumes of waste and biomass available at Whitehorse, capacity to produce both heat and electrical power, and commercially viable operating facilities of a similar size that could be visited and viewed.

The September 2011 business case was based on cost and performance data of smaller systems that are available in the literature and are in the public domain. Since there are very few smaller systems operating in North America, it was decided to enhance the confidence levels in the constant performance estimates by asking vendors to submit an expression of interest (EOI) in the project. Vendors (it was open to all who wished to respond) were given a detailed project scope and description, and a series of questionnaires to fill out. The original questionnaire was made available on November 8th, 2011. A copy of the questionnaire is in Appendix C.

Responses were received on 8 January 2012 from the following vendors:

- Aquilini Renewable Energy Ltd.
- EcoWaste Solutions Ltd
- EnEco Systems Inc
- Ketza Pacific Construction Ltd.
- Novo Energy LLC
- OE Gasification
- TPF Basse Sambre

Responses were reviewed, additional clarifications requested, and final information received February 8th, 2012.

Novo Energy and Ketza offered a small scale mass burn system, EcoWaste Solutions a conventional two-stage combustion system, EnEco,TPF and OE offered different forms of close coupled gasification and Aquilini was teaming up with EnEco.

Based on the submissions, the process technology that was proposed in the original September 2011 study was confirmed. Even though the EOI process was open to newer technologies, all respondents offered conventional technologies (close coupled gasification for the purposes of this study is considered similar to conventional combustion, except the process is separated into two or more closely connected physical components). The business case analysis will therefore proceed based on performance that can be reasonably expected from using conventional combustion technologies.

This was not a technology selection exercise for implementation but rather a choosing of appropriate technologies and performance data for business case evaluation purposes. Actual technology selection, should the project proceed, is expected to take place on a competitive basis. It is possible that advanced technologies could meet requirements in the future.

4.3 Technology performance

The key measurements of performance and those that have the most impact on the business model are net production of electricity and heat per tonne of feedstock. As expected, there was a trade-off between lower capital costs and energy production efficiency (for example higher steam conditions requiring better materials and equipment resulted in better efficiencies but also higher costs). There were also varying approaches to the recovery of heat and power, from using upfront steam extraction for heat with a condensing turbine for electricity, to using an extraction turbine for the most flexible system, to using a back-pressure turbine for steady-state heat output.

The information that was received from the vendors in response to the EOI was evaluated and compared. For electricity only production, net outputs ranged from 600 kWh/tonne to 650 kWh/tonne. With CHP electricity output ranges from 200 kWh/tonne to 420 kWh/tonne while providing 4 MW of heat.

The value chosen for the base case analysis is 420 kWh per tonne of waste, which represents about a 10% electrical efficiency and is typical for smaller CHP systems. This is consistent with the number quoted by one of the vendors that provided a fairly complete and credible submission. It includes the ability to provide up to 4MW of heat for district energy.

All of the vendors claimed to be able to meet the most stringent emission standards (Ontario A7 or the EU standards), therefore there was no difference or issue with emissions.

Staffing levels quoted varied between 14 and 26, but most of the vendors indicated 17 to 18 staff would be required. The business case analysis assumes a staffing level of 18 is required for the facility.

5. SITING, ENVIRONMENTAL & APPROVALS CONSIDERATIONS

5.1 Site Considerations

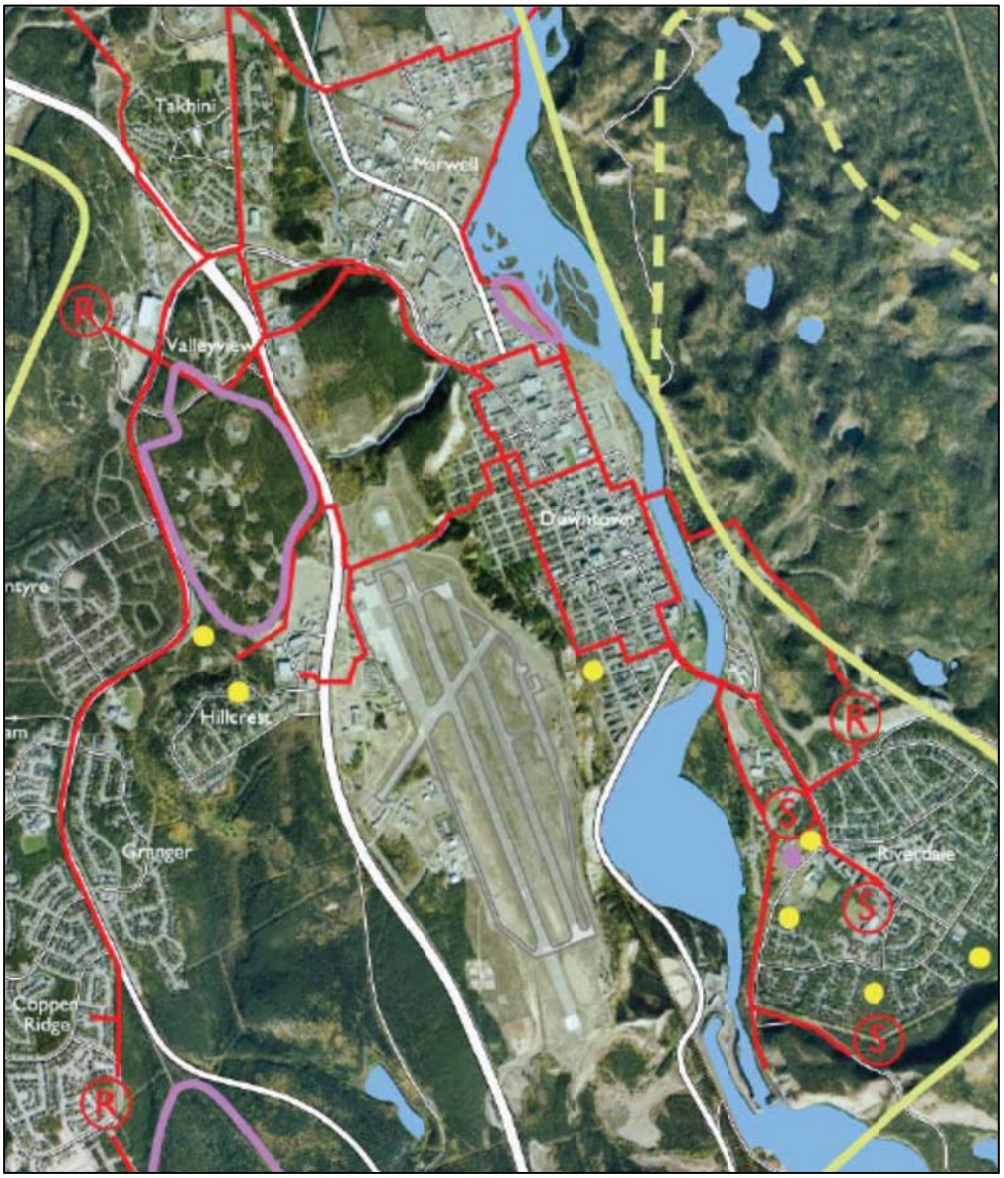
This section describes the site requirements for a Waste to Energy facility, potential economic, social and environmental impacts, and provides an assessment of two potential site areas.

5.1.1 Site and Infrastructure Requirements

A 25,000 tonne per year (70 tonnes per day) facility would require a site approximately 2 hectares in size that is relatively flat. The developed site would include buildings for the waste to energy plant, internal roads for truck access with room to turn around, scale, on-site storage of biomass and C&D waste, and a substation. The anticipated height of the stack would depend on the facility design and air dispersion requirements; however, 20 m – 30 m stack heights are common for smaller scale waste to energy facilities.

The site would require full servicing of electrical, water and sewer infrastructure. Electrical servicing will require access to a transmission line and the construction of a substation on site. Adequate water and sewer infrastructure would be required for the facility. Annual water demand of approximately 14,500,000 litres and 4,500,000 litres of wastewater are anticipated. Water demand can vary depending on the type of air pollution control systems used (dry or wet scrubbers), the cooling process employed in generating electricity and water recycling within the plant design. Figure 8 shows the location of major water and sewer lines in the City of Whitehorse. Generally, most developed areas of Whitehorse have access to sewer and water infrastructure. The area south of downtown near Yukon Energy's office and generation facilities is not serviced by municipal water or sewer. Yukon Energy is currently serviced by well water and uses a sewage holding tank where the effluent is pumped from and sent for treatment.

Figure 8: Major Water/Sewer Lines in Whitehorse



Source: City of Whitehorse OCP 2010 Map 5.

Zoning Bylaws

City of Whitehorse Zoning Bylaw 2006-01 permits public utilities in any zone under Section 1.6, Section 12.5 also applies to public utilities.

Key relevant aspects of Section 12.5 are the development regulations for siting that prescribe maximum building height of 20.0 m, minimum setbacks of 6 m, 3 m and 6 m for front yard, side yard and rear yard, respectively. Additionally, the design, siting, landscaping, screening, and buffering shall minimize and compensate for any objectionable aspects or potential incompatibility with development in abutting zones.

Development near the Whitehorse Airport could be subject to Regulations under Section 11.1 including:

> "No public utility or secondary use shall be permitted that attracts fauna or avifauna, generates electrical current or vibration that may affect the safe operation of aviation activities" and,
>
> "A development within the vicinity of the airport is subject to the obstacle clearance and electronic zoning requirements outlined in the Whitehorse Airport Zoning Plan."

Other development regulations that may apply but are unlikely to influence site selection include Section 5 (yards, projection into yards, accessory development, landscaping and screening); the parking regulations of Section 7; and the sign regulations of Section 8.

If rezoning is required, the process can take approximately 1.5 to 3 months and involves:[8]

- Determination if rezoning is required with the Planner/Development officer
- Submission of a complete rezoning application form plus supporting letters and documents and application fee of $900;
- Application is reviewed by the development review committee and recommendations are made to City Council;
- Introduction of the rezoning application to council;
- Public hearing process which includes public notification within 1 km of the site and notification in the newspaper and the development of a public hearing report;
- 2nd and 3rd reading by council.

Traffic Impacts

Based on the facility design capacity, 8 – 9 truckloads of waste per day would be transported to the facility assuming current capacity vehicles[9]. Truck traffic is only anticipated during daytime hours on waste collection days. Ash removal to the landfill from the waste to energy facility would likely result in one truckload every one or two days depending on the waste composition (ash content and inert materials of the waste stream); however, it would be possible to backhaul the ash on the incoming waste collection trucks resulting in no additional traffic impacts.

[8] Your Guide to the Rezoning Approval Process
http://ww3.whitehorse.ca/Planning/guides/rezoning%20approval%20process.pdf
[9] Assuming 2009 International Model SF62500 7400 SBA 6X4(Tandem) with GVWR 56000lbs and GAWR 20000lbs, payload of 8.6 tonnes.

District Energy Considerations

The utilization of waste heat from a WTE facility in a future DES would significantly improve the overall energy efficiency of the process and add an important additional revenue stream to the business case. Locating the WTE facility as near as possible to the heating demand reduces DES infrastructure costs and system energy losses.

A detailed district energy study is currently underway for the City of Whitehorse (described in Section 2). Preliminary study results indicate that the most cost-effective district energy scenario would supply heat to both the downtown and hospital district.

5.1.2 Air Quality Considerations

The prevailing wind in the downtown area is from the south-southwest, following the topography of the Yukon River Valley. Although air quality in the Whitehorse downtown area is generally very good, poor air quality periods can occur particularly on cold winter days when the winds are calm and dispersion is limited. Under such conditions a temperature inversion occurs trapping the colder air to the ground allowing for the temporary buildup of gaseous pollutants and fine particles in the air. Wood burning stoves, heating of commercial buildings and vehicle emissions have been identified as the primary contributors to periodic poor air quality in Whitehorse.

A CHP WTE facility would likely result in an overall improvement in air quality in the downtown area because multiple ground level point sources such as oil burning furnaces and diesel generators would be replaced with a centralized combustion facility equipped with stringent pollution controls and a stack that would elevate the emissions above the valley bottom. Further evaluation of air emissions is provided in Section 5.2.

Atmospheric dispersion modelling of facility air emissions is typically conducted after a site is selected and preliminary facility design conditions have been specified.

5.1.3 Access to Electrical Transmission System

Electrical power generated for export at the WTE facility would require an on-site substation and a 34.5 kV transmission line to connect to the existing substations in Whitehorse and the distribution system. In addition to the capital costs of constructing transmission lines and on-site substations, related considerations that would need to be confirmed and could have an impact on costs are:

- Space at existing substations for new equipment;
- Land easement;
- Permitting; and,

- Shut down of the bus for connecting the new supply.[10]

Four substations are currently located in Whitehorse, three of which are located within 5 km of the downtown area, as shown in Figure 9. The Whitehorse Substation on the west shore of the Yukon River and the Riverside Substation on the east shore of the Yukon River are located at the Whitehorse Hydro generation facility approximately 2.0 km southwest of the downtown along Robert Service Way. The McIntyre Substation is located approximately 5.0 km northwest of downtown Whitehorse off the Alaska Highway. The Takhini substation (not shown on the figure) is located 22 km north of the downtown on the Klondike Highway.

Major transmission lines originate at the Whitehorse Substation and border the southern end of Riverdale, then head north offset approximately 2 km along the eastern shore of the Yukon River (L172). This line is joined by a transmission line (L169) that connects to the McIntyre Substation approximately 3 km north of downtown Whitehorse near Range Road and Mountainview Drive.

Noise, Odour, and Nuisance Considerations

Noise generation from the operations of a waste to energy facility could be an issue depending on its location. Sources of noise include trucks to bring waste to the facility, plant operations and fans. Assuming the facility is located in a commercial or industrial area, noise impacts associated from the anticipated truck volume and plant operations would be relatively minor.

The waste to energy facility would store any perishable waste within the facility which is under negative pressure preventing the migration of odours. The air is typically drawn from the waste receiving area into the combustion processes where high combustion temperatures eliminate any odours and dust associated with the waste.

Air emissions from a waste to energy facility depend on the pollution control system employed and the standards it is required to meet. Air emissions standards for waste to energy facilities are among the most stringent of all types of combustion processes and generally achieve lower emissions than the burning of wood or heating oil. The European Union, United States, and provinces such as Ontario and British Columbia have adopted best available technology standards which ensure that the standards achieved by the best performing similar facilities are adopted. Generally, emissions from WTE facilities are not visible except perhaps for a water vapour plume on cold days. Air pollution equipment can be configured to remove contaminants to well below the most stringent standards currently in use in Canada and Europe.

It is anticipated that Yukon would adopt WTE specific standards from either BC or Ontario.

5.1.4 Preliminary screening of siting options

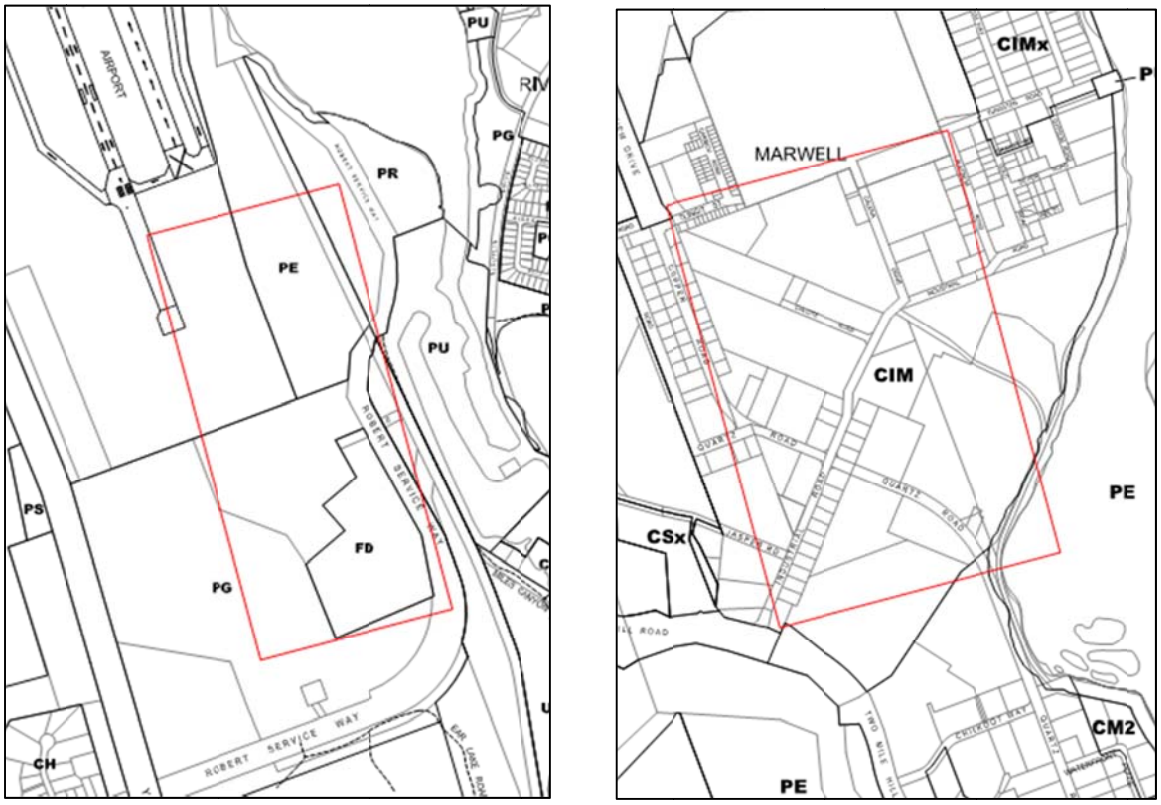
Site selection can have an important impact on project costs, additional revenue opportunities from district energy, environmental and nuisance impacts, and public acceptance. Proximity to district energy heat customers and compatibility with adjacent land uses have been used to screen potential site areas for further analysis.

The preliminary WTE business case analysis (Morrison Hershfield , 2011) indicated that heat sales to a future DES were critical to project feasibility. Accordingly, it is assumed that a future WTE plant must be sited in reasonable proximity to DES heat customers. As discussed in Section 2, preliminary results from the Whitehorse DES Feasibility Study indicate that the most promising DES option is one that serves the hospital and downtown core area.

Compatibility with adjacent land uses is critical to ensure that nuisance issues and traffic impacts are minimized. Based on land use compatibility, proximity to a future DES, and discussions with City of Whitehorse and Yukon Energy staff, two potential areas for siting a WTE facility have been identified. Those areas (illustrated in Figure 10) are:

1. South of downtown along Robert Service Way near Yukon Energy Headquarters;
2. Marwell Industrial Park, north of downtown area.

Figure 10: Siting areas Robert Service Way (Left) and Marwell Industrial Park (Right).



Robert Service Way South of Downtown

The area south of downtown near Yukon Energy head office includes several parcels of undeveloped land with good truck and electrical grid access that would easily meet the size requirements for a waste to energy facility. The haul distance to the Whitehorse landfill is approximately 16 km or 20 minutes. Depending on the parcel location, airport zoning restrictions may apply that could limit building heights and discharge of exhaust or steam from the facility that could affect air traffic. Since there is no residential development in this area and its proximity to the airport approach zone, noise and nuisance impacts to neighbouring sites would be very low. Air quality impacts however, may be of concern because of the location being upwind of downtown and the primarily residential Riverdale area which could be within 500 m of the site. Land in this area is currently zoned as either PG – Protected Green Space or PE – Environmental Protection, though based on the zoning by-law these designations may not prevent utility development, public concern may exist to development in those areas.

The close proximity to the Whitehorse substation means that electrical transmission line costs would be minimal; however, an on-site substation at the plant would still be required at an estimated capital cost of $1.5 million.[11]

A significant limiting factor to this area is the lack of water and sewer infrastructure. Currently, the City is contemplating the development of a 15 ha parcel for a new Municipal Services Building that fronts Robert Service Way and abuts the airport to the north (see figure 3). Such a development could bring water and sewer services to the area as well as a large heat consumer. As shown in Figure 8, currently the closest waste and sewer connections would be approximately 3 km from downtown. Based on the anticipated annual demand, a well could be developed to provide water to the site. Wastewater however, would require connection to the existing system. Water and sewer servicing costs are estimated to be $1.5 to $2.0 million.

Connection to a downtown DES would be between 2.0 and 3.0 km along Robert Service Way depending on the chosen site location. Current land use and topographical constraints along Robert Service Way appear to provide little opportunities for additional development for future connection along the district energy transmission route to downtown thus, constraining additional value that could be gained from the capital cost spent on district energy transmission pipe and water and sewer servicing. However, the WTE business case could improve significantly should the City construct their new Municipal Services Building at the parcel across from Yukon Energy and if further industrial and commercial development takes place in this area. This would provide new heat customers for the facility.

Marwell Industrial Park North of Downtown

Several large parcels of underutilized land (large areas exist that are only being used for surface storage of equipment) are located in Marwell area that would be of suitable size for a waste to energy facility. Marwell is well serviced with water and sewer infrastructure and has good truck access. The haul distance to the Whitehorse landfill is approximately 7 km or 10 minutes. The most accessible substation near Marwell is the McIntyre substation via transmission line L169 to the north. A substation would be required at the facility and a 34.5 KV transmission line to connect to L169 would be between 1.0 and 1.5 km in length depending on site location. The connection and substation costs are estimated to be $1.6 million[7].

Existing zoning CIM – Mixed Use Commercial/Industrial could be compatible with a Waste to Energy facility whose overall noise and nuisance impact would be no greater than other industries with such a designation. It is known that potentially contaminated lands exist in the Marwell area[12]. These sites may be suitable for a WTE facility since remediation requirements would likely be less stringent than for other land uses. Air quality impacts could be less than the location south of the downtown as a result of being downwind of the central downtown area.

Connection to the downtown DES based on the current distribution system layout would require transmission piping between 1.5 and 2.0 km in length depending on

[11] Person. Comm. Marc-Andre Lavigne, YEC, via. e-mail Feb 27, 2012
[12] Person Comm. Pat Hogan YTG Feb 27, 2012

the site location. The transmission piping could provide opportunities for additional customers to be connected to the DES along the route. A WTE location in this area could also support a future extension of the DES to potential customers in the Range Road area.

5.1.5 Preliminary assessment overview

Siting a WTE facility in either the Marwell area or south of downtown along Robert Service Way appears to be technically feasible. Table 5 provides a comparative summary of the two siting options, highlighting relative advantages and disadvantages of each site area. On most criteria, the Marwell Industrial is preferable to the Robert Service Way location. The Robert Service Way location has the advantage of lower electrical tie-in costs; however, this cost advantage is reversed when the costs of water and sewer servicing are considered. While there would be few immediate neighbours to a facility located in the Robert Service Way area, the proximity to the airport could affect the facility design and operations.

For the purpose of updating the WTE business case analysis (Section 6) it is assumed that the WTE facility would be located in the Marwell Industrial area. A more detailed siting analysis, environmental assessment, and associated public consultation will be required before a final siting decision is made.

Table 5: Comparison of siting options

	Area 1: Robert Service Way South of Downtown	Area 2: Marwell Industrial Park North of Downtown
Land Availability	Yes	Potentially; however, no specific sites identified. Siting on contaminated land could result in lower land costs.
Distance to Landfill	Longer haul distance,16 km or 20 minutes	Shorter Haul distance, 7 km or 10 minutes
Compatibility with existing land uses and designations	Some restrictions, airport height and zoning restrictions and existing city zoning would need to be modified. Can be mitigated.	Yes
Access to water and sewer infrastructure	No, potentially mitigated if infrastructure is extended from Riverdale or MSB is constructed. Costs estimated between $1.5 and $2.0 million.	Yes
Access to electrical infrastructure	Yes – On-site substation still required, $1.5 million	No, may require connection to transmission line up to 1.5 km away and/or substation, $1.7 million
Connection to expanded DES in future	Limited, unless the City's new MSB (or other new commercial/industrial facilities) is constructed in this area.	Good potential for expanding DES into Range Road area.

	Area 1: Robert Service Way South of Downtown	Area 2: Marwell Industrial Park North of Downtown
Air quality limitations	Some limitations; need to ensure steam from the facility does not impact airport, close proximity to residential area and upwind of downtown. Detailed air study should determine if significant impacts exist.	Limited limitations, site location is in industrial/commercial area and downwind of downtown. Detailed air study should determine if significant impacts exist.
Noise and nuisance impacts	Minimal, site is located in an isolated area, truck traffic and operations should not have a significant impact to neighbouring properties. Nuisance impacts to Riverdale may be identified.	Minimal, site is located in a more central area, truck traffic and operations could have some impact to neighbouring properties; however, impacts could be mitigated and are minimal since operations are largely compatible with existing land use designations.

5.2 Air Emissions

Comparison of Air Quality Parameters

Waste to energy facilities, just like landfills and all combustion based energy sources, emit air pollutants. In the Whitehorse context, the net air emissions resulting from WTE include emissions associated with the combustion of waste minus avoided air emissions associated with landfilling of waste, displaced diesel-generated electricity, and displaced heating oil used in boilers (assuming implementation of a DES).

The air emissions from a WTE facility are dependent on the waste composition, the thermal conversion technology employed, combustion conditions, and the design of air pollution control system. Standards such as Ontario and BC's maximum achievable technology standards specific to municipal thermal waste treatment facilities are continuously becoming more stringent to ensure emissions are as low as technically feasible. Table 6 illustrates a comparison between the Ontario Guideline A-7: Combustion and Air Pollution Control Requirement for New Municipal Waste Incinerators and the average air emissions from the "top ten" Waste to Energy Research and Technology Council 2006 Industrial award finalists. (Psomopoulos, C.S., 2009). For all parameters, facilities demonstrated an ability to achieve significantly lower levels of emissions than the Ontario standards.

Table 6: Comparison of air emissions from WTE combustion technologies and Ontario Guideline A-7 Standard.

All concentrations are compared at 11% O_2

	Average of 10 Finalists	Ontario Guideline A-7 Standard 2010
Smog Precursors		
Total Particulate Matter (PM) mg/Rm3	3.1	14
Acid Gases		
Nitrogen Oxides (NOx) mg/Rm3	112	198
Hydrogen Chloride (HCL) mg/Rm3	8.5	27
Carbon Monoxide (CO) mg/Rm3	24	40
Total Organic Content (TOC) mg/Rm3	1.02	33
Sulphur Dioxide (SO2) mg/Rm3	2.96	21
Trace Air Contaminants		
Mercury (Hg) ug/Rm3	10	20
Dioxins (TEQ) ng/m3	0.02	0.08
Cadmium (Cd) ug/Rm3	4.9[13]	7
Lead (Pb) ug/Rm3	44.51	60

The government of Ontario conducted a detailed assessment[14] of the human health and ecological risks of a modern well run incinerator that complied with the A-7 Standard in conjunction with a similar study on their landfill standards. The study concluded that:

- No significant human health effects (those being cancer, lung disease, nerve damage or reproductive effects) are likely in a typical suburban community located near an incinerator or a landfill, however both cancer risks and non-cancer risks from incinerators were lower than those associated with landfill emissions[15];

[13] Source: (Psomopoulos, C.S., 2009)

[14] Environmental Risks of Municipal Non-Hazardous Waste Landfilling and Incineration (Ontario MoE, 1999)

[15] Total lifetime incremental cancer risk for a maximally exposed individual from long-term exposure to incinerator emissions range from 4.7x10-8 to 2.3X10-7 versus total combined cancer risk from long-term exposure to landfill emissions containing volatile chlorinated chemicals range from 4.0x10-6 to 1.0x10-5 for landfill emissions. (Ontario MoE, 1999)

- An ecological risk assessment predicts that water and sediment quality near an incinerator or landfill will meet Ministry guidelines for the protection of aquatic life;
- Direct or indirect impacts to the terrestrial environment, vegetation or wildlife resulting from incinerator or landfill emissions are not anticipated to be significant.

Similar conclusions from other comparative studies are summarized by Moy (2005). Most recently, an independent study commissioned by the Commissioner and Medical Officer of Health for Region of Durham, Ontario, determined that there is no conclusive evidence indicating negative impacts of modern incinerators on the health of people living in the vicinity, based on the epidemiologic literature from 2000 – 2007 (Smith, 2007).

Energy from the WTE facility is expected to displace approximately 10,200 MWh diesel generated power and 23,700 MWh of heat derived from burning 3,383,000 litres of heating oil annually. Table 7 illustrates air emissions for these energy sources per unit of energy generated.

Table 7: Comparison of air emission intensities from energy sources in Whitehorse with WTE

	Heating Oil[16] (kg/MWh)	Diesel Generator[17] (kg/MWh)	WTE (kg/MWh)[18]
Total Particulate Matter (PM)	0.042	0.183	0.0228
Nitrogen Oxides (NOx)	0.416	8.82	0.82
Carbon Monoxide (CO)	0.104	0.516	0.176
Sulphur Dioxide (SOx)	1.66e-7	0.014	0.022

Table 8 illustrates the total air emissions based on the anticipated WTE energy output and the emissions of heating oil and diesel that could be displaced as a result of a WTE facility. The results indicate that WTE would result in overall emission reductions of total particulate matter, nitrogen oxides and carbon monoxide and an increase in sulphur dioxide. It should be noted that the WTE emission estimate is based on an average of operating facilities. If the need was established to reduce sulphur dioxide emissions in the Whitehorse area,

[16] Source: Heating oil calculations adapted from emissions calculator by Illinois Environmental Protection Agency for #1 and #2 Fuel Oil http://www.epa.state.il.us/air/aer/calculate/boiler_oil.html . Sulphur content of oil supplied in Whitehorse is Ultra Low Sulphur Platinum 0.0005 ppm. Annual seasonal boiler efficiency is assumed to be 65% according to DES study by FVB Energy.
[17] Source: Diesel emissions data from Yukon Energy

[18] Source: Calculated based on air emissions from average 10 WTE finalists, 9,975 MWh electricity and 23,700 MWh of heat generated.

additional air emission controls limiting sulphur dioxide stack emissions are technically feasible.

Table 8: Total annual air emissions displaced by WTE

	Heating Oil (kg)	Diesel Generator (kg)	WTE (kg)	Air Emissions Displaced (kg)
Total Particulate Matter (PM)	985	1,825	767	(2,044)
Nitrogen Oxides (NOx)	9,854	88,019	27,720	(70,153)
Carbon Monoxide (CO)	2,464	5,147	5,940	(1,671)
Sulphur Dioxide	0.00394	140	733	593

Dioxins and furan compounds can be formed by a wide variety of combustion sources including cars, trucks, diesel generators, wood burning fireplaces and WTE facilities. The implementation of stringent air pollution standards and controls for WTE facilities over the previous decades has dramatically reduced dioxin and furan emissions. The German Ministry of Environment now considers dioxins and furans coming from WTE to be insignificant, since they make up less than 1% of the loading in Germany, even though 35% of the municipal waste in Germany is treated using WTE[19]. In Canada, we have Canada-Wide Standards for dioxins and furans which are the most stringent in the world.

Metals contained within MSW commonly include iron, copper, lead, zinc, cadmium and mercury. Within a WTE facility, most metals remain inert and appear in the bottom ash following combustion. Volatile metals however, particularly mercury and lead will be partially or fully volatized at high temperatures.

The emission of mercury and lead from WTE facilities is a function of the presence of these elements in the waste stream and the capabilities of the air pollution control system. The diversion of hazardous materials from disposal, such as thermostats, barometers and manometers, lighting and electrical appliances, major appliances, electronic waste, and batteries, can eliminate the source while air pollution control systems have been proven to be able to reduce volatile metal emissions to well below environmental regulations. Mercury emissions measured from the top ten North American WTE facilities are now less than 50% of the Ontario standard (see Table 6 above) while lead emissions are also consistently below the Ontario standard for these facilities. According to a German Ministry of Environment publication, lead and mercury emissions from incineration of household waste are no longer significant sources for human exposure to toxic substances, and emissions from all other sources are over 1,000 times greater than the emissions produced by WTE facilities (BMU, 2005).

[19] Germany, Federal Ministry for the Environment, Nature Conservation and Nuclear Safety (2005). *Waste Incineration – A Potential Danger? Bidding Farewell to Dioxin Sprouting*. Accessed October 26, 2008. http://www.bmu.de/files/pdfs/allgemein/application/pdf/muellverbrennung_dioxin_en.pdf

Ultrafine particles (also referred to as “nano-particles”) are the subject of recent research and growing public interest. Ultrafine particles are generated directly by combustion from stationary sources (power plants, heating furnaces, WTE facilities) and mobile sources such as cars, trucks and industrial mobile equipment burning diesel, gas or gasoline. In order to put ultrafine sources into perspective, one study[20] in the literature compared the ultrafine emissions from vehicles with those coming from a WTE facility. Converted to the proposed size for the WTE plant in Whitehorse, about 100 vehicles traveling 3km would release about the same amount of ultrafine particles as a WTE facility in an hour. There is also recent evidence (briefly described below) that suggests that stringent air pollution control requirements for WTE facilities result in significantly fewer ultrafine particle emissions than from other combustion sources. One study conducted by a university in Switzerland on different types of pollution control equipment at WTE facilities found that a certain combination of scrubbers actually reduced ultrafine loadings from the stack to levels lower than in the ambient rural air (UMTEC, 2001). Further study and verification is required and would be addressed in an environmental assessment.

This section provided an overview of WTE air emissions in the context of emissions from displaced energy sources (diesel and furnace oil) and other emission sources. More detailed air quality analysis, including plume dispersion modelling is recommended once a potential site, process technology and air pollution controls have been specified.

5.3 Environmental Approvals and Permitting

Project-specific regulatory issues and requirements should be well understood as early in the life of a project as possible. A well thought out program for meeting these requirements that includes early engagement of relevant regulatory agencies, key stakeholders, and public can greatly reduce the risk of lengthy and costly project delays.

This section provides a brief summary of the expected federal, territorial and municipal regulatory requirements associated with the construction and operation of a WTE facility in Whitehorse, including undertaking an environmental assessment of the project, as well as obtaining all required permits and licenses as per territorial regulations and municipal by-laws. More details on the anticipated environmental assessment process are provided in ***Appendix D***.

5.3.1 Yukon Environmental and Socio-Economic Assessment Act Process Overview

It is anticipated that the construction of a WTE facility in Whitehorse will trigger the requirement to obtain approval under the *Yukon Environmental and Socio-Economic Assessment Act (*YESAA). Based on the type of facility proposed it is expected the assessment will involve a Designated Office evaluation (process used for the majority of assessments conducted in Yukon).

[20] *Buonanno, G., Ficco, G., & Stabile, L. (2009). Size distribution and number concentration of particles at the stack of a municipal waste incinerator.* Journal of Waste Management, *29, 749-755*

An assessment is initiated when a proponent submits a project proposal to the Yukon Environmental and Socio-economic Assessment Board. Project proposals typically contain environmental and socioeconomic information describing baseline conditions, potential project impacts, and mitigation strategies in some or all of the following areas:

- Air Quality
- Geology and Soil
- Water and Water Quality
- Fish and Fish Habitat
- Wildlife and Wildlife Habitat
- Vegetation Age, Composition, and Structure
- Cultural/Heritage Resources
- Recreation
- Health
- Employment
- Education/Knowledge
- Families

Following submission of the project proposal by the Proponent, a review process is coordinated (in this case) by the Designation Office. Following the evaluation phase, the Designated Office prepares a recommendation to applicable Decision Body(s)[21].

5.3.2 Territorial and Municipal Permitting & Licensing Requirements

A WTE facility in the Yukon will trigger permitting and licensing requirements at the territorial and municipal level. Project-specific issues linked to approvals requirements include air emissions, ash disposal, land acquisition needs, socio-economic implications, surface water / groundwater extraction and use, and potential for contaminant spills, amongst others. Table 9 lists the regulatory permits, leases and licenses likely to be associated with a WTE facility, along with information that should be included in environmental permit and approval applications.

Territorial permits and approvals can be issued by relevant regulatory agencies only after release of the YESAB Final Report recommendations and (if undue delay is to be avoided) only after each Decision Body has issued a Decision Document accepting the YESAB recommendations. However, permit application materials can be filed with relevant regulatory agencies prior to the issuance of a Decision Document to help expedite this process. Assuming no major issues arise during the review period, approvals could then be obtained shortly after the Decision Document is issued.

[21] A Decision Body is the federal government, territorial government or First Nation that responds to recommendations made to them by Designated Offices, the Executive Committee of YESAB or a Panel of the Board, and has the authority to determine whether a project may proceed.

Development activities in the Yukon often require additional federal permits or authorizations. Triggers for such permits include impacts to fish or fish habitat, or to navigable waters. It is assumed that no watercourses will be impacted as a result of construction of the WTE facility; as a result, an Authorization as per the *Fisheries Act* or Permit as per the *Navigable Waters Act* will not be required.

Table 9: Overview of Approvals Requirements for a Whitehorse Waste to Energy facility

Project Activity	Approval Requirement	Applicable Act / Regulation / By-Law	Information Requirements for Obtaining Approval (i.e. permit, license or lease)
Territorial Permit / Licensing Requirements			
Operation of incinerators capable of burning more than 5 kilograms of solid waste per day.	Air Emissions Permit	*Environment Act* / Air Emissions Regulations	▪ A description of the source of the contaminants that may be released into the air; ▪ The type and quantity of the contaminants that may be released into the air; ▪ One set of plans and drawings clearly showing the layout of the facility, location of individual equipment, and points of discharge, building dimensions and stack heights; ▪ A description of air quality control devices, including efficiency and other design criteria and photocopies of the manufacturer's specifications for the air quality control devices establishing that the equipment is capable of complying with applicable emission criteria in the permit; ▪ A map or aerial photograph, on a scale of 1:50,000 detailing the location of the facility, homes, buildings, roads and other adjacent facilities within a five kilometre radius of the facility; ▪ Specifications for any equipment, including incinerators, that may be used and a description of the mitigative measures planned to control air emissions and the disposal and handling of all types of ash; and, ▪ A description of any equipment or devices the applicant intends to use to monitor the release of contaminants into the air.
Constructing and operating a waste disposal facility	Permit for the Facility	*Environment Act* / Solid Waste Regulations	▪ The location and size of the proposed waste disposal facility or dump and a description of the type of solid waste to be handled or disposed of the site;
Disposal or handling of special waste[22]	Special Waste Permit	*Environment Act* / Special Waste Regulations	▪ The types of special waste and operations for which the application is made; ▪ Location of any proposed handling or disposal of special waste; ▪ The rate at which special waste will be generated; and

[22] Commonly known as hazardous waste.

Project Activity	Approval Requirement	Applicable Act / Regulation / By-Law	Information Requirements for Obtaining Approval (i.e. permit, license or lease)
			▪ Method of treatment or disposal.
Storage and handling of petroleum products	Storage Tank Systems Permit	*Environment Act* / Storage Tank Regulations	▪ Any plans related to the activity to be undertaken, including storage tank system design plans, safety and inspection plans and closure and reclamation plans; ▪ Identification of on-site and adjacent groundwater and surface water sources; and ▪ The proposed dates and timing of work to be undertaken in relation to the permitted activity.
Establishment of a solid waste disposal facility; **Fuel caches of more than 4000L or any single container of more than 2000L on Commissioner's Land**	Land Lease and Land Use Permit	*Territorial Lands (Yukon) Act, Lands Act* / Land Use Regulations	▪ A preliminary plan showing the lands proposed to be used and an estimate of their area, and the approximate location of all of the following: – existing lines, trails, rights-of-way, and cleared areas proposed to be used in the land use operation; – new lines, trails, rights-of-way, and cleared areas proposed to be used in the land use operation; – buildings, campsites, air landing strips, air navigation aids, fuel and supply storage sites, waste disposal sites, excavations, and other works and places proposed to be constructed or used during the land use operation; and – bridges, dams, ditches, railroads, highways and roads, transmission lines, pipelines, survey lines and monuments, air landing strips, streams, and all other features, structures or works that, in the opinion of the applicant, may be affected by the land use operation.
Water use or the potential deposition of waste materials in water	Water License	*Waters Act*	▪ Where the water is proposed to be used for an industrial, placer mining, or quartz mining undertaking, a description of the undertaking and of all wastes produced and chemicals used in the operation of the undertaking; and ▪ Where the proposed undertaking involves the handling or storage of petroleum products or hazardous materials, a plan for their safe handling, storage, and disposal, and a contingency plan for their containment and for cleaning them up in the event of a spill; and ▪ Plans for the abandonment, or any temporary closing, of the proposed undertaking.

Project Activity	Approval Requirement	Applicable Act / Regulation / By-Law	Information Requirements for Obtaining Approval (i.e. permit, license or lease)
Relevant Municipal Requirements			
Disposal of solid waste	Permit to Dispose of Solid Waste	Solid Waste By-Law	▪ Conditions that may be placed on the permit may include the requirement to provide information on the origin, type and amount of solid waste from outside the city, or laboratory analysis of the concentration of contaminants in the contaminated soil.
Release of waste water, storm water, subsurface water or clear-water waste into the sewer or drainage systems	Permit to Discharge	Sewer and Water By-Law	Information requirements associated with a permit to discharge not explicitly stated in the sewer and water by-law.
Establishment of a solid waste disposal facility	Development Permit	Zoning By-Law	▪ legal description and property address; ▪ statement of the current, proposed use and occupancy of all parts of the lot and buildings; ▪ description of the size of the proposed development with respect to gross floor area, lot coverage, building or structure height, amount and location of parking and loading areas; ▪ be accompanied by a site plan in duplicate, at an appropriate metric scale containing – a north arrow; – the legal property description; – lot dimensions and other reference features such as the location of easements, existing buildings, fences relative to property lines, and existing and proposed grades; – the location of all existing and proposed improvements on the lot including site access and egress, front, side and rear yard dimensions, location and size of required parking, loading and garbage collection areas; – the location of any trees, shrubbery or natural features to be retained; – the location of public sidewalks, hydro poles, light standards, boulevard trees, fire hydrants and other related features; – floor plans and elevation drawings of all proposed buildings, and

Project Activity	Approval Requirement	Applicable Act / Regulation / By-Law	Information Requirements for Obtaining Approval (i.e. permit, license or lease)
			structures including any additions; – the location, size, and placement of signs and future signs in all commercial, institutional and industrial zones; – the location of all existing and proposed services on the property; and – the location of all proposed structures to manage drainage including connections to existing storm mains, ditches, rock sumps and/or storm sewer interceptors for areas with high contamination potential.

5.3.3 Public Utilities Board Requirements

All energy projects proposed for development in the Yukon require an Energy Project Certificate (EPC) prior to construction. As per the *Public Utilities Act*, an energy project includes "… a facility for the generation of electricity from the motion of wind or water, or the combustion of natural gas, oil, petroleum products, coal, or plant products or geothermal energy".

The following is an outline of information that it is expected to be required in an EPC Application, primarily based on the information supplied in the YEC Application for the Mayo Hydro Enhancement Project (2009):

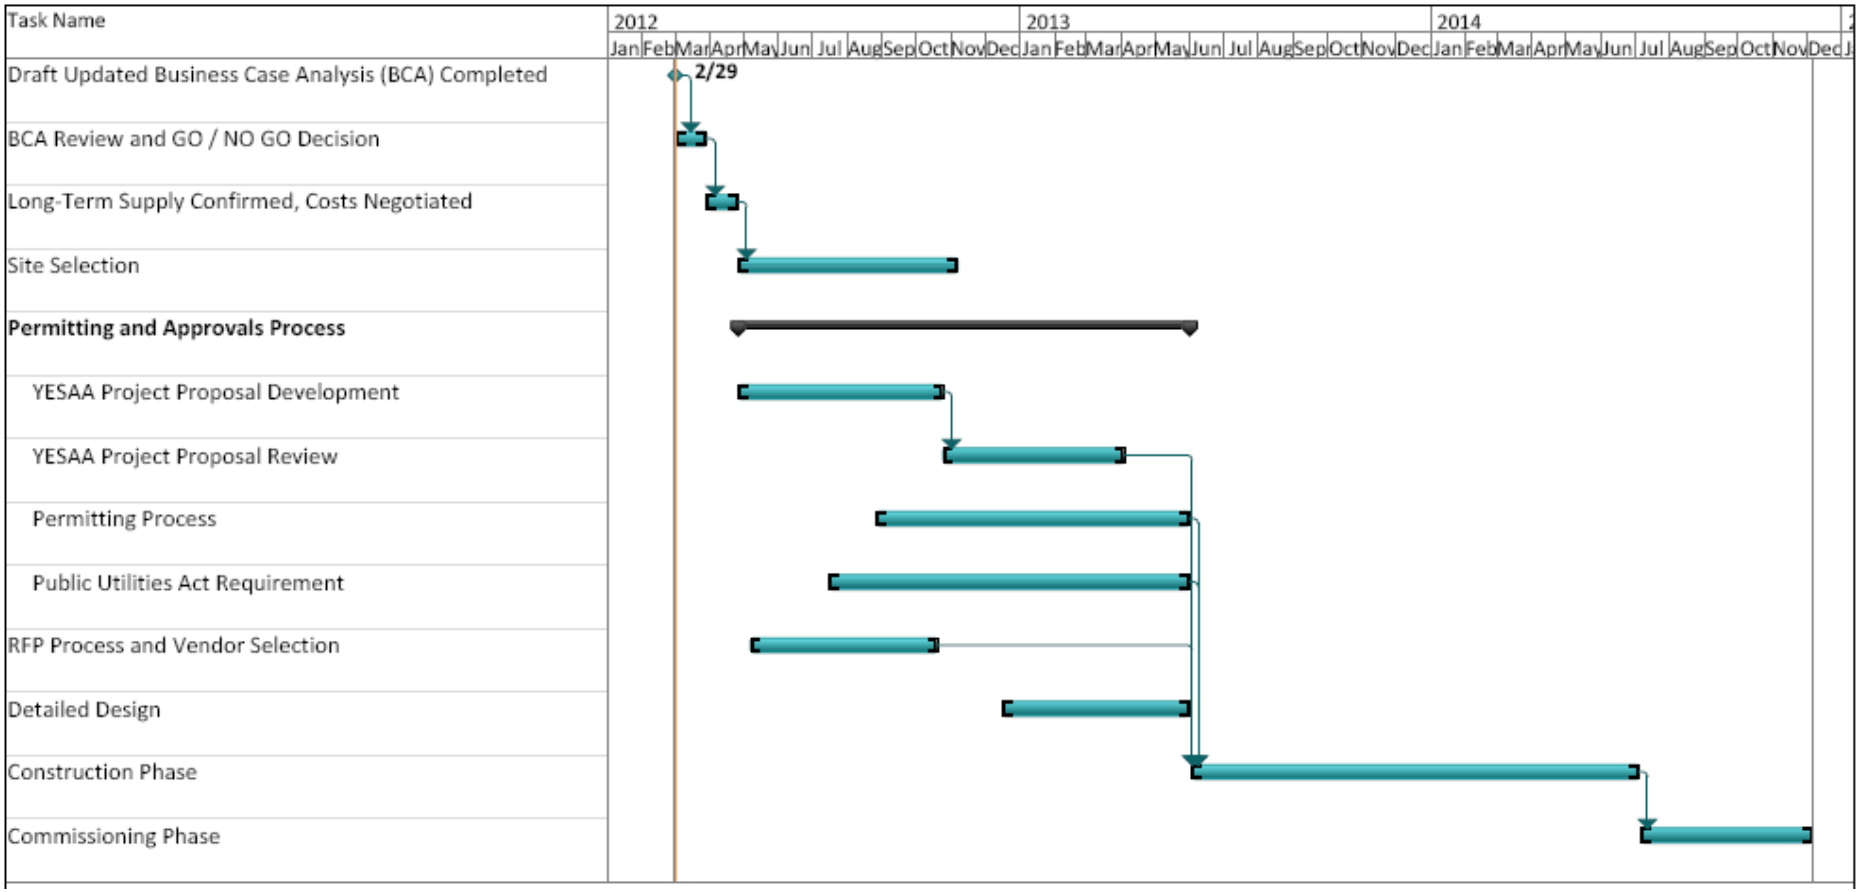
- Introduction and Applicant Information;
- Project Description, including a summary of anticipated environmental and socio-economic impacts;
- Project Justification, including project need, risks and effect on rate payers;
- Consultation Undertaken to Date; and
- Description of other Permitting Applications and Approvals.

5.3.4 Project Scheduling Implications

Figure 11 provides a preliminary schedule for getting a WTE project through the environmental assessment, permitting and approvals phase. The schedule incorporates regulated times associated with the adequacy, evaluation and recommendation stages of YESAA. However, the YESAA timelines have been intentionally structured to incorporate a great deal of flexibility such that both small-scale and large-scale projects can be accommodated. This results in some uncertainty for any particular project in exactly how long the approvals phase will take. To deal with this issue as well as other project uncertainties such as timing of when proposal development will begin, the schedule presented in Figure 11 incorporates the following assumptions:

- Decision whether to proceed with project based on updated Business Case Analysis made by end of March 2012.
- Project Energy Certificate Application and Permit Applications developed in parallel with YESAA Project Proposal Development and Review, requiring little additional time for regulatory decisions to be made (by the Yukon Utilities Board and territorial regulators such as the Yukon Ministry of Environment) following YESAA Decision Body approval.
- Six to 12 month commissioning phase.
- Detailed design phase completed in parallel with permitting review and approval phase.
- A relatively straightforward consultation process, with moderate public interest and few major issues and concerns identified, requiring 1 month for Seeking Views & Information, and an additional 2 weeks to respond to information requests

Figure 11: Preliminary Schedule for a Waste to Energy Project in the Yukon.



6. UPDATED BUSINESS CASE ANALYSIS

6.1 Approach and Key Assumptions

This analysis builds on the preliminary business case analysis, completed in September, 2011 (Morrison Hershfield, September 2011), and determines costs to produce additional power by utilizing municipal solid waste and biomass (wood) as fuel sources.

Research and analysis since the September 2011 study have resulted in the selection of a single scenario based on the most recent waste diversion initiatives and supported by research into residual waste availability, biomass supply, district energy heat needs and costs, technology types and costs (via an EOI) and other research as required. Key parameters and assumptions are presented in Table 10.

Table 10: Business Case Parameters and Assumptions

Business Case Parameter	Assumption	Comments
Nominal capacity of WTE plant	25,000 Tonnes Per Year	
Technology used	Conventional combustion	Two stage combustion, close coupled gasification or mass burn
Actual plant throughput at 95% availability	23,750 tonnes per year	
Feedstock used in in 2015	16,100 tonnes MSW 7,650 tonnes biomass	Based on 50% MSW diversion
Feedstock used in 2035	23,750 tonnes MSW	Based on expected population and waste growth
Tipping fee for waste received	$108 per tonne	Based on what it would cost to otherwise landfill that material
Tipping fee paid for ash disposed	$185 per tonne	Based on what it would cost to operate a smaller ash landfill
Average cost of biomass supply	$104 per tonne	As received wet wood
Net electricity production	9,975 MWh	Based on 470 kWh per tonne of waste
Net heat produced and sold	23,700 MWh	Based on supplying 79% of the heat for a future Whitehorse DES
Value of heat sold	$81/MWh	From separate district energy study
Minimum site size	2 ha	
Waste to energy facility life	25 years	With potential to extend
Remaining landfill capacity with expanded diversion (and no WTE)	Until 2057	Landfill expansion is possible
Remaining landfill capacity with expanded diversion and WTE	Well into next century	Landfill expansion likely not required
Contingency	10%	On capital and operating costs

6.2 Feedstock costs and revenues

6.2.1 Municipal solid waste

Revenues from tipping fees for the acceptance of MSW at the WTE facility are based on an analysis of the life cycle costs of operating the Whitehorse Landfill, Appendix B. The tipping fee will need to be discussed and confirmed with the City when this project moves forward.

The WTE tipping fees used in this analysis are the lifecycle costs of operating the Son of War Eagle Landfill assuming waste volumes are reduced/diverted from landfilling by a total of 50%. In this analysis, it is assumed that the residual waste would be taken to the WTE facility instead of the Son of War Eagle Landfill. The tipping fees paid to the WTE operator would be the same as the City's deferred cost to landfill the waste.

Costs of ash disposal, disposal of some non-burnable waste and small amounts of MSW when the WTE plant is being serviced were also assessed based on what it would cost the City to keep the landfill in operation for the lower volumes with WTE. While overall landfill costs go down when mostly ash is disposed, the unit costs per tonne actually go up because of the much lower volumes (units). For this analysis, it has been assumed that the WTE facility operator would pay the City the true cost of disposal for ash residue. This is substantially higher than the unit fee per tonne that would be paid to the WTE plant operator for acceptance of MSW.

Fly ash would require stabilization treatment prior to disposal into the landfill. An allowance of $30 per tonne has been included for ash stabilization.

6.2.2 Wood biomass

Wood biomass costs are dependent on the annual requirements and quantities available. Cheaper biomass source would be prioritized ahead of more expensive sources. Based on an assessment of the biomass availability near Whitehorse the initial cost is estimated at $104 per wet tonne delivered to the WTE facility. This is an average cost and may be less if greater quantities of cheaper sources of biomass become available. Since the volumes of MSW will increase along with population growth and commercial activity in the Yukon, the amount of biomass required should decrease to zero by about 2035 (more or less, depending on actual growth and actual recycling). Capital and operating cost estimates include provisions for biomass storage, handling and chipping.

6.2.3 Heat Revenues

The waste to energy facility would be able to provide a heat baseload of 23,700 MWh to a district heating system supplying the downtown and hospital district. When

taking into consideration the additional capital and operating costs associated with the district energy, the potential net revenue from heat sales would be $81/MWh[23].

6.2.4 Metal Recycling

Recovered metals are expected to consist of 3% of the annual waste throughput. Revenues from recycled metals will fluctuate with world market demand for scrap. A value of $100 per tonne is used at this time to reflect an expected long term average.

6.3 Facility Capital and Operating costs

6.3.1 Scope included and excluded

At this stage of the project, where the technology has been defined, but a vendor not yet selected, and a site area defined, but a specific site not yet selected, there are some items that can be firmly defined and some that are accounted for with a cost allowance (for confirmation as the project develops).

Capital costs

Included in the capital cost estimates, which are supported by information received through the EOI and supplemented through other research and studies are:

- Purchased equipment to receive, process, combust waste;
- Equipment to recover energy in the form of heat and electricity;
- Air pollution control equipment;
- Ash removal and ash treatment as required;
- Biomass receiving, storage, processing/chipping and feeding;
- Buildings;
- Site work;
- Permits and approvals;
- Cost of land;
- Electrical tie-in and substations; and,
- Utility connections for water and sewer.

Interest during construction is not included.

[23] Calculations by FVB Energy for Whitehorse District Energy feasibility study provided by Robert Doyle February 29, 2012

Operating Costs

Operating costs include:

- labour costs;
- variable operating costs;
- maintenance costs;
- biomass processing;
- bottom ash disposal; and,
- fly ash treatment.

6.3.2 Estimated Costs

Capital costs were estimated using supporting information from vendor submissions, existing data from previous work, and new information from recent studies into the true cost of landfilling and into DESs. Vendor submissions provided a range of capital costs from $19.9 million to $42.8 million, with an average from 5 submissions calculated at about $31 million. The capital cost used in the business case analysis including 10% contingency was $34.6 million.

Operating costs, excluding feedstock costs and revenues, range from $3.3 million per year to $4.6 million per year based on vendor submissions. The higher number was for a technology from Europe, where prices are generally much higher than in North America. The other vendors' operating costs were within 20% of the lowest figure. The estimated operating costs for the business case analysis assume a staff requirement of 18 persons (vendors suggested between 7 and 39), variable operating costs supported by vendor submitted data, ash disposal costs derived from the landfill cost analysis, and an allowance for biomass processing and fly ash stabilization. Including a 10% contingency, the operating costs are estimated at $3.3 million per year and are within the range of operating costs provided by vendors in the EOI process.

A sensitivity analysis was used to account for the potential variability of some key costs.

6.4 Financial Analysis Base Case

Table 11: Base Case WTE Cost Model

MAXIMUM PRODUCTION OF ELECTRICITY (MSW and Biomass)

Combined Heat and Power, 1.6 MW (Electricity)

Base Case

Plant design capacity		25,000	Tonnes per year
Plant feedstock usage		16,098	Tonnes per year MSW
		7,652	Tonnes per year biomass
Complete facility installed and commissioned	$25,500,000	1,020	$ per tonne of installed annual capacity
Additional costs for wood handing, storage & chipping	$ 1,000,000		
Land Costs	$ 1,000,000		
Site work	$ 2,000,000		
AC Connection Costs	$ 1,600,000		
Permits and approvals	$ 50,000		
Total capital cost	***$31,450,000***		
Contingency	*$ 3,145,000*	10%	
Total capital cost + Contingency	***$34,595,000***		
Assumed average cost of capital		5.5	% annual interest rate
Amortization period		25	Years
Annual capital costs	***$ 2,611,923***	$ 110	capital expense per tonne of feedstock
Annual labor costs	$ 1,440,000	18	Assume average staff cost of $80k per year
Variable operation and maintenance costs	$ 900,000	$ 36	$ per tonne of installed annual capacity
Biomass Processing	$ 45,914	$ 6	$per tonne allowance
Bottom ash disposal (17% of MSW, 1% of biomass)	$ 519,113	$ 185	$ per tonne to landfill
Fly ash treatment and disposal (3% of feedstock	$ 145,730	$ 205	$ per tonne to treat and landfill
Total Operating Costs	**$ 3,050,757**		
Contingency	*$ 305,076*	*10%*	
Total Heat Sales		*23,700*	*MWh*
Net Revenue from DE	($1,914,960)	*$ 81*	*$ per MWh heat sold*
Cost of wood supply	$ 795,846	$ 104	$ per wet tonne
Revenue from tipping fees	($1,736,356)	$ 108	$ per tonne of MSW received
Revenue from sale of recyclables (3% of MSW)	($ 48,293)	$ 100	$ per tonne
Net annual cost	***$ 3,063,992***		
Total electricity produced in MWh	9,975	420	kWh per tonne of MSW and tonne biomass
Cost per kWh of electricity generated	**$ 0.31**		

The costs per kWh of electricity generated are higher than in the Preliminary Business Case Analysis (Morrison Hershfield, 2011) of $0.16 - $0.18 per kWh. The changes in the business case include the following:

- Capital costs are lower by about 10% due to a small reduction in capacity, more precise vendor information, and a reduction in contingency. Actual scope of capital items increased and now includes electrical substation and land cost allowances.
- Non-feedstock related operating costs are higher by about 15%. This is due to higher estimated ash disposal costs (arising from the landfill cost assessment) and a better understanding of some of the operating components through vendor input.
- Electricity production is 30% less than originally indicated due to electricity generation efficiency losses resulting from the amount of heat that will be removed for the DES (as indicated by vendors in EOI process). It is expected that vendors would optimize their CHP systems in a competitive bidding situation and may be able to improve on the electricity generation efficiencies quoted under the EOI.
- The amount of biomass required to augment the MSW feedstock in the near-term is substantially higher since we have assumed a 50% MSW diversion target is achieved in 2015. The additional biomass requirements and reduction in MSW tipping fee revenues significantly increase operating costs.

The base case analysis is appropriately conservative for the current stage of project evaluation. The impacts of varying key project variables are discussed in the sensitivity analysis section below.

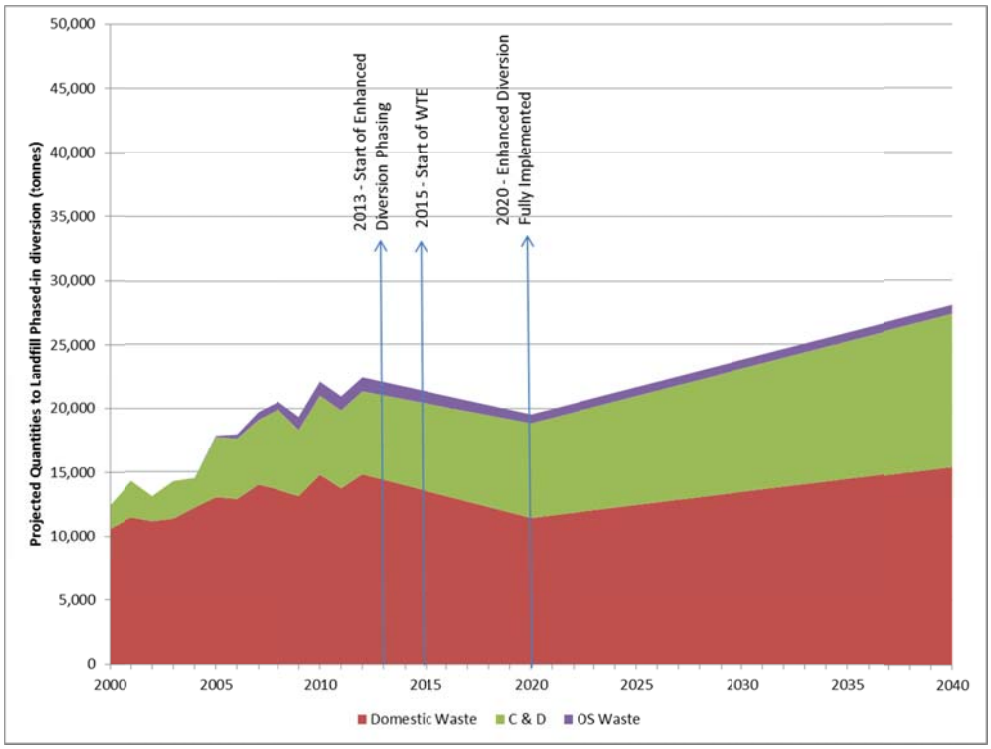
6.5 Sensitivity Analysis

The base case has a higher level of confidence than the preliminary business case analysis completed in September 2011. However, several key areas of uncertainty remain that can have a major bearing on project feasibility. A sensitivity analysis of the business case has been conducted for these key project variables and is described in the sections below.

6.5.1 Sensitivity #1 - Potential for Phased-in Waste Diversion

The base analysis assumes an almost immediate drop in waste generation due to very aggressive recycling efforts. This sensitivity looks at the economics of the WTE facility if the diversion programs are phased in between 2013 and 2020, achieving a diversion of 50% by 2020. The impacts on MSW residual waste volumes are illustrated in Figure 12.

Figure 12: Phased-In Enhanced Diversion Sensitivity



Assuming the 50% waste diversion measures are phased in between 2013 and 2020, additional MSW would be available initially. Waste quantities would continue to increase due to population growth and economic activity while progress was being made towards the 50% diversion goal. With this sensitivity, the cost to produce electricity using WTE is $0.21 per kWh in 2015.

6.5.2 Sensitivity #2 - Federal Grant Funding under the ECO II NRCan program

An application for federal grant funding toward capital costs has been made under the NRCan ECO II program, ***Appendix E***. Since the result of this funding application is not yet known, this funding is not reflected in the base case analysis. Should the grant application be successful, the total capital funds required would be reduced to $21.7 million improving the business case. This case was evaluated based on two scenarios:

- Sensitivity #2a, assumes that the ECO II funding is granted and 50% waste diversion is achieved in 2015. This results in a cost to produce electricity using WTE of $0.21 per kWh in 2015.

- Sensitivity #2b, assumes that the ECO II funding is granted and 50% waste diversion is phase-in as described in sensitivity #1. This results in a cost to produce electricity using WTE of $0.11 per kWh in 2015

6.5.3 Sensitivity #3 - Reduction in landfill costs.

With this sensitivity, the possibility of reduced landfill costs is explored. Should the City of Whitehorse find that estimated costs to operate the landfill can be reduced by, say 20%, then this could reduce the tipping fee revenue for accepting waste at the WTE facility by 20% and also reduce the cost to dispose of ash by 20%. In this case, the cost to produce electricity would rise to $0.34 per kWh because of reduced tipping fee revenues.

6.5.4 Sensitivity #4 - Electricity only

This sensitivity analysis examines the impact of designing the WTE facility for highest electrical generation efficiency and with no possibility of excess heat being available for district energy in any substantial amount. Even though the electricity generation would increase to 625 kWh for each tonne of feedstock consumed, the total energy that can be sold is lower, thus cost to produce electricity would rise to $0.34 per kWh.

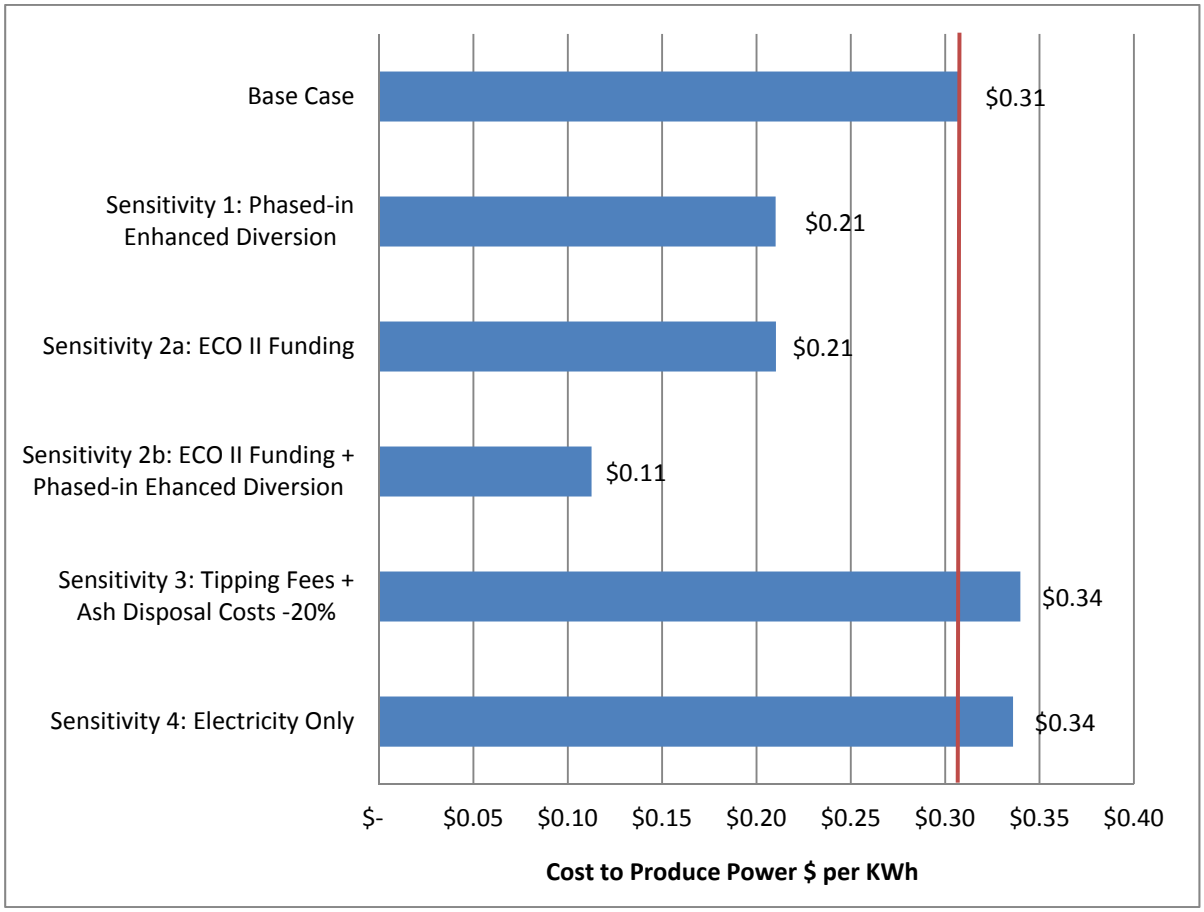
6.5.5 Sensitivity Analysis Summary

A summary of the sensitivity analyses is provided in Table 12. Figure 13 provides a graphical illustration of the electricity production cost for the base case and each sensitivity analysis.

Table 12: Sensitivity Analysis Summary

	Total Capital Cost $	Electrical Capacity MW	Annual Net Electricity Produced MWh/yr	Annual Heat Sales MWh/yr	Cost of Electricity Generated $/kWh
Base Case	34,595,000	1.6	9,975	23,700	0.31
Sensitivity #1 – Phased-in Diversion	34,595,000	1.6	9,975	23,700	0.21
Sensitivity #2a – ECOII Funding	21,700,000	1.6	9,975	23,700	0.21
Sensitivity #2b – ECOII Funding + Phased-in Diversion	21,700,000	1.6	9,975	23,700	0.11
Sensitivity #3 – Reduced Tipping Fees & Ash Disposal Costs	34,595,000	1.6	9,975	23,700	0.34
Sensitivity #4 - Electricity Only	34,595,000	2.0	14,844	0	0.34

Figure 13: Cost of Electricity Production Comparison



7. CONCLUSIONS AND RECOMMENDATIONS

7.1 Conclusions

Several meetings and discussions have been held between Yukon Energy, their consultant team, and key stakeholders including City of Whitehorse, Government of Yukon Community Services Department, Raven Recycling, P&M Recycling, and the Yukon Conservation Society. Yukon Energy organized a half-day workshop and public meeting on October 18, 2011 for the purpose of identifying issues and opportunities and outlining a plan for moving forward. A key theme identified at the workshop and public meeting was support for locally derived energy sources. There was a strong desire expressed to ensure that WTE is part of an integrated waste management system and does not compete with recycling. There was also strong support for increased diversion of materials away from landfill and future WTE, with discussion of the territory and City potentially establishing a 50% waste diversion target.

A WTE design capacity of 25,000 tonnes per year has been selected for the updated business case analysis. This capacity has been reduced from an earlier analysis in response to the desire of key stakeholders to aggressively pursue a 50% waste diversion target. The facility will be capable of burning biomass (waste wood) as well as MSW, so that any shortfall in waste feedstock can be made up with biomass. There is adequate biomass available from reliable sources for the foreseeable future. It is estimated that the WTE plant will be burning MSW without need for biomass by 2035 based on current projections.

A WTE life of 25 years is projected, after which time a decision will have to be made on whether to upgrade the facility and continue operations or to decommission the facility for lack of feedstock or because newer, more effective technologies are available to replace it.

An expression of interest was issued to vendors of WTE equipment in November 2011 and 7 vendors responded in January 2012. All of the vendors offered information on conventional combustion or close-coupled gasification. Technical, performance, operational and cost information provided by the vendors was used to increase confidence in estimates for the business case analysis.

A preliminary siting assessment, informed by the results obtained from a separate Whitehorse District Energy feasibility study, identified potential site locations in the Marwell Industrial area and along Robert Service Way south of the downtown area. While a more detailed siting assessment and consultations will be required prior to final site selection, the business case analysis assumes siting in the Marwell area because of proximity to potential heat customers, access to municipal services and compatibility with adjacent land uses.

Air emissions have been estimated for a WTE facility and compared to emissions from diesel combustion in electrical generators and furnace oil combustion in space heating applications. Assuming the electricity produced from WTE displaces diesel-generated electricity, and waste heat is utilized in a district energy system displacing furnace oil, WTE is expected to result in a net reduction of nitrogen oxide, particulate matter and carbon monoxide emissions and a net increase in sulphur dioxide emissions.

A single business case was reviewed. Cost and revenue estimate uncertainty has been reduced due to separate studies that have been conducted into landfill life cycle costs,

district energy requirements and costs, and biomass supply and costs. Greater certainty in WTE facility capital and operating costs and energy recovery efficiencies have been obtained through submissions received from technology vendors in an EOI process.

The estimated cost to produce electricity from MSW and biomass in the "base case" is $0.31 per kWh. This estimate is similar to the cost of diesel-generated electricity and does not provide a clear incentive to pursue a WTE project. This cost estimate is higher than reported in the September 2011 preliminary business case analysis ($0.16 per kWh) largely as a result of two key factors: (1) requirements for additional biomass (higher cost) feedstock during initial operations, assuming that the waste diversion target of 50% is achieved in 2015; and (2) reduced electricity generation efficiencies reported by vendors when operating in a CHP mode, while meeting the heat quality requirements specified in the separate District Energy study.

Evaluation of the business case identified several areas where there is still considerable uncertainty associated with "base case" assumptions and potential changes in circumstances could beneficially affect the viability of WTE. These areas of uncertainty were investigated using a sensitivity analysis. The following have the potential to significantly improve project economics:

- An application for federal grant funding has been made under the NRCan ECO II program. If awarded, the grant amount that could reduce the required plant capital costs to $21.7 million. Under this scenario the cost to generate electricity would be reduced to between $0.11/kWh and $0.21/kWh.
- The base case analysis assumes an almost immediate drop (by 2015) in residual waste volumes due to very aggressive recycling efforts. A sensitivity calculation examined the economics of the WTE facility if the diversion programs are phased in over 7 years instead of two years, achieving a diversion of 50% by 2020. With a phased-in diversion, there would be a need to manage more residual (non-recycled) MSW initially and until the diversion program is fully implemented. In the meantime, waste quantities continue to increase due to population growth and economic activity. With this sensitivity, the cost to produce electricity using WTE is $0.21 per kWh in 2015.

7.2 Recommendations and Next Steps

Based on the analysis in this report, it is recommended that the following two key project uncertainties be examined further to determine if the project feasibility can be improved:

1. Capital funding grants: Defer any final decisions on feasibility of WTE until the results of the NRCan ECO II application are known. The potential grant has the ability to substantially improve project economics.

2. Waste diversion implementation: The rate of waste diversion implementation is unknown and has a large bearing on project economics. Most aggressive diversion projects require extensive planning and funding, and there is a reasonable chance that achievement of a 50% diversion target would occur sometime after 2015 (potential commissioning date of a WTE facility). It is recommended that Yukon Energy initiate discussions with the City of Whitehorse and Yukon Government to understand diversion strategy implementation plans and schedule. Revise base case business case analysis taking into account waste diversion strategy implementation plans.

1.0 INTRODUCTION

Stantec Consulting Ltd. (Stantec) was retained by Yukon Energy Corporation (YEC) to conduct a desktop conceptual planning and design exercise to support their resource planning activities relative to thermal generation. The objective of this study is to determine a potential site within the Whitehorse and surrounding area for the new facility, and to complete conceptual designs for a power generation plant in size increments of 5 MW_e, 10 MW_e, and 20 MW_e output. In all cases, the plant is to use LNG or diesel as its primary fuel.

The study was conducted in a series of finite tasks, building methodically toward the solutions outlined herein. Siting was conducted in two phases. The first phase identified attributes and characteristics desired for the potential site, with the second phase applying the criteria to the candidate sites, leading to selection of a recommended site. Results for this aspect of the study are outlined in Chapter 2 – Plant Siting.

In parallel to the siting exercise, conceptual designs for the three plant capacities using LNG and diesel fuel were developed. This design process included securing budgetary quotations from major equipment vendors for reciprocating engines and fuel handling equipment. Preliminary site layouts were generated for each option, along with AACE Class 5 opinions of probable capital cost, in order to support YEC planning activities. The engineering effort also included a preliminary implementation schedule, as expected performance of the plant, and commentary on other plant attributes. Results for this effort are covered in Chapter 3 – Conceptual Design.

2.0 PLANT SITING

The plant siting selection was executed as a mainly desktop study. Stantec carried out site visits for some of the sites and had preliminary conversations with City of Whitehorse and Yukon Government officials concerning planning and zoning regulations as well as land tenure and disposition. Mandatory criteria and desired criteria were confirmed with YEC prior to the selection of sites (Appendix A). These criteria were assembled to create a 'level of importance matrix' for site criteria, which is presented in Table 1.

Table 1 Selected Criteria and Level of Importance

	Low	Medium	High
Greenfield –undisturbed land	X		
Brownfield – previously developed land			X
Proximity to existing YEC generating facilities in Whitehorse		X	
Connected to city services (water and sewer)		X	
Inside city limits	x		
Ease of constructability (laydown area, security, heavy equipment access)		X	
Proximity to residential areas (noise, smell, spill containment)			X
Proximity to YEC transmission/substation			X
Proximity to AEY distribution/substation			X
Opportunity to connect to District Energy System	X		
Accessible directly off Alaska Hwy/Klondike Hwy			X
Commissioner's Land		X	

OCP and Zoning Review City of Whitehorse

The City of Whitehorse has advised that any thermal generation plant must be located on land designated 'Public Utilities' in the Official Community Plan (OCP). It must also be within a PU (Public Utilities) zone in the Zoning Bylaw. Because all existing PU land use and zoning designations are on lands that have existing utility uses, the City has advised that both an OCP and zoning amendment will be required to permit the use of a thermal generation plant on a new site. This is not unexpected as new uses require public input and consideration. The City of Whitehorse is carrying out an OCP review in 2017 and it is our recommendation that YEC engage with the City early to identify and plan for future needs.

PLANT SITING
November 21, 2016

Whitehorse Periphery Area Development Regulations

The Yukon Government administers the zoning of lands in the Whitehorse periphery. Similar to Whitehorse's planning and zoning regulations there are no large sites that are currently identified for thermal energy generation. Public Utilities are a permitted use in most zones and are defined as '*the use of land for a sewerage, water, telecommunications, electricity or transportation systems'.*

2.1 SITE SELECTION

Stantec applied the siting criteria and level importance as determined by YEC and identified four (4) sites for consideration: two (2) within the City of Whitehorse, and two (2) just north of the City of Whitehorse boundaries. A site selection memo was prepared to support YEC's decision on a site for the study. See Appendix B for these documents. Following review of the site selection memo, YEC indicated they would like to further investigate two sites, Site 1 – Whitehorse Landfill and Site 3 – Mayo Road Substation (Takhini S164).

2.1.1 Site 1: City of Whitehorse Landfill

This is a land parcel that is owned by the City of Whitehorse and is located within the area of their existing landfill. The land is appropriately zoned and would not require a public planning process. Information on the potential site is outlined below, with the selection criteria in Table 2, and site photos in Figures 1 and 2.

Owner: City of Whitehorse

Size: A 4 hectare parcel would need to be surveyed out of the larger City of Whitehorse War Eagle Landfill

Tenure opportunity: Long term lease from the City of Whitehorse

OCP Designation: Public Utilities

Zoning: PU - Public Utilities

Table 2 Selection Criteria - Landfill

Criteria	Yes	No
Greenfield – undisturbed land		✓
Brownfield – previously developed land	✓	
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	8500 m	
Connected to city services (water and sewer)	345 m	✓

PLANT SITING
November 21, 2016

Criteria	Yes	No
Inside city limits	✓	
Ease of constructability (laydown area, security, heavy equipment access)	✓	
Proximity to residential areas (noise, smell, spill containment)	1400 m	
Proximity to YEC transmission/substation	2500 m	
Proximity to AEY distribution/substation	2500 m	
Opportunity to connect to a DES	✓	910 m
Accessible directly off Alaska Hwy	✓	500 m
Commissioner's Land		✓

Figure 1 Conceptual Map of Potential Site Location (Landfill)

Figure 2 Photo of Potential Plant Location at Landfill

2.1.2 Site 3: Mayo Road Substation - Lot Enlargement

This is a parcel of Vacant Commissioner's land adjacent to the existing Yukon Energy Corporation substation on the Mayo Road, and is within the Mayo Road Area Development Regulations. Information on the potential site is outlined below, with the selection criteria in Table 3, and site photos in Figures 3 and 4.

Owner: Commissioner of Yukon

Size: The existing substation property is not large enough to accommodate the thermal energy plant. However, carving a 4.0 hectare parcel from the Commissioner's land to add to the existing parcel seems to be a reasonable expectation. This additional land is required to maintain a buffer to separate the Agriculture zoned parcel to the north and First Nation Land Use (TKC C-36B) zoned parcel to the south.

Tenure opportunity: Purchase and consolidate with existing parcel

Local Area Planning Zoning Designation: H – Hinterland (Uses include public utilities)

Table 3 Selection Criteria – Takhini Substation

Criteria – Level of Importance in Site Selection	Yes	No
Greenfield – undisturbed land	✓	
Brownfield – previously developed land		✓
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	21,660 m	
Connected to city services (water and sewer)		✓
Inside city limits		✓
Ease of constructability (laydown area, security, heavy equipment access)	✓	
Proximity to residential areas (noise, smell, spill containment)	260 m	
Proximity to YEC transmission/substation	110 m	
Proximity to AEY distribution/substation	110 m	
Opportunity to connect to a DES		✓
Accessible directly off Alaska Hwy/Klondike Hwy	✓	200 m
Commissioner's Land	✓	

Figure 3 Conceptual Map of Potential Site Location (Takhini)

Figure 4 Photo of Potential Plant Location at Takhini

3.0 CONCEPTUAL DESIGN

Using the two selected sites, Stantec was tasked with the development of conceptual designs for the multiple options desired by YEC. The following sub-sections cover each topic of interest to YEC, and present the results.

3.1 BASIS OF DESIGN

In order to drive the conceptual design and document the assumptions made, a Basis of Design (BOD) document was generated. The BOD considers both sites, both technologies, and three (3) unit capacities, resulting in the twelve (12) options. The BOD is a standalone document containing the site layout drawings and opinions of probable capital costs. Please refer to Appendix D for the full BOD document and supplemental information.

3.2 PRIME MOVERS

A budgetary request for quotation was issued to several prominent engine suppliers in order to validate performance and establish lead times and costing for the units required for the YEC plant configurations. Packages were received, but due to the quick turnaround required, they were not complete and did not address all unit sizes requested. Because of the budgetary nature of the request, detailed price break-outs for specific equipment options of interest were not available. For example, half of the units quoted were supplied with enclosures for outdoor installation. Vendor responses have been provided for YEC to future reference.

Similar to the scope of supply, the unit pricing also varied significantly depending on options included and on the extent of construction and commissioning support embedded in the quotation. Therefore, Stantec relied on in-house data and professional judgement as well as the budgetary quotations to arrive at an appropriate Class 5 opinion of probable cost (OPC). Using the following scope of supply, engine equipment costs utilized are presented in Table 4.

Table 4 Summary of Opinion of Probable Capital Cost

Scope of Supply:	Unit / Fuel Type	Unit Cost (CAD)
Prime Mover	2.5 MW_e / NG	$2.0 M
Generator and Auxiliaries	5.0 MW_e / NG	$4.0 M
Mechanical Auxiliaries (circulating pumps / radiator)	2.5 MW_e / Diesel	$1.5 M
Electrical Control Equipment	5.0 MW_e / Diesel	$3.5 M
Heat Recovery / Rejection		
Engineering / Project Management / Drawings		
Sound Attenuation		

3.3 CONCEPTUAL SITE LAYOUTS

Building on the design characteristics outlined in the BOD in Appendix C, site layout drawings were prepared for each option. To appreciate land requirements, a tentative layout of the generating halls and switchyards, as well as fuel storage requirements have been provided. The site layout drawing is embedded within the BOD document in Appendix D and are presented in two forms for each option. The site layout (or general arrangement) is presented on its own to facilitate review and an understanding of the site itself (see sample in Figure 5) as well as on a second sheet with a satellite image in the background to appreciate its impact to the selected site (see Figure 6). Both drawings we used during the course of the study to finalize design considerations in the BOD as well as complete each options' OPC.

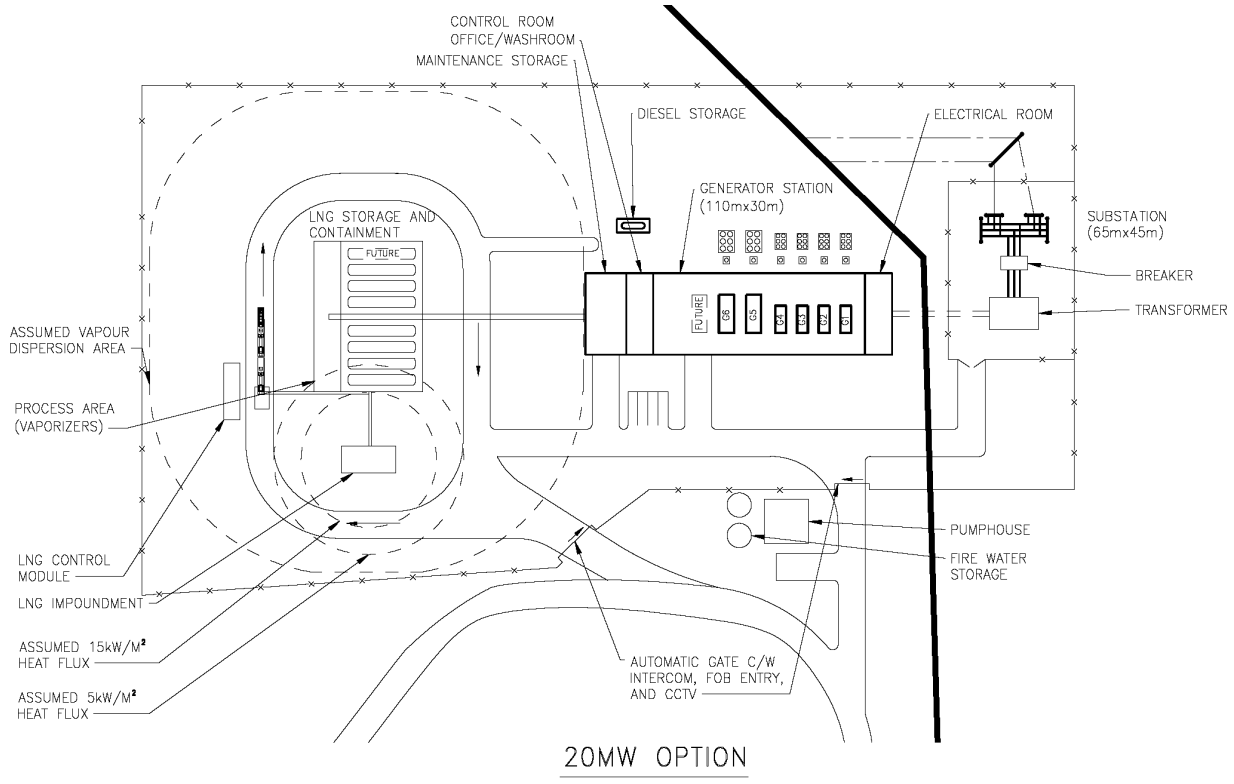

Figure 5 Site Layout Sample for Landfill, 20 MW, LNG (Plant)

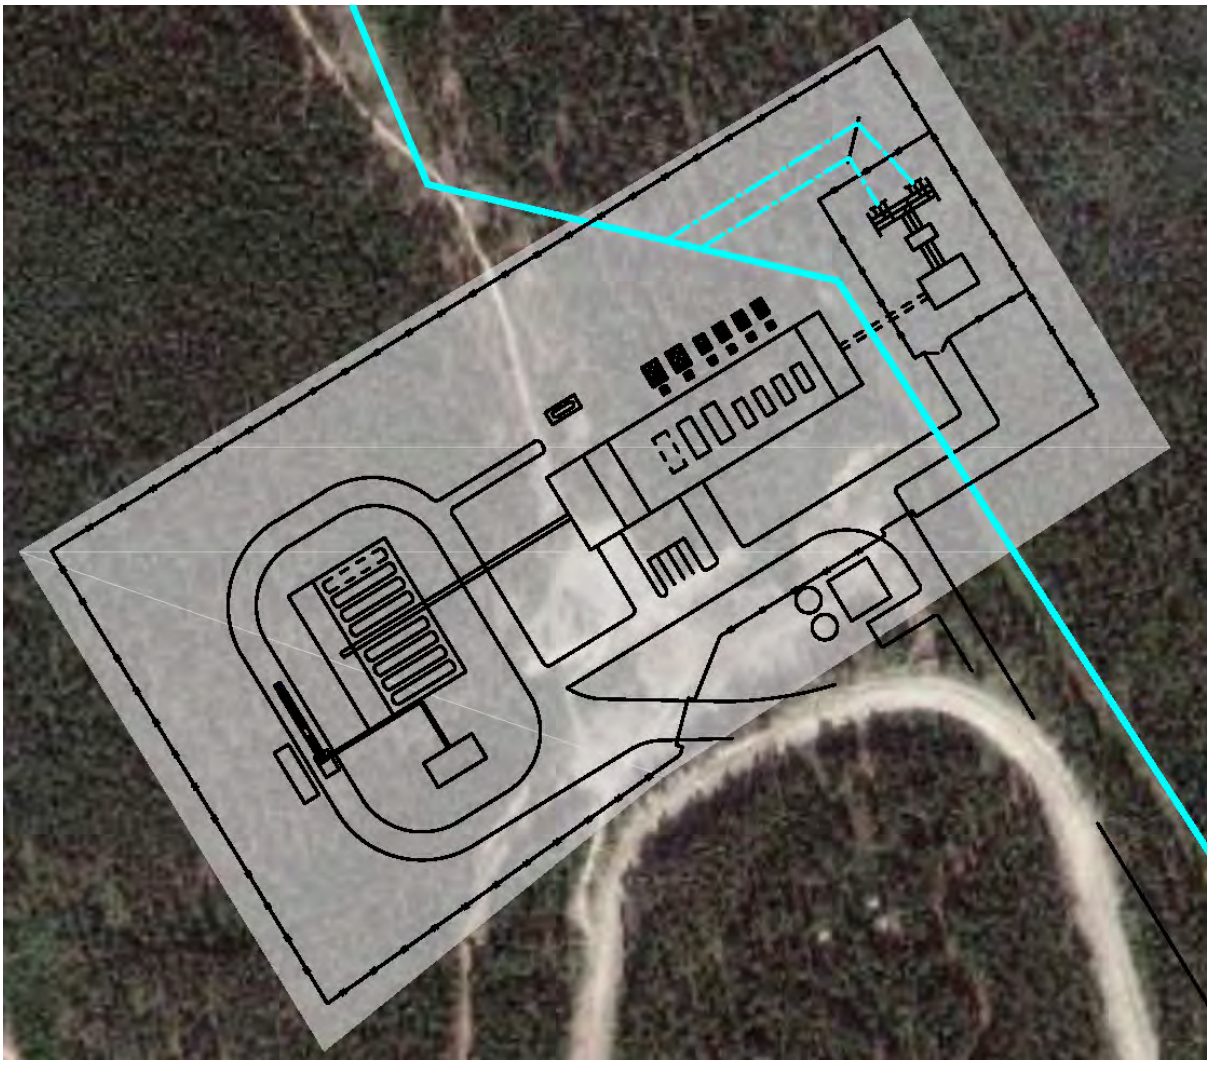

Figure 6 Site Layout Sample for Landfill, 20 MW, LNG (Satellite)

3.4 ENGINE WASTE HEAT RECOVERY, HEAT RATE AND LOAD PICK-UP CAPABILITY

3.4.1 Engine Waste Heat Recovery

A typical reciprocating engine, whether diesel or natural gas, will have a fuel-to-power conversion efficiency based on fuel lower heating value (LHV) and ISO conditions of between 41-48%. The remainder of the fuel energy is rejected as heat in the engine cooling system and the engine exhaust. Most of this 'waste heat' can be recovered and may be sold to heat buildings or provide industrial process heat. Therefore, waste heat recovery should be considered if any significant commercial/industrial heating load is expected near the plant.

Based on the potential site locations selected for the study, there are no existing potential heat customers nearby. Recovered heat can also be transported for use at more distant locations, including for winter site fire water heating. However, this 'district heating' piping is not inexpensive, and an evaluation of district heating network economics is not part of the study.

3.4.2 Heat Rate

Fuel purchases are based on Higher Heating Values (HHV). The difference between the two values is the heat of vaporization of the exhausted water vapor (which is formed during combustion). The ratio of LHV to HHV for natural gas is typically 0.90; and for light or distillate oils is typically 0.93.

Representative heat rates for both diesel and NG reciprocating engines (as provided by Wartsila) are based on Lower Heating Values (LHV) of the fuels. So, suggested heat rates for YEC's financial model are as follows:

For Natural Gas:	7634 Btu/kWh (LHV)/0.90	=	**8842 Btu/Kwh (HHV)**
For Diesel:	7876 Btu/kWh (LHV)/0.93	=	**8469 Btu/kWh (HHV)**

3.4.3 Load Pick-Up Capability

The thermal energy plant would be required to back up existing generation, so would be required to operate continuously in the event of low water (drought) conditions, or intermittently in the event of an outage of a critical unit (n-1), and during a post outage restoration.

As discussed with YEC, diesel and natural gas generators accommodate load fluctuations differently. In general, diesel engines respond better to load changes and are better able to respond to quick electrical load addition.

The performance variation can be depicted in a load application graph as shown in Figure 7 for a sample 'dual-fuel' reciprocating engine. A dual-fuel generator's performance was used to clearly illustrate load step performance based solely on the fuel used, performance will vary by model. The diesel's maximum tolerable instant load step increase is equal or better than the gas engine up to 90% of rated generator load.

Furthermore, considering time step, during operation, the ramp rate on gas would be greater than 50% per minute, but on liquid fuel the operational ramp rate could exceed 100% per minute.

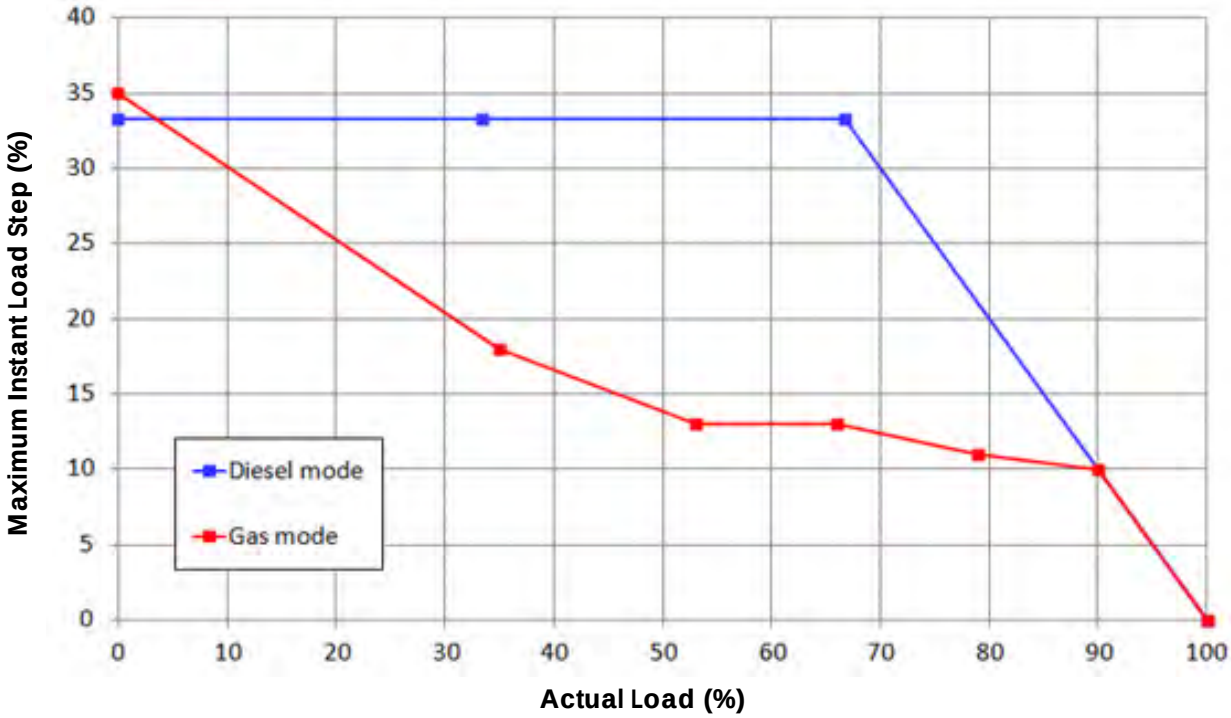

Figure 7 Sample Engine's Maximum Load Step at Varying Loads

3.5 OPINION OF PROBABLE COST

The opinions of probable capital costs (OPC) for the multiple options are outlined in Appendix C as part of the Basis of Design document. A summary of the results of the study are presented in Table 5 for easy reference.

Table 5 Summary of Opinion of Probable Capital Cost

Option #	Fuel Type Natural Gas or Diesel	Site Landfill or Takhini	Plant Capacities 5 MW_e, 10 MW_e, 20 MW_e	Opinion of Probable Capital Cost (OPC)
NG-LF-05	Natural Gas	Landfill	5 MW_e (2x 2.5 MW_e)	$48.6 M
NG-LF-10	Natural Gas	Landfill	10 MW_e (4x 2.5 MW_e)	$66.9 M
NG-LF-20	Natural Gas	Landfill	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$100.1 M
NG-TK-05	Natural Gas	Takhini	5 MW_e (2x 2.5 MW_e)	$48.5 M
NG-TK-10	Natural Gas	Takhini	10 MW_e (4x 2.5 MW_e)	$66.8 M
NG-TK-20	Natural Gas	Takhini	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$100.0 M
DL-LF-05	Diesel	Landfill	5 MW_e (2x 2.5 MW_e)	$32.0 M
DL-LF-10	Diesel	Landfill	10 MW_e (4x 2.5 MW_e)	$42.2 M
DL-LF-20	Diesel	Landfill	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$62.5 M
DL-TK-05	Diesel	Takhini	5 MW_e (2x 2.5 MW_e)	$31.7 M
DL-TK-10	Diesel	Takhini	10 MW_e (4x 2.5 MW_e)	$41.9 M
DL-TK-20	Diesel	Takhini	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$62.2 M

Note that the 10 MW_e Natural Gas options presented result in an OPC of $66.8M - $66.9M ($6.7/MW_e), which compares with a YEC recent LNG plant installed in Whitehorse which was roughly $42M, for 8.8 MW_e ($4.8M/MW_e) using two engines. The existing installation was less costly because existing utilities infrastructure was available at the site and because the generators were installed in weatherproof enclosures instead of in a building.

In detailed design of an LNG plant, attention should be paid to the requirement for a flare stack for commissioning, boil-off gas management and emergencies. There may also be additional O & M costs related to instrumentation, tank and process equipment maintenance.

3.6 OPINION OF PROBABLE O&M COST

Plant operating costs are addressed in discreet categories described below:

Labor - The labor component, excluding fuel cost, is typically the largest cost in an O&M budget. It consists of the salaries and benefits for the plant manager; licensed operators; maintenance staff (mechanical; electrical; and instrumentation techs); plant engineering; and administration staff including safety; purchasing; accounting; etc. The size of the staff can vary significantly depending on the size and complexity of the plant.

For this reciprocating engine plant because of its proximity to other YEC operations in Whitehorse, staff will not be dedicated solely to this plant. Labor costs are therefore expected to be approximately ½ of what they might otherwise be for a standalone plant.

Maintenance and Materials - The cost for maintenance and materials reflects normal daily, weekly, monthly costs for regular plant maintenance.

Environmental Testing - Most environmental operating permits require annual testing for any air, water or waste water discharges from a plant to verify compliance with the permit conditions.

Consumables, Chemicals, & Misc. - The cost of lubricants, oils, chemicals and miscellaneous consumables used during normal plant operation is included in this line item. It also covers the general administrative cost of running the power plant: phones, office supplies, computers, etc.

Major Equipment Repair Reserve Fund - The major equipment in a reciprocating engine plant needs to be overhauled and repaired on a regular basis in accordance with the vendor's recommended procedures. An engine typically has a service life of 100,000 or more operating hours. Wear components such as valves, piston rings and bearings are normally replaced about every three (3) years and a more thorough engine overhaul is carried out two (2) or three (3) times during the life of the engine. During these, the pistons, cylinder heads, piston liners, connecting rods and turbocharger rotors are replaced or overhauled. This reserve fund is primarily associated with the reciprocating engines but could also include other major pieces of equipment. A reserve fund is established so that money is available to cover the significant costs of the equipment overhaul several years in the future.

In lieu of planning and reserving for major equipment overhauls and inspections, owners sometime establish a Long-Term Service Agreement (LTSA) with the reciprocating engine vendor. The LTSA provides annual performance guarantees from the generator supplier as well as responsibility for all reciprocating engine repairs and overhauls. The term of the LTSA can vary from 10 to 20 years (or can be based on operating hours). Note this approach was not taken for this O&M estimate – cost of the packages depend on option/coverage selected and vary significantly by vendor and offering.

The following Table 6 is a summary of estimated O&M costs for an Owner operated reciprocating engine power plant:

Table 6 Opinion of Probable Reciprocating Engine O&M Costs (Excluding Fuel)

Description	5 MW_e	10 MW_e	20 MW_e
Labor	$300,000	$400,000	$500,000
Maintenance & Materials	$80,000	$100,000	$125,000
Major Equipment Repair Fund	$200,000	$300,000	$400,000
Environmental Testing	$40,000	$70,000	$90,000
Consumables, Chemicals, Misc.	$55,000	$65,000	$75,000
Total O&M Estimated Cost*	**$675,000**	**$935,000**	**$1,190,000**

*The estimated cost for O&M reflects the estimated average annual cost. It does not include cost normally incurred by the owner. These costs include insurance; property taxes or asset management fees. It also does not include fees if the O&M is subcontracted out.

3.7 IMPLEMENTATION SCHEDULE

Development of either option on a greenfield site depending on several factors outside YEC's control. Initial planning activities and preliminary engineering need to be further developed to finalize site selection (see implementation schedule in Table 7). With a short-list of sites selected, land negotiations, as well as commencement of the YESAA process will drive the project timeline. Permitting for diesel fuel is expected to be less involved than a new LNG facility, but with the recent LNG installation at the Whitehorse Generating Station, precedence exists for LNG storage and permitting in the Territory. Detailed engineering will need to commence following approval of preliminary engineering activities and YEC go-decision for the project. Engineer will support YESAA activities as well as prepare technical drawings and specifications to support project tendering and/procurement of major equipment. Reciprocating engine lead times require approximately 8 -12 months from receipt of order to delivery to site. Construction and commissioning activities will vary slightly depending on the size of the plant and site accessibility.

Table 7 Implementation Schedule

Task Description	YR1	YR2	YR3	YR4
Planning and Preliminary Engineering				
Environmental Permitting (YESAA) and Site Selection				
Detailed Engineering and Procurement				
Construction				
Start-up & Commissioning				

3.8 YEC PERFORMANCE ATTRIBUTES

A summary table of the performance attributes of the options is presented in Table 8 below. Data provided indicates the high availability and generation capabilities of the technology. YEC is to reconcile final plant capacities to the expected load forecast, in order to determine a true capacity factor for the plant and expected annual energy generation.

The Levelized Cost of Capital (LCOC) for each option has been shown. Financial analysis sheets for each option are included in Appendix C.

Table 8 Performance Attributes by Option

Option #	Installed Capacity [MW_e]	Availability Factor [%]	Maximum Annual Energy [GWh]	Project Life [years]	Opinion of Probable Capital Cost (OPC)	Levelized Cost of Capital (LCOC)
NG-LF-05	5	>95	41.6	20 yr / 60,000 hrs	$48.6 M	$679/kW
NG-LF-10	10	>95	83.2	20 yr / 60,000 hrs	$66.9 M	$467/kW
NG-LF-20	20	>95	166.4	20 yr / 60,000 hrs	$100.1 M	$350/kW
NG-TK-05	5	>95	41.6	20 yr / 60,000 hrs	$48.5 M	$678/kW
NG-TK-10	10	>95	83.2	20 yr / 60,000 hrs	$66.8 M	$466/kW
NG-TK-20	20	>95	166.4	20 yr / 60,000 hrs	$100.0 M	$349/kW
DL-LF-05	5	>95	41,6	20 yr / 60,000 hrs	$32.0 M	$447/kW
DL-LF-10	10	>95	83.2	20 yr / 60,000 hrs	$42.2 M	$295/kW
DL-LF-20	20	>95	166.4	20 yr / 60,000 hrs	$62.5 M	$218/kW
DL-TK-05	5	>95	41,6	20 yr / 60,000 hrs	$31.7 M	$443/kW
DL-TK-10	10	>95	83.2	20 yr / 60,000 hrs	$41.9 M	$293/kW
DL-TK-20	20	>95	166.4	20 yr / 60,000 hrs	$62.2 M	$217/kW

4.0 RISK IDENTIFICATION

As this study was only a desktop effort resulting in a concept design, a series of project risks exist that must be mitigated should any option for a thermal generating station be considered in the future. These initial risks are presented in Table 9 for YEC's consideration.

Table 9 Project Development Risks

Site 1: City of Whitehorse Landfill

No.	Risk Description	Potential Impact
1	Land Tenure	Yukon Energy Corporation currently has no tenure. YEC will need to enter into a long term lease with the City of Whitehorse (City). The City's land disposition process is public and invites comments. Public processes that solicit input always have some risk of local opposition to the project.
2	Access	Yukon Government Highways and Public Works will need to approve access off Alaska Highway. Entrance to the landfill is a fairly steep incline but should not pose a significant issue. The City identified a site behind the landfill as an alternative to the one used in the study for the plant. Increase in truck traffic can be mitigated by securing the site closer to the highway and the existing transmission line.
3	Mineral Claims	There are quartz mining claims on both sites. The subsurface rights are encumbered but should not affect the ability to develop on the surface. Engagement with the claim holder is recommended.

Site 3: Mayo Road Substation - Lot Enlargement

No.	Risk Description	Potential Impact
4	Land Tenure	The site is vacant Commissioners Land. Yukon Energy Corporation currently has no tenure. YEC will need to enter into a long term lease or purchase with Yukon Government. The Yukon Government's land disposition process will trigger a YESAB application which is public and invites

		comments. Public processes that solicit input always have some risk.
5	Adjacent Land Uses	This parcel of land would be situated between a Ta'an Kwäch'än Council (TKC) owned vacant parcel and privately owned agricultural piece of land. TKC future development plans may not be compatible with a thermal generating facility.
6	Land Use and Zoning Designation	The parcel is designated in the Mayo Road Development Area Regulations as Hinterland (H) which allows public utility uses. The existing substation is designated Public Use and Institutional (PI). An argument may be made that a zoning amendment is required. Interpretation of the regulation is a risk.

Fuel Storage and Usage

No.	Risk Description	Potential Impact
7	Diesel fuel option	YEC will need to consider approach to diesel storage, number of tanks, containment, and volume. Study assumed double walled tanks to reduce containment requirements and real estate.
8	LNG fuel option	YEC has recent firsthand experience with the design and permitting constraints associated with LNG. As the site is a greenfield, YEC will have the ability to better arrange tankage to avoid the need for expensive vapour barriers and restriction on road layouts. This should reduce costs and operational issues experienced with the existing plant but will need to be kept at the forefront of design to minimize these impacts while meeting code requirements.
9	Dual fuel	Dual fuel units were not used in the study but provide YEC with an avenue to avoid the issues associated with NG engines poorer load pick-up performance. Fuel blending is also an option. Although operations flexibility would be gained, YEC would have to review fuel storage requirements to have both fuels on site while maintaining code separation requirements.

RISK IDENTIFICATION
November 21, 2016

10	Fuel Procurement	While outside the scope of this study, fuel pricing and security, price hedging, and supply contracts will all impact the project business case and require YEC due diligence. Fuel delivery issues due to weather are also a factor.

Prime Movers

No.	Risk Description	Potential Impact
11	Technology	Reciprocating engines running on either NG or diesel are a mature technology used throughout the continent. Technology risk is minimal. Similarly, auxiliary equipment and infrastructure to support the engines also carry minimal technology risk (transformer, switchgear, controls).
12	Procurement	Procurement processes, cost and schedule control, and ensuring options selected meet the project requirements are main risks with the prime movers. These risks are mitigated with proper planning and engineering to ensure the units selected are fit for purpose and represent the best value for YEC. The project delivery method needs to be determined. Responsibility for project implementation risk can be more easily assigned to 3rd parties under some delivery methods. Whether YEC intends to procure the engine and free-issue to a contractor, or equipment procurement and installation are in a common tender (DB/EPC), remains to be decided, each with their own pros/cons.
13	Enclosures	The study assumes that any option would be executed with a new generating hall to house the units. Alternatively, the project can use stand-alone engine enclosures similar to the existing LNG plant. Future study is needed to properly compare the two options, with input from YEC operations.

General Site

2016-007 – THERMAL ENERGY PLANT DEVELOPMENT STUDY – REV. 1

RISK IDENTIFICATION
November 21, 2016

No.	Risk Description	Potential Impact
14	Safety and Security	Fire protection, fuel system alarms and procedures, site fencing and access, telecom and security, etc. are all critical areas require future study and refinement. Risk in these areas is mitigated with proper planning, assessment, and engineering.

Siting Criteria Memo

Stantec

Memo

To:	Marc-Andre Lavigne Yukon Energy Corporation	From:	Lesley Cabott RPP Stantec
File:	Thermal Energy Plant Development Study: 133547248_21_8	Date:	April 21, 2016

Reference: Thermal Generation Siting Criteria

This memo has been prepared to support the site selection of Yukon Energy Corporation's (YEC) resource planning study of a future thermal generation plant in and/or around Whitehorse. There are some criteria that are mandatory and other criteria that will be preferred by YEC. This memo identifies those items that are mandatory as well as the criteria that YEC may wish to consider. It is the intent of this memo to confirm mandatory criteria and receive direction as to the importance of the other criteria. The feedback we receive will inform the site selection for conceptual design purposes.

OCP AND ZONING REVIEW CITY OF WHITEHORSE

The City of Whitehorse has advised that a thermal generation plant will need to be located on land designated Public Utilities (PU) in the Official Community Plan (OCP) and within a PU zone in the Zoning Bylaw. The existing PU land use and zoning designations are on lands that have existing utility infrastructure – no undeveloped PU land existing today. The City has advised that both an OCP and zoning amendment will be required to permit the use of a thermal generation plant. This is not unexpected as new uses require public input and consideration. The City is carrying out an OCP review in 2017 and it is our recommendation YEC engage with the City early to identify and plan for future needs if a decision is made to pursue a new thermal plant.

WHITEHORSE PERIPHERY AREA DEVELOPMENT REGULATIONS

The Yukon Government administers the zoning of lands in the Whitehorse periphery. Similar to the City planning and zoning regulations, there are no large sites that are currently identified for a thermal generation plant. A rezoning process would also need to be undertaken in the periphery.

SITE CRITERIA THAT WILL BE CONSISTENT FOR ALL SITES (MANDATORY):

As discussed and excluded from our scope of work, any environmental (heritage, archaeology, biophysical, wildlife, water sources/quality, etc.) and socio-economic impact are not included. Our assessment will touch on topics of noise, air quality, and wildlife protected areas as they relate to engine performance and are publically available data but an in-depth site assessment is not included.

DESIRED CRITERIA

In addition to mandatory criteria, several site selection preferences (design criteria) may exist at YEC based on past/recent generation development experience, operational requirements, and current utility needs. Please review the mandatory criteria and confirm and advise as to the importance associated with the desired criteria.

2016-007 – THERMAL ENERGY PLANT DEVELOPMENT STUDY – REV. 1

November 21, 2016

APPENDIX B

Site Identification and Evaluation Memo

Stantec

Memo

To:	Marc-Andre Lavigne Yukon Energy Corporation	From:	Lesley Cabott, RPP Stantec
File:	Thermal Energy Plant Development Study: 13354728	Date:	May 4, 2016

Reference: Thermal Generation – Site Identification and Evaluation

This memo has been prepared to support the site selection of a future thermal generation plant in and/or around Whitehorse for Yukon Energy Corporation's (YEC) resource planning study, and builds upon the background work and siting criteria outline in Stantec's memo of April 21, 2016. Stantec has reviewed the City of Whitehorse Planning and Zoning bylaws and have met with the Managers of Planning and Engineering to discuss potential sites within the City. We have also reviewed the Whitehorse Periphery Planning and Zoning Regulations including: Mayo Road, Ibex, Hotsprings Road, Golden Horn and Mount Lorne. We met with a representative of the Lands Department at Yukon Government and carried out site visits to sites 1, 3, and 4.

The four sites are discussed below. The feedback we receive from YEC will help us identify the "preferred site" that will be used for conceptual design purposes.

The criteria and their associated level of importance were determined as follows in consultation with YEC:

Criteria – level of importance in site selection	Low	Medium	High
Greenfield –undisturbed land	X		
Brownfield – previously developed land			X
Proximity to existing YEC generating facilities in Whitehorse		X	
Connected to city services (water and sewer)		X	
Inside City limits		X	
Ease of constructability (laydown area, security, heavy equipment access)		X	
Proximity to residential areas (noise, smell, spill containment)			X
Proximity to YEC transmission/substation			X
Proximity to AEY distribution/substation			X
Opportunity to connect to District Energy System	X		
Accessible directly off Alaska Hwy/Klondike Hwy			X
Commissioner's Land		X	

Stantec

Reference: Thermal Generation – Site Identification and Evaluation

SITE 1: CITY OF WHITEHORSE LANDFILL

The City of Whitehorse identified the opportunity to lease a portion of land that is within the area of their existing landfill. The land is appropriately zoned and would not require a public planning process.

Owner: City of Whitehorse

Size: A 4 hectare parcel would need to be surveyed out of the larger City of Whitehorse War Eagle Landfill

Tenure opportunity: Long term lease from the City of Whitehorse

OCP Designation: Public Utilities

Zoning: PU - Public Utilities

Criteria	Yes	No
Greenfield – undisturbed land		✓
Brownfield – previously developed land	✓	
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	8500 m	
Connected to city services (water and sewer)	345 m	✓
Inside City limits	✓	
Ease of constructability (laydown area, security, heavy equipment access, rail siding)	✓	
Proximity to residential areas (noise, smell, spill containment)	1400 m	
Proximity to YEC transmission/substation	7300 m	
Proximity to AEY distribution/substation	1890 m	
Opportunity to connect to a DES	910 m	
Accessible directly off Alaska Hwy/Klondike Hwy	✓	2200 m (Alaska Hwy)
Commissioner's Land		✓

This site offers opportunities for synergies with waste to energy with waste from Whitehorse landfill.

Stantec

May 4, 2016
Marc-Andre Lavigne

Reference: Thermal Generation – Site Identification and Evaluation

Figure 1: Landfill Potential Site

Figure 2: Landfill Access Road

Stantec

Reference: Thermal Generation – Site Identification and Evaluation

SITE 2: CITY OF WHITEHORSE LIVINGSTONE TRAIL LAGOONS

The City of Whitehorse identified the opportunity to lease a portion of land that is within the area of the Livingstone Trail Environmental Control Facility (sewage lagoon). The land is appropriately zoned and would not require a public planning process.

Owner: City of Whitehorse

Size: A 4 hectare parcel would need to be surveyed out of the lagoon lands

Tenure opportunity: Long term lease from the City of Whitehorse

OCP Designation: Public Utilities

Zoning: PU - Public Utilities

Criteria – level of importance in site selection	Yes	No
Greenfield – undisturbed land	✓	
Brownfield – previously developed land		✓
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	7,660 m	
Connected to city services (water and sewer)		✓
Inside City limits	✓	
Ease of constructability (laydown area, security, heavy equipment access, rail siding)	✓	
Proximity to residential areas (noise, smell, spill containment)	1,630 m	
Proximity to YEC transmission/substation	1,120 m	
Proximity to AEY distribution/substation	3,800 m	
Opportunity to connect to a DES	12,250 m	
Accessible directly off Alaska Hwy/Klondike Hwy		✓
Commissioner's Land		✓

This site currently has challenges with access. The City is currently doing a planning study that is looking at the timing of development on the east side of the Yukon River and construction of a second crossing. Currently access to the site would be along the Long Lake Road and the Livingstone Trail Road.

Stantec

Reference: Thermal Generation – Site Identification and Evaluation

SITE 3: MAYO ROAD SUBSTATION - LOT ENLARGEMENT

This is a parcel of Vacant Commissioner's land adjacent to the existing Yukon Energy Corporation substation on the Mayo Road within the Mayo Road Area Development Regulations.

Owner: Commissioner of Yukon

Size: There is sufficient area to survey a 4.0 hectare parcel of land from the Commissioner's land to add to the existing parcel and to maintain a buffer to separate the Agriculture zoned parcel to the north and First Nation Land Use (KDFN C- 135B) zoned parcel to the south.

Tenure opportunity: Purchase and consolidate with existing parcel

Local Area Planning Zoning Designation: H – Hinterland (Uses include public utilities)

Criteria – level of importance in site selection	Yes	No
Greenfield – undisturbed land	✓	
Brownfield – previously developed land		✓
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	21,660 m	
Connected to city services (water and sewer)		✓
Inside City limits		✓
Ease of constructability (laydown area, security, heavy equipment access)	✓	
Proximity to residential areas (noise, smell, spill containment)	260 m	
Proximity to YEC transmission/substation	110 m	
Proximity to AEY distribution/substation	15,090 m	
Opportunity to connect to a DES	N/A	
Accessible directly off Alaska Hwy/Klondike Hwy	✓	200 m off
Commissioner's Land	✓	

The Yukon Government Land application process is a public process and includes First Nation and public consultation which can take up to six months. Spot land applications are not accepted for this area; however this can be considered a lot enlargement. This land will not require rezoning. Definition from Area Development Regulations: *'public utility' means the use of land for sewerage, water, telecommunications, electricity, or transportation systems.*

Figure 3: Takhini Substation Potential Site

Figure 4: Takhini Substation Access Road

Stantec

Reference: Thermal Generation – Site Identification and Evaluation

SITE 4: COPPER MINE SITE – CITY OF WHITEHORSE

This is a parcel of Commissioner's land currently within the City of Whitehorse, between the Mt. Sima Road and the Copper Haul Road.

Owner: Commissioner of Yukon

Size: There is sufficient area to survey a 4.0 hectare parcel of land from the Commissioner's land

Tenure opportunity: Purchase/lease

OCP Designation: IH – Industrial Heavy

Zoning: FP – Future Planning

Criteria – level of importance in site selection	Yes	No
Greenfield – undisturbed land	✓	
Brownfield – previously developed land		✓
Proximity to existing YEC generating facility on Robert Service Way, Whitehorse	6,400 m	
Connected to city services (water and sewer)		✓
Inside City limits		✓
Ease of constructability (laydown area, security, heavy equipment access)	✓	
Proximity to residential areas (noise, smell, spill containment)	1,640 m	
Proximity to YEC transmission/substation	6,400 m	
Proximity to AEY distribution/substation	2,790 m	
Opportunity to connect to a DES	N/A	
Accessible directly off Alaska Hwy/Klondike Hwy	✓	2,720 m (Alaska Hwy)
Commissioner's Land	✓	

There are quartz mining claims on the parcel which is consistent with many areas of Whitehorse. The Yukon Government Lands Department advised the subsurface claims should not affect the development of the generating facility; some consultation with claim holders may be required. The Manager of Planning with the City has indicated that an OCP amendment to PU may not be required.

SUMMARY OF RESULTS

The results from the preliminary site assessments are summarized in the table below:

Criteria	Priority	Site 1: Landfill	Site 2: Lagoon	Site 3: Takhini Substation	Site 4: Whitehorse Copper
Greenfield	L	No	No	Yes	Yes
Brownfield	H	Yes	Yes	No	No
Proximity to YEC Generation Plant	M	8.5 km	7.7 km	> 2 km	6.4 km
Serviced by City	M	No	No	No	No
Inside City limits	M	Yes	Yes	No	Yes
Constructability (laydown area, security, access)	M	Excellent	Good	Good	Excellent
Proximity to residence	H	None	> 1.5 km	~ 300 m	> 1.5 km
Proximity to YEC transmission line	H	7.3 km	1.1 km	110 m	6.4 km
Proximity to AEY distribution line	H	1.9 km	3.8 km	15 km	2.8 km
Opportunities for DES	L	1 km	None	None	None
Access to Alaska/Klondike Hwy	H	Good	Poor	Excellent	Excellent
Commissioner's Land	M	No	No	Yes	Yes
Mining Claims	L	Yes	No	No	Yes
Correct Zoning	M	Yes	Yes	Yes	No

Please review the potential sites and let us know YEC's preferred option. We are available to discuss and look forward to receiving your direction.

BASIS OF DESIGN (BOD)
THERMAL ENERGY PLANT STUDY

1.0 Introduction

Design scope for this study effort was broken down by major discipline to support design decisions and discussions to-date. The following document is considered the Basis of Design (BOD) for the study and provides the overall conceptual considerations given to the multiple options and sites.

In general, the plant was to be a stand-alone, greenfield installation adjacent to brownfield sites, but not to be supported by any current YEC infrastructure (i.e., near existing Whitehorse Generating Station). It was desired to site the plant within the Whitehorse area or within a 25 km boundary outside city limits, as well as near suitable infrastructure for interconnection (i.e., existing substations/T&D lines).

The study considered plant options and sites as outlined in Table 1.0 to provide YEC with multiple scenarios for consideration during its resource planning exercise. This resulted in twelve (12) independent options for consideration and AACE Class 5 opinions of probable capital costs.

Table 1.0 – Summary Options and Sites

Fuel Type	Site	Plant Capacities		
Natural Gas or Diesel	**Whitehorse Landfill or Takhini Substation (S164)**	**5 MW_e** (2x 2.5 MW_e)	**10 MW_e** (4x 2.5 MW_e)	**20 MW_e** (4x 2.5 MW_e, 2x 5 MW_e)

Stantec

BASIS OF DESIGN (BOD)
THERMAL ENERGY PLANT STUDY

2.0 Detailed Project Scope Definition

2.1 CIVIL / STRUCTURAL

The civil/structural scope includes:

- Greenfield site (YEC – April 12, 2016 (Kick-off)):
  - Plant will be new, not located near to the existing Whitehorse plant (brownfield sites adjacent to assumed plant locations).
  - Concept layouts completed to allow for up to 20 MW_e plant, allowing for smaller plants to be easily incorporated.
  - Concept design assumed reciprocating engines will be installed inside a generating hall (YEC – April 20, 2016). It is recognized that containerized/enclosures are a possibility to be evaluated in future engineering design efforts (similar to existing YEC LNG plant).
- Site Work including:
  - Clearing and grubbing overall site.
  - Site grading including road and parking preparation.
  - Site drainage and culverts.
  - Base, sub-base, and asphalt for site roads and parking areas, including improvements to access roads from main highway (i.e., upgrading Takhini gated entrance and new road to plant, widening and strengthening landfill access road/hill).
  - Foundation excavation and preparation for structures and slabs.
  - New septic system for plant washrooms and facilities.
  - Site fencing and security - motorized vehicle gates (two gates), separate substation fenced area. Fencing assumes YEC standard 8 ft. chain linked fence with angular barb wire. As per plant layouts, fencing extends beyond assumed vapour dispersion area of the LNG plant to avoid use of vapour fencing. Future study is required to confirm extent of vapour cloud. The current 60 m allowance around impoundment areas is based on a worst case scenario from existing LNG plant modeling. Fencing for diesel options provides at least a 15 m buffer from plant equipment.
- Concrete Work:
  - LNG fuel storage area to meet CSA Z276-15:
    - LNG tank, process area, and truck unloading containment pads.
    - Open trenching to impoundment area.
    - Impoundment sized in excess of 110% of largest tank + 10% (or 50 cm) for snow/rain collection.
    - LNG tankage located outside 15 kW/m^2 assumed heat flux zone. Radii used for heat flux zones based on worse case scenarios from existing LNG plant modelling. New plant will vary based on site specific characteristics.

- Thickened slabs for generator foundations.
- Equipment foundations for: stack and silencers, radiators, transformers, breaker, and steel structures.
- LNG cases include aboveground pipe bridge from LNG process area to generating station. Diesel options use underground double walled pipes connecting the tank farm pump house to the generating station.

- Pre-engineered building unit costs are based on previous work in Whitehorse area and territory. Unit price includes: Building steel, insulated walls, insulated roof, doors, slab and concrete footings. Equipment within the building or building services are not included in the unit cost.
- Allowance for building Internals including Interior rooms & sanitary (washroom).
- Fire protection loop is based on using water storage for site wide protection. Options exist for wells instead of storage, and for a potential hybrid system, which can be investigated in future studies. Current water storage for fire protection system incorporates:
  - Fire water heated storage (2x 30ft dia x 30ft tanks, insulated, 250,000 gal).
  - Fire water pump house (electric and diesel driven fire pumps, building).
  - Fire Loop (allowance) & Recirculation Pumps.
  - Fire Hydrants.

Civil/structural assessment will be based on: area/unit factors, recent Whitehorse projects, and parametric techniques.

2.2 MECHANICAL / MAJOR EQUIPMENT

The mechanical/process as well as major equipment scope includes:

- The generating stations are designed for the dedicated use of one fuel supply. Plants were either LNG/NG or diesel. Blending or dual fuel units were not to be considered, though some vendor's engines are dual fuel capable.
  Desired plant capacities:
  - 5 MW_e nominal:
    - 2 small engines (~2.5 MW_e).
  - 10 MW_e nominal:
    - 4 small engines (~2.5 MW_e).
  - 20 MW_e nominal:
    - 4 small engines (~2.5 MW_e).
    - 2 larger engines (~5 MW_e).
  - Standard vendor submissions included the following as a minimum. Most submissions received did not provide sufficient breakdown in cost, and typically included enclosures, stack heat recovery, site services, testing, and commissioning:
    - Prime Mover.
    - Generator and Auxiliaries.
    - Mechanical Auxiliaries (circulating pumps / radiator).
    - Electrical and Control Equipment.
    - Heat Recovery / Rejection.

    - Engineering / Project Management / Drawings.
    - Sound Attenuation.
- Fuel Delivery and Storage:
    - YEC requested Stantec to allow for 7-days of fuel storage on-site using horizontal tanks.
    - For LNG cases, the following equipment was scaled from YEC's previous LNG project since LNG vendors did not respond to RFQs:
        - LNG storage tanks: 1x 150 m^3 (usable) vacuum jacketed, horizontal storage tank (number of tanks depending on plant capacity).
        - Vaporizers.
        - LNG storage infrastructure, truck unloading station, piping, and infrastructure.
        - Transportation.
    - For diesel cases, pricing for common tank sizes were used and incorporates double wall containment to mitigate the need for dykes or berms. Future study into the desired approach for a diesel tank farm should consider custom sized double wall tanks, single wall tanks with secondary containment, larger single tank instead of horizontal tankage. OPC includes:
        - Diesel storage tanks: Double Walled (100% secondary containment, standard 75,000 L design).
        - Diesel truck unloading and pump house, underground containment tank, sump and lines.
        - Transportation.
- General mechanical and process equipment were based on fuel type and plant capacity (number of units). Allowances were made for larger system to support the overall pricing. Internal fire protection would tie into new fire water loop and include building sprinklers and local protection equipment. Mechanical scope of work includes:
    - Fuel System Piping (from fuel storage, building internal).
    - Glycol Heating System (including unit heaters, electric & diesel boiler).
    - Generating Station HVAC (electric unit heaters, building and combustion ventilation).
    - Allowance for Building Services / Plumbing.
    - Allowance for Lube / Waste Oil System.
    - Continuous Emissions Monitoring System.
    - Instrument and Plant Compressed Air Systems.
    - Generating Station Sprinkler System, extinguisher, fire protection equipment.

Mechanical/process assessment will be based on: area/unit factors, recent Whitehorse projects, and parametric techniques.

Stantec

BASIS OF DESIGN (BOD)
THERMAL ENERGY PLANT STUDY

2.3 ELECTRICAL

The EI&C scope of work includes:

- Pole line brought to the local substation or nearest distribution line at 34.5 kV (Site 1 – S170 McIntyre, Site 3 – S164 Takhini) (YEC – May 16, 2016). Two circuits 10 MW_e circuits assumed for each 20 MW_e site at 10 MW_e each, otherwise one circuit assumed.
- Major equipment:
  - New engines to generate at 4,160V (YEC – April 21, 16).
  - Generator Step up Transformer - 34.5 kV high side, generator bus voltage on low side, +/- 5% off load taps.
  - 34.5 kV incoming breaker.
  - 34.5 kV vertical break, vertical mounted disconnect switch.
  - Medium voltage cable between generator step up transformer and generator switchgear.
  - Bus work / Dead end structure at substation at thermal plant.
  - VTs/surge arrestor and station service transformers.
- Generator Substation:
  - Ground Grid.
  - Substation Fence.
  - Cable and conduit.
  - Cable trench.
- Inside Generator Building Electrical Room:
  - Transformer protection and control panel.
  - 34.5 kV line protection panel.
  - Metering panel.
  - 125 VDC Station service battery.
- The plant control system will be a distributed control system (DCS), with local PLC control for various systems as appropriate.
- Allowance for station service transformer and associated equipment (MCC, etc.).
- Allowance for site wide grounding grid.
- Allowances for plant communication and security, including:
  - Roadway / Site Lighting.
  - CCTV Security and Integration to System Control Centre.
  - Fire and Gas Alarm Systems.
  - Communications (fibre, CAT5, telephone).
- Allowance for Uninterruptible Power Supply (UPS) system and black start genset.
- 34.5 kV Interconnection - poles, conductor, hardware, deadends.
- Allowances will be made for building services, lighting, fire alarms, receptacles, etc.

EI&C assessment will be based on: area/unit factors, recent Whitehorse projects, and parametric techniques.

2.4 MISCELLANEOUS CONSTRUCTION DIRECTS

Most construction directs will be accounted for in a blended labor rate. This would include small tools and consumables. Allowances for required equipment rentals used as part of a normal installation are included in the blended labor rate. Supervision, crew trailer, meals & accommodations for out of territory staff, and personal PPE are also included.

Freight is included in the material and equipment pricing, unless otherwise noted.

Stantec

BASIS OF DESIGN (BOD)
THERMAL ENERGY PLANT STUDY

3.0 Detailed Basis of Estimate

The following sub-sections outline assumptions related to direct and indirect costs for the project as it is understood today. These will be carried forward into the Opinion of Capital Cost (OPC) and presented in the draft study report.

3.1 ENGINEERING

A preliminary engineering allowance of $400,000 was carried which would include generating a feasibility study design and Class 3 OPC for project appropriations (option to conduct study in two phases also exists, with pre-feasibility study for a Class 4 OPC). A detailed engineering allowance is 8% of capital will be included to cover detailed engineering, schedule and cost control.

3.2 PROCUREMENT

Major equipment is assumed to be purchased by YEC and supplied to the installation contractor on site. In this particular study, that would include the reciprocating engines, auxiliaries, switchgear, the step-up transformer, transfer switches, and other vendor supplied equipment. This approach is advantageous in that:

- It ensures adherence to the utility standards for equipment where many options and additions are commonly available.
- It does not delegate away the responsibility of expediting these items to site. By maintaining responsibility, the Owner can exercise greater control of delivery on these critical items.
- It avoids the standard contractor markup of 10-15% (or more) being added to large value line items.

All other items, including piping, cable, cable tray, and all other commodity items required for the installation shall be supplied by the contractor(s) as part of their lump sum installation pricing. This eliminates the need for utility engineers, managers, or consultants to be responsible or concerned with inventory levels of items that are extremely hard to track on a busy construction site.

3.3 PRODUCTIVITY FACTORS

Labour factor adjustments were be applied to the OPC based on the following:

- Work in Whitehorse as it applies to accessing supplies and skilled labour.
- Estimated inventory levels at local supply houses.
- Working outdoors or in non-serviced building in Whitehorse, Yukon weather.

- Productivity was applied as a factor to labour or embedded in allowance made depending on the line item.

3.4 CONSTRUCTION

This OPC is based on the following sources of data for labor and materials:

- In-house databases built from historical or manufacturer's listed prices.
- Direct contact with vendors for indicative pricing of reciprocating engine and auxiliaries (including fuel tankage).
- NECA (National Electrical Contractors Association) Manual of Labor Units for specific items covered by that publication.
- Historical labor costs for other items not specifically listed or requiring special consideration.

3.5 INDIRECT CONSTRUCTION COSTS

At this stage of study and classification of the OPC, indirect costs are assigned as a percentage of expected direct costs based on previous experience, industry norms, and Stantec professional judgement.

3.5.1 Construction Staff & Consultants

An allowance of 2.5% of capital will be carried for an on-site construction manager. An allowance of 1% of capital will be carried for site engineering services to support construction.

3.5.2 Commissioning Costs

Commissioning costs will be carried as 1.5% of capital. This includes allowances to bring vendor representatives to site.

3.5.3 Escalation Costs

An escalation allowance of 3.5% will be allowed based on lead time required before construction begins.

3.5.4 Capital Spares

A capital spares allowance of 2% of the major equipment cost will be included.

3.5.5 Indirects Specifically Not Included

The indirect costs associated with the following are typically not considered and are assumed to be supplied by Owner. At YEC's request, an 18% factor of direct costs will be assigned to these services based on recent utility experience:

- Security.

Stantec

BASIS OF DESIGN (BOD)
THERMAL ENERGY PLANT STUDY

- Lock-out tag-out (LOTO) coordination.
- Waste removal.
- Snow removal.
- Warehousing and utilities including temporary power supply.
- Temporary construction lighting.
- Taxes.
- Interest charges during construction.
- Land acquisition and zoning.
- Environmental studies, YESAB assessment and all permitting.
- Owner's administration costs, including:
  - Legal fees.
  - Insurance.
  - Salaries & expenses of Owner's project staff.
  - Allowance for operators hours & fuel costs during training, commissioning, and start up.
  - Special costs to dispose from site construction waste.

4.0 Opinion of Probable Capital Cost

The Opinion of Probable Capital Cost (OPC) for the study is in line with an AACE Class 5 estimate, following a level of engineering project definition of 0 – 2%. From AACE, "Class 5 estimates are prepared for any number of strategic business planning purposes...typical accuracy ranges for Class 5 estimates are - 20% to -50% on the low side, and +30% to +100% on the high side, depending on the technological complexity of the project, appropriate reference information, and the inclusion of an appropriate contingency determination". Given the expected level of effort for this study, an order of magnitude estimate of +50%/-30% is expected. Full line item OPCs are attached in Appendix A.

Table 2.0 – Summary of Opinion of Probable Capital Cost

Option #	Fuel Type Natural Gas or Diesel	Site Landfill or Takhini	Plant Capacities 5 MW_e, 10 MW_e, 20 MW_e	Opinion of Probable Capital Cost (OPC)
NG-LF-05	Natural Gas	Landfill	5 MW_e (2x 2.5 MW_e)	$48.6 M
NG-LF-10	Natural Gas	Landfill	10 MW_e (4x 2.5 MW_e)	$66.9 M
NG-LF-20	Natural Gas	Landfill	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$100.1 M
NG-TK-05	Natural Gas	Takhini	5 MW_e (2x 2.5 MW_e)	$48.5 M
NG-TK-10	Natural Gas	Takhini	10 MW_e (4x 2.5 MW_e)	$66.8 M
NG-TK-20	Natural Gas	Takhini	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$100.0 M
DL-LF-05	Diesel	Landfill	5 MW_e (2x 2.5 MW_e)	$32.0 M
DL-LF-10	Diesel	Landfill	10 MW_e (4x 2.5 MW_e)	$42.2 M
DL-LF-20	Diesel	Landfill	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$62.5 M
DL-TK-05	Diesel	Takhini	5 MW_e (2x 2.5 MW_e)	$31.7 M
DL-TK-10	Diesel	Takhini	10 MW_e (4x 2.5 MW_e)	$41.9 M
DL-TK-20	Diesel	Takhini	20 MW_e (4x 2.5 MW_e, 2x 5 MW_e)	$62.2 M

4.1 CAPITAL COST RISK ANALYSIS

No detailed risk analysis (Monte Carlo) is planned for the OPC. A contingency of 20% will be allocated.

Knight Piésold CONSULTING

EXECUTIVE SUMMARY

Knight Piésold (KP) has undertaken an assessment of pumped storage hydroelectric potential for Yukon Energy Corporation (YEC). The study focussed on identifying viable pumped storage facilities within a 25 km radius of existing and proposed transmission infrastructure (excluding sites located in existing parks and protected areas). The pumped-storage sites are intended to provide seasonal pumping from May through to September, along with seasonal generation from October through to April. The intention of this assessment is to determine the Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for pumped-storage hydro and compare these values with other potential fossil fuel and renewable generation options that may be available to YEC. The current study identified sites with the following technical constraints:

- 15 MW Capacity and 50 GWh energy storage
- 15 MW capacity and up to 100 GWh energy storage
- 25 MW capacity and 50 GWh energy storage, and
- 25 MW capacity and up to 100 GWh energy storage.

An initial screening assessment was undertaken using KP's in-house GIS and spreadsheet screening tools. This process identified 473 potential reservoir basins in the study area, and approximately 200 sites that were found to be technical viable pumped-storage sites. By ranking these sites by inferred construction cost, the top five (preferred) sites were identified for each of the 50 GWh and 100 GWh energy storage configurations. This resulted in a list of seven sites that were selected for further evaluation. These sites are as follows:

- Tutshi-Moon, near Tutshi Lake, BC
- Atlin-Black Mountain, near Atlin, BC
- Racine-Moon, near Racine Lake, BC
- Racine-Mt. Brown, near Racine Lake, BC
- Lindeman-Fraser, near Fraser, BC
- Squanga-Dalayee, between Johnson's Crossing and Jake's Corner, YT, and
- Canyon-Ittlemit, near Canyon Lake and the Aishihik Hydro Facility, YT.

Further analysis was undertaken to prepare AACE Class 5 cost estimates for the preferred sites, as well as a preliminary financial model for the proposed projects. Using YEC's assumed (real) cost of capital of 3.38%, the following results were obtained:

- 15 MW capacity and 50GWh storage configuration has a minimum $0.28/kWh LCOE and $900/kW-yr LCOC for the Tutshi-Moon facility
- 15 MW capacity and 100GWh storage configuration has a minimum $0.19/kWh LCOE and $1,300/kW-yr LCOC for the Tutshi-Moon facility
- 25 MW capacity and 50GWh storage configuration has a minimum $0.32/kWh LCOE and $650/kW-yr LCOC for the Tutshi-Moon facility, and
- 25 MW capacity and 100GWh storage configuration has a minimum $0.21/kWh LCOE and $840/kW-yr LCOC for the Tutshi-Moon facility.

In all cases, the Tutshi-Moon pumped-storage project was evaluated as the most cost-effective. The Atlin-Black Mt. and Racine-Mt. Brown facilities also have competitive cost profiles. The Racine-Moon and Lindeman-Fraser have technical constraints that make them less promising. The Squanga-Dalayee and Canyon-Ittlemit facilities are less cost effective, but have the advantage of being

relatively closer to existing YEC infrastructure. It is not known at this stage whether a viable project configuration can be found for the Canyon-Ittlemit facility that does not negatively impact the existing Aishihik hydro facility, but this should be investigated in future project stages.

The lowest LCOE ($0.19/kWh) is achieved with the 15 MW/100 GWh configuration. Conversely, the lowest LCOC ($650/kW-yr) is achieved with the 25 MW/50 GWh configuration, suggesting that there is a trade-off between cost of stored energy and capacity for pumped-storage facilities. Reducing energy storage further may provide a lower cost of capacity and would be more in line with the development trend in pumped-storage facilities worldwide (short duration storage of hours to days).

If further assessment of the pumped-storage projects is warranted by YEC, KP recommend the following next steps prior to proceeding with prefeasibility and feasibility studies:

1. Preliminary site visits to the following projects to evaluate technical viability further:
   - Tutshi-Moon
   - Atlin-Black Mt.
   - Racine-Mt. Brown
   - Squanga-Dalayee, and
   - Canyon-Ittlemit.
2. Acquisition of more detailed topographic data (such as PhotoSat) to provide better estimates of dam construction costs and reservoir storage potential.
3. Screening assessment of social and environmental permitting constraints.

1 – INTRODUCTION

1.1 BACKGROUND

Knight Piésold (KP) have undertaken this study in response to a Request for Proposals (RFP) from Yukon Energy to identify potential pumped-storage sites within a 25 km radius of existing and proposed (transmission) infrastructure. The pumped-storage sites are intended to provide seasonal pumping from May through to September, along with seasonal generation from October through to April. The intention of this assessment is to compare the cost of energy and installed capacity with other potential fossil fuel and renewable options that may be available to YEC, including conventional small hydro <20 MW, wind, diesel and natural gas-fired generation. In order to achieve this aim, the current study identified sites with the following technical constraints:

- 15 MW Capacity and 50 GWh energy storage
- 15 MW capacity and up to 100 GWh energy storage
- 25 MW capacity and 50 GWh energy storage, and
- 25 MW capacity and up to 100 GWh energy storage.

Where consideration of other combinations of installed capacity and energy storage may be beneficial, explanation has been included in this report.

1.2 PREVIOUS STUDIES

From the information provided to KP by YEC for the Pumped-Storage and Small Hydro screening assessments, the only document relating specifically to pumped-storage was the 2015 report into the proposed Moon Lake Pumped-Storage Project completed by Midgard Consultants. The report assessed the viability of the project under three possible scenarios:

1. Conventional storage with generation from November to May and a capacity of 7.5 MW.
2. Pumped-storage with a total of 48 GWh of energy storage and a capacity of 20 MW.
3. Pumped-storage with a total of 70 GWh of energy storage and a capacity of 26 MW.

The study found that the facility is limited by the available pumping energy, with more storage capacity than could be pumped during the summer months. The estimated capital costs for these projects ranged from approximately $155 million for the 7.5 MW conventional storage project to $262 million for the 70 GWh pumped-storage project. The estimated levelized cost of energy was estimated at $0.21/kWh for 48 GWh of annual generation (90% capacity factor).

This study aims to provide a comprehensive screening assessment of pumped-storage potential in the Yukon Territory that will, among other things, determine whether there are other pumped-storage sites that might be equally or more attractive than the Moon Lake site.

1.3 OVERVIEW OF PUMPED-STORAGE

Pumped storage differs from conventional hydroelectric systems in that they operate not as a source of energy, but as a form of energy storage and reliable capacity. The conceptual arrangement of a pumped-storage facility is shown on Figure 1.1. Typical applications have included providing peak capacity in systems with a high portion of conventional thermal generating units such as coal and nuclear facilities, which are less amenable to rapid response to match load fluctuations. Increasingly in recent years pumped-storage facilities have been developed and deployed with a view to

managing the integration of intermittent renewable energy such as wind and solar. There is growing worldwide interest in the use of pumped storage to provide reliability for small, isolated grids with at least three of the Hawaiian islands in various stages of developing pumped storage. YEC are considering an alternative arrangement that is intended to shift excess hydroelectric energy available in the summer runoff and shift it to the winter to match the load. Typically, pumped storage facilities provide energy storage durations in the order of hours to days, KP is not aware of any precedents for development of pumped-storage facilities to provide long-term (seasonal) energy storage as is being proposed by YEC for the current report.

Technology for pumped-storage facilities varies depends on the site-specific conditions for a given facility. The use of reversible pump-turbines coupled with synchronous motor-generators is the most common arrangement. The units are optimised for the best round-trip efficiency, so are slightly less efficient than an equivalent conventional Francis turbine. The pumping mode is less efficient than the generating mode, and when coupled with the head losses in the water conveyance system typically result in a round-trip efficiency in the order of 70 to 80% (depending on penstock losses). The round-trip efficiency indicates the portion of pumping energy input to a pumped-storage system that can then be delivered back to the grid in generation mode, with pumped-storage facilities being overall net users of energy. Pumped-storage compares quite well with other grid-scale storage technologies, being both more efficient and more cost-effective on both a per MW capacity and per MWh stored energy basis. While pumped-storage has traditionally been used to shift a block of energy from off-peak to peak load hours, the emerging trend is for more rapid response, particularly using variable-speed units, which make a facility able to provide grid stability, frequency control, voltage regulation, spinning reserve and other grid support ancillary services.

Figure 1.1 Typical Components of a Pumped-Storage Hydropower System

1.4 YUKON'S ELECTRICITY SYSTEM

1.4.1 Current Capacity

YEC currently owns and operates approximately 131 MW of installed capacity, consisting of 92 MW of hydro, 0.8 MW of wind, and 37.8 MW of thermal (diesel and natural gas). Yukon Electrical Company Ltd. (YECL), owned by ATCO, supplies approximately 1.3 MW of hydroelectricity and 6.8 MW of diesel power.

YEC's hydroelectric generating capacity is comprised of:

- 37 MW Aishihik Generating Station, 150 km west of Whitehorse
- 15 MW Mayo Generating Station, 450 km north of Whitehorse
- 40 MW Whitehorse Generating Station, located on the Yukon River at Whitehorse, and
- 1.3 MW Fish Lake Generating Station (YECL).

1.4.2 Power Grid

The Yukon power grid is shown on Figure 1.2 and comprises the following major components:

- 138 kV Whitehorse / Aishihik / Faro (WAF) grid
- 69 kV Mayo / Dawson transmission line, and
- 138 kV Carmacks / Stewart transmission line, connecting the WAF grid and the Mayo / Dawson transmission line.

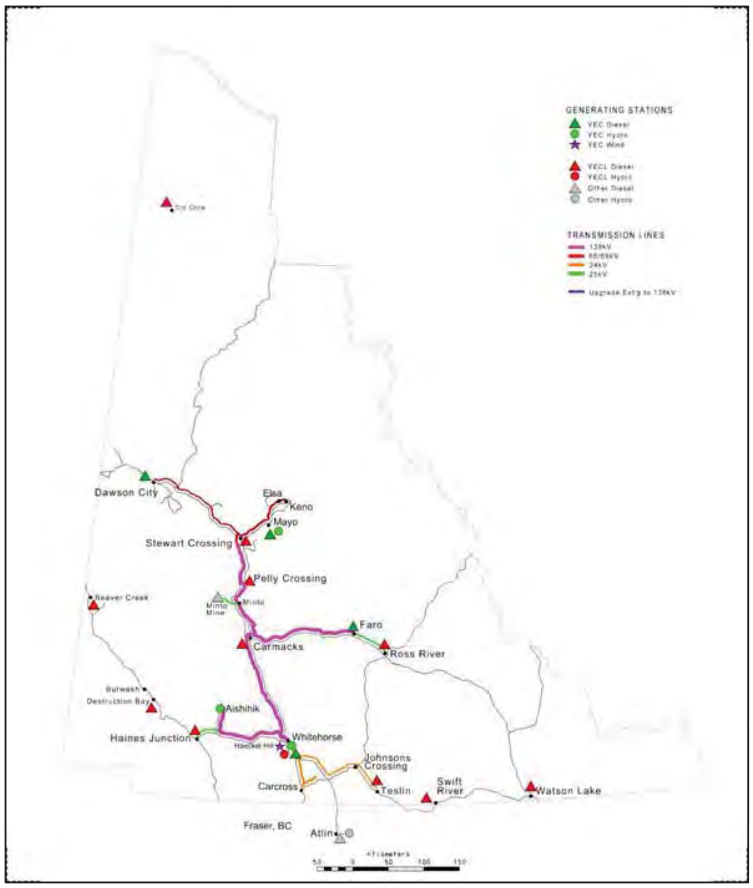

Figure 1.2 Yukon Electricity Network

The Yukon electricity network is an isolated grid, with no connection to other jurisdictions (BC, Alaska, Alberta or Northwest Territory). The Yukon grid currently services all Yukon communities except for Watson Lake, Burwash Landing/Destruction Bay, Beaver Creek, and Old Crow [YDC, 2015].

1.4.3 Proposed Transmission Lines

The following major transmission line extensions have been considered by YEC:

- Aishihik to Destruction Bay
- Skagway to Whitehorse
- Atlin to Whitehorse
- Teslin to Whitehorse, and
- Faro to Watson Lake.

2 – PRELIMINARY SCREENING

2.1 SCREENING METHODOLOGY

2.1.1 Spatial Limitations

The pumped-storage screening assessment for the Yukon was limited to a 25 km buffer from existing and planned transmission lines in the Territory. Within that area, terrestrial parks were excluded, but First Nations settlement land were included. Fish bearing habitat was not specifically excluded, but would be assessed for permitting viability in more detailed assessment phases for any identified projects. A map showing the study area is shown on Figure 2.1.

2.1.2 Generation and Storage Capacity

This study evaluates potential pumped-storage facilities that are able to provide energy generation through the winter months of October through April. This requires pumping through the summer from May through to September in order to provide the stored energy in the upper reservoir ready for the winter months. The pumping in the summer months can be supplemented through runoff through the freshet and summer, thereby reducing the total pumping energy required. Runoff was not included in the assessment at the preliminary screening stage, but was included in the assessment of the 'preferred sites'. The screening study assessed the following four combinations of power generation and energy storage capacity:

- 15 MW capacity and 50 GWh energy
- 15 MW capacity and 100 GWh energy
- 25 MW capacity and 50 GWh energy, and
- 25 MW capacity and 100 GWh energy.

In contrast to typical pumped-storage facilities, the proposed sites in the Yukon are intended for seasonal storage, whereas most applications for pumped-storage are for daily peaking operations. This will increase their overall cost, due to the increased dam size required to provide adequate water storage volume in the upper and lower reservoirs. Daily peaking facilities (with 8-10 hours of storage or less) are the most common configuration for pumped-storage facilities, and KP's prior experience shows reductions in levelized cost of capacity for facilities with shorter storage durations.

2.1.3 Identifying Potential Reservoirs

Construction of a pumped-storage facility requires use of two reservoirs at different elevations which can alternately store and discharge water as the facility moves from pumping to generating modes and vice-versa. Identifying suitable storage basins was one of the more complex portions of this study; there are potentially thousands of locations where water could be stored in such a large geographic area that was covered in this assessment.

All existing lakes within the study area greater than 50 ha in area were included as potential storage basins in the assessment. Potential dam construction locations on existing lakes were sited at the outlet of the lake. In addition, artificial reservoir locations were identified by manually assessing the study area using Google Earth to identify potential storage basins.

SAVED: M:\1\03\00556\02\A\GIS\Figs\1 - Pumped Storage\Figs\Fig2-1_PumpedStorage_Reservoirs.mxd; Jun 24, 2016 10:09 AM; lkavanszova

Using the combination of the existing natural lakes and the artificial reservoirs, the storage potential of the reservoir basin for an approximately 30 m dam height was determined from the following:

$$S = A_L \times D + \frac{(A_R - A_L) \times D}{3}$$

Where:

$$S = A_L \times D + \frac{(A_R - A_L) \times D}{3}$$

$$A_L = Area\ of\ existing\ (natural)\ lake\ (zero\ for\ artificial\ reservoirs)$$

$$A_R = Area\ of\ reservoir\ formed\ with\ a\ 40\ m\ high\ dam$$

$$D = Dam\ height\ (30\ m)$$

The above equation assumes a prismatic shape to the reservoir storage volume. For the first phase of screening, it is sufficient to estimate the order of magnitude water storage volume potential of a particular basin based in comparison to the dam height and length, allowing identification of the most promising sites in the study area. This allowed for the development of a more efficient GIS screening tool than fully developing a depth-area-capacity (DAC) curve for all ~500 potential storage basins.

The assessment of potential reservoir basins was complicated by the low resolution of the data available to KP for completion of this study. YEC provided topographic data with 100 ft. (30 m) contours, which was insufficient to create a complete digital elevation model of the study area that could reliably determine drainage basins automatically. Some potential storage basins have likely been inadvertently excluded from this study due to the poor quality of topographic data. This also may have led to inaccuracies in estimating embankment volumes/water storage ratios. Some spurious data were generated, and most but not all was excluded manually prior to the screening assessment. Nevertheless, KP are confident that despite these data limitations the most promising pumped-storage locations have been included and correctly identified, and that only sites who have less favourable characteristics have been excluded as a result of the low resolution input topographic data.

2.1.4 Technical Constraints

While the identified facilities are smaller than typical pumped-storage facilities, some of the well-recognised hydroelectric generating equipment manufacturers (Voith, Andritz, Alstom) nevertheless have experience in manufacturing reversible pump-turbines of this capacity. Due to the level of design standardisation of generating equipment for small hydro facilities, it may be more cost-effective to adopt conventional turbines and standard pumps in place of reversible pump-turbines for a facility of this size. Determining the trade-off between the two is recommended for future project stages. For the current screening assessment, the use of reversible pump-turbines has been assumed and equipment costs have been extrapolated from published generating equipment costs for reversible pump-turbines.

For the purposes of this screening study, it is not possible to determine what form of water conveyance system (buried or surface penstock, tunnel) would be most appropriate, therefore a buried penstock is assumed for all sites, with a straight line between the upper and lower reservoirs. A maximum straight line water conveyance length of 20 km is assumed between the upper and lower reservoirs. While it is KP's experience that this exceeds the typical water conveyance length for typical hydro plants, the intention was not to unnecessarily exclude potential sites early in the screening process. A more detailed review of penstock alignment is included for the preferred sites

in the next Section of this report. Similarly, determination of the transmission lines distances assumed a straight line between the powerhouse and the nearest existing or planned transmission line was assumed for the preliminary screening and ranking of potential pumped-storage sites. A more detailed assessment of transmission line routing was undertaken for the top-ranked (preferred) sites.

Using the nominal reservoir storage volume calculated in Section 2.1.3, a relationship between dam height, dam crest length and reservoir storage volume can be determined. This allowed the screening tool to extrapolate the approximate dam size to meet a given water volume storage required as need for the screening process. It should be noted that this process is an “order of magnitude” process at best, and the dam dimensions were examined in greater detail for the preferred sites in the following Section of this report. Dams are assumed to be concrete-faced rockfill dams (CFRD). Future project studies may result in evaluations showing that alternate dam designs may be more appropriate for individual facilities, but this construction method was selected on the basis of its wide applicability. It is therefore reasonable to assume all dams are CFRD embankments for the purposes of this initial assessment.

2.1.5 Screening Assessment

From the above method, a total of just under 500 potential storage basins (473) were identified as shown on Figure 2.1. An in-house GIS screening tool developed by KP was used to select the best combinations of freshwater basins (upper and lower reservoirs) that would lead to viable pumped-storage sites. This tool identifies any two basins within 20 km, and then determines if the basins are able to store the required water volume, which is dependent on the elevation difference (head) between the two storage basins. If one or both of the two basins is unable to store the required water volume, that combination of basins is eliminated as a potential candidate pumped-storage site. To minimise the extremely high number of potential combinations, a maximum threshold of 10 Mm^3 was set for the total dam embankment construction volume between the reservoirs.

While the threshold of 20 km for the water conveyance distance and 10 Mm^3 for the embankment construction volume may both be beyond the size expected for an economical facility, the intent was not to screen out any sites prematurely, and thus to set the threshold above what would ordinarily be expected. This allows screening and ranking of the most promising sites before selection of the five preferred sites.

2.1.6 Preliminary Characterisation and Inferred Cost

Using the GIS-based screening tool, combinations of reservoir basins where a pumped-storage site could be developed were identified. A total of 250 sites were identified meeting the 50 GWh storage requirement, and 190 sites meeting the 100 GWh storage requirement. There is no suggestion that these sites are economically viable sites, simply that it is theoretically possible to construct them under the minimum thresholds of embankment construction volumes and penstock distance.

In order to identify the most economically attractive sites, data from the sites flagged using the GIS screening tool were imported to an in-house spreadsheet model that calculates inferred project costs based on overall project details (gross head, design flow, capacity), reservoir information (required storage volume, reservoir area, embankment height and length, embankment volume), and waterway parameters (length, diameter). Due to the coarse resolution of the data, the automated nature of the calculations, and the extrapolation method used to determine some of the key site

parameters (such as dam height, crest length and reservoir area) the tool is considered valid only for a broad ranking of sites and should not be considered accurate for an absolute estimation of cost.

2.2 SCREENING ASSESSMENT RESULTS

2.2.1 Candidate Reservoir Sites

Figure 2.1 shows the location of all 473 candidate reservoir sites included in the pumped-storage screening assessment. These potential storage basins vary from very large existing lakes, such as the 780 km^2 Atlin Lake on the Yukon/BC border in the south of the study area, down to small alpine cirques with no existing lake, but in which an artificial reservoir could be constructed.

2.2.2 Candidate Pumped-storage Facilities

The top 15 sites as ranked by KP's pumped-storage screening tools are included in Table 2.1 through Table 2.4. A minimum level of quality control was applied to the sites before including facilities on the Tables showing the top 15 sites, namely deletion of sites that were identified through manual inspection as overlapping a higher ranked site. It is apparent that some of the highest ranked sites appear in each of the four combinations of energy storage and installed capacity. Figure 2.3 shows the location of all sites that appear in these four Tables.

3 – EVALUATION OF PREFERRED SITES

3.1 SELECTION OF PREFERRED SITES

By examining the top five ranked sites in each of Table 2.1 through Table 2.4, it is apparent that the following three sites appear in the top five for both the 50 GWh and 100 GWh options:

1. Tutshi-Moon
2. Atlin-Black Mt.
3. Racine-Moon

For the 50 GWh option – the following are the top five pumped-storage sites:

1. Tutshi-Moon
2. Atlin-Black Mt.
3. Racine-Moon
4. Racine-Mt. Brown (also ranked number six by a very small margin for the 25 MW, 100 GWh storage option)
5. Lindeman-Fraser

For the 100 GWh option – the following are the top five pumped-storage sites:

1. Tutshi-Moon
2. Atlin-Black Mt.
3. Racine-Moon
4. Squanga-Dalayee
5. Canyon-Ittlemit

3.2 HYDROLOGY

Hydrological characteristics are less of a consideration for pumped-storage facilities as compared to conventional hydro plants. Nevertheless, the long duration of seasonal pumping in the summer months from May through to September warranted an investigation into the likely Mean Annual Runoff to the catchments of the upper reservoirs. Any inflow to the upper reservoir at any point throughout the year can be considered water that does not need to be pumped from the lower reservoir during the summer. Note that inflow into lower reservoirs has not been evaluated. Inflow into the lower reservoirs does not reduce pumping requirements, but sufficient inflow may alleviate the need for dam construction on the lower reservoir(s). In addition, inflow may reduce the size requirement for the upper reservoir dams, and would be a useful aspect for evaluation in future.

Data from a total of 46 Water Survey of Canada (WSC) gauges with catchment areas between 10 and 7,000 km^2 were reviewed to develop an understanding of regional trends in measured runoff for catchments of varying sizes and regions. The data were used to develop estimates of Mean Annual Discharge (MAD) at the upper reservoir for all of the preferred project sites assessed here in Section 3 of this report. No analysis of the expected distribution of flow throughout the year was undertaken for the pumped-storage sites, as all inflow at any stage of the year is assumed to be captured.

Where no previous hydrology information could be obtained, KP has developed estimates on the basis of the Mean Annual Unit Discharge (MAUD) values from the WSC gauges in the region. These gauges are dispersed across the majority of the Yukon and provide a reasonable means of

assessing hydrologic patterns throughout the region. Some of the basic trends evident in the data are as follows:

- MAUD appears to decrease in a south-westerly direction along the border between the Yukon and Northwest Territories (NWT), with lower unit discharge values evident in the dry, lower relief interior zones versus the mountainous terrain along the eastern provincial border, and
- In the south-western corner of the Yukon, MAUD appears to be relatively high due to the onshore movement of moist maritime air from the Pacific Coast. The effects of this moisture influx extends slightly beyond the Coastal Mountain Range, and then drops off markedly due to a 'precipitation shadow' effect that results in a progressive reduction in MAUD moving east.

MAUD values were selected for the project sites on the basis of proximity and similarity of catchment size to the WSC stations. Commonly, there are two to three local gauge stations that provide a basis for estimating unit discharge. Where applicable, consideration was also given to the MAUD values reported for various project sites.

Additional regional considerations when determining a site's MAUD included;

- Glaciers in a watershed, which generally increase MAUD due to melt during the warm summer months
- Lakes in a watershed, which generally decrease MAUD due to greater evaporation, and
- The local relief, with higher elevation watersheds generally having higher precipitation and correspondingly higher MAUD.

3.3 PROJECT CONFIGURATIONS

Using the preliminary site information identified in Section 2 of this report, a more advanced assessment of each of the preferred sites was undertaken, including:

- Selection of a realistic penstock alignment that considers local topographic constraints and most efficient routing. These routes are longer than the straight-line distances between the upper and lower reservoir determined by the automated screening tool in Section 2
- Selection of a realistic transmission line alignment that considers local topographic constraints. These routes are longer than the straight-line distances between the powerhouse and nearest transmission line determined during the automated screening process in Section 2
- Optimisation of dam configuration (including height and length) based on the required water storage volume. This required a site by site assessment of topography and dam construction locations to supersede the dam configurations determined automatically by extrapolation during the screening process in Section 2 of this report, and
- Assessment of whether any saddle dams are required to provide the required storage.

It is apparent that the above changes will alter the anticipated cost for each project site, so the relative ranking of the top projects changes slightly with the benefit of this updated analysis. Technical attributes for all facilities are summarised in Table 3.1 through Table 3.4.

3.4 PROJECT DESCRIPTIONS

3.4.1 Tutshi-Moon

This site is located between Tutshi and Moon Lakes in British Columbia. The configuration is relatively straight forward, with a dam downstream of the outlet on Moon Lake. Since inflows into the project site were not considered in sizing the upper and lower reservoir dams, our analysis indicated that a low dam would be required at the outlet of Tutshi Lake in order to ensure the required storage volume in the lake. The inflows may be sufficient to alleviate the requirement for this dam in a final project configuration.

The penstock route selected for the analysis runs along the eastern side of the valley from Moon Lake down to the powerhouse on Tutshi Lake. The transmission line then heads north across Tutshi Lake to the proposed Yukon-Skagway transmission line that will run along the north-west shore. Without construction of this line, the distance to the nearest point of interconnection increases by approximately 35 km.

This is the same site assessed by Midgard in their 2015 conceptual study report. KP's configuration and analysis for this site is useful in benchmarking KP's analysis and cost assessment for all project sites with the more detailed analysis prepared by Midgard for Moon Lake. The current analysis was completed using KP's own methods without reference to the Midgard report, but yielded similar cost results as those obtained by Midgard. This provides a level of confidence and credibility in the results of the current report, given their similarity to Midgard's estimates which were prepared using different methods and a more detailed level of information.

3.4.2 Atlin-Black Mountain

This project uses the very large Atlin Lake in British Columbia as a lower reservoir and a small lake perched in a hanging valley approximately 2.5 km to the east of Atlin Lake, adjacent to Black Mountain. The upper reservoir requires a saddle dam on the west side in order to achieve the 100 GWh of storage, although no saddle dam is required for the 50 GWh storage arrangement.

The natural drainage direction from the small alpine lake is to the east. The penstock route assumes a deep channel excavation on the west side of the lake in order to minimise penstock length (approximately 2.5 km length as compared to a length of over 12 km for a penstock route that follows the natural terrain to the east of the small lake). Further analysis will be required to determine the technical viability of excavating a deep trench to overcome the terrain limitation, but it appears that the project still remains "competitive" with some of the top ranked projects, even with the assumption of digging a deep channel of approximately 130 m in length to accommodate the penstock drainage. The transmission line distance for this project is short (<1 km) provided that the Atlin-Yukon transmission line is constructed as it would run immediately adjacent to the proposed powerhouse location. Without the proposed transmission line, this site would be over 40 km to the nearest point of interconnection.

No dam is required on the lower reservoir, as the entire 100 GWh energy storage volume would result in a level fluctuation in Atlin Lake of only 10 cm. Given the long duration over which the energy is both stored and discharged, this artificial fluctuation will likely be small compared to background natural fluctuations in lake level.

3.4.3 Racine-Moon

This site utilises Moon Lake as an upper reservoir, but with Racine Lake as a lower reservoir in lieu of Tutshi Lake. The proposed penstock would run along the valley which lies directly between these two lakes. The elevation of this valley lies above the upper surface level of Moon Lake. Much like for the Atlin-Black Mt. site, a section of trench would need to be excavated to maintain a constant downward slope from Moon Lake to Racine Lake. However, unlike for the Atlin-Black Mt. site, this trench section would be quite long at approximately 3,000 m, thereby making this site much less attractive than was predicted by the automated screening tool. Furthermore, it is difficult to envision a situation where this would be constructed in lieu of, or in addition to the Tutshi-Moon pumped-storage facility. This site was ranked in the top five sites for both the 50 GWh and 100 GWh storage configurations during the screening assessment in Section 2 of this report. However, the site was excluded from the 100 GWh analysis in lieu of the Racine-Mt. Brown site due to the high water conveyance system cost making it relatively unfavourable.

The powerhouse is located on the north shore of Racine Lake, and the transmission line would run along the valley to the north of the lake, towards Moon Lake, and then crossing Tutshi Lake. On the north-west shore of Tutshi Lake, the project's transmission line would connect to the proposed transmission line between the Yukon and Skagway, Alaska. Without construction of the proposed line, the nearest point of interconnection for this project would be a further 35 km away from the proposed facility.

3.4.4 Racine Mt. Brown

This site features a small alpine lake at high elevation to the north of Racine Lake. A penstock route would follow along the north-west slope of the ridge separating the two lakes. For the 100 GWh storage option, a saddle dam would be required to create water volume needed for the upper reservoir, while no saddle dam is needed for 50 GWh of storage.

The powerhouse is located on the north shore of Racine Lake, and the transmission line would run along the valley to the north of the lake, towards Moon Lake, and then crossing Tutshi Lake. On the north-west shore of Tutshi Lake, the project's transmission line would connect to the proposed transmission line between the Yukon and Skagway, Alaska. Without construction of the proposed line, the nearest point of interconnection for this project would be a further 35 km away from the proposed facility.

3.4.5 Lindeman-Fraser

This site consists of Lindeman Lake as a lower reservoir, with the upper reservoir formed in an alpine valley to the west of the town of Fraser. The penstock route is long, and follows to the east of a mountain that separates the two lakes, while the transmission line runs in a south-easterly direction to connect with the proposed new transmission line to Skagway, Alaska. Without the construction of this proposed line, the required transmission line distance would be approximately 50 km to the nearest point of interconnection.

The long penstock route and the large dam required on the upper reservoir both put this site at a disadvantage. KP briefly assessed whether a tunnel through the mountain to the north of the upper reservoir may reduce overall costs by shortening the water conveyance distance. However, due to the minimum size required for tunnel construction, the small project capacity would result in a tunnel much larger than would otherwise be needed, and construction of a tunnel may actually increase, rather than decrease construction costs.

3.4.6 Squanga-Dalayee

This proposed facility is located between Squanga and Dalayee Lakes between Johnson's Crossing and Jake's Corner in the Yukon Territory. While the head is lower than some of the other highly ranked sites, the large existing lakes and short transmission distances offset the technical disadvantage of a lower head facility somewhat. The dams are relatively low (at approximately 20 m each for 100 GWh of storage), but are long due to the relatively wide valleys in which the lake outlets are situated. The penstock is a relatively direct route to the powerhouse located on the shore of Squanga Lake, less than 2 km from the nearest transmission line. The location of this facility relatively close to Whitehorse would provide advantages relative to the sites located in British Columbia at a greater distance from the Yukon's major load centre.

3.4.7 Canyon-Ittlemit

This project is located on Canyon Lake, with the upper reservoir formed by a conglomeration of a number of higher elevation lakes, including Ittlemit Lake. For the 100 GWh storage configuration, a large saddle would be required, adding to the cost of the facility. A major extension to the existing Canyon Lake dam would be required to allow construction of this facility, which will be difficult to manage without negatively impacting on flows through the Aishihik hydroelectric facility downstream. The penstock route between the two reservoirs is direct, and the transmission line would run along the western shore of Canyon Lake and the Aishihik River to the point of interconnection at the Aishihik substation. While integrating this facility on the same lake as an existing hydro facility would be challenging, it may provide potential benefits in providing additional regulation to the Aishihik hydroelectric facility. Determining the exact extent and configuration of a pumped-storage facility on Canyon Lake that would not impact the existing Aishihik facility would need to be investigated further in future project stages to determine whether it is possible.

3.5 TRANSMISSION LINE CONSIDERATIONS

For this study it has been assumed the transmission lines from each project would interconnect to the closest possible point along an existing or future proposed transmission line via “Tee-Tap” type interconnection that would require expensive substation and/or switching station infrastructure. A indicative interconnection arrangement is depicted in Figure 3.8 below:

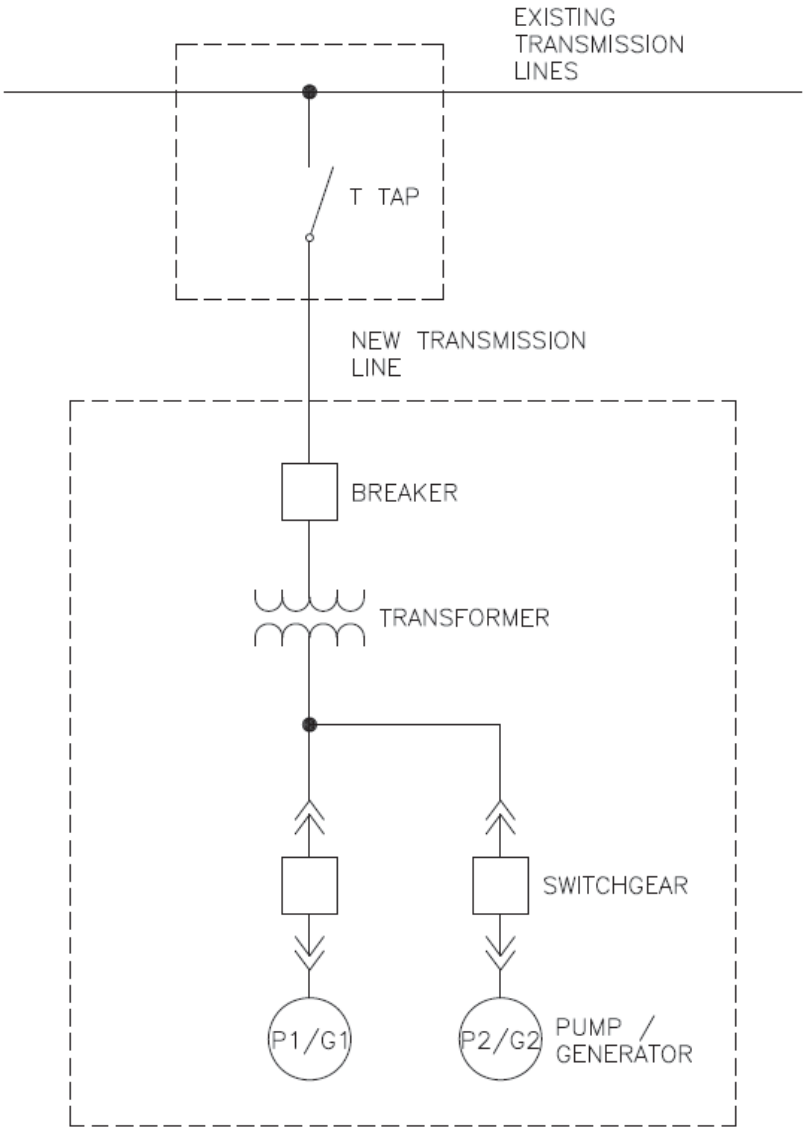

Figure 3.8 Indicative Interconnection Arrangement

However, there may be a few sites where a cheaper option exists to extend the transmission line slightly further to interconnect at an existing substation. In this case the avoided costs of building a new substation or switching station could outweigh the cost of extending the transmission line. This was not considered in this study, but should be in the next level of study.

3.6 CAPITAL COST EVALUATION

The capital cost estimates are based on the project configurations as outlined in Section 3.3. The Project Technical Attributes outlined in Table 3.1 through Table 3.4 were used to establish a size of project components, quantities and constructability. These technical attributes were used to estimate approximate material volumes for excavation, backfill, embankment material and reinforced concrete. Electrical and mechanical equipment requirements were estimated based on empirical data from KP's prior projects and published in industry technical reports.

The capital cost estimate includes an allowance for the Contractor's preliminary and general costs (overheads, insurance, bonus and profit etc.), an allowance for EPCM costs, and a variable contingency.

Unit rates for material production, equipment procurement and installation costs relied on KP's internal costing database including recent, relevant experience with similar sized hydroelectric projects in Western Canada and the Yukon Territory. KP's hydro project cost database also offered an "order of magnitude check of total estimated costs for individual facility components and complete facilities, based on projects with comparable characteristics such as, design flow, penstock pipe characteristics (length, diameter, etc.), gross head, generating capacity, powerhouse area, excavation quantities, reinforced concrete volumes, backfill quantities, switchyard capacity and transmission line capacity and length. Generating equipment costs are based on installed capacity, head and flow, while switchyard costs are interpolated based on installed capacity. Adjustments to reflect the higher construction costs in the Yukon Territory were included where appropriate. All dollars are shown in 2015 Canadian Dollars (CAD).

It is likely that capital costs will vary as more detailed assessments are undertaken. While the level of technical analysis is still preliminary, the estimates have been prepared with sufficient detail for a preliminary AACE Class 5 estimate. The analysis herein should be considered the minimum level required for an AACE Class 5 estimate, and the uncertainty in cost is likely at the higher end of the range for that Class of estimate ($\pm$50%). These costs should be used as a relative comparison estimate for other development options, rather than a reliable indication of the actual construction costs for any of these facilities.

A detailed summary of the estimated capital cost breakdown for the alternate pumped-storage project arrangements are presented in Appendix A, while the overall estimated costs for each project configuration are shown in Table 3.5.

3.7 OPERATION & MAINTENANCE COST

Operation and Maintenance (O&M) Costs have been assessed as fixed and variable (generation and pumping) costs. Fixed costs are estimated at a rate of 2.0% of the total project capital cost based on the methodology used in the BC Hydro's 2013 Resource Options Report[(1)]. This methodology assumed an estimated O&M cost at a rate of 1% of the total project capital cost for 1000 MW fresh water pumped storage sites and 1.5% for 500 MW fresh water pumped storage sites. By linear extrapolation of percent of capital versus project capacity there is a marginal difference between 15MW and 25 MW pumped storage sites, and a single value of 2.0% has been assumed.

1. Reference. Appendix 9A Section 3.2.4, viewed at: http://www.bchydro.com/content/dam/BCHydro/customer-portal/documents/corporate/regulatory-planning-documents/integrated-resource-plans/current-plan/ror-update-appx-9a-20130802.pdf.

It should be noted that estimating fixed operating costs based on a percentage of capital cost is considered a reasonable approach for a conceptual level study. Once final general arrangement layouts of the various alternatives have been developed a more accurate estimation of fixed operating costs can be made that would typically include cost items such as:

- YEC Corporate Overhead
- Operations Staff Salaries and Benefits
- Provincial/Territory Resource Fees: Water Rental (Capacity, Energy Charge, Water Storage Charges), Land Rents and annual operating permits
- Regularly Scheduled Operations and Maintenance Costs
- Insurance, and
- Property and Corporate Taxes.

Variable O&M costs include the cost of energy to pump water from the lower reservoir to the upper reservoir at $0.05/kWh and the cost of generation and an equivalent value of $0.05/kWh. These values are estimated based on KP's experience and actual costs will depend on generation to pumping ratios which vary depending on pump-turbine technology and manufacturer.

3.8 FINANCIAL EVALUATION

KP has developed an in house financial model to assess the Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for the pumped-storage project configurations. The basic parameters used in the financial model include:

- Capital Cost Estimate — Varies by alternative
- Annual Fixed Operating Costs — 2.0% of initial capital cost
- Variable Operating Costs — 0.5¢/kWh of either pumping or generating
- Annual Generating Energy — 50 or 100 GWh
- Annual Pumping Energy — Varies by alternative
- Construction Period — 48 months
- Project Life — 65 years

No time value of money nor escalation/inflation is included in the financial evaluation, but interest rates are assumed for the real cost of capital as follows:

- YEC resource options — 3.38%
- IPP resource options — 4.61%
- High interest scenario — 8.82%

The loaded capital cost, or net present cost at Commercial Operation Date (COD) is calculated to take into account any interest accrued during construction, using the following formula:

$$C = \sum_{\mathrm{yr}=0}^{\mathrm{n}} \mathrm{c}(1+i)^{\mathrm{n-yr}}$$

Where:

$$C = loaded\ capital\ cost$$
$$c = construction\ cost\ in\ given\ year\ of\ interest$$
$$yr = construction\ year\ of\ interest$$

$$n = total\ number\ of\ years\ of\ construction \quad (4)$$
$$i = interest\ rate$$

Next, the levelized capital cost per year is calculated using the capital recovery factor formula:

$$LC = \frac{iC(1+i)^N}{(1+i)^N - 1}$$

Where:

$$LC = levelized\ capital\ cost\ per\ year$$
$$N = total\ project\ life$$

A summary of the project financial attributes is included in Table 3.5, and further detail is provided in Appendix B. Note that the summary Table 3.5 only provides levelized cost results for the assume YEC development real cost of capital rate of 3.38%. Refer to the detail provided in Appendix B for the evaluation undertaken using alternate interest rates.

3.9 DEVELOPMENT SCHEDULE

A high level development schedule has been developed to illustrate the relative time lines for completing critical tasks associated with developing any pumped-storage project. Since the relative timelines for completing the major development tasks is similar for each pumped-storage project described above, this schedule should be taken as indicative. The major development tasks and time lines are listed below and presented in as a Gantt chart on Figure 3.9.

1. Feasibility Study – 1 year
   - Will require on site hydrology data that will require a minimum of one year of data collection
2. Environmental Assessment (Permitting and Baseline Studies) – 2 years (will start concurrent with Feasibiltiy Study)
   - Will include fisheries, hydrological and wildlife/terrestrial studies that will be inputs to the Environmental Assessment for each project
3. EPC Tendering Process – 1 year
   - EPC tender design can start immediately after Feasibility Study
4. Construction – 4 years
   - Will commence once Environmental Assessment Certificate is received and EPC contractor is selected
5. Commissioning – 4-6 months
   - Can start after Construction
6. Operations – 65 years

The minimum total development duration from the start of the Feasibility Study through to the end of Commissioning is approximately 6.5 years.

4 – CONCLUSIONS AND RECOMMENDATIONS

4.1 CONCLUSIONS

A screening assessment of pumped-storage potential in the Yukon Territory has been undertaken and has examined a large area of the territory for potential sites. A total of 473 potential reservoir basins were assessed, yielding over 200 sites that were shown to be technically viable. The top ranked (preferred) sites were evaluated further, yielding the following results:

- 15 MW capacity and 50GWh storage configuration has a minimum $0.28/kWh LCOE and $900/kW-yr LCOC for the Tutshi-Moon facility
- 15 MW capacity and 100GWh storage configuration has a minimum $0.19/kWh LCOE and $1,300/kW-yr LCOC for the Tutshi-Moon facility
- 25 MW capacity and 50GWh storage configuration has a minimum $0.32/kWh LCOE and $650/kW-yr LCOC for the Tutshi-Moon facility, and
- 25 MW capacity and 100GWh storage configuration has a minimum $0.21/kWh LCOE and $840/kW-yr LCOC for the Tutshi-Moon facility.

In all cases, the Tutshi-Moon pumped-storage project was evaluated as the most cost-effective, which is encouraging given that it appears this is the facility for which YEC has currently expended the most effort in evaluating. The Atlin-Black Mt. and Racine-Mt. Brown facilities also have similarly competitive costs, particularly for the 50 GWh configurations. The Racine-Moon facility has technical constraints that make it less promising, as does the Lindeman-Fraser facility. The Squanga-Dalayee and Canyon-Ittlemit facilities are less cost effective than the Tutshi-Moon, Atlin-Black Mt. and Racine-Mt. Brown facilities, but warrant further investigation due to their relative proximity to existing YEC infrastructure, in comparison to the three projects located south of the BC border. It is not known at this stage whether a viable project configuration can be found for the Canyon-Ittlemit facility that does not negatively impact the existing Aishihik hydro facility, but this should be investigated further in future project stages.

The lowest LCOC ($650/kW-yr) is achieved with the 25 MW/50 GWh configuration (Table 4.1), suggesting that there is a trade-off between cost of stored energy and capacity for pumped-storage facilities. Conversely, the lowest LCOE ($0.19/kWh) is achieved with the 15 MW/100 GWh configuration (Table 4.2), suggesting that increasing storage volume and lowering installed capacity tends to optimise cost of stored energy. In contrast to typical pumped-storage facilities where daily or hourly load shaping is targeted, YEC requested KP to evaluate seasonal storage durations. Much lower LCOC could be achieved by reducing the energy storage requirement to a shorter period (10 days for example). Such a facility would not provide seasonal storage and shifting of energy from summer to winter months (as desired by YEC), but would provide additional security against unexpected outages of a key YEC hydro facility or transmission lines in the high-demand winter period.

4.2 RECOMMENDATIONS

Further evaluation of pumped-storage facilities will depend on YEC's desired mix of generation options in the future. While the most effective sites have been identified, the financial viability would have to be assessed by evaluating the potential for any pumped-storage facility to offset diesel, LNG or other costly fuel sources, which KP understand currently only constitute a small percentage of YEC's generation. If it is expected that a pumped-storage facility will offset a significant amount of costly diesel or LNG fuel in the future, further assessment of pumped-storage projects may be warranted.

It is recommended that the following steps be undertaken as part of further assessing the preferred pumped-storage facilities identified in this study:

1. Preliminary site visits to the following projects to evaluate technical viability further:
   - Tutshi-Moon
   - Atlin-Black Mt.
   - Racine-Mt. Brown
   - Squanga-Dalayee
   - Canyon-Ittlemit
2. Prepare depth-area-capacity curves and dam construction volume vs. height curves for these five facilities to better estimate dam construction volumes and costs. This would require the acquisition of more detailed topographic data, such as PhotoSat satellite topographic data.
3. Update Capital Cost estimates based on more accurate construction quantities.
4. Screening assessment of social and environmental permitting constraints at each of the five proposed facilities.

Should the above assessment indicate that there are no technical or environmental showstoppers, further evaluation of the sites through detailed prefeasibility and feasibility studies should be pursued to prove the business case for construction of any of the proposed facilities.

Executive Summary

Yukon Energy Corporation ("YEC") is investigating the potential to develop a storage hydro project on Moon Lake, in northwestern British Columbia. As a utility, YEC experiences a winter peak load, combined with a summer peak in generation potential from its hydroelectric generating assets. A storage project at Moon Lake is intended to seasonally shift freshet flows and augment winter generation potential to better align with YEC's annual load profile.

Moon Lake, located 100 km south-southeast from Whitehorse, and 18 km south of the BC Yukon border, drains into Tutshi Lake from the south and is ultimately a tributary to the Yukon River, above Whitehorse. The project drainage area is estimated at 57.4 km^2 yielding an estimated Mean Annual Daily Flow ("MAD") of 0.79 m^3/s.

Midgard Consulting Incorporated ("Midgard") was retained by Yukon Energy Corporation ("YEC") to perform a preliminary study for a storage facility at the Project. Midgard was commissioned to study the Project as:

1) A conventional storage facility, and
2) A pumped storage facility.

Past studies for the Project as a conventional storage scheme or a run-of-river have been performed by Klohn-Crippen Consultant Ltd ("KCCL") in 1992, KGS Group ("KGS") in 2008 and HDR Inc. ("HDR") in 2011. Past studies have all assumed diverting the flows from at least one adjacent basin increasing the project drainage area by 25.7 km^2 to 57.3 km^2. The energy yield estimated from those studies range from 27.4 GWh to 51.3 GWh for a capacity of 6.7 MW to 11.5 MW.

Midgard has studied the Project under the following three scenarios:

1) Conventional Storage: Assuming the Project regulates the flow of the Moon Lake drainage area of 57.4 km^2 and generates from November 1st through May 14th.
2) Pumped Storage (48GWh): Assuming there is 48 GWh of available pumping energy from weeks 20 to 44 (based on YEC 2022 forecast) in addition to the natural inflows at the Project. Generation is assumed from weeks 45 to 19.
3) Pumped Storage (70GWh): Assuming there is 70 GWh of available pumping energy from weeks 20 to 44 in addition to the natural inflows at the Project. Generation is assumed from weeks 45 to 19. This scenario was not based on forecast but was studied to determine the additional energy the Project could yield given additional pumping energy.

The option's Full Supply Level ("FSL") were sized to utilize the available storage while minimizing spills and drawdowns below Minimum Operating Level ("MOL").

As shown in **Table 1**, the Project yields 20 GWh of winter energy as a conventional storage scheme and 54 GWh to 69 GWh as a pumped storage scheme.

Table 1: Moon Lake Storage Energy Summary

Parameters	Conventional Storage	Pumped Storage (48 GWh)	Pumped Storage (70 GWh)
FSL (m)	1121	1125	1129
MOL (m)	1114	1114	1114
TWL (m)	713.2	713.5	713.5
Gross Head (m)	407.8	411.5	415.5
Generation Flow (m^3/s)	2.2	6.0	7.6
Pumping Flow (m^3/s)	N/A	4.1	6.2
Capacity (MW)	7.5	20.2	26.1
Annual Pumping Energy (GWh)	N/A	48	70
Annual Energy Output (GWh)	**20**	**54**	**69**

A pumped storage scheme will incur energy losses through the pumping phase and the generation phase. For the Project, about 30% losses were estimated. Therefore, the roundtrip efficiency of the pumped storage facility is estimated at 70%.

As a pumped storage scheme, the energy yield is limited by the available pumping energy. With an adequately sized dam, the terrain at the Moon Lake reservoir is able to accommodate more water than would be pumped by both the 48 GWh and / or 70 GWh of forecasted available pumping energy.

As the results from the conventional storage study were generally consistent with the results from past studies, it was agreed to primarily analyze the project as a pumped storage scheme and produce conceptual drawings, operation cost estimates, and levelized cost of energy ("LCOE") for the 48 GWh pumped storage scenario. From this base case alternative, cost estimates were then extended at a high level to the conventional storage and 70 GWh pumped storage alternatives.

The study was based on available previous reports, publically available mapping and hydrological data and from a brief site visit conducted in June 2015.

The proposed 48GWh pumped storage scheme will comprise a 31 m high, 700 m long earth dam at the outflow of Moon Lake, a 5.5 km long, 0.6 m diameter buried steel penstock, and a concrete and structural steel powerhouse some 400 m below on the shore of Tutshi Lake. The installed generation capacity will be 20.2 MW and pumping capacity of 18 MW.

The capital cost estimates for the three alternatives of the studied project options, exclusive of contingency, is shown in **Table 2**.

Table 2: Project Capital Cost Estimates

Project Component	Conventional Storage ($M 2015)	Pumped Storage 48GWh ($M 2015)	Pumped Storage 70GWh ($M 2015)
Project Development	$2.2	$2.2	$2.2
Civil Construction Costs	$105.1	$143.1	$169.1
Generating Equipment Costs	$5.0	$14.0	$22.1
Transmission and Interconnection Costs	$2.8	$2.8	$2.8
Owners Costs During Construction	$2.1	$2.1	$2.1
Total Project Capital Cost	**$117.2**	**$164.2**	**$198.2**
Contingency	$22.6	$32.0	$38.8
IDC	$15.2	$21.4	$25.8
Grand Total Project Capital Cost	**$155.0**	**$217.5**	**$262.9**

Annual operating costs and a financial model for the estimation of the Levelized Cost of Energy ("LCOE") were estimated for the 48 GWh alternative only. For this alternative, the operating costs were estimated to be $1.9 million ($2015).

The resulting project LCOE assuming a full utilization of installed capacity was estimated to be $0.189/kWh. A sensitivity analysis was carried out on LCOE assuming different capacity utilizations. The results of this sensitivity analysis are presented in **Table 3**.

Table 3: LCOE Sensitivity Analysis - 48 GWh PSH Alternative

Capacity Factor	Full Utilization Generation (GWh)	NPE (GWh)	NPV ($M 2015)	LCOE ($/kWh)
100%	54	1,412.8	267.5	0.189
90%	48.6	1,271.5	267.3	0.210
80%	43.2	1,130.2	267.2	0.236
70%	37.8	989.0	267.0	0.270
60%	32.4	847.7	266.8	0.315

Several existing rights have been identified at the project site and its vicinity. Prior to advancing the project further, a detailed investigation of the current and future existing rights is recommended to identify potential development barriers.

If a decision is made to advance the project into the feasibility study stage, the following field studies and data collection programs are recommended:

MIDGARD

V6E 4A4

1) Prepare a submit a **water licence application** to Front Counter BC so as to secure first-in-line water rights to the project ahead of other potential claimants. British Columbia recognizes the rights to water on a first come, first serve basis. Several existing rights have been identified at the project site and its vicinity. Prior to advancing the project further, a detailed investigation of the current and future existing rights is recommended to identify potential development barriers.
2) Project preliminary engineering and design can be further advanced with greater precision topography, obtained with a **LIDAR survey**. This survey is recommended to refine the design and quantity cost estimate. The LIDAR survey area should comprise the dam site, the penstock route, suggested at 200 m each side of the proposed penstock alignment, and the powerhouse site. The estimated area of study is 3.5 km^2.
3) A **geotechnical investigation** program is recommended to assess the foundation conditions of the dam and powerhouse as well potential anchor block locations at select major bends along the penstock alignment.

   During early stage project definition and development, seismic refraction lines present a cost effective alternative to estimate overburden thickness without incurring the cost of mobilization of drilling rigs across Tutshi Lake and into the upper Moon Lake watershed. Two seismic lines are recommended at the dam site: one along the dam axis and one perpendicular to the dam axis at the maximum dam height. Two lines are suggested along the penstock near route and two at the powerhouse. As project certainty is achieved, greater expenditure for project definition is justified and the results from the seismic analysis can be confirmed with boreholes.

   Boreholes are indicated at the powerhouse location because of the importance of better characterizing the construction excavation conditions adjacent to Tutshi Lake as well as characterizing the rock quality at the powerhouse. Further, boreholes are an important along the dam foundation, not only to characterize the depth to bedrock, but to also investigate the rock quality and permeability in order to plan dam foundation treatment. As such, the dam boreholes should extend into bedrock to a depth commensurate with the dam height and include in situ permeability testing of the rock. Location of the boreholes should be determined once greater resolution mapping becomes available.

   Finally, a dedicated site investigation to secure and confirm a source pit for the material for construction or the dam is recommended to be included with any geotechnical programme.

1 Introduction

1.1 Background

Yukon Energy Corporation ("YEC") is investigating the potential to develop a storage hydro project on Moon Lake, in northwestern British Columbia. As a utility, YEC experiences a winter peak load, combined with a summer peak in generation potential from its hydroelectric generating assets. A storage project at Moon Lake is intended to seasonally shift freshet flows and augment winter generation potential to better align with YEC's annual load profile.

YEC has a surplus of summer energy, resulting for a lower demand during those months combined with high freshet flows on the Yukon River and others. Currently, installed capacity on the Yukon River at Whitehorse is underutilized during the summer months and the surplus freshet flows are spilled.

Moon Lake, located 100 km south-southeast from Whitehorse, and 18 km south of the BC Yukon border, drains into Tutshi Lake from the south and is ultimately a tributary to the Yukon River, above Whitehorse. The Klondike Highway, between Carcross Yukon and Skagway Alaska traverses the north shore of Tutshi Lake.

A storage project at Moon Lake would have a double benefit to YEC inasmuch as stored summer flows would provide direct winter generation as well as marginally reduced freshet flows that would be spilled at Whitehorse. The winter generation flows at Moon Lake would also, ultimately report to the Whitehorse generating station as well.

A project on Moon Lake has been investigated several times in the past. These include studies by Klohn Crippen Consultants ("KCCL"), in 1992; KGS Group ("KGS"), in 2008; and HDR Inc. in 2011. KCCL and KGS proposed several arrangements of conventional storage schemes, simply storing summer flows at Moon Lake until winter and then slowly generating with those flows during YEC's peak load period (HDR proposed a run-of-river project directly on Moon Creek).

Tutshi Lake and its catchment have even greater flows than available in the Moon Lake catchment. YEC has proposed to develop a seasonal pumped storage scheme at Moon Lake, wherein spilled flows at Whitehorse, as well as other potential intermittent renewable energy sources (such as wind) would be used to pump flows from Tutshi Lake up to a dam on Moon Lake during periods of surplus energy. These flows, would then be stored with the natural flows in currently in the Moon Lake system to be used for generation during periods of generation deficit.

Midgard Consulting Inc. ("Midgard") has been retained to investigate the viability of a seasonal pumped storage hydro ("PSH") scheme on Moon Lake.

MIDGARD

1.2 Purpose and Scope of the Report

This report describes available background information and site characteristics as the basis for determining the overall viability of a pumped storage scheme for the Moon Lake Pumped Storage Project ("Project"). It details project site conditions, project hydrology estimates, the proposed project layout and ultimately a Class 5 cost estimate.

The Project, although being proposed by YEC, is in the Province of British Columbia. A high level Project Development Plan has also been prepared that outlines the steps and process, at a high level, to develop a hydroelectric project in that Province. This plan also provides preliminary cost estimates associated with project permitting and development activities, which also feed into the project capital cost estimates.

The report has been prepared to provide YEC with an assessment of the Project's potential to store and re-generate surplus energy from the YEC system to quantify its benefit. This combined with the capital cost estimates, and estimates of project operating costs, feed into an estimate the project's Levelized Cost of Energy ("LCOE").

The LCOE can provide a measure of project value relative to competing sources of winter energy that may be available to meet YEC's load in the future.

1.3 Salient Features of the Project

The proposed project will create a 690 ha reservoir over the existing Moon Lake and draw flows as need for generation from the reservoir. Water is stored directly from flows into the reservoir from the upper Moon Creek catchment as well as from pumped flows up from the lower Tutshi Lake.

Tutshi Lake has a nominal water level of 714 metres. The Moon Lake reservoir level will vary from a Minimum Operating Level ("MOL") of 1,114 meters and Full Supply Level ("FSL") of 1,125 metres.

The proposed project arrangement comprises a 31 m high, 700 m long earthfill dam with south abutment spillway and a low level outlet intake; a 5.24 km long, 1.6 m diameter buried steel penstock; and concrete and steel surface powerhouse containing a 20.2 MW vertical axis Pelton turbine and synchronous generator as well as two 9.4 MW peak power, variable speed drive vertical axis pumps. Flows are discharged to or drawn from a 7 m deep sump connected to Tutshi Lake.

MIDGARD

2 Background Information

2.1 Review of Previous Studies

2.1.1 Klohn-Crippen Consultants Ltd. ("KCCL")

KCCL performed a study of the project as a conventional storage facility in 1992. The study proposed three layout alternatives, each involving inter-basin diversion from neighbouring catchments into Moon Lake. For each of the three diversion alternatives, the remaining project layouts remained similar and comprised: an earthfill dam across Moon Creek, downstream of Moon Lake, a combined power canal and buried steel penstock conveyance to a concrete and steel powerhouse, founded on bedrock on the shore to Tutshi Lake.

The three proposed diversion alternatives were the following:

1) **Alternative 1:** Would regulate flows in the 58.9 km^2 Moon Lake catchment and would capture and divert flows from a 25.7 km^2 sub-catchment to the north of Moon Lake. The resulting combined project catchment of 84.6 km^2 would result in a mean annual discharge ("MAD") of 1.35 m^3/s. The 8.5 MW plant would generate an estimated annual energy of 36.3 GWh. Estimated project cost was $28.8 million ($1992) excluding transmission.
2) **Alternative 2:** Would regulate the flow from Moon Lake and divert and capture flow from an additional six neighbouring sub-catchments with a combined drainage area of 57.3km^2. The total resulting project catchment of 116.2 km^2 would result in an estimated average runoff of 1.83m^3/s and annual energy generation of 49.2 GWh from an 11.5 MW plant. Estimated project cost was $35.4 million ($1992) excluding transmission.
3) **Alternative 3:** Would be similar to the Alternative 2 diversion scheme but would generate energy throughout the year as opposed to through the winter period only. This would result in a smaller dam and reservoir as well as a lower installed capacity. Assumed generation throughout the year would be 51.3 GWh on an installed capacity of 8.5 MW. Project cost was estimated to be $30.1 million ($1992) excluding transmission.

It is noted that the proposed project layout by Midgard retains several similarities to the schemes proposed by KCCL. The proposed dam alignment and layout are similar as is the selection of conveyance route and powerhouse location.

However, unlike KCCL, a power canal is not generally suited to a pumped storage scheme, with the need to balance flows both in and out of the reservoir, at varying water levels. Further, in the current permitting regime in British Columbia, it is not considered practical to successfully permit hydroelectric projects that incorporate inter-basin transfer of flows. No such supplementary diversion infrastructure is contemplated in this report.

MIDGARD

2.1.2 KGS Group ("KGS")

In 2007 and 2008, KGS prepared an Assessment of Potential Hydroelectric Sites. This study included a concept study of eight potential hydro project sites, one of which was the Moon Lake site.

KGS proposed a conventional storage project with either a 3 m high dam or a 30 m high dam, with a water conveyance along the left (south) bank of Moon Creek and a powerhouse on the shore of Tutshi Lake. KGS also proposed an inter-basin diversion of flows for a total project catchment of 84.6 km^2. The three alternatives were the following:

1) **Alternative A** – 3 m high dam/intake/spillway and intake, with a canal or penstock to one of two powerhouse locations on the east shore of Tutshi Lake. Estimated annual energy was 33 GWh on an installed capacity of 5.7 MW.
2) **Alternative B** – 30 m high dam/intake/spillway, canal or penstock, intake to the powerhouse options on Tutshi Lake. KGS did not report energy and capacity for this alternative.
3) **Alternative C** – 3 m high dam at Moon Lake and a low level intake located further downstream, and then a canal or penstock to the powerhouse on Tutshi Lake. The estimated annual energy was 28 GWh with an installed capacity of 4.9 MW.

2.1.3 HDR Inc. ("HDR")

HDR performed a study of the Project as a run-of-river facility in 2011. The project estimated capacity was 6.7 MW and annual energy was 27.4 GWh.

2.2 Site Investigation

On June 24th 2015, a helicopter over-flight of the site was carried out for the purpose of confirming the overall site terrain as well as providing visual reference to the geological and geotechnical inferences developed from review of previous studies and desktop available data.

Conditions were ideal, with high visibility and calm winds. The itinerary for the visit was as follows:

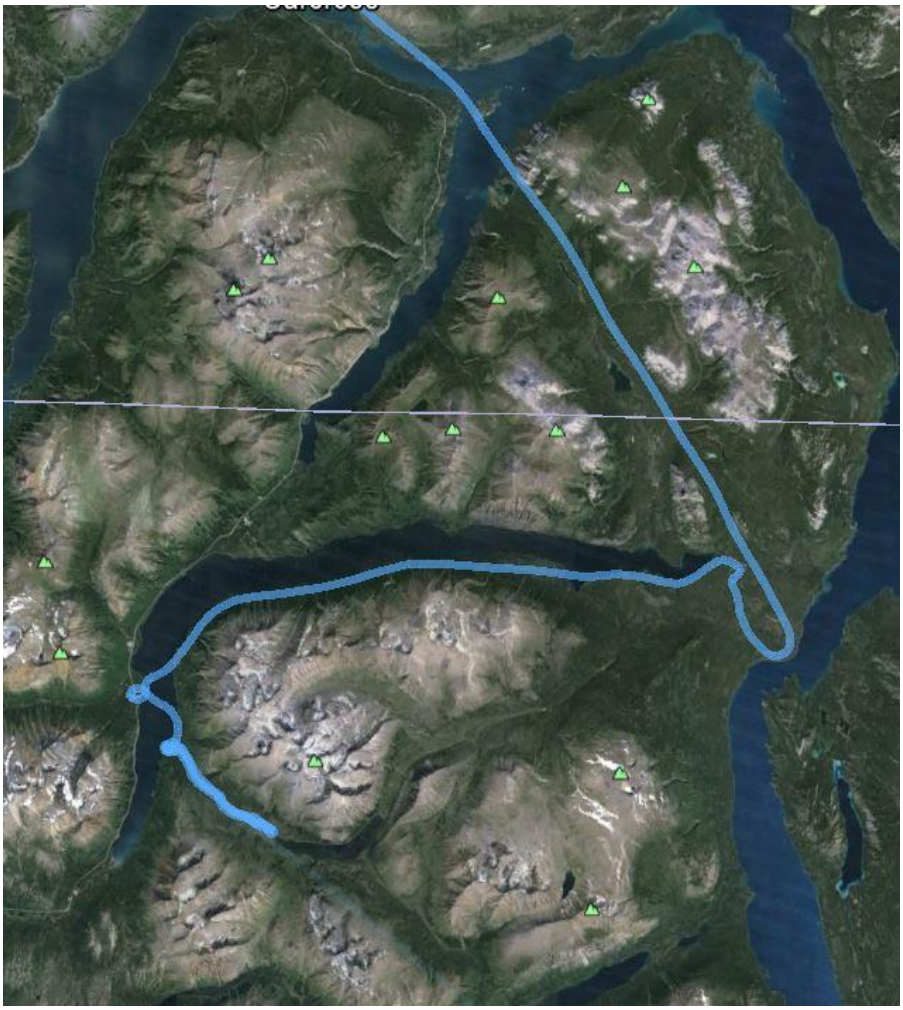
1. Transit from Whitehorse to Bennett, BC;
2. Flight over upper Tutshi watershed to develop a visual sense of terrain and glacier cover;
3. Flight up Moon Creek from Tutshi Lake to upper Moon Lake catchment to confirm terrain;
4. Touch down on lake to confirm barometric elevation;
5. Slow flight down and then up Moon Creek from dam site to powerhouse to confirm conveyance route and powerhouse location;
6. Touch down on Tutshi Lake to confirm barometric elevation of Tutshi Lake;
7. Fly over Tutshi Lake outflow between Tutshi and Tagish Lakes to develop visual sense of reach aquatic habitat;

MIDGARD

8. Return transit to Whitehorse.

Figure 1 shows a partial flight path around Moon and Tutshi Lakes.

Figure 1: Site Visit Flight Path



The following are discussions and conclusions derived from the site visit.

Dam Axis Alignment

During the site visit, several potential dam alignments were reviewed. It was concluded that a dam axis crossing the creek approximately 1.4 km downstream of the outfall of the lake. The approximate coordinates are Latitude 59°50'16.24"N and Longitude 134°41'56.08"W. This location was selected because of evident surficial bedrock and presumed near surface bedrock along the dam alignment as well as favorable topography along the left abutment that will tend to reduce dam height and material volumes. **Figure 2** provides a view of the proposed dam alignment at the creek, looking upstream toward Moon Lake.

MIDGARD

Figure 2: Proposed Dam Location

Maximum Reservoir Containment Elevation

The best available topographic mapping is at a 20 metre contour resolution. A tributary to the lake from the southeast was identified as having a relatively low saddle-break into the adjacent watershed. Using comparative barometric elevations from the lake surface to the saddle-break, it was established that the maximum reservoir elevation that would be contained within the watershed, without the addition of a saddle dam at this location is 1141 metres. The location of the saddle-break is shown on **Figure 3**.

Figure 3: Saddle-Break Location

MIDGARD

Penstock Alignment

A conveyance alignment on the river-left (Southwest) bank was selected due to more favorable terrain and lower gradient cross slopes.

Powerhouse Location and Tutshi Lake Elevation

The powerhouse is proposed at a cleared area north of the confluence between Moon River and Tutshi Lake (See **Figure 4**). The Tutshi Lake water level was measured on site at 714 m.

Figure 4: Proposed Powerhouse Location

MIDGARD

3 Site Characteristics

3.1 Access

The Klondike Highway, between Carcross, Yukon and Skagway, Alaska, runs along the north shore of Tutshi Lake. There is no current or historical road access to Moon Creek. Construction of road access around the upstream end of Tutshi Lake would require 7 km of new, fairly difficult road construction, combined with a significant bridge span across the Tutshi River.

For the purposes of this study, it is therefore concluded that construction access to the site would be by barge across the lake from the Klondike Highway.

For this purpose, there is ample low bank access to the lake along the highway for barge access on the lake.

3.2 Regional Terrain Characteristics

The Moon Lake watershed lies within the Boundary Ranges of British Columbia Coast Mountains. The topography of the region is typified by broad U-shaped valleys flanked by hanging valleys with steep side slopes.

The Boundary Ranges extend some 800 km northwest from the mount of the Nass River along the BC-Alaskan border into the Yukon. The peaks of this range are typically lower than the peaks of the southern coast mountains but retain significant glaciation due to their northern latitude. Geologically, the predominant bedrock of the region is from granitic intrusions of the Coast Arc Range of the Late Cretaceous geologic period (66 to 100 million years ago). The granitic intrusions formed the basement of the Coast Arc volcanoes, which have substantially eroded away. One notable exception is the Bennett Lake volcanic complex, remnants of which remain some 40 km to the northwest of the project.

SLR characterized the project area more specifically as “mountainous with glaciated valleys having veneer of glacial drift over bedrock. Moon Lake is located within a broad U-shaped valley that is flanked by high elevation mountainous terrain. The area of the outflow channel from Moon Lake and several hundred metres downstream appears to have a thicker organic layer that may have be an infilled section of the lake basin composed of alluvial material. Bedrock outcrops are evident a few hundred metres downstream of Moon Lake becoming more frequent with distance from Moon Lake. It appears that the stream to Tutshi Lake is generally bedrock controlled. Glaciofluvial features also appear to be evident down the valley from Moon Lake to Tutshi Lake where there are high banks of exposed overburden. This material is a possible source of both fine and course dam construction fill (to be verified).” See Appendix A for SLR’s Geotechnical Memorandum.

MIDGARD

3.3 Topography

The project general arrangement concepts as well as hydrologic assessment of the watersheds has been carried out using mapping from DataBC with 20 m contours topography based on the Provincial TRIM 20,000 scale dataset.

Bathymetric data for neither Tutshi Lake nor Moon Lake was found. Based on the site visit, it is evident that the outflow of Moon Lake is bedrock controlled, limiting the practicality of accessing negative storage from the existing lake.

3.4 Reservoir Storage Curves

3.4.1 Moon Lake

A reservoir storage curve was developed for the proposed Moon Lake reservoir using the 20 m topography. Reservoir surface areas were measured at 20 m contour intervals and the assumed dam axis alignment. Volumes were computed using an average end area methodology.

In order to establish a base water level, data from the installed Water Survey of Canada ("WSC") gauge near the outflow of the lake was access. Select water levels from that gauge, as measured through 2013, are summarized in **Table 4** below.

Table 4: Moon Lake Measured Water Level

Item	Water Level (m)
Min Water Level (m)	1,113.8
Max Water Level (m)	1,114.2
Average Water Level (m)	1,113.9
Average Winter Lake Level (m)	1,113.8
Average Summer Lake Level (m)	1,113.9

Further, during the June 24th site visit, using a barometric pressure altimeter from the helicopter, the lake water level at Moon Lake was also measured at 1,114 m. For the purposes of this report, it was concluded that, due to the relative low variation in lake level, the base water level at Moon Lake is 1,114 m.

A Moon Lake reservoir storage curve was developed from the base lake level of 1,114 m up to 1,160 m at 20 m intervals. The available live storage volume are shown in **Table 5** and **Figure 5**.

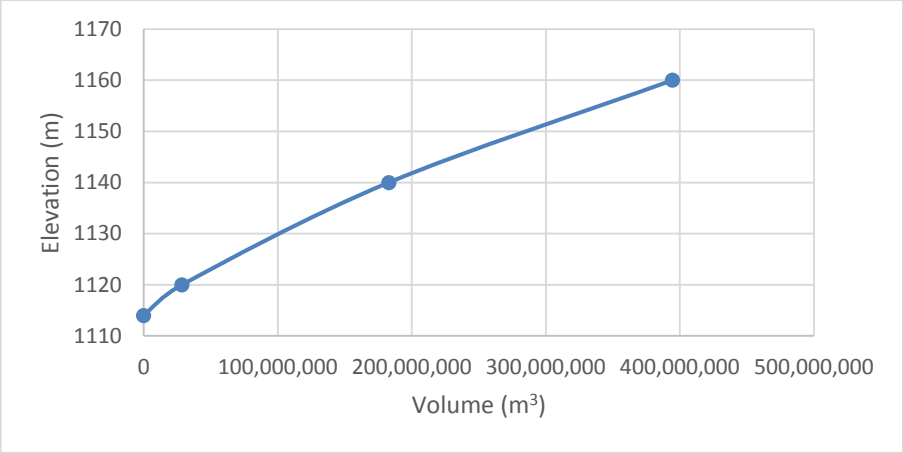
The measured lake area at EL. 1,114 m is 3.44 km^2.

MIDGARD

Table 5: Moon Lake Storage Areas

Elevation (m)	Area(km^2)	Volume (m^3)
1,114	3.437838	0
1,120	6.080000	28,553,514
1,140	9.350000	182,853,514
1,160	11.810000	394,453,514

Figure 5: Moon Lake Storage Curve



3.4.2 Tutshi Lake

Similarly, the WSC gauge, 09AA018, at Tutshi Lake recorded lake levels throughout 2012. The lake water level on Tutshi Lake was measured at 714 m during the June 24th site visit. Select measured water levels on Tutshi Lake are shown in **Table 6**.

Table 6: Tutshi Lake Estimated Water Level

Item	Water Level (m)
Min Water Level (m)	713.1
Max Water Level (m)	714.6
Average Water Level (m)	713.5
Average Winter Lake Level (m)	713.2
Average Summer Lake Level (m)	713.9

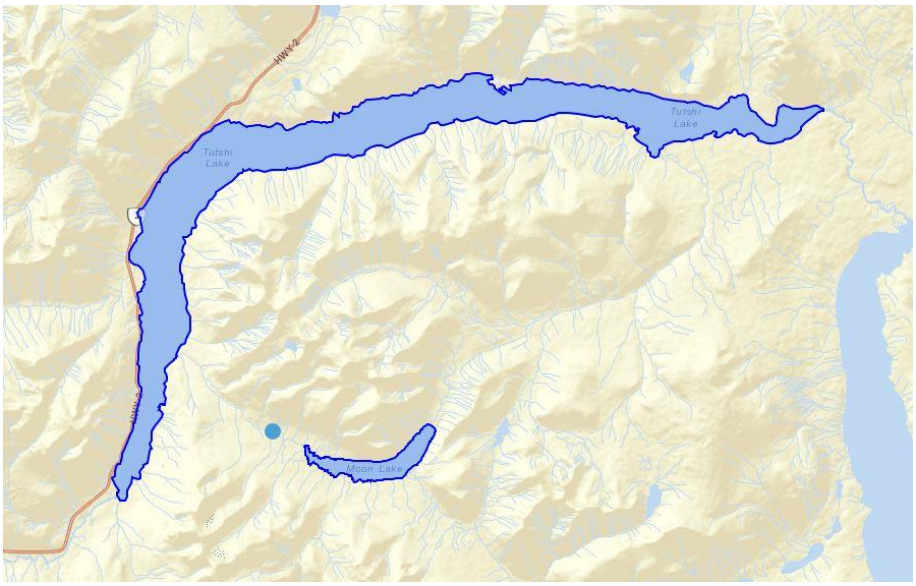
A base lake level of 714 m was selected for this report.

The measured surface area of Tushi Lake at EL. 714 m is 52.84 km^2. The Tushi Lake surface area is significantly larger than the proposed Moon Lake reservoir. Further, inflows and outflows from Tutshi Lake will remain uncontrolled during project operations and as such, project operations are not expected to have a

material effect on the water levels of Tutshi Lake. Particularly not within the resolution of available mapping. Consequently, no storage curve was developed for Tutshi Lake.

The Project Lake and the Tutshi Lake areas are shown in **Figure 6**.

Figure 6: Moon Lake and Tutshi Lake Areas



3.5 Hydrology

3.5.1 General

Moon Creek is a second order creek draining Moon Lake and the flanks of Jack Peak to the north and Skelly Peak to the south. The drainage basin is situated in the Boundary Ranges of the Coast Mountains of BC and Alaska.

Moon Creek has a drainage area of 57.4 km^2 at the proposed dam, of which 6 percent (3.44 km^2) is lake surface area. There is no appreciable glacial ice within the watershed.

Tutshi River is a third order river draining into Tutshi Lake and from Tutshi Lake to Tagish Lake from its headwaters to the west near the Alaska border. Tutshi Lake, at its outflow, has a drainage area of 979 km^2 of which 6.8 percent is lake surface area (66 km^2) and 1.5 percent (14 km^2) is glacial ice or snow field.

The region's hydrology is nival, driven primarily being the melt of annual snowpack over the summer, which produces a moderate but sustained flow.

MIDGARD

3.5.2 Stream Flow Gauges

Environment Canada, through the Water Survey of Canada ("WSC"), maintains two current streamflow gauges in the area of the project. **Table 7** provides a summary of the average annual flows or Mean Annual Runoff ("MAR"), drainage areas and years of record for the two gauges.

Table 7: Regional Stream Flow Gauges

Gauge Name	WSC Number	Period	Complete Years of Record	Drainage Area (km^2)	Mean Annual Runoff ($L/s/km^2$)
Moon Creek near the outlet of Moon Lake	09AA018	2012 - 2015	2	53.0	14.9
Tutshi River at outlet of Tutshi Lake	09AA013	1956-2015	45	989	16.2

The estimation of the project hydrology is very much facilitated in this instance because there has been a gauge installed on the same third order catchment as the project stream and there are at least two concurrent years of data between the project gauge and the long run gauge. The Moon Lake gauge represents 5.3 percent of the Tutshi Lake basin. Both gauges are maintained by the WSC.

Both gauges demonstrate a comparable MAR and both have similar areas of lake coverage. There is marginally more glacial coverage in the Tutshi basin, which, in this period of glacial retreat, can help to explain the marginally higher MAR within that basin.

3.5.3 Hydrology Used in the Energy Production Model

Midgard developed a synthetic daily flow series for the proposed dam site using a regression analysis on the concurrent data from the Moon Lake and Tutshi Lake gauges.

Data was sorted by month and compared using a direct temporal (day for day) comparison in order to generate a relationship for each month. The regression was performed with each daily matched pair of flows from July 27, 2012 through July 6, 2015[1].

The data at the Moon Lake and Tutshi Lake gauges demonstrated strong correlation as expected. The synthetic average monthly flows are listed in **Table 8** and a comparison of flow duration curves of the measured and the synthetic data set is shown in **Figure 7.**

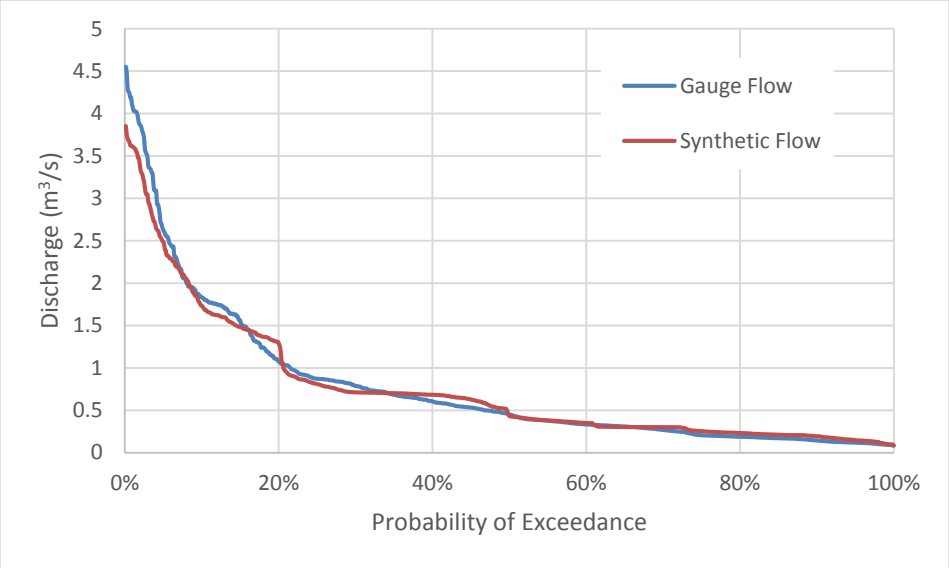
[1] The 2014 to 2015 data are provisional. Provisional data has not undergone WSC's QA/QC confirmation yet. Midgard chose to make use of the additional data because the benefit of the additional data in refining regression results. The results may be refined when WSC publishes its final data.

MIDGARD

Table 8: Synthetic Average Monthly Flows (m^3/s)

Month	WSC Gauge Site	Dam Site
January	0.21	0.23
February	0.23	0.25
March	0.21	0.22
April	0.19	0.20
May	0.72	0.78
June	2.25	2.44
July	1.89	2.05
August	0.85	0.92
September	0.71	0.77
October	0.57	0.61
November	0.36	0.39
December	0.30	0.33
Average	**0.71**	**0.77**

Figure 7: Moon Lake Gauge Flow Duration Curves



Based on the regression model results, a synthetic string was obtained from the Tutshi Lake Gauge data and the area proration between the Moon Lake Gauge watershed area and the Project watershed area. The drainage area factor between the gauge and the project is 1.08.

Data was recorded at the Tutshi Lake Gauge from 1956 to today, however, only the data from 1966 to today was recorded continuously. Only partial data was recorded in 1987 and 2000, and no data was recorded in 1998 and 1999, therefore year 1987, 1998, 1999 and 2000 were removed from the dataset to generate a 45-year synthetic string.

MIDGARD

3.5.4 Frequency Distribution and Flood Estimates

A frequency distribution analysis of the synthetic annual maxima was carried out to estimate expected flood flows and their respective probability at the dam site.

At this level of study, and given the limited amount of regional data, Midgard elected to extend the frequency distribution analysis for extreme floods for the purposes of sizing flood routing capabilities at the dam site up to 1000-year flood. It is acknowledged that an extended frequency distribution for long return period annual maxima is generally considered to be inappropriate for determining the inflow design flood ("IDF") for dam and spillway design. Further flood estimates are warranted if the project advances through higher stages of development and design.

The flood flows, using Log-Pearson III distribution, are presented in **Table 9**. The 500-year and 1000-year floods were estimated by extrapolation.

Table 9: Estimated Flood Flows at the Proposed Dam

Frequency	Flood (m^3/s)
5-year	4.41
10-year	4.98
50-year	6.15
100-year	6.61
200-year	7.06
500-year	7.55
1000-year	7.90

3.6 Existing Water and Land Rights

The successful development of a waterpower project in British Columbia on Crown Land presumes that there are no competing prior rights to either the land base or the surface water rights. A preliminary investigation was carried out using the publically available provincial database to ascertain the potential existence of any prior rights.

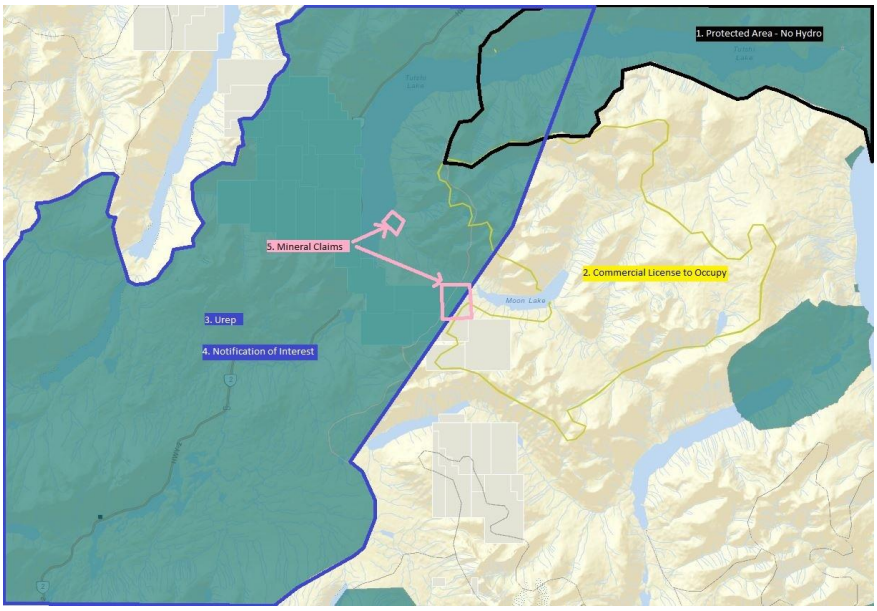
The search revealed several prior land rights and one water licence being present on or near the project area as summarized in **Figure 8**.

1) A protected area tenure exists on the downstream portion on Tutshi Lake. The tenure has an explicit clause precluding the development of hydroelectric projects or any water control facility. The protected area does not include the project area, but it is worth noting.
2) A Commercial License to Occupy exists on the project area for Guide Outfitters. The tenure does not preclude other licenses on the project area. However, in concert with this licence, there is a cabin near the south shore of Moon Lake which would be impacted by the proposed reservoir of the project.

MIDGARD

3) A Use, Recreation and Enjoyment of the Public ("UREP") map reserve exists on Tutshi Lake and the downstream portion of the project. A map reserve is a land use reserve that is established under Sections 11 or 12 of the Land Act over an area of Crown land outside of Provincial Forests to guard against unwarranted disposition or unplanned use (in this case, sale or use that would compromise an area's current or potential recreation values or uses).[2]
4) A notification of interest exists on the project area.[3]
5) Five mineral claims exist on downstream portion of the project area.
6) A historic water licence application was registered in 1991 for a power project on Moon Lake. This application has since been abandoned.

Figure 8: Prior Rights Summary



3.7 Terrestrial Wildlife and Aquatic Habitat

No Specific research was carried out on terrestrial wildlife or aquatic habitat values.

It is noted that the Tutshi River, between Tutshi Lake and Tagish Lake is a broad riffled reach with an average gradient of 0.5% over its 7.3 km length. Visual observation during the over-flight suggests that there are no falls or other potential barriers to fish migration.

[2] https://www.for.gov.bc.ca/hfp/publications/00201/appen05/appen05.htm

[3] A notification of interest is one types of land status regarding the apportionment, setting apart or earmarking of land or water for an indication of interest.

MIDGARD

Due to the nature of the channel, a higher than typical instream flow is assumed to be required to maintain an overall wetted perimeter in the channel and preserve fish habitat. An instream flow in the reach is assumed because, pumping flow from Tutshi Lake into Moon Lake can impact outflows from Tutshi Lake.

The Moon Creek reach between Moon Lake and Tutshi Lake is very steep, with an average gradient over 7 percent. Anecdotally, Moon Lake is fish bearing but this has not been confirmed. A lower instream flow release has been assumed between the dam and Tutshi Lake but a cost allowance has been made for maintaining fish passage over the dam.

There were no evident showstoppers to the project from the perspective of terrestrial wildlife values.

MIDGARD

4 Facility Description

4.1 Background

The basic concept of the facility is to develop an upper reservoir on Moon Lake that will enable the generation of winter energy, when regional flows and flows on the Yukon River basin are at their lowest. To achieve this, a dam is proposed downstream of the outlet of the lake equipped with a gated intake tower, spillway and low level outlet. A buried penstock will convey flows from the intake to a powerhouse on the shores to Tutshi Lake, some 400 m below in elevation.

As a conventional storage facility, the dam height would be optimized to accommodate the annual freshet and summer flow from the upper basin of Moon Lake, with some allowance for potential spill during extreme flood years. The penstock would be optimized for its cost versus the present value of foregone energy that result from hydraulic losses of head in the system. The powerhouse would house a turbine and generator unit, most likely a Pelton unit given the head and flow profile of the project.

For a pumped storage scheme, the overall project layout would remain the same as a conventional scheme with the following exceptions. First, the dam height would increase to not only impound natural flows from the upper catchment, but also the volume of flow that would be pumped from Tutshi Lake; second, the penstock would be optimized for a higher design flow; and third, the powerhouse would also have to accommodate a pump and intake from Tutshi Lake.

This section describes the conceptual layout of the Project as a pumped storage facility. During high flow period, the energy generated from the spill at Whitehorse hydroelectric station or other to be determined energy sources on the YEC grid, will be used to pump water from Tutshi Lake into the Moon Lake reservoir for winter energy storage. During low flow periods, energy will be generated form the stored water to contribute to the Yukon winter load demand.

4.2 Diversion

In order to construct the dam across the outlet of Moon Lake, it is necessary to divert flows from the dam foundation. Typically, this is accomplished with a temporary diversion channel or tunnel, which allows the dam to be constructed in the dry. In the case of this project, a low-level outlet pipe is proposed under the dam foundation. During construction, the water at Moon Lake will be diverted through the low-level outlet pipe of the dam.

The 200 m long diversion pipe will be encased in concrete. The dam will constructed be on top of the diversion pipe, which will stay in place after construction.

MIDGARD

4.3 Dam

The dam will be founded on bedrock. The depth of overburden is assumed to be 3 m and will need to be verified through a geotechnical investigation program. The overburden is assumed to be consisting of glacial moraine deposits and organics. Primary to tertiary grouting curtains will be placed to prepare the foundation.

The project is designed with a 31 m high[4] and 700 m long earthfill dam. The dam structure is primarily composed of a homogeneous core of fine local till material. At this stage the material is assumed sufficiently fine to limit most of the seepage. An upstream bituminous liner may be installed to provide additional seepage control but was no included at this stage. Bituminous liners are often used in the north because of the ease of placement during cold weather and its ability to handle extreme temperature fluctuations. An internal drainage system consisting of a downstream gravel filter and drainage blanket will be incorporated to the structure. Riprap will be placed on the upstream face to provide erosion protection.

Per the Canadian Dam Association's Dam Safety Guidelines:

1) "Significant" hazard classification implies only temporary population at risk within the dam-breach inundation zone (e.g., seasonal cottage use, passing through transportation routes, or participating in recreational activities). In the event of a dam failure, the potential loss of life is unspecified, no significant loss or deterioration of fish or wildlife habitat is expected, and losses to recreational facilities, seasonal workplaces, and infrequently used transportation routes are expected.
2) "High" hazard classification implies only permanent population at risk within the dam-breach inundation zone. In the event of a dam failure, the potential loss of life is 10 or fewer, significant loss or deterioration of *important* fish or wildlife habitat is expected, and high economic losses affecting infrastructure, public transportation, and commercial facilities are expected.

For conservatism at this stage of the study, the dam is classified in the "High" hazard category and is designed for a 2475-year seismic event. The design includes 3 m of freeboard for flood retention and to prevent overtopping, and a spillway over the south rock abutment to pass high flow events such as floods and summer peak flows. The dam crest is assumed to be 6 m wide.

4.4 Spillway

The dam includes a 2 m wide and 300 m long gated concrete spillway structure on the river-left (South) bank rock abutment that controls water flow releases during high flow periods. The spillway is designed to release flows up to the Inflow Design Flood ("IDF")[5]. The spillway structure includes a concrete inlet channel with a 2 m X 2 m gate, stoplogs and concrete chutes which return the water to the river. The foot of the spillway and

[4] Includes 3 m of excavation.

[5] At this stage of study, the IDF is assumed as 1000-year return period flood flow.

area immediately downstream includes a stilling basin designed to withstand the erosive effects of the spillway water flows and to dissipate energy.

4.5 Fish Passage

A fish passage has been assumed to facilitate potential downstream fish migration. Given the overall gradient of the creek below the dam, it is assumed that there will not likely be significant upward fish migration. However, given anecdotal suggestion that the lake is fish bearing, it bears consideration that the lake population may seed downstream fish populations in the creek. Additional research is required to ascertain the practicality of fish passage over the dam.

4.6 Reservoir

The proposed dam creates a reservoir upstream of the dam site. The natural lake level area is 3.44 km^2. The minimum operating level ("MOL") of the water reservoir is 1,114 m. The estimated FSL of the water reservoir is 1,125 m and floods a total area of approximately 6.90 km^2, providing a live storage volume of 67.1 million m^3.[6] The incremental flooding area is from the lake level to FSL is 3.46 km^2.

The flooded area includes an existing outfitter cabin in the southeast shore of Moon Lake.

4.7 Intake

The water intake is a concrete tower structure located on the river-right (North) bank and is based on rock foundation. The intake is connected to the penstock that will convey water for electric generation and pumping during operation up to the full plant design flow of 6 m^3/s. The intake box will provide sufficient submergence to prevent vortex formation from FSL to Minimum Operating Level of 1,114 m.

The main components of the intake include:

1) Trash Racks - To prevent driftwood and other floating debris such leaves from being entrained by the water conveyance structures.
2) Trash Rack Cleaning Equipment - To allow for clearing of entrained debris.
3) Head Gate Structure - To provide the ability to stop water flow into the water conveyance structures as part of regular maintenance or for emergency purposes.
4) Sluice Gate – To flush out the sediment from the intake box.
5) Fish exclusion screen – To prevent fish and other aquatic species from entering the penstock.
6) IFR pipe design for constant IFR of 5% MAD, through the dam
7) Electrical Power Supply and Controls.

[6] Live storage volume is between FSL and MOL.

MIDGARD

All steel metal work shall be galvanized for corrosion protection.

4.8 Penstock

A 1.6 m diameter buried steel penstock will convey water for generation and pumping. A minimum of 1.2 m of soil cover is assumed at this stage. The proposed alignment is 5.5 km long on the river-left (Southwest) bank. The alignment includes 7 bends that will likely require structural restraint such as soil restraint or anchor block. The penstock crosses 4 stream channels that will likely require overdrains or bridge crossings. A surge shaft is assumed at this stage, however further transient analysis studies may discard the need for a surge shaft. The penstock includes a bifurcation at the end of the alignment to connect to the pumping and generating unit at the powerhouse.

4.9 Powerhouse

The surface powerhouse is located downstream of the dam on the river-left (Southwest) bank. The approximate footprint of the powerhouse is 550 m^2. The powerhouse is designed one horizontal Pelton unit and one vertical shaft pump.

The powerhouse will be a cast concrete substructure, founded on bedrock, with a pre-fabricated structural steel superstructure.

The powerhouse contains all required operational, maintenance, and protection and control equipment required to operate the facility. Loading bays and an overhead crane will allow for maintenance access during operations. A tailrace channel directs water from the submergence pool back to the river.

4.10 Generating Equipment Selection

The relative smaller scale of the project limits the commercially available alternatives for turbines and pumps. A larger scale pumped storage scheme would typically combine the turbine and pump equipment by using a Francis Turbine, which is physically capable of both modes of operation.

When generating with a Francis turbine, available flows are controlled by the use of wicket gates that can close or open to either control the throughput of the unit, or maximize the efficiency of a unit to available flows. The wicket gates are not used during pumping operations. Pumping can be made more flexible with the addition of a variable frequency drive (“VFD”) which allows the unit to be optimized to available flow and power.

It is unlikely that an optimized and efficient solution is commercially available for an under 20 MW Francis unit. Further, the head and flow profile of the scheme indicates a Pelton generating unit, which is not capable of pumping operations.

MIDGARD

Consequently, the selected solution for this report is a vertical axis Pelton turbine with synchronous generator mounted above the 200-year flood level (715.6 m) of Tutshi Lake. The Pelton unit will accommodate generation flows from 3 m^3/s to 6 m^3/s.

Two separate, vertical axis, pumps, with direct coupled VFD and an extended shaft, will be 7 m below normal lake level of 713.5 m for submergence. The pumps have a combined design flow capacity of 4.1 m^3/s. The use of Variable Frequency Drive will allow the pump to accommodate flows from 50% to 100% of the capacity of each pump. Multiple pumps have been selected because of the potential range in pumping energy as well as to minimize overall size of the units.

4.11 Switchyard

The switchyard is a fenced area which contains transformers and electrical protection equipment (such as circuit breakers and disconnect switches). The approximate footprint of the switchyard is 250 m^2. The electricity produced via the turbine-generators inside the powerhouse is conveyed at an intermediate voltage to the switchyard located adjacent to the powerhouse. In the switchyard, the intermediate voltage is transformed up to a 138 kV transmission voltage and transported to the Yukon electrical grid via a 138 kV transmission line.

4.12 Transmission Line and Interconnection

The work assumes the pre-existence of a 138 kV transmission corridor along the South Klondike Highway all the way to Whitehorse.

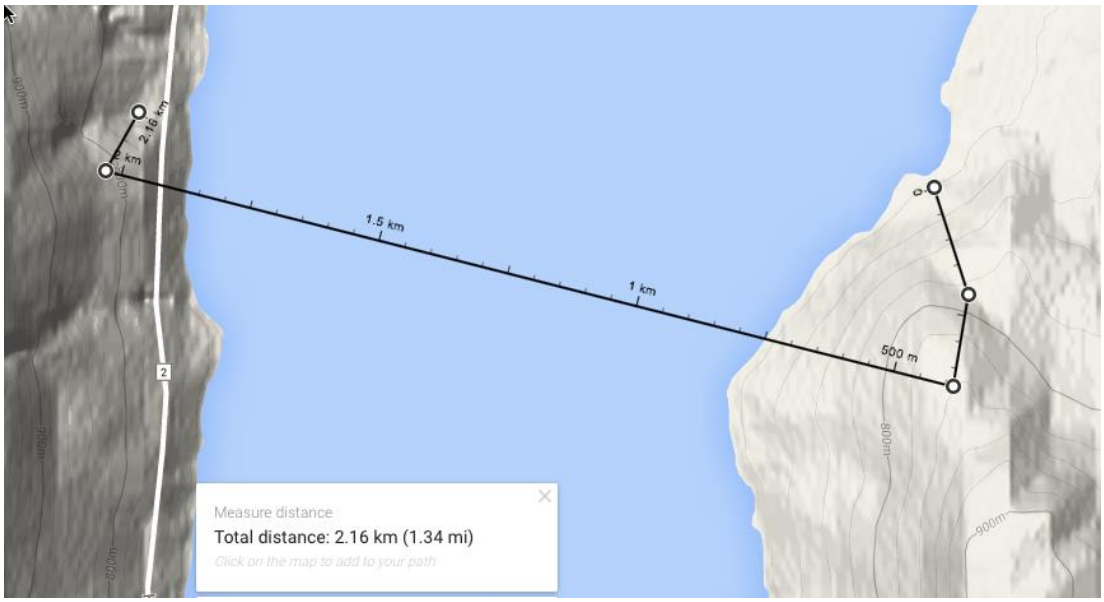
Two potential interconnection options are available. These are either an overhead span across Tutshi Lake or a sub-marine cable under the lake.

The overhead alternative would comprise an overhead transmission line 400 m south from the powerhouse switchyard up the hill to elevation 840 m, then a 1.6 km span across the lake and a 200 m overhead line down to the assumed 138 kV ROW along the Klondike Highway.

This transmission option is shown in **Figure 9**.

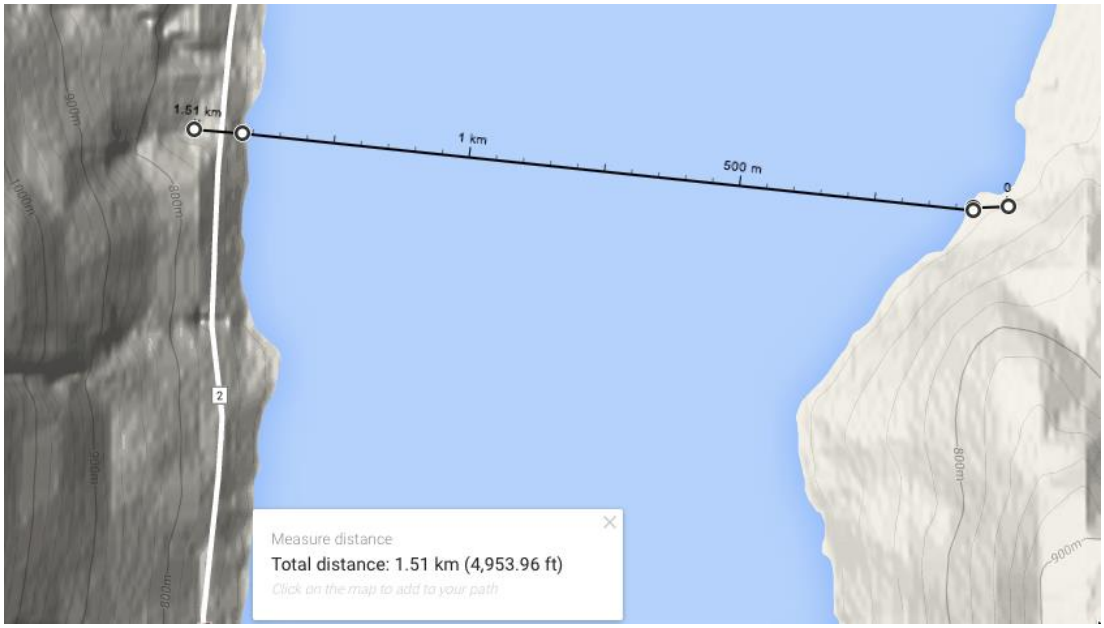
MIDGARD

Figure 9: Overhead Transmission Route Alternative



The underwater alternative would comprise a 50 m buried cable, directly from the powerhouse switchyard to the lakeshore and a 1.4 km underwater cable across the lake and a 50 m buried cable to a riser structure at the assumed ROW. This alternative is shown in **Figure 10**.

Figure 10: Underwater Transmission Route Alternative



High level cost estimates indicate that both alternatives have the same order of magnitude cost. The final selection of the alternative will be combination of final cost and permitting constraints.

MIDGARD

4.13 Temporary Construction Works

Additionally, a number of temporary construction phase facilities are anticipated during the construction period, including:

1) Site Office and Construction Camp
2) Workshops, labs, and testing facilities
3) Fabrication shops
4) First aid / safety / safety stations
5) Staging / lay down areas
6) Waste water treatment plant
7) Concrete batch plants
8) Truck washing stations
9) Explosives storage
10) Fuel storage and refuelling

4.14 Access Structure

A barge access from the Klondike Highway to the east shore of Tushi Lake is assumed. Approximately 5.5 km of new road is required to access the project from the barge access to the dam site. The proposed access infrastructure is required for both construction activities (e.g. moving of heavy equipment and materials) and operations activities (e.g. operator access). The road alignment will approximately follow the penstock alignment.

4.15 General Arrangement

Figure 11 shows the proposed general arrangement.

5 Energy Yield Models

The conversion of a long run flow series to an appropriate forward looking estimate of Project energy generation requires the application of project specific design parameters, environmental in-stream flows and operating assumptions and limitations.

Two energy yield models were developed by Midgard to estimate the energy production of the Project based on the daily synthetic flow series;

- Conventional Storage Model; and
- Pumped Storage Model (48 GWh and 70 GWh scenarios).

The conventional storage model operates on a daily water balance basis. The model estimates the energy generation as a conventional storage project, with flows available only from the upper Moon Lake catchment.

The pumped storage model was created to estimate the energy consumption and net generation of the Project with flows available from both Moon Lake and Tutshi Lake, where flows from Tutshi Lake are pumped into the Project storage reservoir during high flow/low energy demand periods.

Inputs to both models include the daily estimated flow series (based on the WSC gauges); the environmental flows that have been assumed based on the diversion reaches; the conceptual project layout; the available gross head and the estimated hydraulic efficiency of the water conveyance system; the assumed turbine and generator efficiencies; and estimates of transmission and transformer losses.

For the conventional storage scenario, the model examines the daily average flow for each day of the flow series and deducts the In-stream Flow Releases ("IFR") to obtain the available flows for generation, then calculates the head losses and the resulting net head, selects the appropriate water-to-wire efficiency and calculates the daily energy generation.

For the pumped storage scenario, the model performs an analysis on the season and available flows in Tutshi Lake for pumping to first fill the reservoir and then, estimates winter energy generation as in the conventional scenario.

5.1 Inputs and Assumptions

5.1.1 Hydraulics

The gross and net heads of the plants are governed by natural and existing features as well as the head losses incurred at the plant. For Pelton turbines, the available gross head is defined as the difference between the headwater level in the reservoir and the centreline of the turbine runner.

MIDGARD
Midgard Consulting Inc

midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

The powerhouse floor and the resultant turbine runner centreline are typically controlled by the flood elevations for varying flood events with the setting normally being higher than the 200-year flood event level. The gross head inputs for the three scenarios are listed in **Table 10**.

5.1.2 Hydraulic Losses

Hydraulic losses are losses of energy that typically result from the following:

- Hydraulic friction between the water flowing through the passages;
- Changes in flow velocities; and
- Factors that disturb the flow pattern such as trash racks, penstock, trifurcation, needle valves, etc.

The hydraulic losses are measured in meters and vary exponentially with flow velocity. These losses result in a corresponding reduction in the available net head and resultant power output and energy.

Midgard has assumed friction losses within the penstock using as a maximum of 5% of the maximum gross head of the project. The penstock was sized from this assumption. At lesser flows, the hydraulic losses are estimated with the following relationship:

$$Head\ Loss = k \times Q^2$$

Where:

$$k = \frac{5\% \times Max\ Gross\ Head}{Q_D^2}$$

Table 10 presents the Project's hydraulic characteristics utilized as inputs to the energy models.

Table 10: Hydraulic Characteristics

Input	Conventional Storage Model	Pumped Storage Model (48WGh Case)	Pumped Storage Model (70WGh Case)
Maximum Plant Flow (m^3/s)	2.2	6.0	7.6
Full Supply Level (m)	1121	1125	1129
Minimum Tailwater Level (m)	713.2 (Winter Average)	713.5 (Yearly Average)	713.5 (Yearly Average)
Maximum Gross Head (m)	407.8	411.5	415.5
Modeled Maximum Head Losses (5% of Gross Head) (m)	20.4	20.6	20.8
Minimum Net Head (@ Q_D)	387.4	390.9	394.7

5.1.3 Other Model Inputs

The daily flows and the reservoir storage levels that played into the storage models are described in Section 3.5: Hydrology and Section 3.4: Reservoir Storage Curve, respectively.

Vancouver BC, Canada
V6E 4A4

In-stream Flow Requirements ("IFRs") were assumed to be the following:

a. Moon Lake: Estimated at 5% of MAD throughout the year.
b. Tutshi Lake: Estimated at 10% of MAD from November through May, and 30% of MAD from June through October.

Other major inputs that played into the storage models were assumed as described in **Table 11** below.

Table 11: Energy Model Inputs

Input	Conventional Storage Model	Pumped Storage Model
Turbine efficiencies[1]	90%	90%
Generator efficiencies	98%	98%
Transmission Line Losses[2]	1%	1%
Transformer efficiency	99.5%	99.5%
Pump Efficiency[3]	N/A	90%
Scheduled and Unscheduled Outage	4%	4%
Station Usage	50 kW	50 kW
MOL (m)	1,114	1,114
Daily Generation/Pumping Profile	15 hrs	15 hrs
Yearly Generation Profile	November 1st through May 15th	November 1st through May 15th
Energy output estimate	At POI	At POI

Note 1: A preliminary turbine efficiency is assumed to be a flat 90%. This will be refined when the models are refined and the turbine and generator solution for the project is selected.
Note 2: Assumed from the point of interconnection ("POI") to the switchyard.
Note 3: Preliminary assumption of 90% until a final pump solution is determined.

5.2 Conventional Storage Scheme

The conventional storage scheme assumes the project would regulate the flow of the Moon Lake drainage area of 57.4 km^2 (MAD = 0.79 m^3/s). The dam height was optimized to:

- Contain most of the summer flows in the reservoir while spilling excess water for 4 years out of 45-year hydrology string,
- Use all the storage water for generation while drawing down to MOL only 1 year out of the 45-year hydrology string.

The estimated FSL of the project is 1,121 m and its gross head is 407.8 m. The design flow is assumed at 2.2 m^3/s.

5.3 Pumped Storage Scheme

The Yukon energy load and surplus energy profile forecast was provided by YEC for years 2022, 2028, 2029 and 2030 as shown in **Table 12** below. The available energy for pumping includes surplus hydro (Whitehorse spill) and wind generation. The diesel generation to be displaced represents the load "shortfall" that is

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

forecast to be generated with thermal generation sources (diesel or the LNG system in Whitehorse). This is effectively the target energy that winter generation at Moon Lake could serve over time.

Table 12: Yukon Energy Forecast

Year	Surplus Energy Available for Pumping (MWh)	Diesel Generation to be Displaced (MWh)
2022	47,939	23,754
2028	39,183	36,360
2029	34,789	45,878
2030	30,946	56,308

As can be noted, over time, the system load increases, which both reduces the available surplus for available for pumping and increases the load that would be served by Moon Lake.

After discussions with YEC, it was concluded to size a project that reflected the surplus available in 2022 based on the assumption that incremental renewable generation resources could be added to the system which the PSH project at Moon Lake could support.

In order to model the project's performance from week to week, the forecast weekly distribution of surplus energy, including that estimated from potential wind generation resources was applied to the model. This distribution, as provided by YEC, is shown in **Table 13**.

Table 13: Surplus Energy Available for Pumping

Yearly Generation /Pumping Profile			
Week	**Surplus Energy with Wind (MWh)**	**Week**	**Surplus Energy with Wind (MWh)**
20	389	33	2912
21	701	34	2501
22	1190	35	2476
23	1544	36	1814
24	1860	37	1944
25	2194	38	1913

Vancouver BC, Canada
V6E 4A4

The pumped storage scheme assumes the project regulates the flow of the Moon Lake drainage area of 57.4 km^2 (MAD=0.79 m^3/s) in addition to pumped flow. The assumption was made that the desired scheme would be to store during the weeks where surplus energy for pumping is available (i.e., week 20 to 44) and generate during the other weeks (i.e., week 45 to 19).

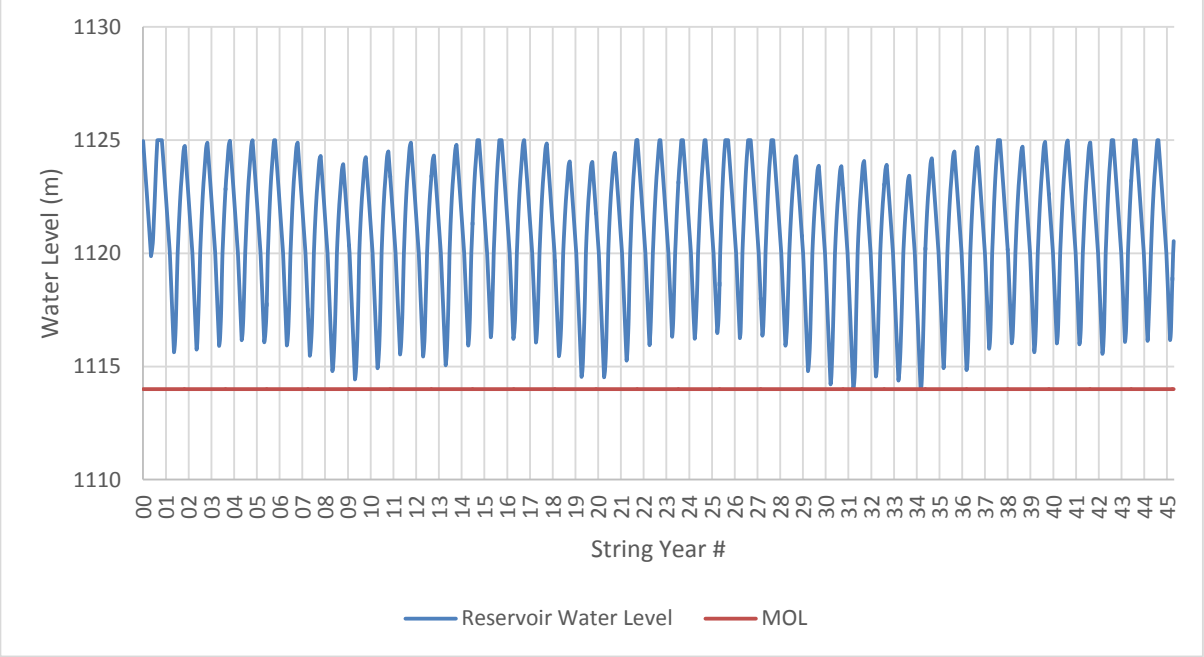
The dam height was optimized to contain most of the summer flows and pumped flows in the reservoir, and use all the storage water for generation while remaining above MOL.

5.3.1 48 GWh Scenario

In the 48 GWh scenario, the available pumping energy is based on the available surplus energy forecast listed in **Table 13**. The estimated FSL of the project is 1,125 m and its gross head is 411.5 m. The generation design flow is assumed at 6 m^3/s and the pumping design flow is estimated at 4.1 m^3/s.

Assuming the available pumping energy remains constant at 48 GWh, the water level at the Project over the 45-year hydrology string is shown in **Figure 12**. Out of the 45-year string, the water at the reservoir is estimated to spill 16 years and draw down to MOL 2 years out of the string.

Figure 12: Pumped Storage – 48GWh Scenario – Water Level



5.3.2 70 GWh Scenario

A second scenario was assessed, which would assume an annual surplus of 70 GWh available for pumping. The intent of this second scenario was to evaluate the potential system performance assuming greater increment generation resources on the YEC system over time. The project described herein does not

MIDGARD
Midgard Consulting Inc

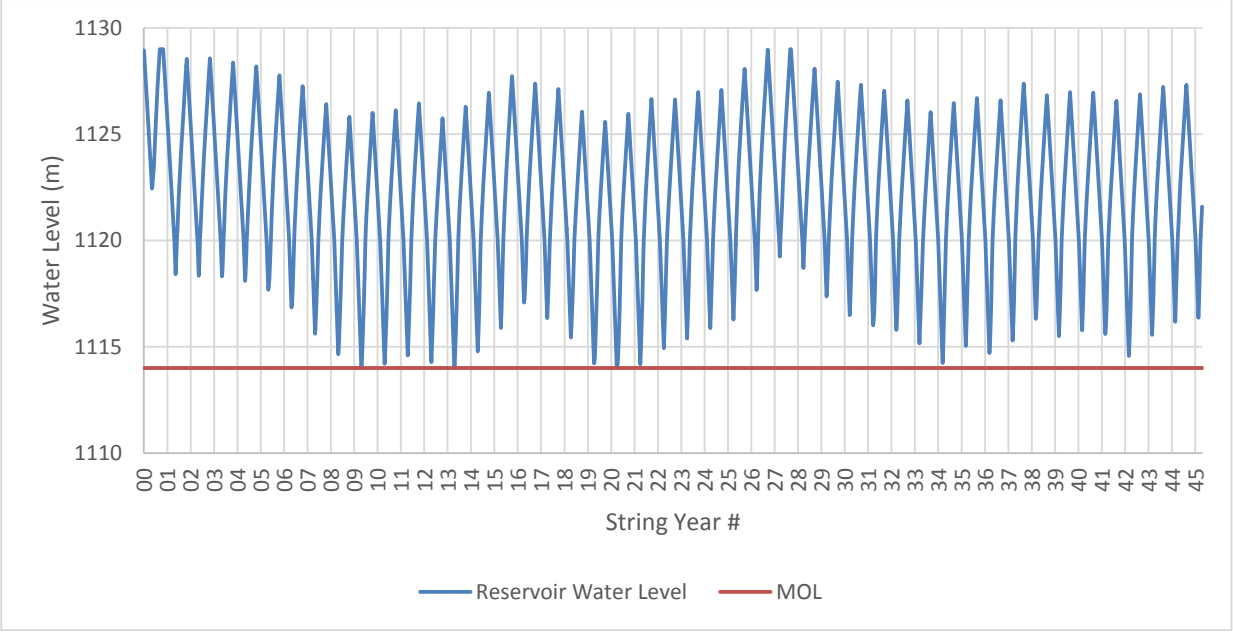
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

contemplate the infrastructure required for this larger system. The scenario is described here only as the energy potential of a larger scheme.

In the 70 GWh scenario, the available pumping energy is not based on forecast but was rather suggested by YEC. The weekly available energy for pumping was assumed constant from week 20 to 44 (25 weeks) for a total of 70 GWh over the pumping period (2.8 GWh/week). This scenario illustrates the ability to store and generate additional energy at Moon Lake should additional surplus energy for pumping become available in the future.

The estimated FSL of the project is 1,129 m and its gross head is 415.5 m. The generation design flow is assumed at 7.6 m^3/s and the pumping design flow is estimated at 6.2 m^3/s. Assuming the available pumping energy remains constant at 70 GWh, the water level at the Project over the 45-year hydrology string is shown in **Figure 13**. Out of the 45-year string, the water at the reservoir is estimated to spill 2 years and draw down to MOL 3 years out of the string.

Figure 13: Pumped Storage – 70GWh Scenario – Water Level



5.4 Results

As a conventional storage scheme, the project yields an annual winter energy output of 20 GWh from the natural inflows at Moon Lake with a capacity of 7.5 MW.

As a pumped storage scheme with an annual summer pumping energy of 48 GWh, the project yields an annual winter energy output of 54 GWh for a plant capacity of 20.2 MW. The energy yields at Moon Lake for the different surplus energy at a given year are shown in **Table 14**.

Table 14: Pumped Storage – 48GWh Scenario - Results

Year	Surplus Energy Available for Pumping (GWh)	Diesel Generation to be Displaced (GWh)	Moon Lake Generation (GWh)	Net Diesel Generation (GWh)
2022	48	24	54	-30
2028	39	36	47	-11
2029	35	46	43	3
2030	31	56	40	16

As a pumped storage scheme with an annual summer pumping energy of 70 GWh, the project yields an annual winter energy output of 69 GWh for a plant capacity of 26.1 MW.

In addition, the pumped energy will incur losses through the pumping and the generation process. Overall, the pumped storage scheme roundtrip efficiency is estimated at 70% which includes all losses described in Section 5.1: Inputs and Assumptions.

Average monthly energy yields for the three alternatives are shown in **Table 15**.

Table 15: Monthly Energy Yields (GWh)

6 Project Development in British Columbia

6.1 Project Permitting

Water rights in BC are owned by the Crown and are devolved through water licences on a first in line rights basis. A water licence is appurtenant to a neighbouring land parcel.

The development of a waterpower project in BC requires the proponent to secure a water licence and rights to the land base. A well defined process has evolved over the past 15-years which outlines the expectations of provincial regulators prior to the issuance of a waterpower water licence.

In the instance of Moon Lake, this would require a water licence with a Point of Diversion ("POD") on Moon Creek, at the dam site. A second POD would be required under this licence for Tutshi Lake. Finally, a Storage Licence would be required to permit the creation of the reservoir. This process will be complicated by the Commercial Licence to Occupy land tenure in the Moon Lake catchment.

The dam, penstock and powerhouse would be covered under a long term licence of occupation. The bed of the reservoir would likely be covered under a Permit Over Crown Land.

The process to obtain these primary permits requires the preparation of a Project Development Plan. The Development Plan is a key deliverable and contains a detailed description of the project as well as a summary of environmental and hydrological studies. It is submitted as part of the Water Licence application to FrontCounter BC.

The Development Plan must include:

- Introduction, project purpose and description
- Preliminary or conceptual design drawings
- Description of electrical works, to point of grid interconnection
- Description of: staging areas, access roads, fish passage requirements, intake, penstock, powerhouse and tailrace, switchyard and transmission lines, debris management, area flooded
- Elevation/capacity curves, slope stability
- Geotechnical considerations: site geology and any subsurface exploration
- Seismic considerations
- Flooding and erosion concerns
- Complete legal description of affected lands including new roads and transmission lines
- Water *quantity* information including:
    - Period of time and amount of water required
    - Any reserves or restrictions
    - Climatic information
    - Watershed area, aspect and slope
    - All sources of inflow

MIDGARD
Midgard Consulting Inc

midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

  - Flow estimation methodologies, hydrographs, mean annual discharge
  - Flow duration for streams that are not year-round
  - Inflow design flood, design flood water level
  - Return period of design flood
  - Area-Elevation curves
  - Flow estimates of water availability (mass curve and water balance)
- Water *quality* information (e.g. temperature)
- Instream requirements: assessment of fish species, distribution, timing.
- Recreational, aesthetic and cultural uses
- Affected water users downstream
- Construction schedule, methodology and timeframe, including description of how instream work can be done to minimize impacts, engineering review if required
- Downstream consequences of failure, and hazard classification according to Schedule 1 – Dam Safety Regulation
- Operation order or rule, monitoring and record keeping
- Archeological information known, use of environmental monitors
- Labour pool requirements

Site environmental baseline studies are multi-year studies, which are expected to collect baseline data over multiple seasons and several years. Each project is unique and subject to its own data requirements.

After the collection of baseline data and the preparation of the Project Development Plan, a review period of 6-months to a year often passes before the issuance of licence and land tenures.

The Moon Lake project proposes a larger dam with a significant reservoir and would project its zone of impact to Tutshi Lake and below because of the withdrawals of water from that waterbody. For these reasons, we would estimate project permitting costs, for studies, application preparation, process shepherding, and project management to be in the range of $1.0 to $1.5 million.

Because the rated capacity of the Moon Lake Project is less than 50 MW, the project falls below the threshold of review by the Environmental Assessment Office (“EAO”) of the BC Government.

6.2 Development phases

Four phases of development have been assumed for the Project. Below is a brief summary of those phases as well as estimates of project costs that have been assumed for each phase. Those costs have been assumed to be capitalized into the total project cost for the purposes of estimating the LCOE.

The timelines proposed are high level estimates. It is expected that the can be some overlap in the phases – particularly in early stage collection of baseline environmental data. In total, it is expected that, this project, pursued continuously and diligently, would take in the order of 6 years to achieve operations.

MIDGARD
Midgard Consulting Inc

Vancouver BC, Canada
V6E 4A4

A. **Feasibility and Preliminary Engineering** *(Estimated 1 year)* - The purpose of the Feasibility phase is to study the project to a sufficient level of detail to allow for a go/no-go gate review decision to continue investing and begin the permitting phase of development. Work completed in this phase includes refined assessments of available resources (using site specific gauge data), site investigations, updated design and preliminary engineering, capital cost estimates, and financial modeling. A review of existing data, including environmental assessments done to date, is completed in preparation for the commencement of multi-year field studies. *Budget assumed is $200,000.*

B. **Project Permitting** *(Estimated 2.5-3 years)* - Obtain all licenses, tenures, and other material permits required for construction and commissioning of the project. *Budget assumed is $1.5 million.*

C. **Design & Pre-Construction** *(Estimated 6 months)* - The purpose of Design & Pre-Construction is to prepare the execution of project construction. Work completed in this phase includes contractor selection, negotiation and execution of engineering and construction contracts, submitting for and obtaining all required late-stage permits, ensuring all other required agreements are in place, and completing the design of the project. The construction contractor is readied to initiate work and any long-lead time equipment is selected and ordered as required. *Budget assumed is $500,000. This budget is for preliminary engineering only and does not include the cost of final engineering and design of the project, which has been included within the project capital cost estimates.*

D. **Construction** *(Estimated 2.5 years)* – The Construction phase (the most critical phase) covers the project's construction. Additional tasks also fall into this phase, including continued environmental monitoring, and the execution of the environmental management plan.

The project development schedule is shown in **Figure 14**.

Figure 14: Project Development Phases Schedule

7 Cost Estimates

Project costs, which are a fundamental input into estimates of the project's LCOE are comprised of upfront capital costs, and ongoing operation costs.

7.1 Project Capital Costs

A capital cost estimate has been developed for the project which is comprised of capitalized development costs, civil construction costs, water to wire equipment costs, transmission and interconnection costs, and capitalized interest costs from the construction period.

It is important to note that at this stage, no estimate was considered for the following project aspects:

1) First Nation consultation, assessments, studies, agreements, royalty payments etc.
2) Archeological assessments
3) Impact benefit assessments
4) Property tax

7.1.1 Project Development Costs

A high level estimate of project development costs was presented in Section 6. These costs are summarized in **Table 17**.

Table 17: Project Development Costs

Development Phase	Cost Estimate ($ 2015)
Feasibility and Preliminary Engineering	$200,000
Project Permitting	$1,500,000
Design and Pre-construction	$500,000
TOTAL	**$2,200,000**

7.1.2 Civil Construction Costs

Kawa Engineering ("Kawa") was retained to develop a civil capital cost estimate and corresponding bill of quantity.

The estimate was specified as a Class 5 estimate, per the standardized AACE International Cost Estimate Classification System. A Class 5 estimate is intended for concept screening and represents a level of project

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

definition of 0% to 2%. The expected low accuracy ranges from -20% to -50% and the high accuracy ranges from +30% to +100%.[7]

Kawa prepared the cost estimate using a combination of quantity estimates for the large, significant project components such as the dam and penstock etc., and used a parametric relationships for the balance of the plant. A summary of the Kawa cost estimate is presented in **Table 18**.

Table 18: Summary of Civil Capital Costs

Project Component	Cost Estimate ($M 2015)
General Cost[8]	$32.7
Dam (Earthworks, Grouting, Spillway)	$55.9
Diversion	$1.0
Intake	$1.1
Powerhouse Civil	$5.5
Penstock	$43.6
Switchyard – Civil Works	$2.0
Roads	$1.3
Total Civil Works Cost	**$143.1**

The detailed bill of quantity from Kawa is presented in Appendix B: Generating Facility Capital Cost Estimate.

7.1.3 Generating Equipment Costs

The cost estimate for the turbine, generator and associated balance of plant was estimated based on previous delivered equipment for projects in BC. These are summarized in **Table 19**.

Table 19: Summary of Generating Equipment Costs

Project Component	Cost Estimate ($M 2015)
Turbine and Generator	$5.5
Pumps with variable frequency drives	$5.0
Balance of plant	$3.5
Total Generating Equipment Cost	**$14.0**

[7] AACE International Recommended Practice No. 17R-97

[8] General costs include mobilization and demobilization, reservoir clearing, engineering, miscellaneous metals, contractor's insurance, permits, land use and survey.

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

An inquiry was initiated with equipment supplier, Andritz, who have significant experience in the smaller hydro space as well as with pumped storage equipment. At the time of this report, response was still outstanding.

7.1.4 Transmission Line and Interconnection Costs

The estimated cost for the transmission is $2.3 million and is based on the sub-marine cable cost estimate. The transmission line costs were estimated based on parametric assumptions based on previous similar operating voltage projects in BC, taking into account the voltage and capacity of the line.

The main step-up transformer, disconnects and circuit breakers for the switchyard plant was been assumed to be $500,000 installed.

Transmission and interconnection costs are summarized in **Table 20**.

Table 20: Transmission and Interconnection Cost Estimate

Project Component	Cost ($M)
Transmission Line	$2.3
Switchyard Electrical	$0.5
Total Tx and Interconnection Costs	**$2.8**

7.1.5 Owner's Costs During Construction

Certain costs will be incurred be the owner during the construction period. These include onsite administration and overhead, engaging the Independent Engineer and Independent Environmental Monitor, as required under water licencing regulations, and funding ongoing compliance monitoring during construction.

The estimate of these costs are provided in **Table 21**.

Table 21: Owners Costs During Construction

Project Component	Cost ($M)
Administration and Overhead	$0.5
Land Tenure Surveys	$0.2
Compliance Monitoring	$0.2
Independent Engineer	$0.4
Independent Env. Monitor	$0.8
Total Owners Costs During Construction	**$2.1**

MIDGARD

Vancouver BC, Canada
V6E 4A4

7.2 Capital Cost Summary

The total estimated project capital cost estimate, exclusive of contingency, for the 48 GWh pumped storage scenario is show in **Table 22** below. A project contingency of 20% of capital costs exclusive of owner's costs has been added at this time and interest during construction estimated assuming a 2-year construction term, with 100% debt finance at the blended cost of capital of 5.45%.

Table 22: Project Capital Cost Estimate

Project Component	Cost ($M)
Project Development	$2.2
Civil Construction Costs	$143.1
Generating Equipment Costs	$14.0
Transmission and Interconnection Costs	$2.8
Owners Costs During Construction	$2.1
Total Project Capital Cost	**$164.2**
Contingency	$32.0
IDC	$21.4
Grand Total Project Capital Cost	**$217.6**

For comparison purposes, a high level capital cost estimate for the conventional storage and the 70 GWh pumped storage options was extended from the 48 GWh alternative cost estimate. This was achieved by scaling the quantity estimates and unit costs from the 48 GWh alternative based on dam height, penstock diameter, reservoir size and installed capacity. A summary of the cost estimates for the conventional storage and the two pumped storage options (48 GWh and 70 GWh) is shown in **Table 23**.

Table 23: Project Options Capital Cost Estimate

Project Component	Conventional Storage ($M 2015)	Pumped Storage 48GWh ($M 2015)	Pumped Storage 70GWh ($M 2015)
Project Development	$2.2	$2.2	$2.2
Civil Construction Costs	$105.1	$143.1	$169.1
Generating Equipment Costs	$5.0	$14.0	$22.1
Transmission and Interconnection Costs	$2.8	$2.8	$2.8
Owners Costs During Construction	$2.1	$2.1	$2.1
Total Project Capital Cost	**$117.2**	**$164.2**	**$198.2**
Contingency	$22.6	$32.0	$38.8
IDC	$15.2	$21.4	$25.8
Grand Total Project Capital Cost	**$155.0**	**$217.5**	**$262.9**

MIDGARD

Vancouver BC, Canada
V6E 4A4

7.3 Operating Costs

Project operating costs are categorized into the general operating and maintenance expenses in running and maintaining the plant and indirect and overhead costs associated with plant operations. The O&M expenses arise from labour costs for plant operators, minor spare parts, consumable supplies, and contract labour for irregular maintenance activities. Other direct operating costs comprise water rental and land lease fees to the BC government. Indirect operating costs include overhead and administration costs, insurance etc.

Finally, a fixed annual contribution to a Major Maintenance Reserve Account ("MMRA") is assumed for sustaining capital investments and is intended to account for semi-regular major maintenance items that are expected over the life of the plant.

All costs are stated in $2015.

The general O&M cost is estimated based on an assumed labour pool of 2 full time equivalent operators and an allowance for expenses, consumable supplies and contract labour. It is assumed that operating labour will be staffed by YDC and appropriate shift coverage will be allocated across plants. **The all in cost is estimated to be $400,000**.

An MMRA deposit of $75,000 is assumed to be adequate for covering major maintenance items.

The annual water rental rates associated with power production are estimated based on published rates established by the BC government. As of 2015, rates are assessed for both the installed capacity of the plant and the actual energy generated. Further, there is a rental rate for water storage. Land costs have been estimated based on published rates. The rates and project costs are summarized in **Table 24**.

Table 24: Provincial Resource Fees

Resource	Rate ($2015)	Project Cost $2015
Water Rental – Capacity Charge	$4.334 / kW	$90,000
Water Rental – Energy Charge	$1.301 / kWh	$70,000[9]
Water Rental – Storage Charge	$0.01 / 1000 m^3	$1,000
Permit over Crown Land - Dam	$120 / ha.	$1,000
Permit over Crown Land – Flooded Reservoir	$7.50 / ha.	$5,000
Land Lease – Powerhouse	Based on land value	$500
ROW - Penstock	Based on land value	$500
ROW – Transmission Line	Based on land value	$500
Total Resource Fees – Operating Cost		**$168,500**

[9] This assumes a plant output of 24 GWh, which is the forecasted energy deficit for 2022. The cost is variable from year to year depending on the amount of energy actually generated at the plant.

Management, administration and overhead cost is assumed to be $250,000/year. Insurance, using a premium based on $3 per $1,000 of constructed cost, is assumed at $500,000/year. Finally, it is assumed that the project will attract property tax at the assumed rural mill rate of $2.87 per $1000 of assessed value, which equals $500,000. The resulting estimated annual operating cost associated with the project is summarized in **Table 25**.

Table 25: Project Annual Operating Costs

Component	Cost ($2015)
General O&M	$400,000
Major Maintenance Allowance	$75,000
Provincial Resource Fees	$168,500
Management, Administration and Overhead	$250,000
Insurance	$500,000
Property Tax	$500,000
Total Annual Operating Cost	**$1,893,500**

8 Financial Modeling

8.1 LCOE

In the 2011-2030 Resource Plan YEC defined the LCOE as:

> *"LCOE indicates on a consistent and comparable basis each option's overall costs per kWh. It includes capital and operating costs and, where specified, any related transmission, storage or capacity costs. This cost is subject to ongoing annual inflation for each subsequent year of operation in order to assess costs over the option's economic life."*[10]

The LCOE is calculated as follow:

$$LCOE = \frac{Present\ Value\ of\ Costs}{Present\ Value\ of\ Energy\ Output}$$

The Project LCOE was calculated for the 48 GWh pumped storage scenario and is described in the following sections.

8.2 Assumptions

The following economic assumptions were used to calculate the Project LCOE:

1) Blended cost of capital: 5.45%;
2) Inflation: 2%;
3) Real Discount Rate: 3.38% based on blended cost of capital and inflation rate from the RFP. LCOE discounts both costs (numerator) and energy (denominator) using the Real Discount Rate; and
4) Life Span: 65 years.

8.3 Full Utilization LCOE

The full utilization LCOE assumes constant pumping energy and constant load profile. It implies that the Yukon will install new generation (wind or hydro) to maintain the amount of available low cost summer energy for pumping as the energy load increases. It also implies that the full energy output at Moon Lake is generated every year for the life of the project and that all energy is consumed.

The project Full Utilization LCOE is $0.189/kWh.

8.4 LCOE Sensitivity Analysis

The LCOE is directly related to the actual usable energy from the project. Because the YEC grid is islanded from other load jurisdictions, the utilization of the Moon Lake project is dependent on both the surplus energy from the YEC system that is available energy for pumping, as well as the system load that can ultimately be served from the reciprocal generation. Further, the surplus energy and load balance will change over time, depending of the planning forecast of the system.

The LCOE estimate was based on a 65-year project life, which, while appropriate for a long-lived asset such as a hydroelectric plant, is beyond the planning horizon of YEC. In order to estimate the sensitivity of the Moon Lake project to differing scenarios of surplus energy and load, a sensitivity analysis was performed for the Project LCOE by simply adjusting plant capacity factors ranging from 60% to 100% as shown in **Table 26**.

The capacity factor represents the plant utilization over the generation period. The 100% capacity factor scenario is the base case scenario for which the energy yield were estimated in this report.

Table 26: LCOE Sensitivity Analysis

Capacity Factor	Full Utilization Generation (GWh)	NPE (GWh)	NPV ($M 2015)	LCOE (S/kWh)
100%	54.0	1,412.8	267.5	0.189
90%	48.6	1,271.5	267.3	0.210
80%	43.2	1,130.2	267.2	0.236
70%	37.8	989.0	267.0	0.270
60%	32.4	847.7	266.8	0.315

9 Results and Recommendations

9.1 Results

As shown in **Table 27**, as a conventional storage scheme, the Project yields 20 GWh of winter energy. As a pumped storage scheme, the Project yields 54 GWh of winter energy with 48 GWh of available pumping energy, or 69 GWh with 70 GWh of available pumping energy.

Table 27: Moon Lake Energy Yield Summary

Parameters	Conventional Storage	Pumped Storage (48 GWh)	Pumped Storage (70 GWh)
FSL (m)	1,121	1,125	1,129
MOL (m)	1,114	1,114	1,114
TWL (m)	713.2	713.5	713.5
Gross Head (m)	407.8	411.5	415.5
Generation Flow (m^3/s)	2.2	6.0	7.6
Pumping Flow (m^3/s)	N/A	4.1	6.2
Capacity (MW)	7.5	20.2	26.1
Annual Pumping Energy (GWh)	N/A	48	70
Annual Energy Output (GWh)	**20**	**54**	**69**

A breakdown for estimated cost estimate exclusive of contingency for the 48 GWh pumped storage scenario is show in **Table 28**.

Table 28: Project Capital Cost Estimate

Project Component	Cost ($M)
Project Development	$2.2
Civil Construction Costs	$143.1
Generating Equipment Costs	$14.0
Transmission and Interconnection Costs	$2.8
Owners Costs During Construction	$2.1
Total Project Capital Cost	**$164.2**
Contingency	$32.0
IDC	$21.4
Grand Total Project Capital Cost	**217.6**

The estimated yearly cost associated with the projects are shown in **Table 29**.

Table 29: Project Annual Operating Costs

Component	Cost ($2015)
General O&M	$400,000
Major Maintenance Allowance	$75,000
Provincial Resource Fees	$168,500
Management, Administration and Overhead	$250,000
Insurance	$500,000
Property Tax	$500,000
Total Annual Operating Cost	**$1,893,500**

The project full utilization LCOE is $0.189/kWh.

9.2 Recommendations

Several existing rights have been identified at the project site and its vicinity. A detailed investigation of the current and future existing rights is recommended to identify potential development barriers.

If a decision is made to study the project further, first and foremost, it is strongly recommended that YEC prepare and submit a Water Licence Application from Front Counter BC to secure first-in-line rights to the water. Subsequent to this, the following steps, field studies and data collection programs are recommended:

1) Prepare a submit a **water licence application** to Front Counter BC so as to secure first-in-line water rights to the project ahead of other potential claimants. British Columbia recognizes the rights to water on a first come, first serve basis. Several existing rights have been identified at the project site and its vicinity. Prior to advancing the project further, a detailed investigation of the current and future existing rights is recommended to identify potential development barriers.
2) Project preliminary engineering and design can be further advanced with greater precision topography, obtained with a **LIDAR survey**. This survey is recommended to refine the design and quantity cost estimate. The LIDAR survey area should comprise the dam site, the penstock route, suggested at 200 m each side of the proposed penstock alignment, and the powerhouse site. The estimated area of study is 3.5 km^2 (See **Figure 15**).
3) A **geotechnical investigation** program is recommended to assess the foundation conditions of the dam and powerhouse as well potential anchor block locations at select major bends along the penstock alignment (See **Figure 16**).

   During early stage project definition and development, seismic refraction lines present a cost effective alternative to estimate overburden thickness without incurring the cost of mobilization of

V6E 4A4

drilling rigs across Tutshi Lake and into the upper Moon Lake watershed. Two seismic lines are recommended at the dam site: one along the dam axis and one perpendicular to the dam axis at the maximum dam height. Two lines are suggested along the penstock near route and two at the powerhouse. As project certainty is achieved, greater expenditure for project definition is justified and the results from the seismic analysis can be confirmed with boreholes.

Boreholes are indicated at the powerhouse location because of the importance of better characterizing the construction excavation conditions adjacent to Tutshi Lake as well as characterizing the rock quality at the powerhouse. Further, boreholes are an important along the dam foundation, not only to characterize the depth to bedrock, but to also investigate the rock quality and permeability in order to plan dam foundation treatment. As such, the dam boreholes should extend into bedrock to a depth commensurate with the dam height and include in situ permeability testing of the rock. Location of the boreholes should be determined once greater resolution mapping becomes available.

Finally, a dedicated site investigation to secure and confirm a source pit for the material for construction or the dam is recommended to be included with any geotechnical programme.

Memorandum

To:	Michael Potyok	**From:**	Stephen Morison, M.Sc., P.Geol. Irwin Wislesky, P.Eng.
Company:	MIDGARD Consulting Inc.		
cc:		**Date:**	December 18, 2015
Subject:	***FIELD SITE REPORT FOR THE PROPOSED MOON LAKE HYDRO PROJECT***		

1.0 INTRODUCTION

Midgard Consulting Inc. (Midgard) retained SLR Consulting (Canada) Ltd. (SLR) to assist them in providing a geotechnical/geological assessment with regards to design and construction of an earth fill dam near the outlet of Moon Lake. Moon Lake is located about 100 km south of Whitehorse in British Columbia, just south of the Yukon border.

The purpose of constructing a dam across the outlet of Moon Lake is to provide additional water storage capacity within the Moon Lake Basin for winter hydro-power production. The intention is to pump water from Tutshi Lake into Moon Lake during the summer months when there is excess water and store it there until the winter when water availability for hydro-power is limited and demand is high.

SLR's scope of work for this project included a review of existing documentation and participation in a reconnaissance site visit by helicopter. The site visit took place on June 24, 2015 along with Michael Potyok and Anna Le of Midgard and Glen Ichikawa of Kawa Engineering. The information provided for review included the following documents:

- KGS Group draft report to Yukon Energy on the Assessment of Potential Hydroelectric Sites, Conceptual Study, dated February 2008.
- KGS Group Draft Memorandum to Gord McPhail Re: Summary of site inspection and Terrain Assessment for the Moon Lake Site, Northern British Columbia, dated February 14, 2008.
- Klohn-Crippen report to Yukon Electrical Company Ltd. titled, "Moon Lake Hydroelectric Project, Layout Report (Report No. KCCL-106, dated January 1992.
- Moon and Tutshi Hydroelectric Projects, General Arrangement Plan, by HDR for Peter Kiewit Infrastructure Co., October 31, 2011, DWG 172193-G-0001 Revision A.
- Moon and Tutshi Hydroelectric Projects, Earthworks quantities, by HDR for Yukon Energy, October 31, 2011

2.0 SITE VISIT

Prior to the site visit, the information provided by Midgard was reviewed to gain a general appreciation of the site conditions and to plan the field visit. There are no roads to the site, thus the site was accessed by helicopter from Whitehorse. The field visit included:

- Aerial tour of Moon Lake and the surrounding catchment;
- Aerial view along the outlet channel from Moon Lake down to Tutshi Lake;
- Aerial view in the likely area for the proposed powerhouse near the shore of Tutshi Lake, by the outflow from Moon Lake;
- Aerial view along Tutshi Lake and the outlet stream into Tagish Lake and one stop on land downstream of Moon Lake where extensive bedrock outcropping was observed; and
- Two landings downstream of Moon Lake to traverse and view ground conditions at potential dam locations and one upstream of Moon Lake along one of the tributaries that flow into Moon Lake.

During the site visit several photographs were taken and approximate GPS coordinates/ elevations were recorded to mark key features and elevations.

2.1 Visual Site Description

The area can generally be characterized as mountainous with glaciated valleys having a variety of glacially related landforms over bedrock. Moon Lake is located within a broad U-shaped valley that is flanked by high elevation mountainous terrain. The area of the outflow channel from Moon Lake and several hundred metres downstream appears to be dominated by a wetlands with a thicker surface organic layer that may have been an infilled section of the lake basin composed of alluvial material. Bedrock outcrops are evident a few hundred metres downstream of Moon Lake becoming more frequent down gradient from Moon Lake. It appears that the stream to Tutshi Lake is generally bedrock controlled. Glaciofluvial features also appear to be evident down the valley from Moon Lake to Tutshi Lake where there are high banks of exposed gravelly sediments. This material is a possible source of both fine and course dam construction fill (to be verified).

2.2 Possible Dam Locations

Three possible locations have been previously identified by others for a dam near the outlet of Moon Lake. One is at the lake outlet; a second is located about 800m downstream and; a third is located about 1300m downstream in an area where bedrock outcropping is predominant. During this site reconnaissance, the downstream area was flown over to view the outcrops and general ground conditions. Scattered bedrock outcroppings were observed a few hundred metres downstream of the Moon Lake outlet along with the occasional overburden knoll rising a few metres above the generally flat terrain. From these observations it appears that bedrock is generally located at shallow depth but could be quite variable and is likely at greater depth near the lake. The stream flow near Moon Lake (within 1 km) is shallow and meandering, with the stream bottom covered in gravel, indicating possible shallow bedrock. The quality of the bedrock was difficult to assess, however bedrock was highly fractured where exposed in the stream.

Several considerations must be evaluated prior to selecting the optimum location for the dam and these include the following:

- The height of the required dam will be greater the farther it is from Moon Lake because of an increase in the catchment area and the drop off in the ground level.
- The elevation requirement for the dam and ultimate lake level may be lower, the farther the dam is from Moon Lake because of the greater area available for storage.
- Additional streams can enter Moon Lake and add to the catchment the further downstream the dam is located (this may not be important if pumping water into Moon Lake during the summer is considered free).
- If bedrock is relatively shallow, the depth of cut-off required may not be significantly different between locations suggesting the location providing the shortest and least height (least fill volume) might be the best (from a strictly geotechnical perspective).
- The location for the dam should take into consideration a spillway within bedrock at one of the abutments.

From the site visit and review of the data, the preliminary recommendation for the dam location is in the area near the first bedrock exposure downstream of the lake (see photo below). This site was selected because of bedrock outcrops and an apparent rise in the ground level on both sides of the stream which could minimize excavation as well as fill materials required to construct the dam. In addition, the ground level has not dropped off significantly at this point from Moon Lake.

Proposed Dam Location (red line). Easterly view towards Moon Lake.

2.3 Geological Hazards and Construction Considerations

A detailed assessment of geologic hazards has not been carried out for this study, however during the field investigation no major hazards were observed. However, given the location of the Moon Lake site and the high elevation setting, possible effects from earthquake must be considered in the design of the dam including foundation stability and the possible consequences of a failure. This would require a surface and subsurface assessment of the bedrock including lithology, faulting, depths and subsurface profiles, distribution, thickness and genesis of surficial geological landforms, permafrost characteristics and other features such as organic landforms. There are other factors that will need to be integrated into the planning of this facility including local climate characteristics such as snow depth, hydrology, storm events and other natural events.

Construction in this area will likely involve issues such as excavation in discontinuous permafrost, a short construction season, frozen overburden that must be thawed prior to use as fill, bedrock grouting where frozen rock and possible ice lenses occur, dewatering, water diversion and restricted access for equipment and supplies. Clear logistics planning and scheduling will be required to facilitate construction of the dam and ancillary features.

3.0 CONCLUSIONS AND RECOMMENDATIONS

This assessment has been based primarily on a short aerial field tour and review of reconnaissance level information. Of primary importance is the need for better ground survey data since the contour accuracy from existing topographic maps that are available are not sufficient to accurately establish a location, length and volume of the dam. Once this has been made available, several seismic lines could be investigated to establish depth of bedrock along preferred locations. This could be followed by a drilling investigation to confirm overburden depths and the bedrock profile and condition along the dam alignment, as well as investigate possible borrow materials for dam construction.

4.0 CLOSURE

SLR trusts that this report suitably provides the preliminary site assessment requested by Midgard. Please contact the undersigned to discuss any of the issues raised in this document or your needs with respect to the next phase of this project. It has been a pleasure working with you on this most interesting project and hope to be of continued service in the near future.

Yours very truly,

Irwin Wislesky, P. Eng.
Technical Director, Tailings and Mine Waste

Stephen Morison, M.Sc., P.Geol.
Director, Mining Business Sector

TECHNICAL MEMORANDUM

To: Marc-Andre Lavigne
Yukon Energy Corporation
Box 5920, 2 Miles Canyon Road
Whitehorse, YT Y1A6S7

Project 1355-1

From: Stephen Taylor, P.E., EMC²-Picacho

Date: March 10, 2016

Subject: Faro Mine Pumped Storage
Conceptual Assessment of Seasonal Pumped Storage Power Facilities at the Faro Mine Complex

Introduction

In response to a series of discussions with Yukon Energy Corporation (YEC) in June 2015, EMC²-Picacho proposed a scope of work to YEC to perform a high-level assessment of the economics, social acceptability, regulatory requirements; environmental impacts; geotechnical issues; and geographic/geological attractiveness of a pumped storage facility at the Faro Mine. The purpose was to provide YEC with information to support and inform their decision-making process for further research into, or elimination of, the Faro Mine Complex area for consideration for potential pumped storage project development. This high-level study relied on:

- The judgment of experienced individuals;
- Existing industry cost databases developed for hydro power projects; and
- EMC²-Picacho's own cost databases.

In September 2015, EMC²-Picacho's Stephen Taylor and Joe Flynn met with YEC representatives in Whitehorse and travelled to the Faro Mine for a site visit and for an initial pumped storage options review and technical discussion. Completion of this visit provided the basis for refining the evaluation.

This technical memorandum presents results of our assessment based upon the above considerations.

Background

The purpose of this evaluation was to complete conceptual site assessments and conceptual designs, including economic viability, for several seasonal pumped storage projects. The studied sites are within the vicinity of the Faro Mine Complex, including the Faro Mine area, Rose Creek Tailings area and the Vangorda Plateau area (see Figure 1 attached in Appendix A).

The Faro Mine Complex is located in south-central Yukon, approximately 14 kilometers (km) north of the town of Faro. The Faro Mine Complex began mining in 1969 and lasted approximately 30 years.

The mine is currently being reclaimed and remediated to a stable condition. The current layout of the mine consists of large open pit, the Faro pit, which is approximately 1,675 meters by 975 meters in surface area. The pit is surrounded by approximately 250 million tonnes of waste rock. To the southwest of the Faro Mine pit lies the Rose Creek Tailings, containing approximately 55 million tonnes of tailings. The tailings facility consists of a series of three dams to hold the tailings, and a fourth dam to store water. To the East of the Faro Mine, and connected by a haul road, lies the Vangorda Plateau consisting of two open pits: the Vangorda Pit, with approximately 20 million tons of waste rock; and the Grum Pit, with approximately 100 million tonnes of waste rock.

The study range for this conceptual assessment was confined to the Faro Mine Complex and nearby surrounding areas. Potential site locations of the pumped storage schemes were kept to within a reasonable distance of waste rock (pit areas) to try to exploit previously-disturbed areas and to minimize the cost of new transmission lines and access roads.

A total of 11 different locations and schemes were analyzed in this study (Schemes A through K). Due to factors affecting scheme viability, we selected three potentially promising schemes (Schemes, A, B and C) for further more detailed study.

A brief summary describing each scheme layout and its potential is provided, as well as the reasons why each scheme was discarded or carried forward for further study. For Schemes A, B and C, detailed cost estimates (accurate to approximately -20% to +50%) are provided, assuming 1) costs with no support from mining operations and 2) costs if some support is received from a current mining operation (i.e., closure) or a potential future mining operation, e.g., the further development of ore bodies in the Vangorda Pit or from the Grizzly Deposit.

Design Criteria and Assumptions

Potential Seasonal Pumped Storage Schemes

Numerous potential locations were assessed at a high level for siting pumped storage facilities. From these, a total of 11 schemes were analyzed having a wide range of design concepts, capacities and costs. Many schemes were eliminated as viable economics seemed unlikely. This report presents in detail three potential pumped storage locations: the Faro Pit Scheme (Scheme A), the Rose Creek Scheme (Scheme B) and the Vangorda Scheme (Scheme C). See Figure 1 for a plan view of the three schemes. Some of the rejected schemes are briefly summarized and shown in Figure 5.

Power and Energy Potential

Storage capacities for each scheme were chosen based on the suitability of the topography. In all cases we tried to find the maximum possible storage without making the reservoir embankments excessively large. Based on the storage volume, the head between upper and lower reservoirs and the requirement to deliver power during the four or five winter months, capacities for each scheme were chosen. For the three schemes A, B and C studied in detail, the capacities were 4, 8 and 40 megawatts (MW), and the stored energy 9.4, 9.6 and 134 gigawatt hours (GWh), respectively. For all schemes a system efficiency of 82% was assumed.

Hydrology

Weather in the area consists of long cold winters and warm summers. The annual precipitation for the study area ranges from 300-400 millimeters (mm), with a little over two-thirds falling as rain and one-third as snow. Climate normal and rainfall averages for the Yukon were obtainable from the Canadian Environmental department. The Yukon area contains approximately 19 weather stations. The data range used for this study is from 1981 to 2010. The total yearly average precipitation is 319.7 mm. May to October yields the highest precipitation depths during the year.

Catchment areas were delineated using topographic information obtained from the United States Geological Survey. The available topographic contour interval for the area is 10 meters (m). Yearly catchment volumes were determined using the rational method with a runoff coefficient of 0.80.

Geology

Most of the superficial geological materials within the Faro Complex area were deposited during the McConnell Glaciation period, and include thin till veneers and rock blankets which cover much of the mid to upper slopes. Glacial river sand, gravel, lake silts, sand and clays are common on low valley slopes contiguous to existing drainage pathways. Recent alluvium and organic deposits are found throughout the mid to lower valleys.

The central Yukon shows signs of moderate seismic activity. The rocks in the Faro Mine site are sulphide-rich and are currently undergoing treatment for Acid Rock Drainage (ARD) so ARD should be expected from waste dumps until closure plans are implemented. A preliminary desk-top geologic study was done for the area and is presented in Appendix B.

This conceptual site assessment assumes that low-permeability material is potentially available for the earthen embankments, and the in-situ impoundment materials are fairly impermeable. However, allowances are made for impoundment and embankment lining using an 80-mil high-density polyethylene (HDPE) geomembrane placed on a bedding. The proportion of the area chosen for lining was based on high-level judgment considering embankment size, impoundment depth, soils underlying the impoundment, and amount of storm water run-on into the impoundment that could offset seepage losses. The cost of the geomembrane is a significant part (~10%) of the overall capital cost.

Reservoirs

Embankments

All reservoir embankments dams were designed as earth fill with side slopes of 2.5:1, and a 5m crest width as shown on the figures. It is possible that if suitable rock is available, these sideslopes could be steepened.

It is also possible that steeper embankments built out of roller-compacted concrete could more economical in some locations; however, this option was not explored. The stability and constructability of the dams would need further geotechnical evaluation including seismic assessment. The earthwork volume quantities are based on neat-line values and do not include soil swell or shrinkage.

Pits

Only for Scheme A was a pit, the Faro Pit, used as a lower reservoir, and we could not exploit the entire Pit volume due to limitations on the size of the upper reservoir. The Grum and Vangorda Pits were found to be too small and do not have suitable surrounding topography to be useful.

Pumped Storage Layout and Equipment

For the three most promising schemes pumped storage capacities ranged from 4 to 40 MW, flows from 1.5 to 11.6 m3/s, heads from 92 to 390m, and seasonal storage from 11.7 to 123 million m^3.

In all cases, above-ground penstocks and power houses were chosen. This seemed like the most economical alternative; however, if any one of the options were to advance to the next level of design, then the full range of penstock design alternatives should be investigated. For Scheme A, a floating barge was chosen as a means to support the turbine-pump and generators. The full ramifications of such a solution would need to be investigated in further studies, but it does seem to be a viable solution based on the success of floating barges used for pump stations by the mining industry.

With the above flows, a preliminary screening showed that a Francis turbine is likely the most cost-efficient turbine choice, and hence was used for each of the schemes.

Types of electrical generation, control and other equipment were not studied in detail beyond estimating costs of typical equipment.

Existing power lines to Faro Mine were assumed to be adequate and would require only relatively short extensions (up to 6,000m) for the schemes considered.

Costs and Economic Analysis

Preliminary cost estimates were performed for all 11 schemes, but only the three most promising schemes results are presented. The major cost and financial analysis assumptions are listed below.

TABLE 1
Major Cost Analysis Assumptions

Life of the Project	50 years
Term	40 years
Debt Interest Rate	6%
Inflation Rate (over past 5 years)[1]	2%
Operations and Maintenance (O&M)	EPI Formula (HDR 2014)
Contingency	25%
Summer power rate[2]	US$0.03
Winter power rate[3]	US$0.20

1. Future inflation of power rates and O&M was assumed to match chosen interest rates.
2. A nominal amount to cover O&M.
3. Based off YEC personal communication; assuming CDN$0.2 for natural gas generated power, CDN$0.29 for diesel generated power, an assumed 50/50 mix and a 0.8 US$ to CDN$ conversion.

Cost and financial tables are presented in Appendix C.

The cost estimates developed are high-level and based on limited design. Accordingly, costs are expected to fall within the range of -20% to +50% of the presented cost.

Scheme A: Faro Pit

The Faro Pit pumped storage scheme consists of an upper reservoir located on top of the existing waste rock dump south of the Faro Pit, with the Faro Pit itself serving as the lower reservoir. Figure 3 shows a possible layout for the reservoir and penstocks.

The waste rock dump is believed to have approximately 250 million tonnes of waste. Waste rock areas west of the Faro Pit are smaller in size and are not suitable for a reservoir.

This scheme assumes closure and remediation of the waste rock slopes could be undertaken in a way that meets both closure criteria and forms the upper reservoir. For closure, the existing waste sideslopes (assumed to be 1.5:1) would likely be cut back to 3:1 slopes to provide a stable, erosion-resistant surface that could be revegetated. In addition, the waste dump surface would likely need to be covered with a geomembrane to prevent water infiltration and contamination of groundwater. By regrading the 1.5:1 slopes to 3:1 slopes, cut waste would be used to create the embankments for the upper water storage reservoirs. See Section 1 on Figure 3 for this cut configuration. The dam embankments would be 20m high, with a 5m top width and sideslopes of 3:1. Lining the impoundment and embankment surfaces would provide the necessary environmental protection and a watertight reservoir. The storage volume for the scheme is constrained by the limited space available on top of the waste dump and is approximately 11.7 million m^3.

There is limited information on the existing conditions of the Pit. For completion of this assessment, the pit was assumed to have 1:1 side walls and to be approximately 300m deep, with an estimated total volume of 134 million m^3. Top and bottom pit elevations of 1190m and 840m, respectively, were estimated. Using an existing water surface elevation depicted on Google™ Earth images, the water level of the pit water was estimated at approximately 1,240m for an estimated water volume of 79 million m^3.

The Faro Pit scheme will consist of a pump/turbine in the pit area which will pump stored water to the waste dump reservoirs. In return, water will drop via a penstock pipe to the pump/turbine installed on a floating barge on the pit lake. The total available head is estimated to be at least 300m.

The assumption of the pump and turbine on a floating barge would require a somewhat flexible penstock from the upper reservoir to the pit lake. As the capacity of the scheme is relatively small, the penstock pipe would need to be about 500mm in diameter, and could be made of articulating steel pipe or possibly even steel-reinforced HDPE pipe. Although this would present somewhat of a challenge, this could be more economical than excavating for the penstocks and power house.

Based on this design, the Scheme A could provide 4 MW capacity and a seasonal storage of 9.6 GWh. The scheme was estimated to cost US$89 million as a standalone project with no support from the Mine. If the Mine picked up 50% of the reclamation costs (i.e., regrading the upper reservoir sideslopes and lining the upper reservoir with an 80mil HDPE geomembrane), then the capital costs reduce to US$47

million. Similarly if the Mine picked up all the upper reservoir costs, which is work they would do anyway to close the dump, then the scheme would cost US$4.5 million leading to a profitable venture.

Scheme B: Rose Creek

The Rose Creek Scheme is located between the Faro and Grum pit. In this scheme, water is pumped out of the Faro Pit, is treated and then further pumped to the upper reservoir. Water from the upper reservoir is then released directly into Rose Creek. The scheme assumes that there would be sufficient ground water inflows into the Faro Pit, possibly augmented by surface flows redirected from the pit diversion channel. In total, about 18 million m^3 of inflows would be required per year, which is likely attainable just from the diverted surface water. If this assumption is not true, then the scheme is not technically viable. Creating such an inflow into the pit will reduce groundwater contamination and is environmentally beneficial.

The upper water reservoir is about 4.8 km southeast of the pit and about 4 km north of the haul road. The distribution waterline system is a combination of steel pipe at lower elevations, and HDPE pipe at higher elevations. The elevation difference from Faro Mine to the reservoir's discharge point is 290m. The pumps and pipeline were designed for a flow of 0.93 m3/s (14,700 gpm) or 17.9 million m^3 in seven months.

The dam embankment is 27m high, 5m top width and sideslopes of 2.5:1. The reservoir will provide a total water storage volume of 17.9 million m^3. The total available head is 192m with a 4,400m-long penstock leading to the power house located along the haul road. The contributing catchment area will provide an approximate flow volume of 3.2 million m^3 per year of natural inflow. See Figure 3 for scheme layout.

The economics of this scheme are only viable if support for the water treatment plant is provided by the mine.

Scheme C: Vangorda Pit

The Vangorda Scheme is located just east of the existing Vangorda Pit. This option consists of two reservoirs: the upper reservoir with a storage volume capacity 123 million m^3 and a lower reservoir with a storage capacity of 70 million m^3. Water from the Vangorda Pit operations could be blended into the 106 million m^3 per year of natural inflow volume from the upper and lower catchments, as shown on Figure 5. Such a blending could be beneficial to the Mine treatment operations currently ongoing at the Pit.

The upper reservoir dam embankments would be a maximum of 95m high, with 5m top crest width and sideslopes of 2.5:1. The upper reservoir would be built on the generally flat plateau east of the Vangorda Pit, abutting the waste dump on the south side of the Vangorda Pit. Just west of the upper reservoir is the Grizzly Deposit, an unexploited zinc/lead/nickel deposit previously identified as a potentially viable deposit (see Appendix B). If this ore body were ever to be developed, the upper reservoir embankment could be created from mine waste at almost no extra cost to the mining operation. This would make this an attractive option. For costing purposes, we have assumed that 50% of the upper reservoir is lined with an 80-mil HDPE geomembrane. We are not certain as to the likely seepage

in this area, but the inflow of 6.3M m^3 of stormwater would offset some leakage, hence the 50% estimate, which is likely conservative.

The lower reservoir embankment would be a maximum of 80m high, with a 5m top width and sideslopes of 2.5:1, and would be located in a very narrow region of the stream below the upper reservoir. The lower reservoir has a large natural inflow of water and hence can be smaller than the upper reservoir.

The total available head is 390m with a 1,780m-long penstock leading to the power house located next to the lower embankment. This gives a length to height ratio (l/h) of 4.6, which is attractive. See Figure 5 for a schematic layout.

Several other options in this area that may provide greater head and a larger upstream catchment. Thus there is a good chance that a better scheme in the area could be identified in a more in-depth and comprehensive study.

This option shows viable economics if the embankment costs are offset by at least 50% by using mine waste.

Other Schemes

As part of the site assessment process, several other schemes were considered. Some had more potential than others; however, due to a lack of head elevation, distance, or storage capacity the economic viability of these schemes was assessed to be low, and hence they were rejected for further study. Each of these schemes is briefly described below.

Scheme D

Scheme D is located just south of the Vangorda Pit. Similar to Scheme C, this option consists of two reservoirs: the upper reservoir with a storage volume capacity of 205 million m^3 and the lower reservoir (same as Scheme C) with a storage capacity of 70 million m^3. Water from the Vangorda Pit operations can be used, as well as a combined 107.2 million m^3 per year of natural inflow volume from catchment areas north of the reservoir.

The upper reservoir consists of two embankments with 2.5:1 sideslopes and 5m top width. The total available head is 310m with a penstock leading to the power house located on the lower reservoir (see Figure 5).

This scheme would have similar economics as Scheme C and hence was not studied further.

Scheme E

Scheme E is located south of the Faro Mine Pit. Similar to Scheme A, this option consists of using the Faro Pit as an upper reservoir and the Rose Creek tailing area as a lower reservoir (see Figure 5).

The limited head differential and relatively small storage volumes made this option unattractive.

Scheme F

Scheme F is located between Faro Mine pit and the Grum Pit. Similar to Scheme B, water from the Faro Mine complex will be pumped in an easterly direction to the water reservoir 3 kilometers (km) northeast of the Haul road.

The dam embankments are 40m height, 5m top width a sideslope of 2.5:1. The reservoir will provide a total water storage volume of 17 million m^3. The total available head is 430m with a 3,500m-long penstock leading to the power house located along the Haul road (see Figure 5).

This scheme would have similar economics as Scheme B and hence was not studied further.

Scheme G

Scheme G is located north of the Grum Pit. Similar to Schemes B and F, water from Grum Pit will be pumped in a northerly direction to the water reservoir 4.1 km northeast of the Haul road.

The dam embankments are 90m high, 5m top width and a sideslope of 2.5:1. The reservoir will provide a total water storage volume of 25 million m^3. The available head is 375m with a 4,175m-long penstock along the Vangorda Creek and leading to the power house located north of the Vangorda Pit (see Figure 5).

Scheme H

Scheme H is located north of the Vangorda Pit and Grizzly Deposit. Similar to the Vangorda schemes (C and D), Scheme H consists of an upper and lower reservoir. The upper reservoir dam embankments are 338m high, 5m top width and a sideslope of 2.5:1. Storage capacity for the upper reservoirs is approximately 470 million m^3. The lower reservoir dam embankments are 40m in height, 5m top width and a sideslope of 2.5:1. Storage capacity for the lower reservoirs is approximately 180 million m^3. The available head is 660m with a 6,457m-long penstock leading to the power house located along the lower embankment (see Figure 5).

The upper reservoir embankment is very large and would likely make the scheme less economical.

Scheme I

Scheme I is located 17.6 km east of the Faro Pit. Scheme I does not contain dam embankments but instead uses the natural topography for water storage. The reservoir has a storage capacity of 4.2 million m^3. The total available head is 300m with a 17,603m-long penstock leading to the power house located along the Rose Creek/Haul road (see Figure 5).

The extremely long penstock makes this scheme unattractive.

Scheme J

Scheme J is located directly north of Faro Pit. The dam embankment consists of 2.5:1 sideslopes, 60m high, 5m top width and a storage capacity of 7.3 million m^3. The total available head is 163m with a 3,166m-long penstock leading to the power house located at the Faro Pit (see Figure 5).

The long penstock and small upper reservoir makes this scheme unattractive.

Scheme K

Similar to Scheme J, Scheme K is located directly north of the Faro Pit but higher in elevation from Scheme J to produce greater head. Several dam embankments were designed, all consisting of 2.5:1 sideslopes, 20m high and 5m top widths. Storage capacities varied from 0.3 million m^3 to 3.7 million m^3. The total available head is 420 meters with a 6,911m-long penstock leading to the power house located at the Faro Pit (see Figure 5).

The long penstock and small upper reservoirs makes these schemes unattractive.

Results

Table 2 below provides a summary of the physical characteristics, storage, capacity and capital cost for each of the schemes.

TABLE 2
Scheme Characteristics

Scheme	Upper Reservoir Storage Volume (Mm^3)	Design Head (M)	Power Capacity (MW)	Energy Storage (GWh)	Estimated Cost (US$ 2015) Millions	Estimated Cost with Mining Support (US$ 2015) Millions
A: Faro Pit	11.7	300	4	9.6	89	48
B: Rose Creek	17.9	192	8	9.4	46	38
C: Vangorda	123.3	390	40	144.5	392	230

Table 3 provides a summary of the financials for each of the schemes. As can be seen, using our best assumptions, none of the schemes are financially viable without some support from the mining operations.

However, with some mining support, using our best estimate of an equitable sharing of costs, we see that Schemes A and C could be financially viable. We do caution that this viability is sensitive to interest rates, capital costs, winter and summer power costs/rates, and the capital costs would need to be confirmed in more detailed studies. In all schemes, the highest cost is the upstream reservoir, required to store the season's energy.

Notes
1. Shaded cells have variables that can be changed.
2. Based on EPRI Formula. See HDR 2014.
3. Power rates and O&M assumed to increase at rate of inflation for calculation of Present Values.
4. The Present Value based on 50 years assumes that there are no debt payments for the last 10 years.

Conclusions

A range of seasonal pumped storage schemes were found within the relatively small Faro Mine Complex area, showing how rich the area is in potential opportunities for pumped storage.

From the range of schemes studied, the most significant cost in all the schemes is the large upper reservoir and embankment required for the seasonal storage volume. This has a correspondingly large influence on the seasonal pumped storage economics. When comparing seasonal pumped storage schemes to daily or weekly pumped storage schemes, we see that the more frequent use of the upper reservoir by the daily/weekly schemes results in a smaller upper reservoir and better economics.

Only when the costs of the upper reservoir are shared by a mining operation do any of the schemes studied become potentially economically viable. When the Vangorda Scheme (Scheme C) is developed in conjunction with the Grizzly resource, we see a yearly income of about US$4 million on an investment of US$230 million. This is largely due to being able to locate the upper reservoir adjacent to the ore deposit, which would allow the mine's waste rock to be judiciously dumped to form the upper reservoir's embankment. We are of the opinion that this dumping would cost the mine little, if any more, than if dumped in a conventional heap. As an upper bound, we estimated that the additional dumping cost (due to building a dam rather than a waste dump) could potentially be $4.38/m^3 of dumped rock. If this US$4.38/m^3 were reduced to a still-credible US$2.38/m^3, then the yearly return rises to US$8 million and the investment drops to US$176 million.

Another factor influencing project economics is the catchment area to the upper reservoir. Obviously a large catchment provides free energy to the upper reservoir and improves the project economics. Several of the schemes were able to exploit large catchments.

Based on this study, we see good potential for seasonal pumped storage facilities co-developed with mining projects, as the plentiful mine waste can be used to inexpensively build the large upper reservoir required by seasonal storage. Of course, the cost of power transmission is also absorbed by the mine development.

We see the Yukon Territory itself proving good opportunity for seasonal pumped storage due to the rugged terrain and strong flowing water often providing near-ideal locations. Admittedly, a thorough and intensive search would be needed to find suitable locations.

Vangorda Pumped Storage Feasibility Study

Author: H. Blyth, P. Geo. of Blyth Consulting

Location

The Faro area, which in this report includes the Vangorda and Grum pits as well as the Grizzly deposit, is located within central Yukon, approximately 10 kilometres east of Faro, at 62°14'20.67"N, 133° 9'2.87"W (Figure 1).

Figure 1: Study area, including approximate catchments in green and magenta

Climate

Typical of much of the Yukon, climate in the Faro area consists of long cold winters and warm summers ranging from -60° to +35° Celsius (C) but average about -23° in the winter and 19° C in the summer. Total annual precipitation is ranges from 300-400 mm, with a little over two-thirds falling as rain one-third as snow. Winter snow pack rarely exceeds 1 metre in depth (McFaull, 1996).

Physiography

Faro, Yukon lies in the north of the western most physiographic region of Canada known as the Canadian Cordilleran physiographic region (Fulton, 1989). The complex nature of the Cordilleran Region encompasses steep mountains with narrow valleys, plains and plateaus. The Faro, Grum, Vangorda and Grizzly sites are located within the Anvil District of the Yukon Plateau physiographic subdivision. At the core of this district is the Anvil Range, which rises to 1800 metres above sea level (m asl) and is flanked by the midland, Vangorda Plateau.

The Canadian Cordillera is composed of five northwest-trending morphogeological belts (Hart, 2002), which are parallel to the continental margin (Figure 2). The Faro area lies within the glaciated portion of the Omineca Belt, the most varied complex of the five morphogeological belts, composed of a variety of metamorphosed sedimentary and granitic rock (Hart, 2002). The Omineca Belt presents itself as large mountain ranges with localized centres of high mountains called massifs. The Massifs tend to centre on granitic intrusions whose heat has metamorphosed the surrounding sedimentary bedrock (Hart, 2002).

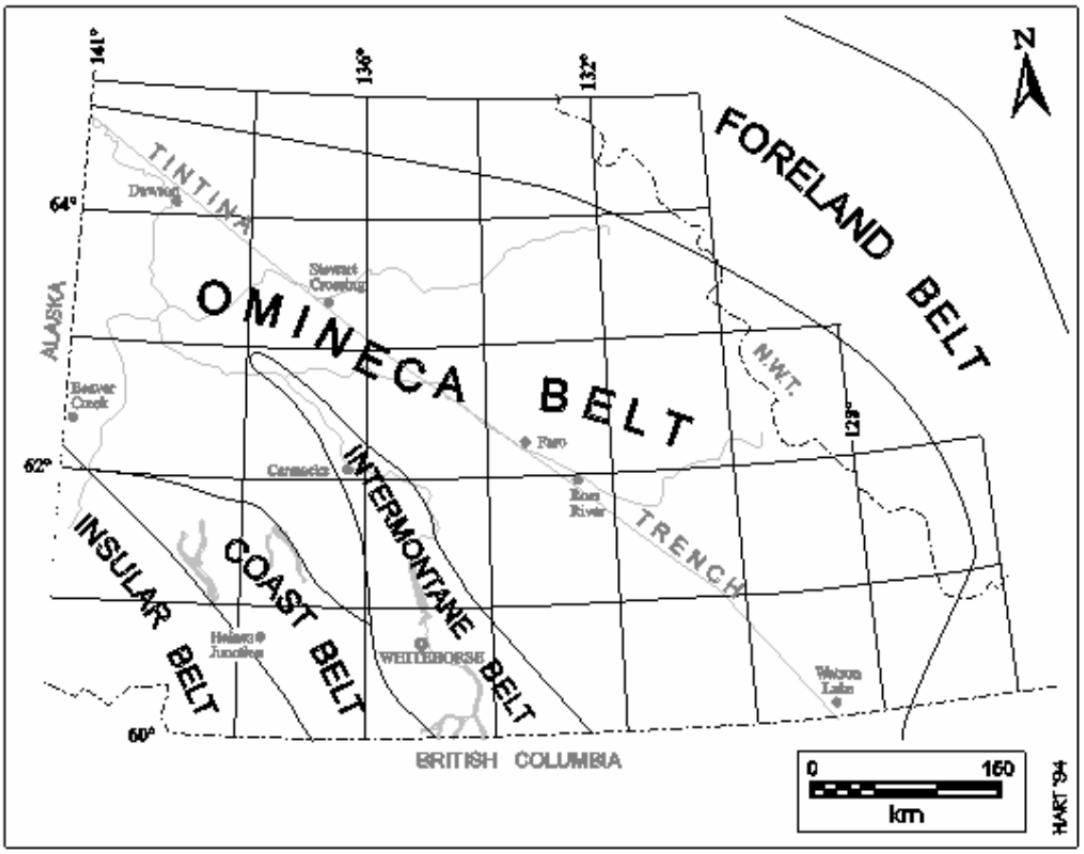

Figure 2: The five northwest-trending morphogeological belts of the Canadian Cordillera (After: Hart, 2002)

The study area lies at the edge of the Tintina Trench/Valley and the McMillan Plateau (Bostock, 1948) and ranges in elevations from 1120 m asl to as high as 2050 m asl in the upslope catchment areas (Figure 1).

Bedrock Geology:

The Grum and Vangorda pits, as well as the Grizzly deposit, rest within the Selwyn geologic Basin, west of the Selwyn Mountains (Figure 3). The Selwyn Basin is an area, in east-central Yukon, where deep water clastic sediments (e.g. siltstone, chert and minor carbonates) accumulated along the margin of the ancestral North American basin during the late Proterozoic and Paleozoic (Figure 3 - Yellow) (McFaull, 1996).

Between the Jurassic and Cretaceous a period of oblique, tectonic collision occurred, which initiated metamorphism and deformation of the Selwyn Basin rocks by northeast directed thrust faulting and folding. The Tintina Fault (within the Tintina Valley) developed during this period of oblique tectonic collision as allochthon of volcanic-plutonic rocks (Slide Mountain Terrane - brown) overrode the rocks of the Ancestral North American craton (Figure 3 – yellow), culminating with the intrusion of mid-Cretaceous granites (McFaull, 1996; Colpron and Nelson, 2011).

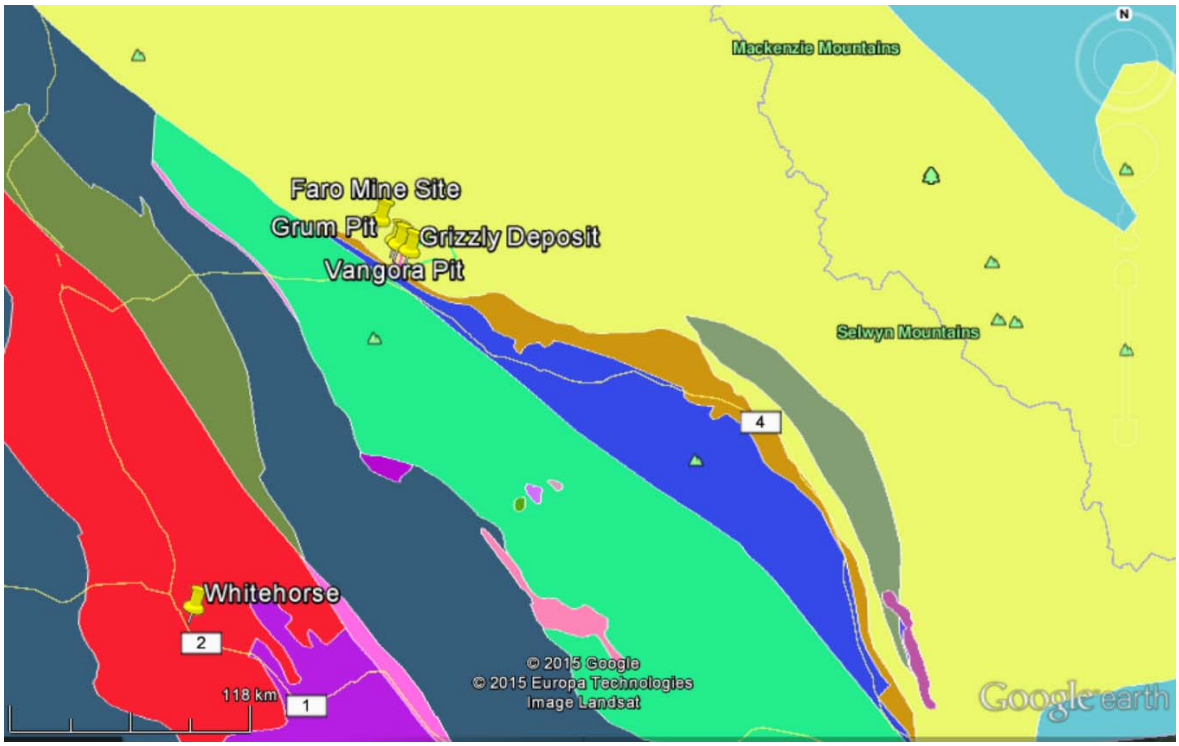

Figure 3: Geologic Terranes of the Faro area (McFaull, 1996; Colpron and Nelson, 2011)

Consistent with the regional history, the bedrock surrounding the Grizzly deposit as well as the Grum and Vangorda pits consists of phyllite, schist and graphitic phyllite of the Vangorda (Figure 4 – burgundy and lime green) and Mount Mye Formations (Figure 4 – forest and olive green) (Pigage, 2004; YGS, 2015). The locally calcareous and carbonaceous phyllite and schist commonly contain thin quartzose siltstone interbeds and interbands of dark green gabbro dykes and sills (Pigage, 2004). The stratigraphic sequences of which the Precambrian to Ordovician Mount Mye and Vangorda Formations are generally

composed consist of: deep marine schists and phyllite sequences intruded by granite, granodiorite and quartz monzonite of the Anvil Range Plutonic suite (Robertson and Kirsten, 2002).

Figure 4: Detailed geology of the Faro area (After: Pigage, 2004)

Mineral Reserves

Yukon metallurgical deposits are typically located along the margins of Selwyn Basin in fault-controlled basins and troughs (MacIntyre, 2005). The Grum and Vangorda deposits appear to rest on or near a north-south trending normal fault. The Grizzly deposit may also be associated with a northeast-southwest trending strike-slip fault (Pigage, 2004). The following table (Table 1) shows proven or inferred reserves for the Faro, Dy (Grizzly), Grum and Vangorda deposits.

Table 1: Sedimentary Exhalative Zn-Pb-Ag - Faro Yukon Area									
Deposit	**Tonnes**	**Ag (g/t)**	**Pb (%)**	**Zn (%)**	**Au (g/t)**	**Mineralogy**	**Host Rock**	**Minfile #**	**Activity**
FARO	57,600,000	36	3.4	4.7	N/A	py, sph, galena, pyrrhotite, chalcopyrite, marcasite with patchy barite and trace tetrahedrite, bournonite, arsenopyrite in siliceous gangue, magnetite	Mt Mye biotite-andalusitemuscovite-schist, 100 m below contact with Vangorda calc-silicate. Amphibolite grade.	105K 061	Mined out
DY (GRIZZLY)	Inferred and indicated mineral resource: 21,300,000	81.1	5.54	7.33	0.87 (using 9% combined cut-off grade)	sphalerite, galena, pyrite and minor chalcopyrite	Poorly defined Mt Mye/ Vangorda contact, uppermost horizon within Vangorda fm, remainder of horizons in Mt Mye fm.	105K 101	Drilling discovery, additional exploration required. Mining would be underground.
GRUM	Proven mineral reserves 16, 900,000 (open-pit mineable)	47	3	4.9	N/A	sphalerite, galena, pyrite (cp, aspy and sulphosalts) (po, mt); massive sulphide facies within each of the main horizons	From approx. 50m below Mt Mye/ Vangorda contact to 100m above it; lowest horizon 30m below main graphitic phyllite, another one immediately below it, others within Vangorda fm.	105K 056	Partially mined
VANGORDA	71,000,000	48	3.4	4.3	0.75	pale yellow sphalerite, galena, minor amounts of chalcopyrite, and traces of tetrahedrite, bournonite and arsenopyrite	Basal Vangorda carbonaceous phyllite, very well developed and thick.	105K 055	Mined out
After: Yukon Geological Survey - Selwyn Basin Metallogeny (2014) pp. 55. http://www.geology.gov.yk.ca/metallogeny_projects.html									

Acid Rock Drainage:

Acid Rock Drainage (ARD) refers to the outflow of acidic water as a common side effect to with mining projects associated with metal sulphides (Spitz and Trudinger, 2009). Though the generation of sulphuric acid is a natural occurrence over thousands of years of weathering of sulphide bearing rocks, mining accelerates the process by fragmenting and exposing sulphide bearing materials to the atmosphere and removing the filtering topsoil layers (Spitz and Trudinger, 2009).

As the rock types in the Vangorda, Grum and Grizzly deposits are similar to those of the sulphide rich Faro Mine site (YGS, 2014, IPRP, 2007), which is presently undergoing treatment for ARD, ARD should be expected throughout the study area.

Seismic Activity:

The northern Cordillera and southwestern Yukon Territories are some of the most seismically active areas of Canada. The largest earthquake recorded in this area, to date, is the magnitude 6.9 earthquake of December 23, 1985 in the Mackenzie Mountains of the Northwest Territories and numerous magnitude 6-plus earthquakes have occurred in the Richardson Mountains of the Yukon Territory (NRC, 2015). The central Yukon (e.g. around Faro, Yukon) shows signs of moderate to low seismic activity (Figure 5) (NRC, 2015).

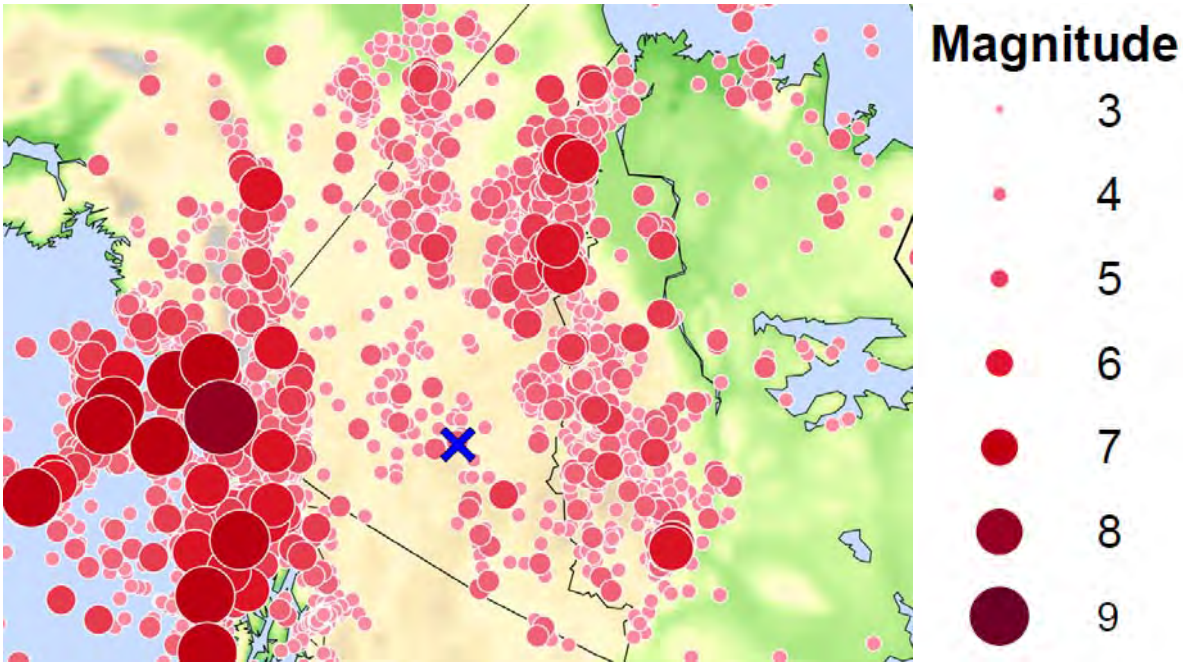

Figure 5: Earthquakes in the Yukon from 1627-2012 (X is the approximate location of Faro Yukon)

Surficial Geology:

The Faro region has undergone several glaciations, the last of which occurred between 25,000 and 10,000 years ago in the Late Wisconsinan and is known as the McConnell Glaciation (Bond, 2001). Significant surficial materials were deposited during this period including thin till veneers (<1m thick) and blankets (>lm thick), which cover much of the mid to upper slopes. Glaciofluvial (glacial river) sand and gravel and glaciolacustrine (lake) silts, sands and clays are common on low valley slopes flanking active drainage channels. Recent alluvium and organic deposits are found throughout the mid to lower valleys while veneers of colluviated till and rock blanket the upland slopes. Figure 6 below, shows the surficial geology of the Faro area followed by a written description of their common characteristics.

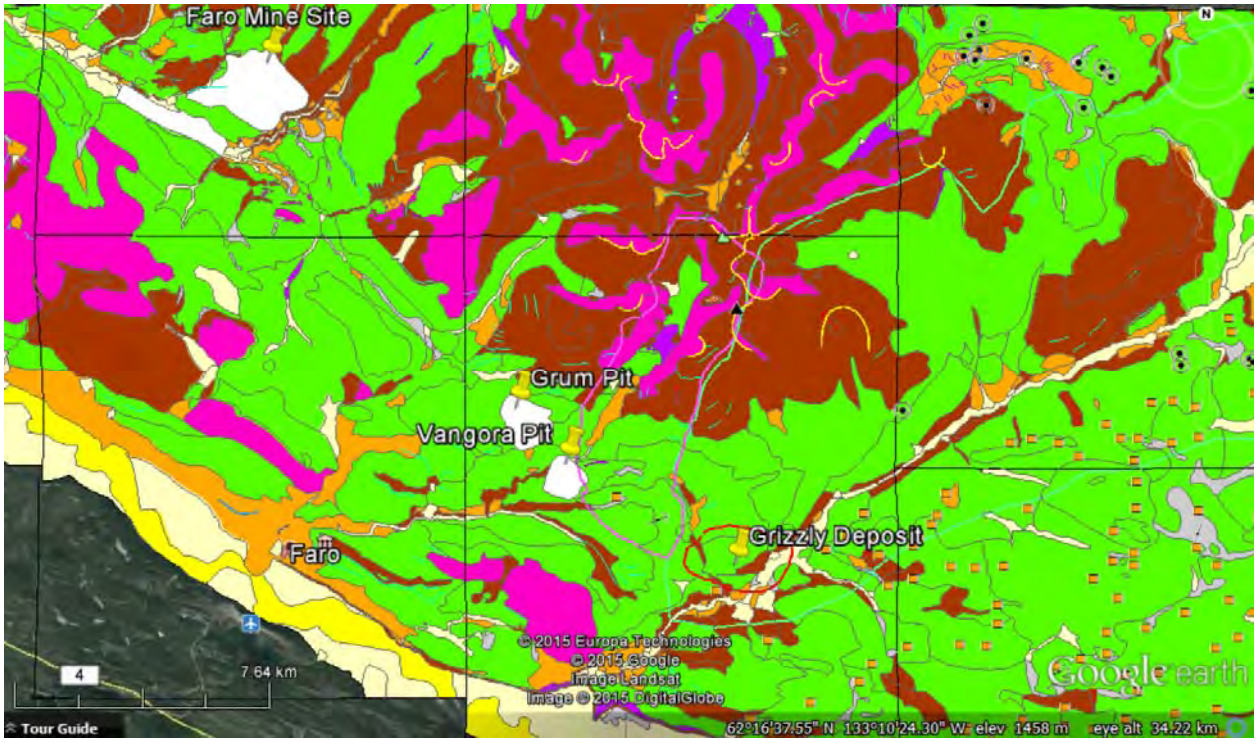

Figure 6: The surficial geology of the Faro area (After: Bond, 2001, 1999)

Green = Till (may contain oversized material, otherwise it consists of clay to boulder sized clasts, is abundant in the area and should compact well for embankments).

Orange = Glaciofluvial sand and gravel (tends to consists of interbedded sand to boulder gravel; is generally a good source of aggregate/construction material; and tends to be very porous unless interbedded with fine, glaciolacustrine sediments). There appears to be a reasonable sized source up stream of the Grum pit and downslope of the Grizzly Deposit.

Purple = Glaciolacustrine sediments (interbedded sand, silt and clay with rare drop-stones; commonly contains low porosity layers of silt and clay but is potentially unstable, particularly if undercut). If needed, there appears to be a source up valley of the Grum pit. The source up slope of the Grum pit indicates post-glacial lake impoundment; expect sub-surface glacial lacustrine deposits and seepage below the colluvium in this area.

Grey = Organic (poorly decomposed organic material; tends to be prone to seepage and permafrost). Small occurrences may be found throughout the area, the largest notable ones are due east of Vangorda pit, northwest of the Grum pit and below the Grizzly deposit in the valley.

White = Anthropogenic. These are areas altered by human activity and would need to be seen to determine porosity/seepage and other characteristics.

Beige = Fluvial material (interbedded silt, sand and gravel; usually porous, a good source of aggregate if away from active riparian zones). There may be available deposits down slope of the Grizzly deposit.

Magenta = Bedrock and colluviated till (bedrock colluvium in these area may be useful as construction material but the characteristics of each deposit will be variable depending on the source).

Dark reddish brown = Colluvium over bedrock (irregular porosity due to stratification and variable source material).

Notes: Seepage commonly occurs between materials of varied texture and compaction. This includes any surficial material contacting bedrock, stratified surficial materials and textural variations derived along weathering fronts.

Permafrost is soil or rock that remains frozen from one year to the next and may or may not contain significant quantities of ice. Permafrost covers approximately 25% southern Yukon and is continuous north of Dawson but the Faro area is within what is known as *The Extensive Discontinuous Permafrost Zone* where anywhere from 50-90% of the ground may be frozen (YGS, 2015b).

Warming and thawing of permafrost occurs in response to fires, climate change and to environmental disturbances associated with human activity and can cause ground instability and alter drainage patterns. Warming, thawing and refreezing of permafrost has implications for natural systems and infrastructure integrity, including but not limited to, landslides and ground subsidence (thermokarst). The extent of permafrost in the project area should be established during the planning stage of any construction project in this area to avoid structural problems, cost overruns and slope instability.

Summary

Upon completion of this preliminary desktop review there appears to be extensive till and some glaciolacustrine sediment, which should prove an acceptable aquatard for a pumped storage facility in the Vangorda area.

The geology at the Vangorda, DY (Grizzly) and Grum sites is similar to that of the very productive Faro mine site. The reserves, though requiring further confirmation at the DY (Grizzly) site, appear richer in silver, lead, zinc and gold than at the confirmed Faro mine site and even at the Grum site appear similar or better than those at the mined-out Faro site. This similarity, with the Faro mine site also extends to the bedrock being conducive to acid rock drainage.

Recommendations

A detailed gap analysis should be conducted to identify data weaknesses in the bedrock and surficial geologic knowledge of the area. This could include but not be limited to: bedrock distribution, specific ARD susceptibilities, stratigraphy and structural characteristics, material depths, distributions, textural and drainage characteristics; as well as detailed permafrost characteristics, avalanche, slope stability issues and the geochemical characteristics of potential aquitard materials. Accurately locating contacts between various materials (e.g. interbeds of porous and non-porous material) and structures (e.g. faults or sharp contacts) as well as textural and geochemical characteristics of till, glaciolacustrine and mineral deposits will be paramount to the success of this project.

TECHNICAL MEMORANDUM

FARO MINE PUMPED STORAGE
CONCEPTUAL ASSESSMENT OF SEASONAL PUMPED STORAGE POWER FACILITIES AT THE FARO MINE COMPLEX
YUKON ENERGY CORPORATION – YUKON TERRITORY, CANADA

EMC² – Picacho

Conceptual Assessment of Seasonal Pumped Storage Facilities at the Faro Mine Complex
Scheme A: Faro Pit
P=4MW, E=9.6GWh, h=300m, L=600m, V=11.7M m3
Preliminary Cost Estimate US$2015

Work Item	Unit	Unit Cost (2015 US$)	Estimated Quantity	Estimated Cost
Direct Costs (supply and install without profit and overhead)				
Reservoirs				
Upper Reservoir Embankment (cut to fill)	m3	6	7,900,000	$ 47,400,000
Upper Reservoir Liner (80 mil HDPE on bedding)	m2	12	775,000	$ 9,300,000
Lower Reservoir (Upgrade)	sum	200,000	1	$ 200,000
Penstocks & Power Station Complex				
Penstocks Excavation/Anchoring/Intake	sum	200,000	1	$ 200,000
Penstock pipe (d=500mm, t_{av}=7mm). [4]	m	730	600	$ 438,000
Barge Pump Platform and Ancillaries.	sum	350,000	1	$ 350,000
Maintenance/ Access Roads	m	100	500	$ 50,000
Equipment (supply and install without profit and overhead)				
Substation	sum	$ 85,000	1	$ 85,000
Mechanical/ Electrical Equipment. [5.]	sum	$ 1,150,000	1	$ 1,150,000
Sub-Total Direct Costs				**$ 59,173,000**
General Requirements				
Land acquisition/ rights	sum	$ 500,000	1	$ 500,000
Water Fill	m3	$ -	-	$ -
Additional Power Line	m	$ 250	500	$ 125,000
Feasibility Studies, including geotech, water quality investigations, etc.	sum	$ 130,000	1	$ 130,000
Engineering Procurement, Permitting/Licensing [1, 2]	%	$ 2	-	$ 1,183,460
Construction Management, Surveying, QA/QC	%	$ 2	-	$ 1,183,460
Sub-Total General Requirements Costs				**$ 3,121,920**
Indirect Costs (as a percentage of direct costs)				
Contractor Mobilization/ Demobilization	%	$ 3	-	$ 1,775,190
Contractor Site Personnel and Other Indirect Costs	%	$ 8	-	$ 4,733,840
Contractor Profit/ Overhead	%	$ 10	-	$ 5,917,300
Contingency/Unpriced Items/Market Conditions	%	$ 25	-	$ 14,793,250
Sub-Total Indirect Costs				**$ 27,219,580**
Total Project Cost (-20% to +50%)				**$ 89,514,500**

Notes:

1. Percentages are percent of direct costs.
2. Assume most environmental compliances are in place.
3. None.
4. Above-ground penstocks with special provision for pipe articulation joints.
5. Supply and install electromechanical equipment including the turbine-generator(s), governor and controls, electrical protection and control (including remote monitoring system and powerhouse electrical equipment), pumps, gates, powerhouse crane.

Conceptual Assessment of Seasonal Pumped Storage Facilities at the Faro Mine Complex
Scheme A: Faro Pit with Mining (3)
P=4MW, E=9.6GWh, h=300m, L=600m, V=11.7M m3
Preliminary Cost Estimate US$2015

Work Item	Unit	Unit Cost (2015 US$)	Estimated Quantity	Estimated Cost
Direct Costs (supply and install without profit and overhead)				
Reservoirs				
Upper Reservoir Embankment (cut to fill)	m3	$ 3	7,900,000	$ 23,700,000
Upper Reservoir Liner (80 mil HDPE on bedding)	m2	$ 6	775,000	$ 4,650,000
Lower Reservoir (Upgrade)	sum	$ 200,000	1	$ 200,000
Penstocks & Power Station Complex				
Penstocks Excavation/Anchoring/Intake	sum	$ 200,000	1	$ 200,000
Penstock pipe (d=500mm, t_{av}=7mm). [4]	m	$ 730	600	$ 438,000
Barge Pump Platform and Ancillaries.	sum	$ 350,000	1	$ 350,000
Maintenance/ Access Roads	m	$ 100	500	$ 50,000
Equipment (supply and install without profit and overhead)				
Substation	sum	$ 85,000	1	$ 85,000
Mechanical/ Electrical Equipment. [5.]	sum	$ 1,150,000	1	$ 1,150,000
Sub-Total Direct Costs				**$ 30,823,000**
General Requirements				
Land acquisition/ rights	sum	$ 500,000	1	$ 500,000
Water Fill	m3	$ -	-	$ -
Additional Power Line	m	$ 250	500	$ 125,000
Feasibility Studies, including geotech, water quality investigations, etc.	sum	$ 130,000	1	$ 130,000
Engineering Procurement, Permitting/Licensing [1, 2]	%	$ 4	-	$ 1,078,805
Construction Management, Surveying, QA/QC	%	$ 4	-	$ 1,078,805
Sub-Total General Requirements Costs				**$ 2,912,610**
Indirect Costs (as a percentage of direct costs)				
Contractor Mobilization/ Demobilization	%	$ 3	-	$ 924,690
Contractor Site Personnel and Other Indirect Costs	%	$ 8	-	$ 2,465,840
Contractor Profit/ Overhead	%	$ 10	-	$ 3,082,300
Contingency/Unpriced Items/Market Conditions	%	$ 25	-	$ 7,705,750
Sub-Total Indirect Costs				**$ 14,178,580**
Total Project Cost (-20% to +50%)				**$ 47,914,190**

Notes:

1. Percentages are percent of direct costs.
2. Assume most environmental compliances are in place.
3. Mining support decreases costs of highlighted items. Reduce rates by 50%
4. Above-ground penstocks with special provision for pipe articulation joints.
5. Supply and install electromechanical equipment including the turbine-generator(s), governor and controls, electrical protection and control (including remote monitoring system and powerhouse electrical equipment), pumps, gates, powerhouse crane.

Conceptual Assessment of Seasonal Pumped Storage Facilities at the Faro Mine Complex
Scheme B: Rose Creek
P=8MW, E=9.4GWh, L=4220m, V=17.9M m3
Preliminary Cost Estimate US$2015

Work Item	Unit	Unit Cost (2015 US$)	Estimated Quantity	Estimated Cost
Direct Costs (supply and install without profit and overhead)				
Treatment				
Lime Treatment Plant	Sum	$ 5,000,000	1	$ 5,000,000
Water Supply				
Open Channel	m	$ 500	1,253	$ 626,500
Vertical Pump + Motor	Each	$ 350,000	12	$ 4,200,000
Steel Pipeline (600 mm diameter)	m	$ 630	3,845	$ 2,422,350
HDPE Pipeline (400mm diameter)	m	$ 412	7,512	$ 3,094,944
Water Tank (Steel)	Each	$ 45,000	1	$ 45,000
Maintenance Road	m	$ 100	4,041	$ 404,100
Reservoirs				
Upper Reservoir Embankment	m3	$ 6	773,271	$ 4,639,626
Upper Reservoir Liner (assume run-on equals seepage)	m2	$ 12	-	$ -
Lower Reservoir Embankment	m3	$ 5	-	$ -
Lower Reservoir Liner	m2	$ 12	-	$ -
Penstocks & Power Station Complex				
Penstocks Excavation/Anchoring/Intake	sum	$ 1,500,000	1	$ 1,500,000
Penstock pipe (d=1m, t_{av}=7mm). [4]	m	$ 800	4,220	$ 3,376,000
Power Station Complex (above ground)	sum	$ 500,000	1	$ 500,000
Maintenance/ Access Roads	m	$ 100	550	$ 55,000
Equipment (supply and install without profit and overhead)				
Substation	sum	$ 155,000	1	$ 155,000
Mechanical/ Electrical Equipment. [5.]	sum	$ 2,400,000	1	$ 2,400,000
Sub-Total Direct Costs				**$ 28,418,520**
General Requirements				
Land acquisition/ rights	sum	$ 1,000,000	1	$ 1,000,000
Water Fill	m3	$ -	-	$ -
Additional Power Line	m	$ 250	3,500	$ 875,000
Feasibility Studies, including geotech investigations.	sum	$ 500,000	1	$ 500,000
Engineering Procurement, Permitting/Licensing [1, 2]	%	$ 4.00	-	$ 1,136,741
Construction Management, Surveying, QA/QC	%	$ 4.00	-	$ 1,136,741
Sub-Total General Costs				**$ 4,648,482**
Indirect Costs (as a percentage of direct costs)				
Contractor Mobilization/ Demobilization	%	$ 3	-	$ 852,556
Contractor Site Personnel and Other Indirect Costs	%	$ 8	-	$ 2,273,482
Contractor Profit/ Overhead	%	$ 10	-	$ 2,841,852
Contingency/Unpriced Items/Market Conditions	%	$ 25	-	$ 7,104,630
Sub-Total Indirect Costs				**$ 13,072,519**
Total Project Cost (-20% to +50%)				**$ 46,139,521**

Notes:

1. Percentages are percent of direct costs.
2. Assume most environmental compliances are in place.
3. None.
4. Above-ground penstocks.
5. Supply and install electromechanical equipment including the turbine-generator(s), governor and controls, electrical protection and control (including remote monitoring system and powerhouse electrical equipment), pumps, gates, powerhouse crane.

Executive Summary

Energy storage technology for power system application has recently attracted significant interest and attention as an enabling technology for energy management and integrating the growing capacity of variable renewable energy resources into the electric grid. Energy storage systems are likely to become an essential contributor to grid modernization investments to meet the future constraints under low carbon emissions limits.

The report will provide the Yukon Energy Corporation better understanding of what types of energy storage technologies are available to support their power system requirements. The selection of an appropriate energy storage technology combined with a responsive power conversion system will have to accommodate their present and future energy demands in terms of power quality, grid support and load shifting and possible integration of other renewables in to their power grid.

Based on the requirements for a reduction of their diesel generation utilization during peak load conditions and addressing power quality aspects, two energy storage options have been selected to address this. Electrochemical battery technology using lead acid batteries or lithium ion batteries are capable to supply the power and energy demands during the peak load conditions and as well as mitigating power quality concerns on the electrical grid.

Based on the financial model provided by Yukon Energy, the power and energy requirements determined from the 2015 load data and the total cost of a completely installed Battery Energy Storage System (BESS) under study, the net present value was calculated for 4 storage options. There were 3 lead acid based systems rated at 4 MW, 40 MWh (power/energy), 6 MW, 60 MWh, and 8MW, 80 MWh capacities and a lithium ion with an 8 MW, 40 MWh capacity. Over the 30 year lifetime of the project, all options studied had significantly higher costs as compared with their respective benefits and hence a negative NPV.

The lead acid 4 MW, 40 MWh Battery Energy Storage System (BESS) had the best Net Present Value followed by the lithium ion 8 MW/40 MWh BESS. The timeline for bringing this system online is approximately 18 months. This includes engineering and drawing, preparatory civil works, purchase and delivery of the system components, construction, and testing.

1. Introduction

The Yukon Energy Corporation is entering a new planning cycle scheduled to be completed at the end of 2016 with the issuance of its Integrated Resource Plan. An early component of the planning process is to look at potential resource options to meet the long term load forecast (2016-2035). With the higher penetration of intermittent energy sources, Yukon Energy would like a better understanding of the various energy storage technologies to offset the use of diesel generation and to support integration of renewables. The energy storage system would increase capacity during period of shortage in terms of power quality, T&D grid support, and load shifting and bulk power management. Hence, Yukon Energy is looking for technical support for a review of current energy storage technologies and to recommend viable technologies could assist the Corporation in the future.

Energy storage mediates between variable sources and variable loads. Without storage, the present energy generation must equal energy consumption. Energy storage works by moving energy through a time period, energy generated at one time can be used at another time through storage when needed. Electricity storage is one form of energy storage.

The objective of this project is to identify and evaluate energy storage technologies that would help the system meet its present and future long term energy demand by increasing capacity during times of power shortage, and that would support the integration of renewables (intermittent energy sources). Currently, the Yukon power system's main source of energy is supplied via three hydroelectric plants.

2. Scope of Work

The scope of work is to review the current energy storage technologies available for Yukon Energy Corporation's power/energy requirements for power management, grid support & load shifting and power quality. The work will include the following topics.

2.1 Literature Review

The literature review includes a high level evaluation of the mature and emerging energy storage technologies including the pros and cons of each of these technologies as they apply specifically to the Yukon power system. The evaluation will also take into consideration the sizing of the power and energy requirements of the storage system to offset some of the existing diesel generation and provide an energy storage system capable of suppling optimal power and energy requirements during peak load conditions. Included will be a review of the maturity and current trends in cost of each of these technologies and identify sites if possible where these technologies have already been implemented.

The literature review will also consider storage options based on the following specific usages for the Yukon power grid:

- Power quality
- T&D grid support and load shifting
- Bulk power management (excluding pumped storage)

2.2 Cost Estimation/Project Schedules/Footprints

Develop cost estimates and high level project schedules from early planning to commissioning of any viable options of these technologies and the potential life of these various assets will be assessed. Additionally, the minimum footprint required to implement the storage technologies will be evaluated.

2.3 Risks and Show stoppers

The report will also assess each potential energy storage technology in terms of the risks, located within or near Whitehorse and potential barriers based on:

- Pros and cons of each technology
- Maturity of each technology
- Current trends
- Sites where the energy storage technology has been implemented
- Financial attributes
- Technical attributes
    - Installed capacity in terms of power(MW) and energy (MWh)

The evaluation of energy storage options against environmental and socio-economic attributes will be completed as a separate project by Yukon Energy.

The current scope of work does not include an evaluation of pumped storage as an energy storage technology or obtaining any environmental, geotechnical or physical data collection.

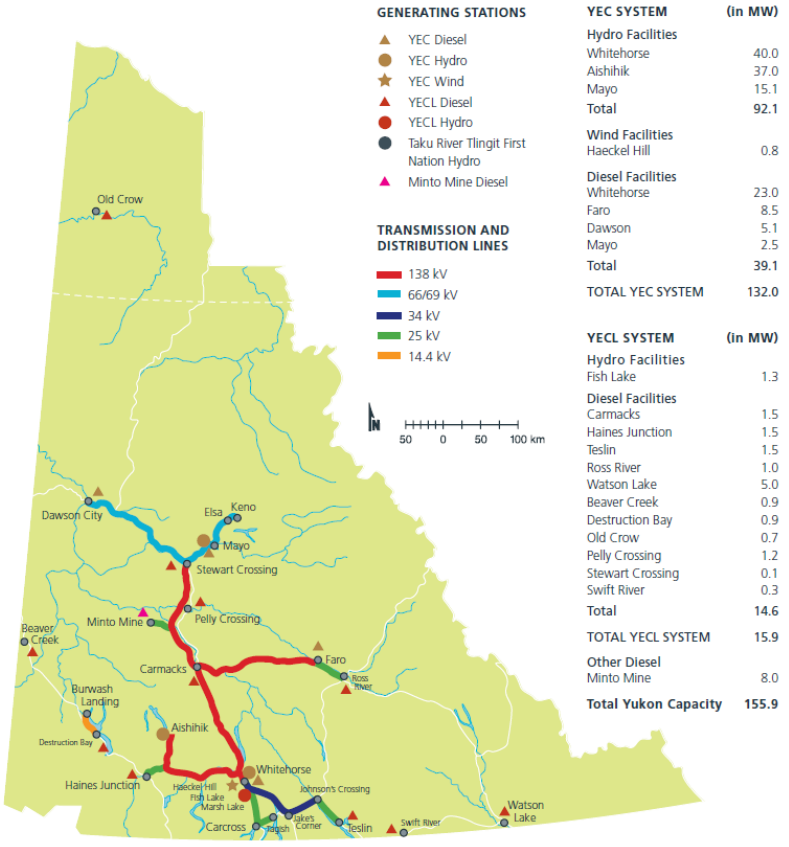
3. Yukon Energy Load Profile

The Yukon Territory is located in the northwestern part of Canada, bordered by the State of Alaska to the West, the Province of British Columbia which is to the South and the Northwest Territories to the East. As of March 2015, the population of the Territory was approximately 37,178. The Territory's capital is Whitehorse, having a population of 28,700 people and is the largest load center.

Current and committed generation capacity owned and operated by Yukon Energy Corporation (YEC or the Corporation) includes approximately 130 MW of installed generation on the Yukon Power System (approximately 92 MW hydroelectric, 0.8 MW wind, 37.8 MW thermal (diesel and natural gas)). The remaining generating assets connected to the Yukon Power System are owned by ATCO Electric Yukon and consist of about 1.3 MW of hydroelectricity and 6.8 MW of diesel.

As shown in Figure 1, there are three hydroelectric plants supplying more than 99% of the energy within the Territory. The plants are Aishihik Generating Station (37 MW, ~150 km west of Whitehorse), the Mayo Generating Station (15 MW located 450 km north of Whitehorse) and the Whitehorse Generating Station (40 MW). Transmission is at a voltage of 138 kV with the exception of the Mayo-Dawson line that operates at 69 kV.



YEC SYSTEM	(in MW)

© TransGrid Solutions Inc, 2016

Yukon Energy is entering a new planning cycle scheduled to be completed at the end of 2016 with the development of its Integrated Resource Plan. An early phase of the planning process is to explore potential resource options to meet the long term non-industrial load forecast under base case (2016-2035) as shown in Figure 2.

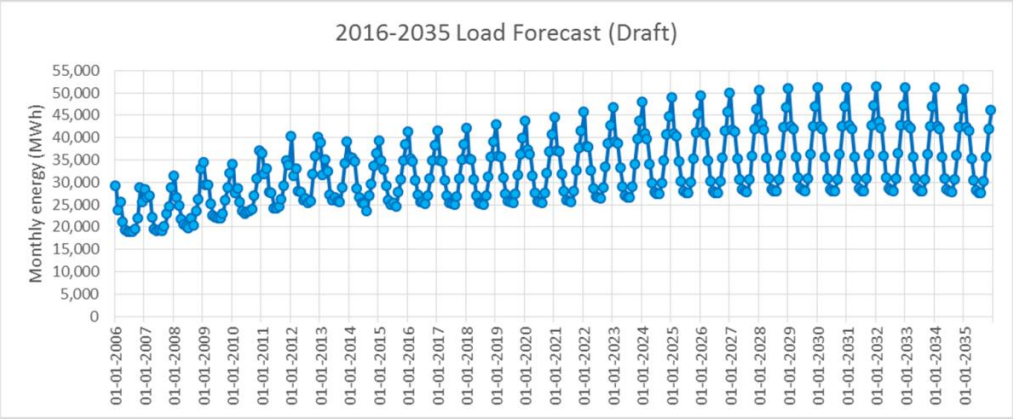

Figure 2 Yukon Energy Load Forecast

With the higher penetration of intermittent energy sources, Yukon Energy would like to better comprehend energy storage technologies to support integration of renewables and increase capacity during periods of shortage (i.e., power quality, T&D grid support, load shifting and bulk power management).

In terms of the verbal information provided during the conference calls, Yukon Energy is looking at basically two categories of an energy storage/delivery system to resolve:

1. Daily load variations
2. Intermittent generation , overvoltage problems and frequency variations

Yukon Energy has provided recent load profiles showing the electrical generation supplied from both hydro and diesel installations over the 2015 period as shown in Figure 3.

© TransGrid Solutions Inc, 2016

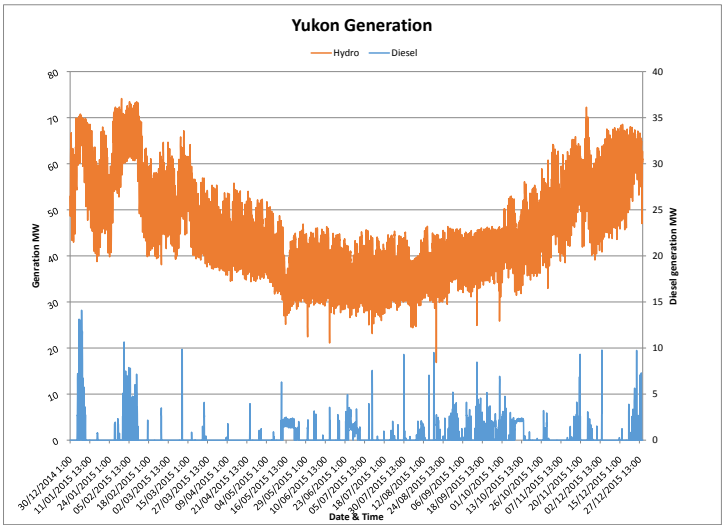

Figure 3 Hydro and Diesel Generation for 2015

Upon closer examination of the diesel generation output, the most active diesel generation time periods in terms of magnitude, frequency and duration were during the months of January and February of 2015. During these periods, the diesel generation reached a peak of 14 MW and the diesel activity was on a regular basis depending on weather conditions and customer energy demands.

As well, Yukon Energy has indicated that their electrical grid does experience overvoltage problems and some frequency deviations from time to time. Actual data was not provided regarding the severity of the frequency shifts (approximately 3 Hz), nevertheless the type of energy storage system must be capable of responding quickly to mitigate these power quality concerns.

Therefore the selection of an appropriate energy storage technology combined with an advanced power conversion system will eventually have to accommodate the present and future energy demands by Yukon Energy in terms of power quality, grid support and load shifting and possible integration of other renewables in to the power grid.

© TransGrid Solutions Inc, 2016

4. Energy Storage Technologies

Information regarding the literature review originates from various research and technical papers as listed in the References section of this report.

An important characteristic of electricity is that electrical energy cannot be stored directly. Consequently, the supply of electricity must be balanced continuously with the demand for it. The constant balancing of supply and demand has significant operational and cost implications. For example, sufficient generating capacity needs to exist to supply the highest level of demand.

The following section outlines a description of various groups of popular energy storage technologies that were chosen according to the form of stored energy that is employed. Figure 4 illustrates these broad categories in terms of: mechanical energy storage, electrochemical (and chemical) energy storage, electrical and magnetic field energy storage and thermal energy storage.

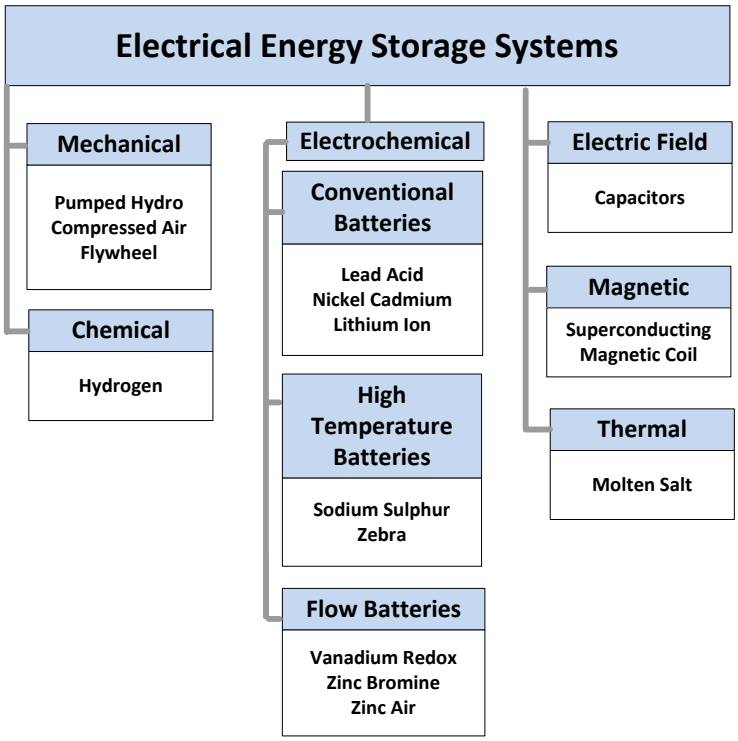

Figure 4 Classifications of Energy Storage Systems

© TransGrid Solutions Inc, 2016

4.1 Mechanical

4.1.1 Pumped Hydro Storage

4.1.1.1 Technology

Many locations in the United States and around the world use pumped hydro electric energy storage as a large, mature, and commercial utility-scale technology for an energy storage option. Off peak electricity is used to pump water from a lower level reservoir up to another high level reservoir at a higher elevation. When electricity is required, water is released from the upper reservoir through a hydroelectric turbine into the lower reservoir to generate electricity as shown in Figure 5.

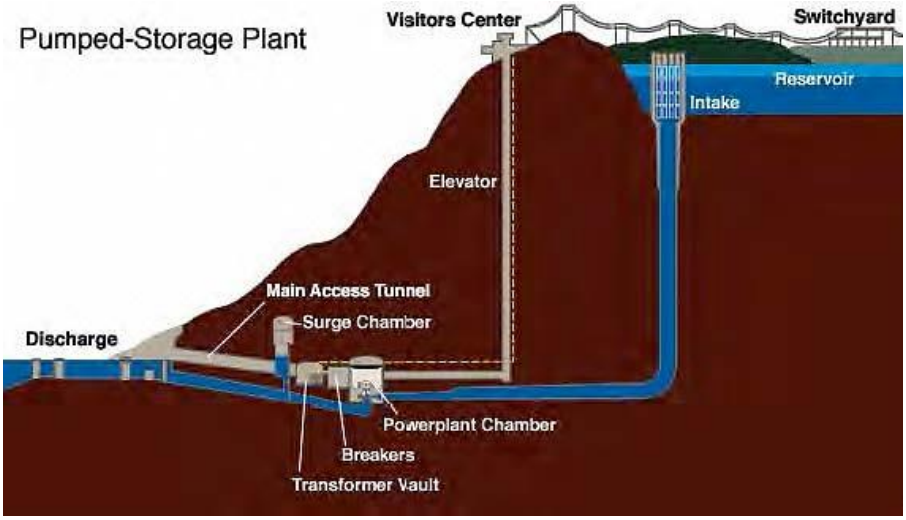

Figure 5 Cutaway of a Typical Pumped Storage System
DOE/EPRI 2013 Electricity Storage Handbook [1]

4.1.1.2 Performance

Depending on design, some projects may be practically sized up to 400 MW and operate at about 76%–85% efficiency. Pumped hydro plants have lifetimes on the order of 50-60 years. Typically a reservoir one kilometer in diameter, 25 meters deep and having an average head of 200 meters would hold enough water to generate around 10,000 MWh. [1]

4.1.1.3 Maturity and Commercial Availability

Pumped hydro storage is a mature form of energy storage. There is growing interest in opportunities for pumped hydro in the United States, however the siting, permitting, and associated environmental impact processes can take many years.

4.1.1.4 Pros and Cons as Applicable to Yukon Energy

For the scope of this work, Yukon Energy has excluded the subject of pumped hydro storage and will not be considered in this report.

© TransGrid Solutions Inc, 2016

4.1.2 Compressed Energy Storage

4.1.2.1 Technology

Compressed Air Energy Storage (CAES) systems use off-peak electricity to compress air and store it in a reservoir, either an underground cavity or aboveground pipes or containers. When electricity is required on the grid, the compressed air is heated, expanded, and directed through an expander or conventional turbine-generator to generate electricity. [1] Figure 6 shows a typical diagram for an underground compressed air storage system.

There are two general types of CAES: bulk and small. Bulk CAES is practical for storage needs greater than 5 hours and hundreds of megawatts. Typical storage capacity ranges from 300 to 400 MW over the course of 10 to 30 hours. Aboveground systems typically are smaller and have capacities on the order of 10 to 20 MW and shorter discharge times (less than 6 hours). Small CAES systems use pipes, bladders, or other man-made vessels to store compressed air. [2]

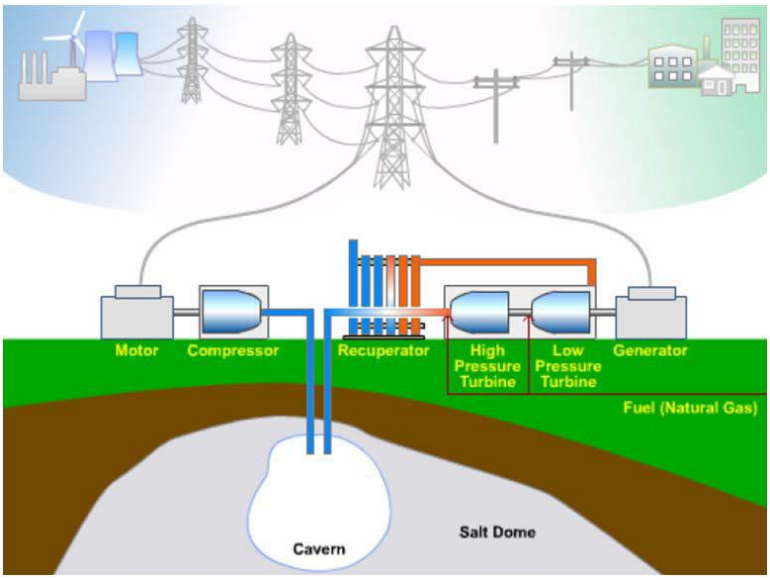

Figure 6 Diagram of a Compressed Air Storage System

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

4.1.2.2 Performance

Aboveground CAES storage would typically be smaller than plants with underground storage, with capacities on the order of 10 to 20 MW. The discharge times would be 2 to 6 hours. Aboveground CAES plants are easier to locate but more expensive to build (on a $/kW basis) than using underground CAES systems. The reason is primarily due to the incremental additional cost associated with aboveground storage medium. [1]

© TransGrid Solutions Inc, 2016

4.1.2.3 Maturity and Commercial Availability

CAES is a relatively mature energy storage technology and is the only commercial bulk energy storage plant available today other than pumped hydro. There are two operating first-generation systems: in Germany and Alabama. In the past few years, improved second-generation CAES system cycles have been defined and are being designed. Second-generation CAES hold the potential for lower installed costs, higher efficiency, and faster construction time than the first-generation systems

4.1.2.4 Site Implementation

Aboveground CAES plants are easier to site but more expensive to build (on a $/kW basis) than CAES plants using underground air storage systems, primarily due to the additional cost associated with aboveground storage medium.

Underground CAES storage systems are most cost-effective with storage capacities up to 400 MW and discharge times of 10 to 30 hours. Placement of such plants involves finding and verifying the air storage integrity of a geologic formation appropriate for CAES in a given utility's service area. [1]

4.1.2.5 Pros and Cons as Applicable to Yukon Energy

Yukon has advised that due to the local ground conditions, underground storage could not be considered and aboveground storage would have to be assessed on risk, ease of site implementation and environment considerations.

Recently Toronto Hydro has installed the first ever underwater compressed air storage system in 55 metres of water using balloon like structures. As a pilot project, this is a unique energy storage system as it uses compressed air and water pressure to run its system.

4.1.3 Flywheel

4.1.3.1 Technology

Flywheel Energy Storage (FES) stores energy in the form of the momentum in a rotating mass called the rotor. The work done to spin the rotor is stored in the form of kinetic energy. A flywheel energy system then changes the kinetic energy into AC power through the use of its controls and power conversion systems.

Most modern flywheel technology has some type of sealed housing for safety, reducing friction and performance enhancement purposes. The housing is usually a thick steel vessel surrounding the rotor, motor-generator, and other rotational components of the flywheel. See Figure 7 for a breakdown of the FES components. If there is a failure while spinning, the containment vessel would stop or impede flying parts and fragments, preventing injury and damage to the surrounding equipment or human contact. Containment systems are used also to enhance the performance of the flywheel by means of a vacuum or filled with a low-friction gas to reduce the effect of friction on the rotor. [1]

The rotor is the most important element of flywheel assembly. The rotor mass (diameter and material) influences its energy capacity. The bearings and casing are designed primarily to decrease the friction (which reduces efficiency and shortens life time). The motor-generator and power electronics characteristics determine the maximum power output of flywheel storage systems. An important aspect of flywheel systems is that power and

© TransGrid Solutions Inc, 2016

energy capacities are relatively independent from each other. This permits the flywheel technology energy and power capacity to be optimized for specific applications. [2]

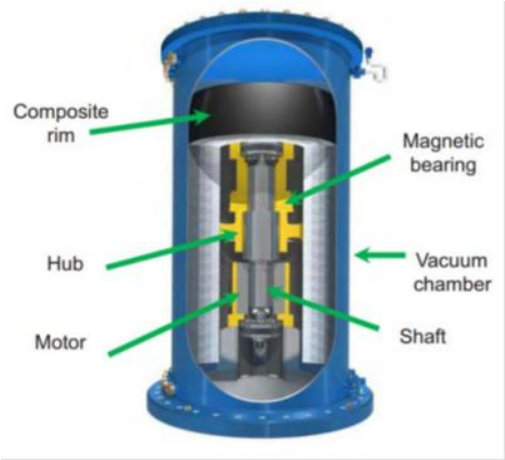

Figure 7 Flywheel Cross Section.

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

4.1.4 Performance

The overall efficiency and standby power loss are critical design factors in energy flywheel design since the losses represent a degradation of the primary purpose provided by the storage system (energy). Losses are immaterial in a power flywheel design, although standby losses are a factor in operating cost in comparison with other storage technologies that have significantly lower losses. For these reasons, flywheels for energy usage usually require more advanced technologies than power flywheels applications.

The energy flywheels usually have composite rotors enclosed in vacuum containment systems, with magnetic bearings. Such systems typically store between 0.5 kWh and 10 kWh. The largest commercially available systems of this type are in the 2- to 6-kWh range, with plans for up to 25 kWh. Energy flywheels available currently are DC output systems. Overall efficiencies for energy flywheels are usually between 70% and 80%. The standby losses are very small, typically less than 25 W DC per kWh of storage and in the range of one to two percent of the rated output power.

Flywheels can be charged relatively quickly with recharge times comparable to discharge times for both power and energy flywheels designs. High-power flywheel systems can often deliver their energy and recharge in seconds, if adequate recharging power is available.

FES in general exhibit excellent cycle life in comparison with other energy storage systems. Most developers approximate the cycle life in excess of 100,000 full charge-discharge cycles. The rotor is subject to fatigue effects arising from the stresses applied during charge and discharge cycles. The most common failure mode for the rotor is the formation of cracks through the rotor over a period of time. The rotor parts may become loose and propelled by momentum into the surrounding environment, posing danger to personnel or equipment. There is also operating noise that may pose a constraint on the siting of flywheel systems. [2]

© TransGrid Solutions Inc, 2016

4.1.4.1 Maturity and Commercial Availability

FES is currently being marketed as environmentally safe, reliable, modular, and high-cycle life alternatives to lead-acid batteries for UPS and other power-conditioning equipment designed to improve the quality of power delivered to critical or protected loads. Okinawa Power has installed a demo 23 MW flywheel system for frequency regulation. Fuji Electric has demonstrated the use of flywheel technology to stabilize wind power generation. [1]

They have a very fast response time of four milliseconds or less and can be sized typically between 100 kW and 1650 kW. FES is commonly used for short durations of up to one hour for power quality type applications. They are approaching very high efficiencies ranging from 80 to 90%, with lifetimes estimated at 20 years.

4.1.4.2 Pros and Cons as Applicable to Yukon Energy

Flywheel storage is currently employed for shorter energy duration systems, typically for durations of less than half an hour suitable for power quality type applications or for emergency back up and not generally suitable for Yukon Energy's energy storage requirements. Since FES are generally applicable to short term duration, the cost per kWh is very high ranging from $7800 to $ 8800 US (2010).

4.2 Chemical

Chemical energy storage relies on electric energy to create fuels that may be burned in conventional power plants. An advantage of synthetic methane (and hydrogen to some degree) is that it can be injected into the existing natural gas storage infrastructure. The benefit of chemical storage over some of the other technologies is the high energy density (kWh/liter) of chemical storage compared to most of the other technologies. [3]

4.2.1 Hydrogen

4.2.1.1 Technology

Hydrogen can be used in the combustion process with the compressed air storage technology. [2] In using hydrogen as a fuel, an above ground storage vessel would be advisable due to safety or environmental concerns in Whitehorse.

4.2.1.2 Performance

A typical hydrogen storage system consists of an electrolyzer, a hydrogen storage tank and a fuel cell. An electrolyzer is an electrochemical converter which splits water with the help of electricity into hydrogen and oxygen. It is an endothermal process, i.e. heat is required during the reaction. Hydrogen is stored under pressure in gas bottles or tanks, and this can be done practically for an unlimited time. To generate electricity, both gases flow into the fuel cell where an electrochemical reaction which is the reverse of water splitting takes place: hydrogen and oxygen react and produce water, heat is released and electricity is generated. For economic and practical reasons oxygen is not stored but vented to the atmosphere on electrolysis, and oxygen from the air is taken for the power generation. [5]

© TransGrid Solutions Inc, 2016

4.2.1.3 Pros and Cons as Applicable to Yukon Energy

Yukon Energy advised that due to the ground conditions, underground gas storage could not be considered and deployment of above ground storage vessels would be a significantly risky option especially when dealing with hydrogen gas with safety and environmental concerns.

4.3 Electrochemical

The Electrochemical classification involves storage technologies that convert electricity to chemical potential for storage and then back again. There are three main categories of electrochemical batteries**:** conventional, high temperature, and flow batteries. This section reviews the basic components, functions, and common examples of each category of battery storage. [3]

4.3.1 Conventional Battery

Conventional batteries are composed of cells which contain 2 electrodes (a cathode and an anode) and electrolyte in a sealed container. During discharge, a reduction-oxidation reaction occurs in the cell in which electrons migrate from the anode (oxidation) to the cathode (reduction). During recharge, the electrochemical reaction is reversed through the ionization of the electrolyte that links the anode and cathode. Numerous combinations of electrodes and electrolytes exist for conventional batteries. Common chemistries for conventional battery energy storage projects include: lead-acid, nickel-cadmium, and lithium-ion. [2]

4.3.2 Lead Acid

4.3.2.1 Technology

Lead-acid batteries are the most established form of rechargeable battery technology. The positive electrode is composed of lead-dioxide, PbO2, while the negative electrode is composed of metallic lead, Pb as shown in Figure 8. The active material in both electrodes is extremely porous to maximize surface area. The electrolyte is a sulfuric acid solution, usually around 37% sulfuric acid by weight when the battery is fully charged.

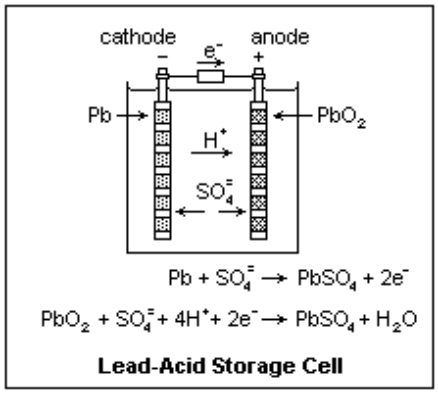

Figure 8 Lead Acid Storage Cell

Lead-acid energy storage technologies are divided into two types: lead-acid carbon technologies and advanced lead-acid technologies. Lead-acid carbon technology has a fundamentally different approach to lead-acid battery and is vented or flooded (VLA) through the inclusion of carbon to improve the power characteristics of the battery and to mitigate the effects of partial states of charge. [1]

Certain advanced lead-acid batteries are conventional valve-regulated lead-acid (VRLA) batteries with technologies that address the inadequacies of previous lead-acid products through incremental changes in the technology. [1]

Maintenance requirements for a lead acid battery involve a float charging, the equalization charging, water replacement and cell post maintenance. To prevent self-discharge, voltage is continuously applied to the already charged battery to generate a small current. Equalization charging corrects the inconsistency in state of charge between individual battery replacement is only necessary for flooded lead acid batteries (not for valve-regulated lead acid) to compensate for water lost through evaporation and electrolysis.

Furthermore, lead acid batteries contain toxic materials that pose environmental and safety hazards. In part due to regulation, lead acid batteries are one of the most recycled products. Regulations typically apply a fee when the battery is purchased which can be used to cover environmental consequences.

4.3.2.1.1 Lead-acid Carbon

Lead-acid carbon technology can exhibit a high-rate characteristic in both charge and discharge with no apparent detrimental effects as are typically experienced in traditional VLA and VRLA batteries. This characteristic allows the lead-acid carbon batteries to deliver and accept high current rates only available with higher-cost nickel metal-hydride (Ni-MH) and lithium ion (Li-ion) batteries. [1]

Presently there are three major lead-acid carbon technologies moving into the market with each having a different implementation of carbon integrated with the traditional lead-acid battery negative plate. The improvements include: significantly faster recharge rates, considerably longer cycle lives in deep discharge applications, and minimal maintenance requirements. The new cell configurations allow thousands of cells to be gathered in massive parallel and series matrices, suited for use in large-scale utility applications requiring many megawatts of power while still maintaining a manageable footprint. [1]

4.3.2.1.2 Advanced Lead-acid Technologies

Advanced lead acid technology has the properties that reduces maintenance requirements, extends life expectancy, and improves cell uniformity which increases both battery life expectancy and cost. These advanced lead-acid products focus on technology enhancements such as carbon-doped cathodes, granular silica electrolyte retention systems high-density positive active material, and silica-based electrolytes. [1]

Some advanced lead batteries even have supercapacitor-like features that give them fast response, similar to flywheels or Li-ion batteries. Advanced lead-acid systems from a number of companies are currently in early field trial demonstrations. [1]

One commercial example is the ultra-battery which is a hybrid advanced lead acid battery-capacitor that claims extended life expectancy. Thin metal film lead acid technology applies a new and fairly difficult construction

© TransGrid Solutions Inc, 2016

technique to considerably increase power density at the expense of energy density. This research has dropped off due to manufacturing difficulty and short cycle life of these batteries.

4.3.2.2 Performance

Traditional VLA and VRLA batteries are typically designed for optimal performance in either a power application or an energy application, but not both. Which means that a battery specifically designed for power applications can indeed deliver significant amounts of energy but it is not designed to deliver substantial amounts of energy (e.g., 80-percent deep discharges) on a regular basis. [1]

Disposal of lead-acid batteries is an important part of the life cycle. The environmental and safety hazards associated with lead require a number of regulations concerning the handling and disposal of lead-acid batteries. Lead-acid batteries are among the most recycled product in the world.

Lead acid batteries have a 2 V nominal voltage and efficiency ranges between 75% and 85%. Some problems of lead batteries include: self-discharge, sensitivity to temperature, sulfation, hydration, and degradation. These batteries are inclined to self-discharge but can be resolved by injecting a float charge through the battery while it is not operational. Optimal operation for a lead acid battery is at room temperature, approximately 77°F (25°C). [2]

Some advanced lead batteries have supercapacitor-like features that give them fast response, similar to flywheels or Li-ion batteries. [1]

4.3.2.3 Maturity and Commercial Availability

Lead-acid batteries are the most commercially mature rechargeable battery technology in the world. VRLA batteries are used in a variety of applications, including automotive, marine, telecommunications, and uninterruptible power supply (UPS) systems. However, there have been few utility T&D applications for such batteries due to their relatively heavy weight, large bulk, cycle-life limitations, and perceived reliability issues (stemming from maintenance requirements).[1]

Lead acid is the most technologically mature of the battery technologies. It remains popular due to its low cost, despite toxicity, low specific energy and power, short life cycle and maintenance requirements. Lead acid is generally best suited to power quality applications. Overall efficiency is between 75 and 85% and expected life, depending on technology is between 3-10 years. A total of 35 MW of lead acid batteries are deployed for power applications worldwide. [3]

For example a 1-MW, 1.5-MWh lead-acid battery has been operating for 12 years in Metlakatla, AK. In this project, the battery system exhibited very little visible degradation upon post-test analysis and was replaced in 2008, after 12 years of continuous shallow discharge service. Other lead-acid carbon energy systems have been deployed in sizes of 10 to 20 MW. [1]

Hitachi is developing their advanced lead-acid product for renewable integration and smart grid projects in Japan, with the intent of competing with sodium-sulfur (NAS) and Li-ion batteries. In August 2009, Hitachi completed a 10.4-MWh battery, built to stabilize a 15-MW wind facility at Goshogawara in northern Japan. A similar plant was installed in late 2010 at another wind-generation site at Yuasa. This battery is now available to companies for integration into the United States, although costing for the United States is uncertain at this time. [1]

4.3.2.4 Pros and Cons as Applicable to Yukon Energy

Based on the power/energy requirements by Yukon Energy during the cold and winter months, lead acid battery storage should be able to meet both the required power and energy prerequisites. Power quality attributes for frequency control is available with response times within milliseconds and is dependent on performance characteristics of the front end power conversion/inverter system.

4.3.3 Nickel Electrode

4.3.3.1 Technology

Nickel electrode batteries are known as dry cell batteries. Each dry cell contains a pair of electrodes, a positive nickel electrode and a negative electrode of cadmium, zinc, hydrogen, iron, or a metal halide. Depending on the chemistry of the negative electrode material, a divider is chosen to separate the two electrodes. After cell construction and packaging, liquid electrolyte is circulated into the porous electrodes. Only nickel-cadmium and nickel-iron have utility scale energy storage demonstrations or commercial installations. Of these two, nickel-cadmium remains the most popular for utility energy storage applications. [2] See Figure 9 which shows a typical Nickel Cadmium cell.

Figure 9 Nickel Cadmium Battery

4.3.3.2 Performance

Nickel electrode batteries experience both reversible and irreversible degradation. Reversible forms of degradation are reversed by completely discharging the cell and then recharging. Irreversible degradation varies across electrode types and application but is related to temperature and the depth and number of charge/discharge cycles. Some common irreversible degradation sources include: nickel-electrode corrosion, organic material decomposition into the electrolyte, formation of dendrites on the negative electrode, gas barrier failure, and electrode poisoning. [2]

Nickel electrode batteries have a nominal voltage of approximately 1.2 V and have an overall efficiency ranging from 65 to 85 %. Nickel cadmium batteries typically have much lower efficiency, around 60 and 70 percent (not including losses from ancillary equipment). Unfortunately cadmium is a highly toxic substance.

© TransGrid Solutions Inc, 2016

This range in efficiency is caused from differences in electrolyte concentration, charging procedures, stand-by time, and operation temperature. Nickel electrode batteries tend to have relatively higher charge losses resulting from a variety of chemical interactions within the battery cells and deviances from ideal operating temperatures. Like many batteries nickel electrode cells are susceptible to "thermal runaway," a vicious cycle of heating and increased discharge and voltage. [2]

4.3.3.3 Maturity and Commercial Availability

Nickel cadmium batteries are the most common nickel electrode battery technology in the utility energy storage industry. Although more costly than lead acid batteries, the relative low cost, high energy density, high power delivery capabilities, hardiness, reliability, and life expectancy of nickel cadmium batteries makes them a popular choice for substation batteries and bulk storage. They are technologically mature and offer a longer life span than lead-acid of around 10-15 years. [3]

Several other nickel electrode battery chemistries are under development, but not yet in commercial use for utility scale storage. Nickel hydrogen batteries have attractive operational features, such as long cycle life, low maintenance requirements, and high reliability, but very high costs. The nickel metal hydride, an offshoot of the nickel hydrogen battery, has many of the same advantages of the nickel hydrogen battery and lower costs. However, it tends to be less hardy to electrical abuses such as overcharge and high rate discharge than nickel cadmium batteries. [2]

There has been one application of 27 MW of installed capacity for 15 minutes and commissioned in 2003 that is being used for electric power systems applications. Ni-Cd has also been used for stabilizing wind-energy systems, with a 3 MW system on the island of Bonaire commissioned in 2010 as part of a project for the island to become the first community with 100% of its power derived from sustainable sources. [ESA website]

4.3.3.3.1 Pros and Cons as Applicable to Yukon Energy

Nickel cadmium batteries are generally suited for grid angularity stability, grid frequency excursion suppression, short duration power quality, which suits some of the small scale applications. However for Yukon Energy, the amount of energy storage requirements for the grid support could not be met.

4.3.4 Lithium Ion

4.3.4.1 Technology

When compared to the long history of lead-acid batteries, Lithium Ion (Li-ion) technology is relatively new to the bulk power/energy storage field. In saying this, the technology is mature and well used in consumer applications and plug in hybrid electric vehicles.

In a Li-ion battery cell there are two reactive materials capable of undergoing an electron transfer chemical reaction. To experience this reaction, the materials must contact each other electrically, either directly or through a wire, and must be capable of exchanging charged ions to keep the overall charge neutrality as electrons are transferred. The battery cell is designed to keep the materials from directly contacting each other and to connect each material to an electrical terminal isolated from the other. These terminals are the cell's external contacts. [1]

© TransGrid Solutions Inc, 2016

As shown in Figure 10, Lithium ion battery's components include: a carbon (graphite) negative electrode, a metal-oxide positive electrode, an organic electrolyte (ether) with dissolved lithium ions, and a micro-porous polymer separator. When the battery is charging, lithium ions flow from the positive metal oxide electrode to the negative graphite electrode. When the battery is discharging the reverse flow of ions takes place. [2]

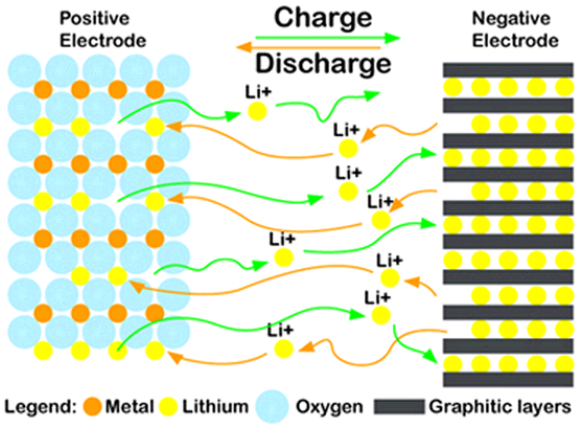

Figure 10 Lithium Ion Function and Components

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

4.3.4.2 Maturity and Commercial Availability

Since 2000, Li-Ion batteries have become a popular choice for electric vehicle and aerospace applications. This resurgence in research and development of Li-Ion technology for electric vehicle purposes has also led to interest in demonstrating the battery's potential to perform utility functions. [2]

The large scale manufacturing of Li-ion batteries (estimated to be approximately 30 GWh by 2015) may result in possibly lower-cost battery packs which could also be used and integrated into systems for grid-support services that require about 4 hours of storage. Many stationary systems have been deployed in early field trials to gain experience in siting, grid integration, and operation. Li-ion systems now dominate the landscape for grid-scale storage systems in the United States. [1]

Recently, a large investor owned utility in California wanted to evaluate the performance of a battery energy storage system combined with new smart inverter technology. In 2013, the utility installed an 8 MW – 4 hour (32 MWh) lithium-ion battery combined with two 4.5 MVA EssPro PCS units from ABB. The installation was in one of California's largest wind resource areas. The many project benefits of installing this battery energy storage system include added voltage support and grid stabilization, decreases in transmission losses and congestion, frequency regulation support and optimization of the wind energy output through capacity firming and smoothing. [4]

One of the largest Li-Ion installations in the United States is in Elkins, West Virginia. This facility connects 98 MW of wind generation with 32 MW of storage for reserve capacity and renewables integration. [2]

© TransGrid Solutions Inc, 2016

The technical characteristics of Li-Ion batteries are dependent on the electrodes and electrolyte materials but some observations can be made.

1. Due to their high energy density, Li-Ion cells have nominal voltage of 3.7 V. This is much higher than many other battery cell chemistries, which means fewer Li-Ion cells are needed to produce the same power output.
2. Like some other batteries, the response times are on the order of 20 milliseconds.
3. Li-Ion batteries have relatively high overall efficiency, usually ranging between 87 to 92 %
4. Li-Ion batteries have expected lifetimes of 2,000 to 3,000 cycles or 10 to 15 years.[2]

Li-Ion batteries have several disadvantages [2] as well such as:

1. The expected lifetime is related to the cycling depth of discharge. Li-Ion batteries should not be used for applications that require full discharge.
2. The metal oxide electrode can become thermally unstable due to over discharge or charge and be subject to thermal runaway if left unchecked.
3. Li-Ion batteries still face significant cost barriers.

4.3.4.3 Pros and Cons as Applicable to Yukon Energy

Lithium Ion battery system would be a good fit for the power and energy requirements as well as power quality (frequency regulation) for Yukon Energy needs. In 2013, an 8 MW (32MWhr) lithium-ion battery combined with two 4.5 MW power conversion units by ABB were install and California for grid support and frequency stabilization.

4.4 High Temperature Batteries

4.4.1 Sodium Sulphur Battery Energy Storage

4.4.1.1 Technology

Sodium-sulfur (NAS) batteries are a commercial energy storage technology which is finding applications in electric utility distribution for grid support, wind power integration, and high-value grid services. NAS battery technology has the potential for use in grid services because of its long discharge period (about 6 to 8 hours). Using a suitable inverter, it is capable of prompt and precise response to such grid requirements such as mitigation of power quality events. [1]

NAS battery cells contain a molten sodium (Na) anode as the negative electrode, a solid ceramic electrolyte, with a molten sulfur (S) cathode as the positive electrode. Positively charged sodium ions flow through the solid ceramic electrolyte into molten sulfur where an electrochemical reaction generates a current as shown in Figure 11. To enable ion transfer, the sodium and sulfur are kept molten at temperatures between 300° and 360°C (572° and 680°F). [2]

© TransGrid Solutions Inc, 2016

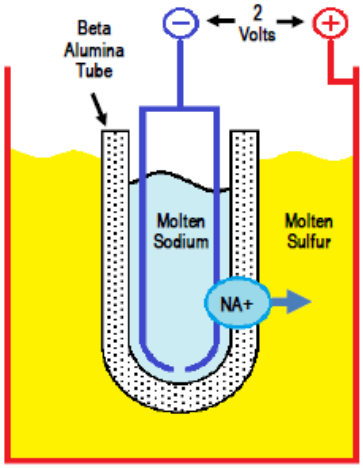

Figure 11 Sodium Sulfur Cell Diagram

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

4.4.1.2 Performance

Energy density by volume for NAS batteries is 170kWh/m3 and by weight is 117kWh/ton. NGK projects its NAS to have a cycle life of 4500 cycles for rated discharge capacity of 6 MWh per installation MW. Rated at 4500 cycles, NAS batteries are projected to have a calendar life of 15 years. [1]

NAS batteries are suitable for energy, power, or both energy and power applications. Typically, NAS batteries primary function is long duration energy storage, used for load leveling, arbitrage, “islanding,” and renewables output smoothing. However, quick response time (1 millisecond) and the ability to provide pulse power make them suitable for many power quality applications [2].

4.4.1.3 Maturity and Commercial Availability

NAS installations providing the functional equivalent of about 160 MW of pumped hydro storage are currently deployed within Tokyo. NAS batteries are only available in multiples of 1-MW, 6-MWh units with installations typically in the range of 2 to 10 MW. The largest single installation is the 34-MW Rokkasho wind-stabilization project in Northern Japan that has been operational since August 1, 2008. At this time, about 316 MW of NAS installations have been deployed globally at 221 sites, representing 1896 MWh. Customers in the United States include American Electric Power (AEP) (11 MW deployed at five locations), PG&E (6 MW, in progress), and Xcel Energy (1 MW, deployed). [1]

NAS batteries are suitable for energy and/or power applications, generally long duration energy storage. This includes load leveling, arbitrage, “islanding,” and renewables output smoothing, although their fast response time (1 ms) and the ability to provide pulse power make them suitable for a very wide range of applications. [2]

NAS batteries are still in the early stages of commercialization, especially on the grid scale. Thus far, most of the grid applications are in Japan. The overall efficiency is generally high (70 to 90%), although the energy required to maintain the electrodes in a molten state may reduce this efficiency figure.

© TransGrid Solutions Inc, 2016

Due to their early stage of commercialization, costs remain high and as with many other battery technologies, there are toxicity concerns. There are also safety concerns due to the high operating temperatures and explosive nature of sodium when exposed to water. [3]

In summary, NAS batteries are located in over 190 sites in Japan. More than 270 MW of stored energy suitable for 6 hours of daily peak shaving have been installed. The largest installation is a 34 MW 245 MWh unit for wind stabilization in northern Japan. US utilities have deployed 9 MW for peak shaving.

4.4.1.4 Pros and Cons as Applicable to Yukon Energy

Sodium-Sulfur batteries must operate at extremely high temperatures and can explode if they come into contact with water, making them a safety hazard if not handled properly. Like any battery, toxicity concerns, especially related to decommissioning and disposal, are still major obstacles to widespread installation. Consumers and environmentalists may protest the prospect of batteries located close to residential or highly populated areas.

Since this is still emerging as a commercial grid-scale energy storage technology, cost estimates still remain high. The NAS battery technology does provide the power and energy requirements for Yukon Energy as well as the power quality support available on demand. A drawback is there is currently one major off shore supplier of this technology and competitive pricing would be difficult.

4.4.2 Zebra (Sodium Nickel Chloride)

4.4.2.1 Technology

Sodium nickel chloride batteries are also referred to as Zero Emission Battery Research or (Zebra). Like the NAS battery, it is a molten sodium based battery. It contains a molten sodium negative electrode and a nickel chloride positive electrode as illustrated in Figure 12. To support in ion transfer, the battery operates around 270°C (518°F). [2]

When charging a Sodium-nickel-chloride battery at normal operating temperatures, salt (NaCl) and nickel (Ni) are transformed into nickel-chloride ($NiCl_2$) and molten sodium (Na). The chemical reactions are reversed during discharge and there are no chemical side reactions. The electrodes are divided by a ceramic wall (electrolyte) that is conductive for sodium ions but an isolator for electrons. The cell reaction can only occur if an external circuit allows electron flow match to the sodium ion current. The porous solid $NiCl_2$ cathode is impregnated with a sodium ion conductive salt ($NaAlCl_4$) that offers a conductive path between the inside wall of the separator and the reaction zone. Cells are hermetically sealed and bundled into modules of about 20 kWh each. [1]

© TransGrid Solutions Inc, 2016

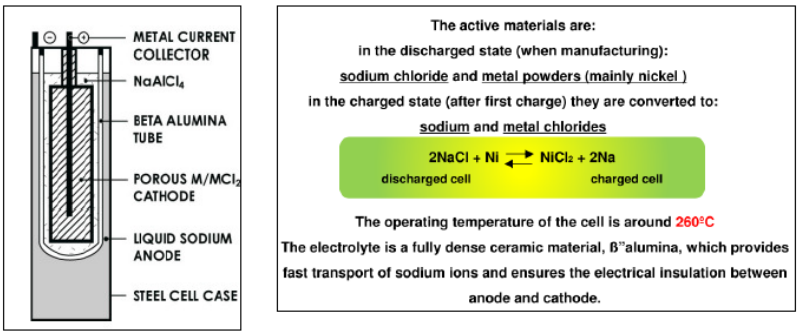

Figure 12 Deign and Features of a Zebra Battery

DOE/EPRI 2013 Electricity Storage Handbook [1]

This technology has been commercially available since 1995. So far, much of the recent research has been with electric vehicles however, there is development of Zebra systems for renewables integration and load leveling applications. [2]

4.4.2.2 Performance

Technically Zebra batteries are so far rated power between 5 and 500 kW with up to 100 kWh of energy. Zebra units have 85-90% overall efficiency, 20 millisecond response times, and expected cycle lives of up to 3,000 cycles at 80 percent depth of discharge.[2]

4.4.2.3 Maturity and Advantages

Advantages of Zebra over NAS technology includes:

- tolerance of overcharge and discharge
- higher cell voltage
- potentially better safety characteristics

Due to its high tolerance to short circuits, the failure of one cell does not cause complete failure of the Zebra battery. [2]

4.4.2.4 Pros and Cons as Applicable to Yukon Energy

Sodium nickel chloride technology does not have the energy capacity requirements of Yukon Energy.

4.4.3 Flow Batteries

Flow batteries are unlike conventional batteries and high temperature batteries because of cell construction. The electrolyte material is stored in tanks external to the electrodes. During discharge and charge, electrolyte is pumped from its container into the cell stack to interact with the electrodes, see Figure 13. Flow batteries are now considered a practical choice for energy applications requiring discharge durations greater than 5 hours due to cost efficiencies with large volumes of relatively low-cost electrolyte material. [2]

© TransGrid Solutions Inc, 2016

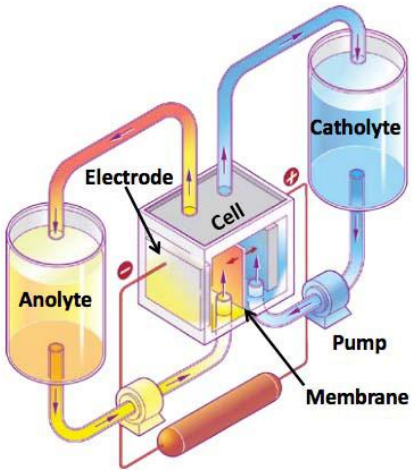

Figure 13 Flow Battery Construction

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

Unique to flow batteries is the ability to independently control and vary energy and power capacity. The discharge duration (energy) is determined by the volume of electrolyte, while the power ratings are determined by the number of cells. The ease with which electrolyte can be chemically managed and replaced as well as tolerance for overcharge/discharge and partial state of charge makes them robust to processes that degrade conventional and high temperature batteries' lives.[2]

Disadvantages of flow batteries relate to cost and construction complexity. The addition of pipes, plumbing, tanks, and other non-electrochemical components increase probability and cost of repair and electrolyte leakage. Flow batteries have relatively low power and energy density compared to their conventional and high temperature counterparts. Additionally, there are efficiency losses accrued by auxiliary equipment used to pump electrolytes from tanks to cells. [2]

There are two types of flow batteries: hybrid flow batteries and redox flow batteries.

Hybrid Flow

Hybrid flow batteries have one or more electro-active components deposited as a solid layer and the battery cell contains one battery electrode and one fuel cell electrode. A hybrid flow battery's energy is limited by the size of the battery electrode. [2]

Redox Flow

Redox flow batteries are a reversible fuel cell in which electro-active components are dissolved in the electrolyte. A redox flow battery's energy is related to electrolyte volume and power is related to electrode area in the cells. Common redox flow battery chemistries include zinc bromine and vanadium. [2]

© TransGrid Solutions Inc, 2016

4.4.4 Vanadium Redox

4.4.4.1 Technology

Vanadium redox flow batteries (VRB) contain vanadium ions that are dissolved in an acid aqueous solution. The main components of a VRB are the electrolyte, a carbon felt electrode, an ion exchange membrane that separates the electrolytes, a bipolar plate that separates cells, and the electrolyte tanks, pumps, and piping as shown in Figure 14. [2]

Both the negative and positive electrolytes (sometimes called the anolyte and catholyte, respectively) are made of vanadium and sulfuric acid mixture at approximately the same acidity as that found in a lead-acid battery. The electrolytes are stored in external chambers and pumped as needed to the cells. [1]

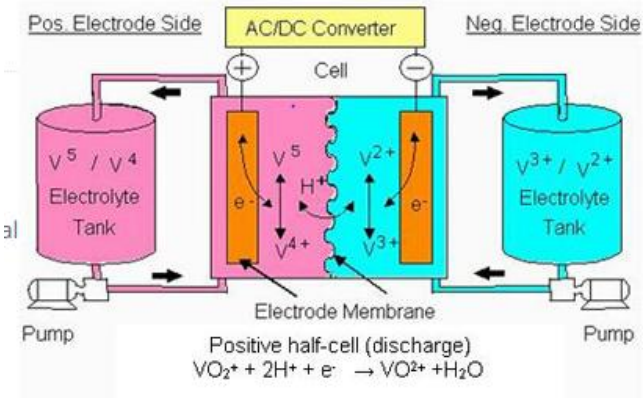

Figure 14 Vanadium Redox Battery System

4.4.4.2 Performance

VRB flow battery is suited for energy applications such as peak shaving and spinning reserve. Their full power discharge ranges from four to ten hours. Life expectancy is 10 to 15 years, with the internal membrane the limiting factor, although refurbishment can extend the lifetime to 20 years. Efficiencies are in the 60 to 70% range with nearly instantaneous response times for the battery itself (0.35 ms), although the pumps and power electronics have a slower response time, overall one can expect a response of several milliseconds. [3]

Vanadium redox batteries have recently demonstrated their compatibility with PV and wind generation, load leveling, and power quality and reliability, as well as spinning reserve. Like all flow batteries, rated energy and rated power are independently determined. Both the concentration of vanadium ions in the electrolytes and the tank volumes determine the energy storage capacity in a VRB. There are about 20 to 30 watt-hours per liter of electrolyte when the battery is fully charged. [3]

The electrode surface area determines the power of a VRB system. In contrast to conventional batteries, VRBs are generally useful for energy applications because the volume of electrolyte determines energy capacity. Full power

© TransGrid Solutions Inc, 2016

discharge ranges between four and ten hours for systems as of 2006. Each cell has a nominal voltage of 1.4 V and supplies about 26 watts.

4.4.4.3 Maturity and Advantages

Flow batteries, including the VRB have a much larger space requirement than other electrochemical storage technologies, for example a VRB system rated at 2.5 MW and 10 MWh requires between 12,000 and 17,000 square feet. This is about twice as large as the estimated space requirements for other electrochemical storage technologies.

Current commercial units are around 5 kW in size, although some demonstration units are around 250 kW and expected rated power is between 100 kW and in the future up to 10 MW. Each liter of electrolyte provides 20 to 30 Whr at full charge. [2] Presently there are 50-kW, 100-kW, 500-kW, 600-kW, and 1000-kW systems in operation. The largest in the U.S. is a 600-kW/3600-kWh system in a customer energy-management application. A 1-MW, 5-MWh system is in operation in Japan.

Advantages

Vanadium redox batteries have two main advantages over other flow battery chemistries:

1. The positive and negative electrolytes are the same when the battery is in a discharged state. This has several implications for cost, manufacture, and efficiency. Costs to ship, store, and manage electrolyte are low and the electrolytes will not contaminate each other should they be mixed (the battery will only self-discharge).

2. The sulfuric-based electrolyte does not release poisonous or corrosive vapors like other flow batteries using halide-based electrolytes.

The Vanadium redox battery could be suitable for power systems with future demonstration projects ranging in size with ratings of 100kW to 10 MW and storage durations in the 2 to 8 hour range.

4.4.4.4 Pros and Cons as Applicable to Yukon Energy

Size is a concern, as a flow battery generally has twice the footprint of a similar electrochemical storage device. Figure 15 shows system consists of 200-kW modules providing a total of 6 hours of electrochemical energy storage.

This type of technology could be suitable for the requirements of Yukon Energy depending on the rating and size requirements and as long as there are no physical constraints on site. The socio- economics still would have to be evaluated for this technology.

© TransGrid Solutions Inc, 2016

Figure 15 Prudent Energy 600kW/3 600 kWh VRB

DOE/EPRI 2013 Electricity Storage Handbook [1]

4.4.5 Zinc Bromine

4.4.5.1 Technology

Another type of flow battery is the Zinc-bromine battery in which the zinc is solid when charged and dissolved when discharged. The bromine is always dissolved in the aqueous electrolyte. The cell is made of two electrode surfaces and two electrolyte flow streams separated by a micro-porous film. The positive electrolyte is called a catholyte; the negative is the anolyte. Both electrolytes are aqueous solutions of zinc bromine (ZnBr2). [1]

During the charging, elemental zinc is plated onto the negative electrode. Elemental bromine is formed at the positive electrode. Ideally, this elemental bromine remains only in the positive electrolyte. The micro-porous separator allows zinc ions and bromine ions to migrate to the opposite electrolyte flow stream for charge equalization as shown in Figure 16. At the same time, it inhibits elemental bromine from crossing over from the positive to the negative electrolyte, reducing self-discharge because of direct reaction of bromine with zinc. [1]

Zinc bromide batteries are still in the initial stages of development, but have the potential for low cost and high energy density. Sometimes the zinc builds up unevenly on the electrodes and as a result the battery must be fully discharged every 5 to 10 cycles.[3]

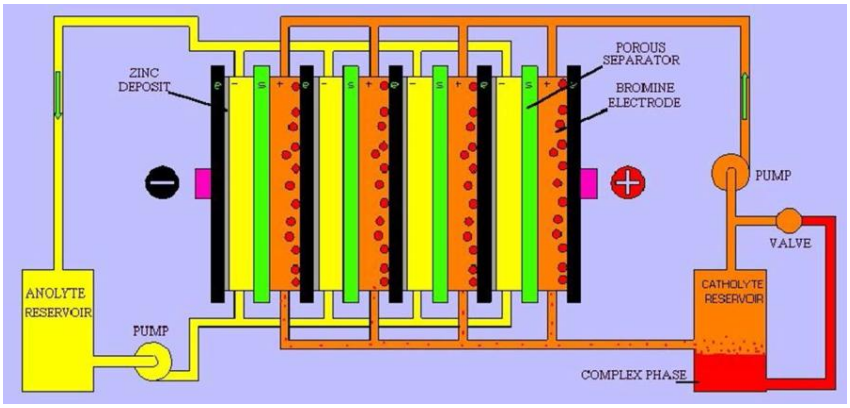

Figure 16 Zinc Bromine Cell Configuration

DOE/EPRI 2013 Electricity Storage Handbook [1]

© TransGrid Solutions Inc, 2016

4.4.5.2 Performance

The most common factor in degradation and potential failure of Zinc-bromine batteries arises from the extremely corrosive nature of the elemental bromine electrolyte. This substance tends to attack all the components of the Zinc-bromine system that are exposed to it. Past failure modes have included damaged seals, corrosion of current collectors, and warped electrodes. The active materials themselves do not degrade. The significance of this fact is that the lifetime is not strongly dependent on the number of cycles or the depth of discharge, but on the number of hours that the system has been operational. During normal operation, Zinc-bromine batteries do not present unusual environmental hazards. They do contain materials however that can become environmental contaminants. Bromine is a toxic material and should be recovered in the event of a spill or when the unit is decommissioned. Zinc-bromine is a corrosive and should be handled appropriately. Zinc is considered a transition-metal contaminant in some locales and thus should be properly recovered when the unit is decommissioned [1].

Zinc bromide flow batteries have relatively high total efficiencies ranging between 70 and 80 percent depending on system design. A typical ZnBr cell has a nominal voltage of 1.8 V and operates at or slightly above room temperature, between 20ºC and 50ºC. Although system temperature does impact efficiency, it is to a lesser degree than some other storage technologies. [2]

As bromine is extremely corrosive the limiting factor in lifetime of the units is not charge cycles but simply hours the storage system has been in operation, with estimates of around 6,000 hrs. The corrosive property is potentially a human and environmental hazard as well.[3]

4.4.5.3 Maturity and Applicability & Availability

Zinc-bromine batteries are in an early stage of field deployment and demonstration trials. While field experience is currently limited, vendors claim estimated lifetimes of 20 years, long cycle lives, and operational AC-to-AC efficiencies of approximately 65%. Module sizes vary by manufacturer but can range from 5 kW to 1000 kW, with variable energy storage duration from two to six hours. In the United States, electric utilities plan to conduct early trials of 0.5 – 1.0 MW systems for grid support and reliability by 2014. [1]

Zinc bromine flow batteries are best suited for load shifting and applications requiring high energy density as opposed to high power density. Example applications currently in use include load shifting (peak shaving) (Japan and Australia), regulation control (load following) (Detroit, Michigan), and renewables time shifting (50 kW, 100 kWh New York). The Imajuku plant in Fukuoka, Japan is rated at 1 MW and 4 MWh and is directly connected to the grid to perform peak shaving purpose. [2]

4.4.5.4 Pros and Cons as Applicable to Yukon Energy

As a consequence of corrosive liquid bromine in the electrolyte there is the possibility of hazardous environmental event or personnel exposure. Although not expected to leak, should some electrolyte contaminate the surrounding area, it could prove hazardous to proximate personnel.

The corrosiveness of the liquid bromine is a significant environmental concern when making decommissioning and disposal preparations. Due to energy limitations this technology would not be applicable to Yukon Energy requirements.

© TransGrid Solutions Inc, 2016

4.4.6 Zinc Air

4.4.6.1 Technology

Zinc-air batteries are a type of metal-air electrochemical cell technology. Metal-air batteries use an electropositive metal, such as zinc, aluminum, magnesium, or lithium, in an electrochemical couple with oxygen from the air to produce electricity. Since these batteries only require one electrode, they can potentially have very high energy densities. In addition, the metals used in most metal-air designs are relatively low cost. The oxygen serves as an electrode, while the battery construction includes an electrolyte and a zinc electrode that channels air inside the battery as shown in Figure 17.[1]

A current is created when the air electrode is discharged with the help of catalysts that produce hydroxyl ions in the liquid electrolyte. The zinc electrode is then oxidized to releases electrons to form an electric current. During recharging, the process is reversed, and oxygen is released into the air electrode.

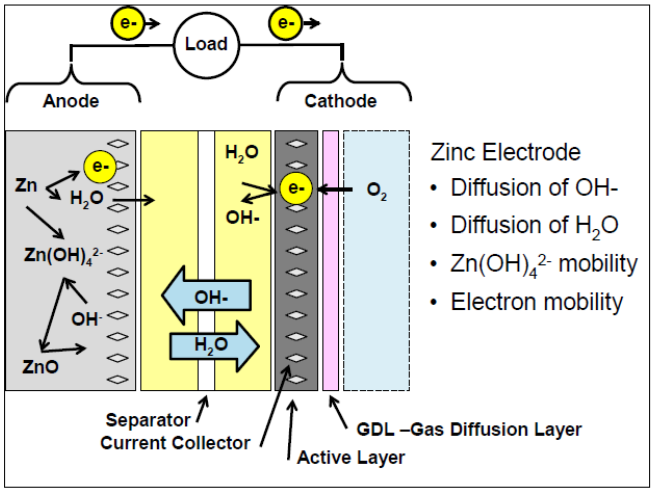

Figure 17 Zinc Air Battery Diagram
DOE/EPRI 2013 Electricity Storage Handbook [1]

4.4.6.2 Performance

Electric recharge has been challenging and inefficient with metal-air batteries, with typical overall efficiencies between 50 and 75% percent. Various manufacturers have tried to overcome low efficiencies with mechanically rechargeable systems in which the discharged metal anode is replaced with a fresh metal anode and the system continues to operate. [1]

Zinc-air batteries have up to three times the energy density of Li-ion, but unlike Li-ion, Zinc-air batteries neither produce potentially toxic or explosive gases, nor contain toxic or environmentally dangerous components., The main material in a zinc-air battery is Zinc-oxide which is 100-percent recyclable.[1]

© TransGrid Solutions Inc, 2016

4.4.6.3 Maturity and Commercial Availability

Zinc-air technology is still in early R&D phase for stationary storage systems for grid services markets although technology holds a great deal of potential due to its low capital cost for grid support and potentially for electric transportation applications.

Research and Development is underway by several manufactures to bring this energy-dense, high-operating-efficiency, better depth-of-discharge stationary technology into the market for utility T&D grid support, with some research still in the university laboratory stage.

4.4.6.4 Pros and Cons as Applicable to Yukon Energy

Zinc air energy storage is a relatively new technology and would not be suitable for the requirements of Yukon Energy.

4.5 Electrical Field

4.5.1 Electrochemical Capacitors

In general capacitors consist of two electrical conductors separated by a non-conducting material (a dielectric), is used to store energy in the form of an electric field. When a charge is applied across the conductors, opposite electrical charges build up on the conductors, creating an electric field. Energy is stored in the electric field. The capability of the capacitor to store energy is determined by the surface area of the conductors and the distance between. Most capacitors consist of two plates separated by a thin dielectric.

There are three types of capacitors: electrostatic, electrolytic, and electrochemical. An electrolytic capacitor is distinguished from an electrostatic capacitor because it uses a liquid electrolyte as one of the plates. [2]

In electrochemical capacitors (also called double layer, super-capacitors or ultra-capacitors) have a higher energy density than other capacitors. Some double layer capacitors have a voltage rating at or above 600V. This makes them suitable for power quality and intermittent renewables fluctuation suppression applications. [2]

4.5.1.1 Technology

Electrochemical capacitors are usually called double layer capacitors (DLC) or commonly known as super-capacitors or ultra-capacitors. They are distinct from other capacitors because of their high energy density. Electrochemical capacitors consist of two electrodes, a separator, an electrolyte, two current collectors and a container as shown in Figure 18. Capacitors store energy statically as opposed to batteries which store energy chemically. Electrochemical technology is similar to battery technology in that they use aqueous electrolyte and are configured into cells. [2]

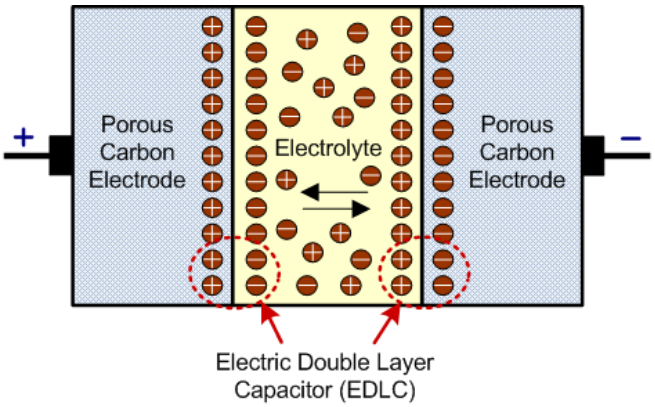

Figure 18 Capacitor Construction Diagram

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies

General Electric introduced a two-terminal charge storage device in the late 1950's and by 1979, capacitor storage was used for computer memory backup applications. They have since evolved and are able to store much more electricity, with some series of electrochemical capacitors having voltages at or above 600 V. These high power levels make it suitable for power quality and intermittent renewables fluctuation suppression applications. [2]

© TransGrid Solutions Inc, 2016

There are two basic double-layer capacitor (DLC) electrode configurations, symmetric and asymmetric. Symmetric configurations have identical electrodes, while asymmetric designs have different electrodes. [2]

The two main features of capacitor technology are the extremely high capacitance values, of the order of many thousand farads, and the possibility of very fast charges and discharges due to extraordinarily low inner resistance which are features not available with conventional batteries. [5]

4.5.1.2 Performance

The disadvantages of DLCs are firstly the interdependence of the cells, sensitivity to voltage imbalances between cells and maximum voltage thresholds, and the safety issues. If just one cell in the string fails, it may lead to the breakdown of the entire string, or it may lead to a voltage and stress increase across the other cells. This then follows into the second disadvantage that the cells life expectancies are directly tied to stringent maximum voltages. [2]

Due to their chemical properties, DLCs are suited especially to applications with a large number of short charge/discharge cycles, where their high performance characteristics can be used. However DLCs are not suitable for the storage application requiring energy over longer periods of time because of their high self-discharge rate, their low energy density and high investment costs. [5]

4.5.1.3 Safety

There are several safety issues associated with electrochemical capacitors including electrical, chemical, fire, and explosion hazards. Electrical and chemical hazards are similar to those common to batteries. The voltages of double layer capacitors are often lethal and should be treated with the same precautions as other high voltage devices. Type I and III capacitors have aqueous electrolyte which eliminates the possibility of hazardous fires, but allows for the possibility to chemical burns similar to those from other electrochemical storage devices. Type II poses a potential fire threat and health threats if inhaled, ingested, or contacts skin. [2]

There are also environmental implications due to the lack of recycling programs for electrochemical capacitors. This may contribute to siting, permitting, and disposal costs.

4.5.1.4 Applicability to Yukon Energy

Due to their low energy storage capacity, short duration of discharge and safety issues with capacitor technology, the use of DLC technology is not considered a viable option for Yukon's application.

4.6 Magnetic Field

4.6.1 Superconducting Magnetic Energy Storage

4.6.1.1 Technology

Superconducting Magnetic Energy Storage (SMES) uses the flow of direct current through a cryogenically-cooled, superconducting coil to produce a magnetic field that stores energy. Once the superconducting coil is charged, the current does not decay and the magnetic energy can be stored for an indefinite amount of time. The stored energy can be released whenever needed by discharging the coil. To keep the magnetic coil cool enough to have superconducting properties, cryogenic refrigeration must be an essential part of the storage system. See Figure 19 which shows a simplified diagram of the system. [2]

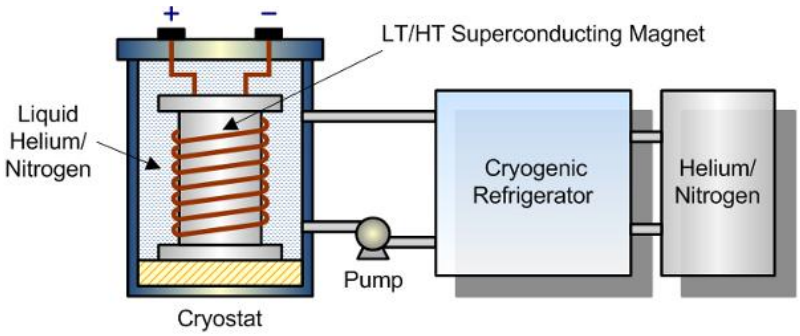

Figure 19 Diagram of a SMES System

4.6.1.2 Performance

SMES systems have several advantages including permanent storage, immediate response, life expectancy that is independent of duty cycle, high efficiency, and high reliability. The implied permanent storage relates to the stored energy may be held indefinitely, meaning that there are no standby losses. This is due to the sources of efficiency loss such as heat dissipation, and evaporation do not exist for SMES technology. Also a SMES system is capable of almost instantaneous response and is limited only by solid state materials ability to react in a charge/discharge cycle. [2]

The charging and discharging characteristics of the magnetic field has a much faster process than the mechanical and chemical energy conversion processes. This quality makes a SMES an excellent choice for UPS and power quality applications. The life expectancy of SMES a does not rely on the number of cycles or the depth of discharge as other storage technologies. The SMES overall efficiency is above 95 percent and there are very few mechanical moving parts. This means that there are less chances of failure and makes the SMES highly reliable technology. Some major disadvantages of SMES technology are the refrigeration energy requirements, the use of huge magnetic fields, and system costs.

The only commercial large scale SMES systems available around the 2000 to 2002 time frame were the D-SMES systems manufactured by American Superconductor (AMSC). The D-SMES unit is trailer-mounted system with a

© TransGrid Solutions Inc, 2016

capacity to deliver 3 MW for about 1 second and 8 MVAR continuously at 480 Volts (AC). Their primary use was for grid stabilization.Table 1 below shows the locations and applications of these three D-SMES systems. [2]

Table 1 Commercial D-SMES in the United States

In Service Date	Utility	Location	Application
June 2000	Wisconsin Public Service	Northern Wisconsin	Transmission loop stability
July 2000	Alliant Energy	Reedsburg, Wisconsin	Transmission voltage stability
May 2002	Entergy	North Texas	Voltage stability

4.6.1.3 Maturity and Commercial Availability

Prior to making the D-SMES units, American Superconductor had manufactured several smaller SMES units designed for power quality applications where fast response times are needed. These units were used mostly in industrial settings to deal with voltage sag issues.

4.6.1.4 Pros and Cons as Applicable to Yukon Energy

SMES technology does not have the energy and discharge capability to supply the Yukon power grid's energy requirements.

© TransGrid Solutions Inc, 2016

4.7 Thermal

There are several thermal storage technologies that are used to provide support to the electric power grid. Only molten salt energy storage will be considered since most of the other thermal storage technologies are on the consumer's side of the meter.

4.7.1 Technology

In a basic system, molten salt is pumped to a receiver which absorbs reflected sunlight from a heating chamber. The molten salt then is circulated through highly specialized piping in the receiver (heat exchanger) during the day, and held in storage tanks at night. The tanks store the salt at atmospheric pressure. Use of molten salt for both heat transfer and thermal energy storage minimizes number of storage tanks and salt volumes needed. Molten salt is stored at 1050°F (566°C) until electricity is needed, whether or not the sun is shining. As electricity is required, molten salt is pumped from the hot tank through a heat exchanger to create super-heated steam which then powers a conventional steam turbine. The molten salt never needs replacing or topping up for the entire 30+ year life of the plant. Heat loss is usually only 1°F per day. The molten salt, an environmentally friendly mixture of sodium nitrate and potassium nitrate, is able to be utilized as high grade fertilizer when the plant is eventually decommissioned. [3]

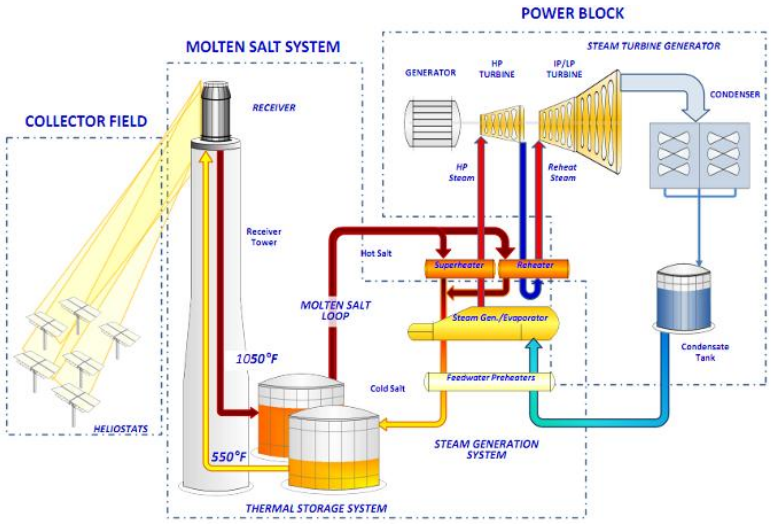

Figure 20 Molten Salt Energy Storage System

4.7.2 Performance

There a two solar heat facilities in the United States. One is the Abengoa's Solana 280 MW solar power station in Arizona which began operating in October 2013 with six hours of thermal energy storage.

Another project is Solar Reserve's 110 MW Crescent Dunes power tower solar thermal plant near Tonopah, Nevada that will have 10 hours of storage and is scheduled for completion in 2014. [3] In late September, 2011, the project received a $737 million loan guarantee from the US Department of Energy. ACS Cobra was the EPC contractor which carried out the engineering design, procured the equipment and materials necessary, and then constructed and delivered the facility to Tonopah Solar Energy. The project entered commissioning phase in

© TransGrid Solutions Inc, 2016

February 2014 following completion of construction. See Figure 21 which shows an overview of this solar collector site.

Figure 21 Crescent Dunes Solar Collector Site

All power generated by the Crescent Dunes project in the next 25 years will be sold to Nevada Power Company for $0.135 per kW hour. It has been in operation since September 2015.

The relatively low efficiency (25-35%) may be offset by relatively low capital costs if the resistance heating capability is added to an existing solar thermal plant.

4.7.3 Maturity and Applicable to Yukon Energy

Molten salt energy storage is widely used with solar power energy applications. This type of technology would not be compatible with the energy storage requirements for Yukon Energy as there are no solar energy installations at present.

© TransGrid Solutions Inc, 2016

5. Comparison of Energy Storage Technologies

There is a wide range of different energy storage technologies that are available as documented in the previous section. The selection of the most applicable technology(s) depends on the particular application which is based on the rated power, rated energy, and discharge duration demands of the electrical grid. The selected technology must also address any power quality requirements such as frequency regulation with a front end inverter and storage that can quickly respond to these variations.

Table 2 summarizes the various energy storage systems that were looked at for this project. From this table, there are four promising storage technologies that have been identified based on an estimated power rating requirement ranging from 1 to 10 MW and with an energy component ranging from 30 to 60 MWh with discharge duration between 2 to 5 hours. The power, energy and discharge requirements are an approximation derived from the Yukon Energy's diesel power generation over the 2015 time period. The selection of the four technologies was also verified by Figure 22 which confirms that the technologies that were selected were appropriate for the energy capabilities. Figure 23 shows how quickly these technologies can discharge and is useful when considering which technologies are best for providing power quality and grid support aspects.

There are also requirements that that promising technologies be mature and proven with minimal risks and be a cost effective solution to offset the present diesel generation of their grid.

The four promising energy storage technologies that were identified were all electrochemical based and are as follows:

1. Lead Acid Battery
2. Lithium Ion Battery
3. Sodium Sulphur Battery
4. Vanadium Redox Battery

Of these four energy storage technologies, only two were selected based on safety, overall cost and proven technology, and those were the lead acid battery and lithium ion battery.

The determination of the power, energy and discharge characteristics will be determined which will provide further information into the costing and footprint of the system. The next section of the report explains the cost estimates and physical size of these two technologies and options for the integration into the electrical grid. A comparison then can be made of which energy storage system would be most economical and best fit.

As reported previously, there is only one off shore supplier of the Sodium Sulphur battery, therefore competitive pricing would be an issue and there are safety concerns due to high operating temperatures. The Vanadium Redox battery would have a large footprint and is still in the development stage with the largest commercial system in service system at 600 kW

Note 1 : Costs are estimations based on several sources between 2003 and 2013 and are representative of that time period and do not reflect the 2015 dollar values. [1], [2], [3], [7]

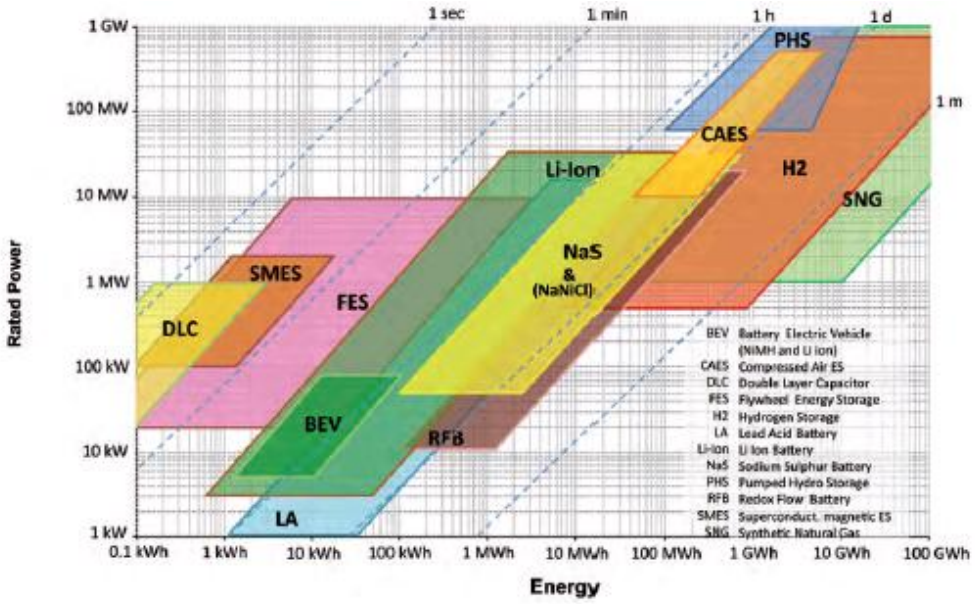

Figure 22 Rated Power Energy and Discharge Duration

Utility Scale Energy Storage Systems Benefits, Applications, and Technologies [2]

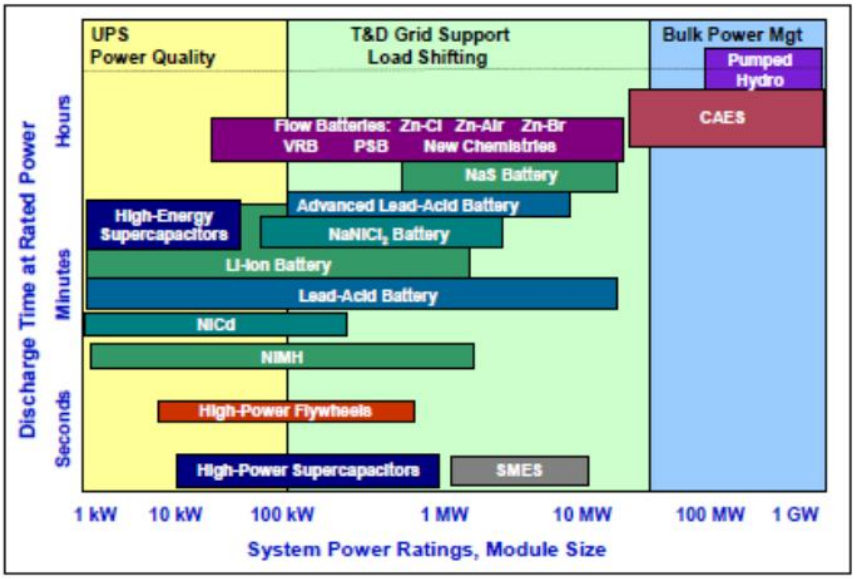

Figure 23 Comparison of Discharge Time Rating

Prospects for Large Scale Energy Storage in Decarbonized Power Grids [7]

5.1 Determining the Energy Storage System Power and Rating

The battery energy storage system power rating will be determined to reduce the use of the diesel generation while utilizing the two natural gas reciprocating engines (8.8 MW in total) during peak demand. Yukon Energy provided information that the two gas units are rated at 4.4 MW each and can be base loaded for at least 4 hours. The use of the gas generation will decrease the rating of the storage system to an optimal size based on the Yukon's Energy's requirements for a safe and mature technology.

In order to understand how often the peak power demand in 2015 reaches distinct values, a chart was developed which shows the frequency of the peak diesel power demand (see Figure 24).

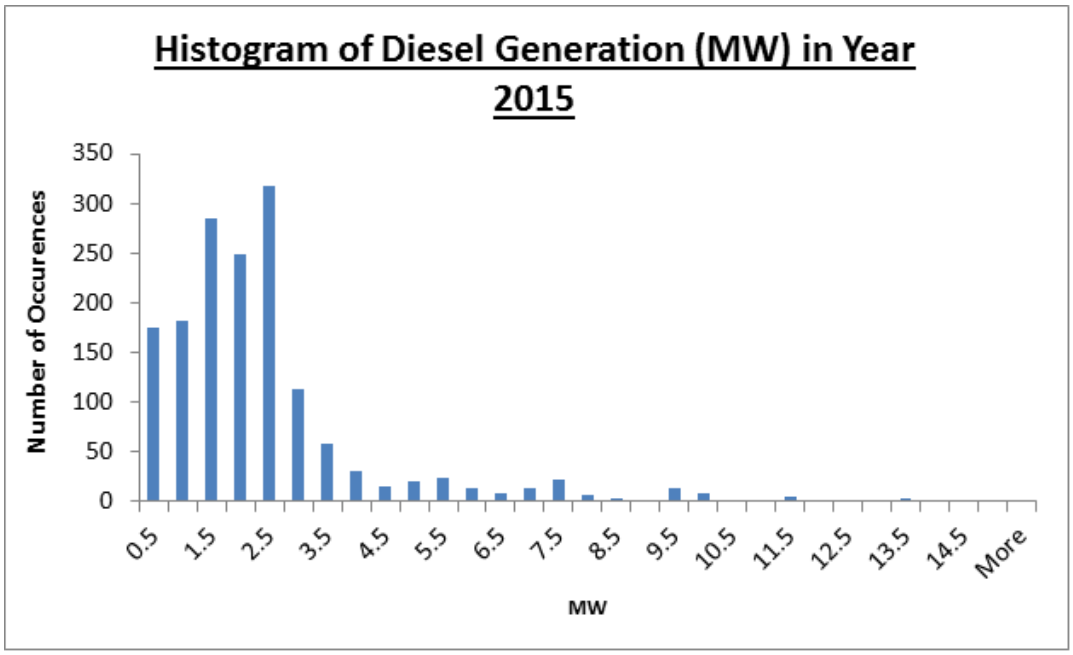

Figure 24 Frequency Plot for Different Power Levels

The general shape of the histogram is that of a Weibull distribution rather than a normal distribution, so that the median and mean values are not equal. Figure 25 shows the cumulative probability distribution for the peak power demand.

© TransGrid Solutions Inc, 2016

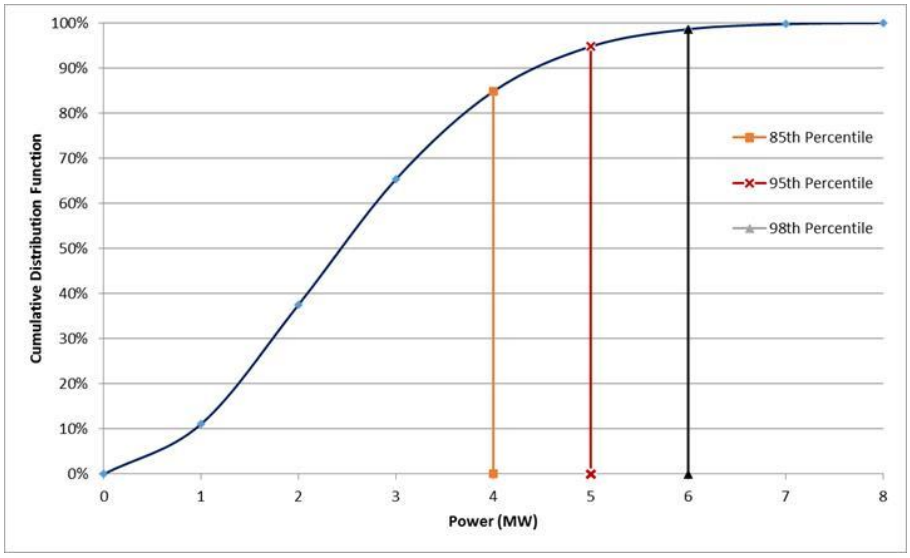

Figure 25 Cumulative Distribution Function of Optimum Power Levels

The mean value was calculated as the average of the power values, which was 2.58 MW. More importantly, from this curve, the 85th percentile value for peak power demand was approximately 4.0 MW. This means that 85% of the time (during the year 2015) the power demand was equal to or less than 4.0 MW. Only for 15% of the time did the power demand have very brief excursions above that value. Similarly, the 98th percentile value for peak power demand was approximately 6.0 MW. Therefore, 4.0 MW value was chosen as the minimum desired power output rating of the system.

With a 4.0 MW energy storage system added to the available natural gas reciprocating engine power of about 8.0 MW, the total production would be 12.0 MW to offset the diesel generation used for peaking purposes. The diesel generation is still expected to operate should the peaking demand grow greater than the combined generation of the energy storage system and natural gas units. In the data provided, this higher demand was found during the winter months.

Similar to determining the desired power rating of the energy storage, its energy rating was determined by analyzing the cumulative probability distribution of diesel energy requirements for the entire year of 2015 (see Figure 26). The median for the distribution is approximately 22.81 MWh. Using the 90th percentile point, an energy rating of approximately 40 MWh would cover greater than 90 percent of the energy demand. Similarly, the 96th percentile value for the energy demand was approximately 50 MWh. Therefore, 40 MWh value was chosen as the minimum desired energy output rating of the system.

© TransGrid Solutions Inc, 2016

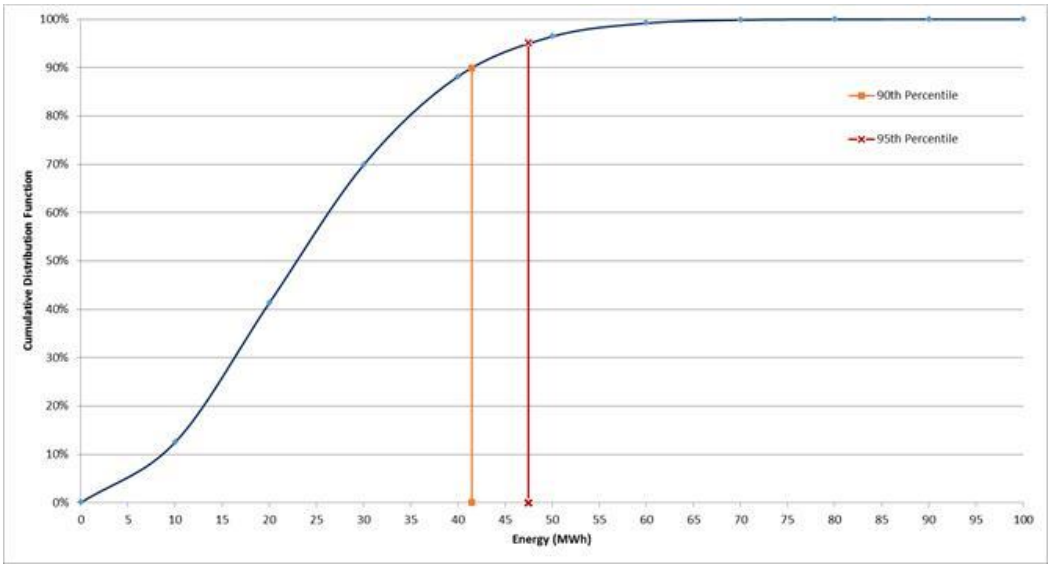

Figure 26 Cumulative Distribution Function for Energy Levels

Therefore the minimum recommended ratings for power and energy of the storage system are 4 MW and 40 MWh.

One of the mature energy storage technologies capable of providing the recommended ratings is the lead acid storage technology. Other technologies, due to having a significantly shorter discharge time, would have to have a significantly higher power output to have the same energy rating. Another mature battery energy storage technology capable of meeting the recommended energy and discharge ratings is the lithium ion battery system.

For this study, a 4 MW, 40 MWh lead acid battery energy storage system (ESS) was first selected. Due to the high MW and MWh usage in the months of January and February, this ESS will need to be complemented by the use of both 8 MW natural gas generation units. To reduce the use of the natural gas generation units, a 6 MW/60 MWh and an 8 MW/80 MWh lead acid battery energy storage systems were also studied as options. For price comparison purposes, an 8 MW/40 MWh lithium ion battery energy storage system was also considered.

© TransGrid Solutions Inc, 2016

6. Cost Estimates, Schedule, and Footprints

The 2015 load data for hydro-electric and diesel generation provided by Yukon Energy Corporation (see Figure 3) was used to assess the power capacity need of an energy storage system. The data showed diesel and natural gas generation was used mainly for peak demand. Diesel generation is a mature and well developed technology and has a low capital cost but a very high operation and maintenance cost. The diesel generators, as well as the trucks transporting the fuel, produce environmentally damaging SOx and NOx gas emissions. Other known problems associated with diesel generation include fuel storage leaks, leakage of generator lubricants, and variations in fuel price. Hence there is a focus to curtail diesel generation with an energy storage system together with the natural gas generation.

As discussed in Section 5, the type of energy storage chosen was a battery energy storage system (BESS), specifically either the lead acid or lithium ion batteries. Going forward in this report, all references to an ESS will imply battery energy storage. Battery Energy Storage Systems possess many advantages for the improvement of power reliability over diesel generation. One advantage is that these systems (both the power conversion systems and energy storage technologies) are modular so that they can be installed in a reasonable time frame and power capacity can be added in small increments as the demand grows. The modular concept is also beneficial for equipment transportation. Most energy storage technologies should be built in a modular arrangement and not install the energy storage system with full capacity at the beginning. This could be wasteful in terms of the utilization of the energy storage technology due to their relatively short lifespan and high costs. Also, by adding to the BESS in increments, one can take advantage of future improvements in battery technology and efficiency.

These systems are considered multifunctional, aside from assisting in continuing the supply of power during peak demand, the energy storage systems may contribute for improvements in transient stability, voltage stability, frequency regulation, transmission and distribution grid support, load shifting, bulk power management and power quality.

6.1 Battery Energy Storage System Components and Footprint

To evaluate the minimum footprint of each energy storage system one needs to examine the major components of a battery energy storage system. The BESS can be broken down into the following three categories.

1. The Energy Storage Technology (EST) consist of all equipment necessary to store and supply energy to the Power Conversion System (PCS), duties, shipping and installation at site, and engineering support for installation and commissioning. For this study, the lead acid and lithium ion battery manufacturer's recommended battery connections to the PCS are shown in Table 3.

Table 3 Battery Configuration to the PCS

Energy Storage System Model	Battery Connections to the PCS
4 MW 40 MWh Lead Acid	Four (4) 1 MW connections
6 MW 60 MWh Lead Acid	Eight (8) 750 kW connections
8 MW 80 MWh Lead Acid	Eight (8) 1 MW connections
8 MW 40 MWh Lithium Ion	Four (4) 2 MW connections

© TransGrid Solutions Inc, 2016

2. The PCS consist of all necessary power electronic equipment that will control the supply of electrical energy from the utility grid to the ESS and that will later discharge the stored energy in the ESS, returning it to the grid. The PCS converts the DC power of the energy storage device to AC power used by the utility grid and vice versa when the grid power is used to re-charge the storage device. Table 4 lists the major PCS equipment required for the four options of battery energy storage systems being studied.

Table 4 Power Conversion System Major Equipment List

Energy Storage System Model	PCS Equipment
4 MW, 40 MWh Lead Acid	One (1) PCS Module packaged in one 40' trailer. The one module includes the following: • Four (4) 1 MW inverters with AC and DC circuit breakers; thermal management; control and protection • Four (4) 1000 kVA padmount transformers : 35 kV : 267 VAC • One (1) MUC (Multiple Unit Control)
6 MW, 60 MWh Lead Acid	Two (2) PCS Modules packaged in two 40' trailers. Each module includes the following: • Four (4) 750 kW inverters with AC and DC circuit breakers; thermal management; control and protection • Four (4) 750 kVA padmount transformers : 35 kV : 267 VAC • One (1) MUC (Multiple Unit Control)
8 MW, 80 MWh Lead Acid	Two (2) PCS Modules packaged in two 40' trailers. Each module includes the following: • Four (4) 1 MW inverters with AC and DC circuit breakers; thermal management; control and protection • Four (4) 1000 kVA padmount transformers : 35 kV : 267 VAC • One (1) MUC (Multiple Unit Control)
8 MW, 40 MWh Lithium Ion	Two (2) PCS Modules packaged in two 40' trailers. Each module includes the following: • Two (2) 2 MW inverters with AC and DC circuit breakers; thermal management; control and protection • Two (2) 2000 kVA padmount transformers : 35 kV : 454 VAC • One (1) MUC (Multiple Unit Control)

3. The Balance of Plant (BoP) consists of the utility's costs for the project engineering, construction management and grid connection to build an energy storage system substation.

   For the study the major equipment and requirements included:

© TransGrid Solutions Inc, 2016

- All required site preparation, foundations, grounding, support structures, cabling, bus work, protection, controls, and SCADA at the substation.
- The building for housing the batteries
- The slabs on grade for the PCSs,
- 3 three-phase 34.5 kV circuit breakers
- 3 three-phase motor operated disconnects
- 3 three-phase manual disconnects
- Cabling between the substation and PCS
- Cabling between the PCS and EST

The proposed development single line diagrams of the battery energy storage systems are shown in Figure 27 for the 4 MW, 40 MWh BESS and Figure 28 for the 6 MW, 60 MWh, the 8 MW, 80 MWh and the 8MW, 40 MWh (lithium ion)BESS.

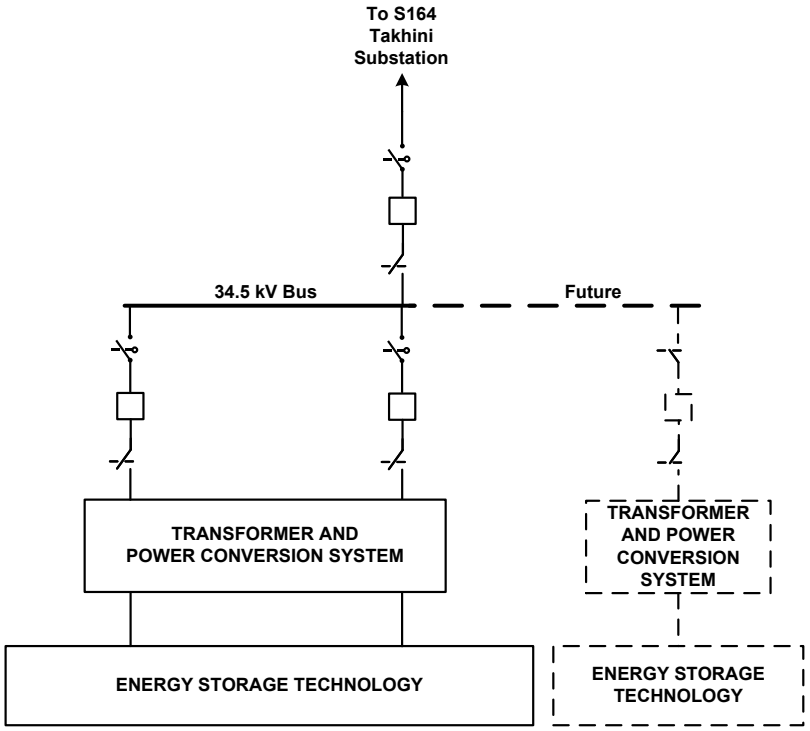

Figure 27: 4 MW, 40 MWh Battery Energy Storage System Configuration

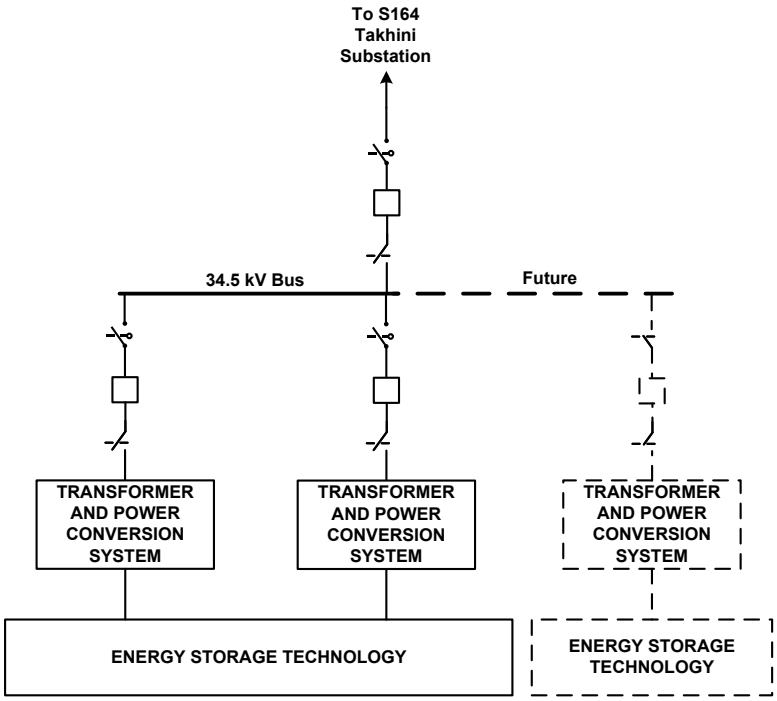

Figure 28: 6 MW, 60 MWh; 8 MW 80 MWh and 8 MW, 40 MWh Battery Energy Storage Sytems Configuration

The energy storage system was treated as a separate substation and the anticipated location is near the S164 Takhini 138 kV / 34.5 kV substation. The energy storage system will connect to the 34.5 kV system as shown in Figure 27 and Figure 28. By connecting to the relatively low transmission line voltage of 34.5 kV, the need for a second step-up transformer was avoided. A detailed engineering study of the electrical system at the S164 Takhini substation was not studied in regards to the effects on and the interaction with the energy storage system and should be considered if the project proceeds. Modular design was considered when designing the energy storage system. The proposed footprints for the different energy storage systems are shown below in the following figures.

6.2 Development of Cost Schedule

The economic viability of implementing either of the BESS applications (lead acid or lithium ion) was explored by performing a 30 year life cycle cost-benefit analysis. The analysis was performed using an economic model developed especially for this purpose that detailed the estimated costs and expected benefits over the projected total life of the energy storage system. Future costs and benefits are converted to present value using a user defined discount rate. The total of all present value costs are then subtracted from the total of all present value benefits to provide a total Net Present Value (NPV) for the project. When the NPV value is negative, the project represents an overall economic burden to the system owner while a positive NPV provides an overall benefit to the owner.

The financial model takes into account the following costs and benefits:

- Capital cost of energy storage system equipment
- Capital cost of the building and auxiliary systems
- Capital cost of the civil works
- Operating and maintenance cost of the energy storage system and building
- Replacement cost of energy storage system components (primarily the batteries) after 15 years for lead acid batteries and after 20 years for lithium ion batteries
- Cost of power losses
- Cost of energy production differential benefit for using hydro power in place of diesel power

To evaluate different alternatives and scenarios, the model allows for certain economic parameters to be changed to assess the impact on the overall NPV. A base case was established based on current conditions and information obtained from Yukon Energy Corporation, summarized in Table 5.

Table 5 Economic Parameters

Financial Parameters	
Year for NPV and Currency Exchange Rates	2016
Study Period (years)	30
Nominal Discount Rate - annual	5.45%
Cost for Electric Power Losses (cents/kWh)	6.0
Electricity Cost Escalation rate - annual	2.0%
Owner's Portion of the Total Capital Cost	100%
Cost of Electricity Production from Hydro(cents/kWh)	6.00
Cost of Electricity Production from Diesel(cents/kWh)	30.80

The NPV was calculated to 2016 Canadian dollar values. The expected useful life for the energy storage system was set at 30 years, which required replacement of all batteries after 15 years for lead acid batteries and after 20 years for lithium ion batteries. No salvage value for the batteries was considered, nor was any anticipated decrease in future battery prices. The nominal discount rate used to calculate the Net Present Value of future costs was 5.45

© TransGrid Solutions Inc, 2016

percent, provided by Yukon Energy Corp. YEC was assumed to provide 100 % of all costs, with no outside incentive funding. A 2.0 percent per year electricity escalation rate was assumed. The cost differential between utilizing diesel generation and hydro generation represented a savings of 24.80 cents/kWh.

The energy storage system parameters, shown in Table 6 , were obtained through consultation with Exide Technologies for lead acid batteries [9], LG Chem [10] for lithium ion batteries, ABB for the PCS [11], and Tru-Steel [12] for buildings that will house the batteries. Information provided included the efficiency of the system, the replacement period for the EST and cost parameters such as capital cost, operation and maintenance (O&M) costs and replacement costs. All other costs which are not included in the EST and PCS portion of the energy storage system costs are found in the Balance of Plant cost.

Table 6 Energy Storage System Parameters

BESS Parameters	**Lead Acid**			**Lithium Ion**
Energy Storage System Model	**4000 kW, 10h**	**6000 kW, 10h**	**8000 kW, 10h**	**8000 kW, 5h**
Power (kW)	4000	6000	8000	8000
Duration (h)	10	10	10	5
Power Discharge Efficiency (%)	80	80	80	90
Replacement period (years)	15	15	15	20
Capital Cost (PCS +EST)	$19,597,000	$30,086,000	$39,057,000	$25,670,000
Replacement Cost	$17,389,000	$26,084,000	$34,779,000	$22,082,000

Based on discussions with Exide Technologies and LG Chem., replacement of the energy storage technology (batteries) is expected to take place in the fifteenth year and twentieth year respectively, and have been estimated at the respective battery cost. The battery power discharge efficiency was quoted by Exide Technologies as 80 percent for lead acid and by LG Chem as 90 percent for lithium ion. The batteries costs included the engineering, installation and commissioning of the battery racks and enclosures. The PCS costs included the engineering, installation and commissioning of the units described in Table 4.

Table 7 shows the balance of plants parameters consisted of the building for the batteries and substation controls and the 34.5 kV substations.

Table 7 Balance of Plant Parameters

BESS Parameters	**Lead Acid**			**Lithium Ion**
Energy Storage System Model	**4000 kW, 10h**	**6000 kW, 10h**	**8000 kW, 10h**	**8000 kW, 5h**
EST Building Type /Size (m)	45 x 45 x 6.6	54 x 54 x 6.6	62 x 62 x 6.6	30 x 30 x 6.6
Building Costs	$820,000	$1,201,000	$1,583,000	$423,000
Substation Costs	$1,300,000			

© TransGrid Solutions Inc, 2016

Based on the discussion with Tru-steel the cost included the installation and supply of a Pre-engineered building. The cost did not include soil conditions, site access, winter work, travel expenses and accommodations. The substation estimates were validated using in-house cost-estimating tools. The major equipment and requirements include all required site preparation, foundations, grounding, support structures, cabling, bus work, protection, controls, and SCADA at the substation, 3 three-phase 34.5 kV circuit breakers, 3 three-phase motor operated disconnects, 3 three-phase manual disconnects, Cabling between the substation and PCS and Cabling between the PCS and EST. Since the substation costs were negligible in the overall cost calculations, the 8000kW 10h was selected to represent all the different substation configurations costs.

Table 8 shows the operation and maintenance parameters as well as the annual energy savings.

Table 8 Operation and Maintenance Parameters

BESS Parameters	Lead Acid			Lithium Ion
Energy Storage System Model	**4000 kW, 10h**	**6000 kW, 10h**	**8000 kW, 10h**	**8000 kW, 5h**
Annual Energy production (MWh)	2443	2667	2780	2780
O&M Costs Escalation Rate (%)	2.00	2.00	2.00	2.00
Estimated Annual O&M Cost	$210,200	$321,300	$416,800	$260,900

The annual energy production for the different energy storage systems were calculated as the amount of energy required to replace the diesel energy production in 2015. For an example, the 40 MWh lead acid BESS is used to replace 2443 MWh of diesel energy production per year. Annual O&M assumed the facility heating and air conditioning, janitorial, storage system maintenance and general building upkeep. The cost for maintaining the different battery systems were also include in the annual O&M costs. The annual O&M cost for was subject to a 2.0 percent escalation rate.

The present value costs for the different energy storage systems included the capital costs of the battery technologies, the power conversion systems, and the balance of plant, the sum of the annual operation and maintenance cost, the sum of the annual costs of energy use to recharge the batteries and the replacement cost of the batteries. The equation used was as follows

$$PV_{Cost} = Cap_{Total} + \sum_{i=1}^{30} OM_{F\,i} * 1 + d^{-yr\,i} + \sum_{i=1}^{30} EL_{i} * (1+d)^{-yr(i)} + \mathrm{Rc} * (1+\mathrm{d})^{-Rp}$$

Where

Cap_{Total} = Capital Cost + BoP

OM_F = $Annual\ O\&M\ cost * (1 + O\&M\ Escalation\ rate)^{yr}$

EL = $Energy\ production * Electricity\ cost\ for\ losses * 0.01 * (1 + electricity\ Escalation\ rate)^{yr}$

Rc = Replacement cost

Rp = Replacement year

d = nominal discount rate

© TransGrid Solutions Inc, 2016

The expenditure savings realized by utilizing the energy stored in the batteries was the net difference in energy production cost from replacing diesel energy with stored hydro energy. The net income from peak demand power was considered to be zero, as the power supplied by diesel was being directly replaced by the hydro power.

Based on all parameters in Table 5, Table 6, Table 7 and Table 8 the base case NPV value for the two energy storage systems being considered are shown in Table 9.

Table 9 Base Case NPV for Energy Storage Systems

	Lead Acid			Lithium Ion
Energy Storage System Model	**4000kW, 10h**	**6000kW, 10h**	**8000kW, 10h**	**8000kW, 5h**
Present Value – Benefits ($)	$11,085,000	$12,102,000	$12,615,000	$12,615,000
Present Value – Costs ($)	$35,981,000	$53,008,000	$68,119,000	$42,860,000
NPV ($)	-$24,896,000	-$40,906,000	-$55,504,000	-$30,245,000

Table 9 shows that over the lifetime of the four projects, all would have significantly higher costs compared with their respective benefits and hence a negative NPV. This evaluation considers only presently available technology. For the lead acid energy storage systems, the change in cost was directly related to the ratio of power. For example, the 6 MW and 8 MW lead acid energy storage systems costs 1.5 times and twice that of the 4 MW lead acid energy storage system.

Another way to evaluate and compare different energy technologies is to divide the total costs to construct, finance, operate and maintain a plant by its useful output. The costs are levelized using the cost of capital or discount rate to calculate a flat dost for energy in $/kWh and the capacity $/kW-yr over the life of the plant.

The primary basis for comparison of generation assets is the levelized cost of energy (LCOE) in $/MWh. The cost or value of capacity is levelized on an annual basis (LCOC) is expressed as $/kW-yr. The capital cost represents the cost of the plant being available to provide electrical generation whether or not it actually operates and is analogous to an insurance policy. The equations that were used for LCOE and LCOC were calculated as follows:

$$LCOE = \frac{PV_{Cost} * CRF}{\text{Annual Energy production}}$$

$$LCOC = \frac{PV_{Cost} * CRF}{\text{ESS Power (kW} - \text{yr)}}$$

Where

$$CRF = \frac{d * \ 1 + d\ ^{30}}{[\ 1 + d\ ^{30}] - 1}$$

Nominal discount rate is d = 5.45%

In Table 10 the LCOE and LCOC were determined for the different energy storage systems under evaluation.

Table 10 LCOE and LCOC

	Lead Acid			Lithium Ion
Energy Storage System Model	**4000kW, 10h**	**6000kW, 10h**	**8000kW, 10h**	**8000kW, 5h**
LCOE ($/MWh)	$1,010	$1,360	$1,680	$1,060
LCOC ($/kW-yr)	$620	$600	$580	$710

Since the operation of the Lithium ion is expected to operate at half its rated value the ESS power is 4000 kW in the LCOC calculation.

6.3 System Cost vs Utilization Sensitivity Study

To realize a positive NPV from any of the BESS, the system must be utilized more than it would be for only intermittently replacing up to 4 MW of diesel power production. As an example, the 40 MWh lead acid BESS is used to replace 2443 MWh (approximately 60 days of operation per year) of diesel energy production per year (based on the year 2015). Table 11shows the approximately number of days in operation per year based on the year 2015 for the different BESS.

Table 11 Operation Parameters

BESS Parameters	Lead Acid			**Lithium Ion**
Energy Storage System Model	**4000 kW, 10h**	**6000 kW, 10h**	**8000 kW, 10h**	**8000 kW, 5h**
Annual Energy production (MWh)	2443	2667	2780	2780
Approximate Days of operation	60	45	35	70

It was assumed the efficiency losses as the energy consumed during the charging cycle but not delivered to the loads during the discharge cycle. If the BESS can be used for providing more of a base load, either by load shifting or by load growth, then this unused capacity can generate more revenue or hence increase the NPV. Figure 33 shows the resulting increase in NPV for all 4 BESS with increased utilization.

© TransGrid Solutions Inc, 2016

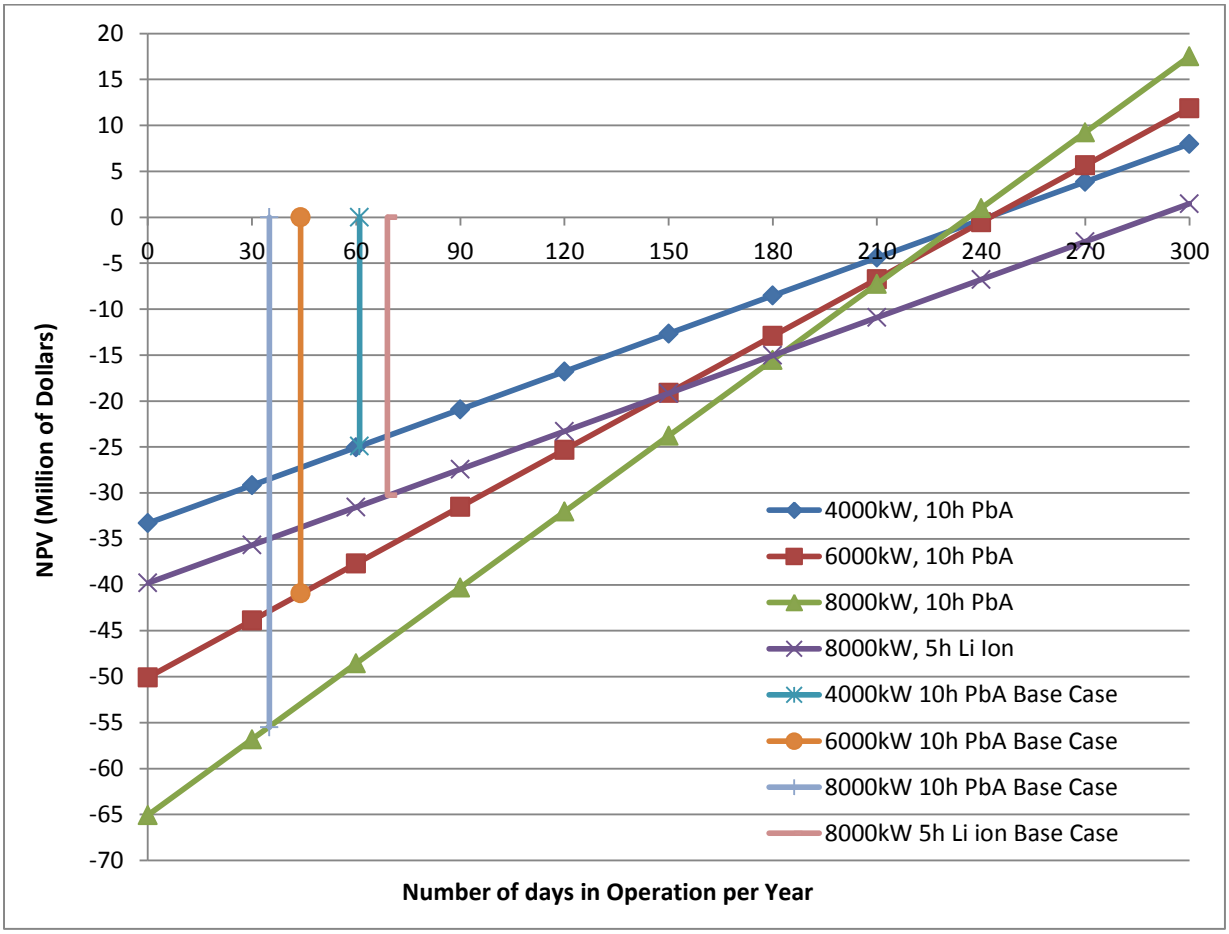

Figure 33 Battery Energy Storage System vs NPV Utilization

A day in operation, shown in Figure 33 , was represented by 10 hours of discharge and approximately 12 to 14 hours of recharge. As the number of days increased the NPV values improved. For the Lead Acid BESS would need approximately 240 days (approximately 8 months, 7 days a week) to the break-even. The Lithium Ion BESS would need approximately 290 days (approximately 9.5 months, 7 days a week) to the break-even.

6.4 Generation of high level project schedule

The high level project timeline was based on contributions from the manufactures of the different components for the energy storage systems. Figure 34 shows the time in weeks for each energy storage component; project planning and engineering, construction and site improvement and testing and commissioning. The duration of the total project is also shown.

© TransGrid Solutions Inc, 2016

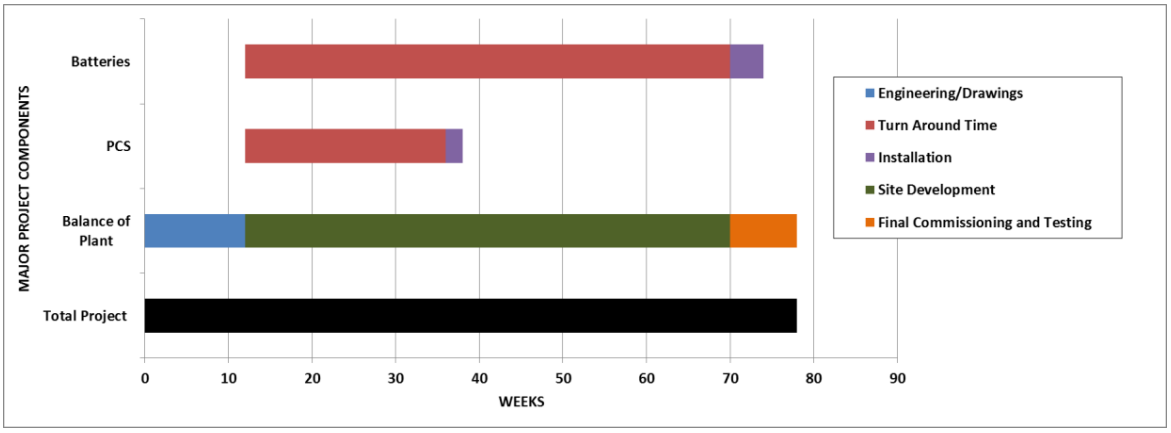

Figure 34 Battery Energy Storage System Timeline

Turnaround time includes procurement, manufacturing, and delivery. The estimated time to build the battery energy storage system from start to finish is 78 weeks (approximately 1.5 years).

6.5 Environmental and Societal Considerations

Although the life cycle costs are a major part of selecting any energy storage system, one must also consider the impact these energy storage systems will have on the environment and society.

Most of the chemicals used for creating the selected battery technologies are mined. The process from mining to manufacturing the batteries is energy intensive. Lead, when mined in large quantities produces a large amount of pollution within its mining areas. Lead, by itself, is also hazardous to human health. The chemical Lithium, on the other hand, is minor component when building lithium ion cells. The major chemicals required for these cells are copper and aluminum and the environmental impacts are more significant [8].

Furthermore, disposal of both battery technologies are an important part of the life cycle. There a number of regulations and safety concerns when handling and disposing of lead-acid batteries. Lead-acid batteries are among the most recycled products in the world [1]. Many lead acid manufactures accept old batteries and recycle the batteries. Recycling lithium ion batteries is still a challenge due to cells not having the ability to recharge. However, the newer lithium ion batteries are showing signs of recovering [8]. Therefore the recyclability of lithium ion batteries should rise.

In addition, battery layouts of this size are not common in utility systems. Both batteries have been known to have incidents of “thermal runaway” where the batteries rapidly increase in temperature causing fire and dangerous gases. During the design, construction and operation of the energy storage system, the utility and local authorities should familiarize themselves with the handling, operation and the chemical contents of the batteries. Since the battery facilities are large buildings, they should also be aware the location of emergency and critical components in the building and around the project site. Manufacturers should provide Material Safety Data Sheets to utility and local authorities.

© TransGrid Solutions Inc, 2016

6.6 Spinning Reserve

The definition of spinning reserve is the online capacity that is synchronized to the grid and ready to supply the electrical demand within 10 minutes of a dispatch instruction by the independent system operator. Spinning reserve is required to maintain system frequency stability during emergency type operating conditions and random load swings.

Earlier research indicated that large energy storage systems could be designed to accommodate a utilities' spinning reserve by installing extra power capacity into its dc to ac advanced power converter system. The rating of the converter could be sized about 20% greater than the normal output rating. With the recent technology advancements involving a BESS with an advanced PCS, some power markets may assign a value to this function and allow the BESS facility with this characteristic to acquire monetary benefits.

However for the type of BESS being considered in this report, the cost of the converter is a very small portion of the overall cost. With oversizing the inverter, it would be difficult to find enough benefits to evaluate and justify the advantage of having the increased spinning reserve.

© TransGrid Solutions Inc, 2016

7. Conclusions

Several Energy Storage System (ESS) options were considered to:

a. provide additional power to the YEC transmission system for “load levelling” purposes, and

b. avoid additional environmentally unfriendly diesel generation

From the extensive list of ESS options, the most technically viable were chosen based on the calculated power, energy, and discharge time characteristics required. Maturity of the ESS was also considered; as this is not an academic R&D project, using a proven, mature technology was important. This brought battery energy storage systems (BESS) to the forefront, and in particular lead acid and lithium ion batteries.

These two types of BESS, besides meeting the technical operational requirements, have other advantages. As they are a modular system, BESS power capacity can be added in small incremental steps to meet future power demand. This allows for easier financial planning, as well as taking advantage of future improvements in battery technology.

Using the known diesel power generation profile for the year 2015, the operational requirements of the BESS were determined to be:

a. Power rating = 4 MW

b. Energy rating = 40 MWh

c. Discharge time = 10 hours

The above BESS power rating of 4 MW, plus an anticipated 8 MW of natural gas reciprocating engines generation in the near future, provides a total of 12 MW of available power. 95% of the diesel power generation for 2015 was equal to or less than 12 MW, so the BESS plus NG solution can fully replace the present demand for diesel power 95% of the time. Future load growth can be met incrementally by adding modules of the BESS.

For cost comparison, four options of a BESS were considered:

a. 4 MW, 40 MWh, 10 hour discharge time, lead acid battery system

b. 6 MW, 60 MWh, 10 hour discharge time, lead acid battery system

c. 8 MW, 80 MWh, 10 hour discharge time, lead acid battery system

d. 8 MW, 40 MWh, 5 hour discharge time, lithium ion battery system

Budgetary prices of all major components of each BESS were provided directly by vendors. The financial model and approximate cost of civil works was provided by Yukon Electric Corp. A thorough consideration of costs and income was made over the next 30 years to arrive at the lowest total cost option for a BESS.

Based on the information provided from Yukon Energy, the power and energy determined from the load data and the total cost of a completely installed BESS system under study, the net present value was calculated for each option. Over the lifetime of the projects, all 4 options would have significantly higher costs compared with their respective benefits and hence a negative NPV. The lead acid 4 MW, 40 MWh BESS had the best NPV followed by the lithium ion 8 MW, 40 MWh BESS.

© TransGrid Solutions Inc, 2016

The timeline for bringing this system online is approximately 18 months. This includes engineering and drawing, preparatory civil works, purchase and delivery of the system components, construction, and testing.

1 Introduction

This objective of this report is to update the assumptions and results of 2011 Conservation Potential Review (CPR) for the Yukon Energy Corporation (YEC). YEC updates their 20-year resource plan every five years, with the next update planned for 2016. In preparation for YEC's upcoming Resource Plan, YEC is seeking to update some of the CPR model input assumptions to better reflect the current state of the modeled technologies and more accurately project the conservation potential. Following the 2011 study and subsequent program design work, YEC was able to obtain more accurate information on the penetration of certain technologies and the participation rate of certain program implementations. The scope of this update is summarized below:

- **Base year:** Updated base year with 2014 energy sales data
- **Reference case:** Updated reference case with new load forecast
- **Measure-level assumptions:** Updated avoided cost, discount rate and measure-level assumptions such as cost, energy savings, measure life, current penetration and applicability
- **Participation rates:** Updated participation for certain measures, including showerheads, pipe and tank insulation

The scope of the updates to the assumptions were limited to the hydro grid-connected region. The large diesel, small diesel, and Old Crow regional models were omitted. Dwelling types, commercial building types, and energy end uses definitions remained unchanged from the 2011 study. Further information on these definitions can be found in the 2011 report.

The overall analysis approach and methodology for this study remains unchanged from the original 2011 study. For further information on the major analytical steps and modelling approach please refer back to the 2011 report. The following sections of this report are organized as follows:

- **Section 2** presents the revised assumptions for the update of the 2011 study. This includes changes to measure level assumptions, applicability and participation assumptions.
- **Section 3** presents the revised energy savings results for the residential and commercial sectors.

2 Assumptions

2.1 General Assumptions

This section presents the details of all changes that were made to the study assumptions. The following changes were made across both sectors:

- **Base year:** 2014 sales data provided by YEC was used to update the base year and the base year was changed from 2010 to 2014
- **Reference case:** YEC provided load forecast insights to inform a revised reference case and the reference case was extended to 2035 (i.e. the last milestone year for the 2011 study was 2030)
- **Avoided cost and discount rate:** The avoided costs were changed to $0.2871/kWh and the real discount rate was changed to 3.38%.

2.2 Residential Assumptions

2.2.1 Residential Measure-Level Assumptions

The following list of measure-level assumption changes were made in the residential sector measures:

- **Cold Climate Air Source Heat Pumps:** Costs updated to $12,000 based on Zuba model pricing provided from client consultation with HVAC specialists.
- **Programmable Thermostats (Central Heating):** Updated to Smart Learning Thermostats
  - Savings: Savings percentage was increased to 8%
  - Costs: Upgrade costs set to $300.00 based on cost of average nest/ecobee cost.
- **CFLs – Indoor:** Measure was deleted (superseded by LED measure)
- **CFLs – Outdoor:** Replaced measure with LED Lamps – Outdoor
  - Upgrade: Changed to 15 W PAR38 LED lamp
  - Savings: Measure savings percentage increased to 83.3% due to lower wattage of outdoor LED lamps
  - Costs: Set to $51.75 based on a retail scan of outdoor LED Lamps
  - Lifetime: Set to 25,000 hours (14.4 years based on 4.75 hours of use per day)
- **PAR CFLs:** Replaced measure with Dimmable PAR LED Lamps
  - Upgrade: Changed to 8 W dimmable PAR LED lamp
  - Savings: Measure savings percentage increased to 87%
  - Cost: Set upgrade costs to $15.00 based on a retail scan of PAR LED lamps.
  - Lifetime: Measure lifetime set to 25 years
- **Dimmable CFLs:** Measure was deleted (superseded by LED measure)
- **LED Lamps:**
  - Baseline: Changed baseline to a blended baseline of incandescent and CFL lamps
  - Savings: Savings assumptions were decreased from 80% to 76% relative to the new blended baseline of CFLs and incandescent lamps.
  - Costs: Reduced cost per lamp to $11.00 based upon retail scan of globe-type, screw-in 8 W LED lamps
- **High Performance New Homes:**
  - Baseline: Changed baseline from EGH rating of 80 to EGH rating of 82
  - Cost: Updated to $6,570 with 33% cost factor

- Savings: Savings assumptions were updated to 15% based on change in baseline scenario

2.2.2 Changes to Residential Penetration & Participation Rates

The following changes were made to penetration and participation rates in the residential sector measures:

- **LED Lamps:**
  - Reference penetration: Estimated at 50% by the end of the study period
- **LED Lamps – Outdoor:**
  - Reference penetration: Estimated at 50% by the end of the study period
  - Participation rates: Updated to match LED Lamps
- **PAR LED Lamps:**
  - Reference penetration: Estimated at 35% by the end of the study period
  - Participation rates: Updated to match LED Lamps
- **Smart Learning Thermostats:**
  - Reference penetration: Estimated at 10% by the end of the study period based on decrease in natural adoption compared to programmable thermostats

2.3 Commercial Assumptions

2.3.1 Commercial Measure-Level Assumptions

The following measure-level assumption changes were made to the commercial sector measures:

- **T8 Lighting:** Switched to LED Fluorescent Fixtures measure
  - Baseline: Standard 2-lamp F32T8 fixture consuming 58 W
  - Upgrade: Upgrade is a 2-lamp LED Fluorescent Fixture consuming 18 W
  - Cost: Upgrade cost set to $120 per fixture based upon client data
- **CFL Lamps (Indoor):** Measure was deleted (superseded by LED measure)
- **White LED Lamps:**
  - Cost: Upgrade costs set to $23.00 based on ICF's database of average LED lighting costs for previous lighting program implementations
- **Pulse-Start Metal Halide Lamps:** Changed measure to LED High Bay Fixtures
  - Upgrade: Changed to 125 W LED High Bay Fixture
  - Costs: Upgrade cost adjusted to $300 per fixture and baseline material cost adjusted to $200/fixture based upon costing data provided by the client
  - Lifetime: Adjusted to 50,000 hours based upon the average life expectancy of LED fixtures
- **T5HO High Bay:** Measure was deleted (superseded by LED measure)
- **CFL Lamps (Outdoor):** Changed this measure to LED Lamps (Outdoor)
  - Upgrade: 10 W LED Lamp
  - Costs: Updated cost to $28.45 per lamp based on ICF's database of average LED lighting costs for previous lighting program implementations
  - Lifetime: Updated to 20,000 hours
- **Induction (Outdoor):** Measure was deleted (superseded by LED measure)
- **Pulse Start Metal Halide Lamps (Outdoor):** Changed to LED Wallpack Outdoor Fixtures
  - Baseline: Standard 230 W metal halide wallpack
  - Upgrade: 50 W LED wallpack

  - Costs: Upgrade costs updated to $460/fixture, baseline cost of $345/fixture
  - Lifetime: Upgraded to 50,000 hours for LED fixture
- **Digital HID Street Lighting:** Measure was deleted (superseded by LED measure)
- **LED Street lighting:**
  - Cost: Costs were updated with a $185/fixture cost for LED Streetlight and a cost of $250/fixture for the baseline HPS streetlight
- **HP Glazing:**
  - Cost: Updated costs based on pricing list provided by Northerm. Unit window costs provided were used to derive incremental cost of approximately $5.03/ft^2
- **Super HP Glazing:**
  - Cost: Updated costs based on pricing list provided by Northerm. Unit window costs provided were used to derive incremental cost of approximately $13.32/ft^2
- **Programmable Thermostat:** Changed to Adaptive Thermostat measure
  - Savings: Upgraded savings to 15% based on average adaptive thermostat savings from case studies
  - Costs: Updated costs to $700/thermostat per 2000 ft^2 plus location factor

2.3.2 Changes to Commercial Penetration & Participation Rates

The following changes were made to penetration and participation rates in the commercial sector measures:

- **LED fluorescent fixtures:**
  - Reference penetration: Estimated at 15% by the end of the study period
  - Participation rate: The participation rate was decreased up to a maximum participation of 46%
- **LED High Bay Fixtures:**
  - Reference penetration: Estimated at 15% by the end of the study period
- **LED Lamps (Outdoor):**
  - Reference penetration: Estimated at 8% by the end of the study period
  - Participation rate: Updated to match white LED Lamps measure
- **LED Wallpack Outdoor Fixtures:**
  - Reference penetration: Estimated at 19% by the end of the study period
- **LED Streetlighting:**
  - Reference penetration: Estimated at 30% by the end of the study period
- **Adaptive Thermostats:**
  - Reference penetration: Estimated at 10% by the end of the study period

3 Results

The following section provides the updated results for the residential and commercial sector. Note that all results presented in this section represent the electrical consumption and savings only in the hydro grid connected region of Yukon. Below is a summary of the exhibit updates with the corresponding exhibit numbers from the 2011 Yukon Residential and Commercial sector reports:

- Residential (R) Exhibit Updates:
  - Exhibit 7R: Base Year Consumption by Dwelling Type & End Use
  - Exhibit 25R: Technology Screening
  - Exhibits 35R and 36R: Energy Efficiency Supply Curves
  - Exhibits 54R and 58R: Achievable Potential Energy Savings
  - Exhibits 62R, 62-2R, 65R, 65-2R: Achievable Electric Peak Load Reductions
  - Exhibits 41R and 42R: Electric Peak Load Reductions from Capacity Measures
  - Exhibits 42-2R and 42-3R: Lower Achievable Electric Peak Load Reductions from Capacity Measures
- Commercial (C) Exhibit Updates:
  - Exhibit 10C: Base Year Consumption by Sub Sector & End Use
  - Exhibit 25C: Technology Screening
  - Exhibits 35C and 36C: Energy Efficiency Supply Curve
  - Exhibits 54C and 58C: Achievable Potential Energy Savings (commercial sector equivalent to residential)
  - Exhibits 62C, 62-2C, 65C, 65-2C: Achievable Electric Peak Load Reductions (commercial sector equivalent to residential)
  - Exhibits 40C and 41C: Electric Peak Load Reductions from Capacity Measures
  - Exhibits 41-2C and 41-3C: Lower Achievable Electric Peak Load Reductions from Capacity Measures

3.1 Residential Results

Base Year

This section presents the results of the analysis of electricity consumption for the Base Year 2014. Electricity consumption is measured at the customer's point-of-use and does not include line losses.

Exhibit 7R presents total residential sector hydro grid electricity consumption by dwelling type and end use.

Base Year Electricity Use by Dwelling Type

Single detached dwellings account for the majority of residential electricity use in Yukon, with approximately 73% of residential hydro grid electricity consumed. Apartment buildings, including both the suites and common areas, account for the next largest share, using 11% of residential hydro grid electricity. Attached houses (duplexes, row houses, and townhouses) and mobile homes each account for 7% of residential hydro grid electricity.

Seasonal houses (using less than 3,000 kWh/yr. each) account for 2% of total residential hydro grid electricity consumption. Residential garages and sentinel lighting each consume less than 0.5% of residential hydro grid electricity.

Base Year Electricity Use by End Use

HVAC accounts for 33% of consumption, with 29% of that being electric space heating and the remainder being fans and pumps, including furnace fans, boiler circulation pumps, HRV fans, and bathroom and kitchen exhaust.

Domestic appliances (white goods) consume approximately 17% of total residential hydro grid electricity. Of this, clothes dryers account for 6% and refrigerators for 4%. Cooking appliances consume 4% and freezers each consume approximately 3%. Dishwashers and clothes washers consume less than 1% each, but this does not include the associated DHW consumption if DHW is heated electrically.

Domestic water heating accounts for approximately 15% of residential hydro grid electricity consumption.

Household electronics consume approximately 15% of residential hydro grid electricity, including 9% by computers and their peripherals, 3% by televisions, 1% by the various set-top boxes associated with televisions, and 3% by other home entertainment electronics.

Indoor, outdoor, and holiday lighting together account for 6% of residential hydro grid electricity consumption; 5% of this is indoor lighting and 1% is outdoor lighting. Holiday lighting is well under 1%.

Other end uses account for 13% of residential electricity consumption. Of this, 6% is consumed by spa heaters and pumps and 2% is consumed by block heaters and car warmers.

Exhibit 7R Base Year Annual Residential Electricity Consumption by Dwelling Type and End Use (MWh/yr.)

Dwelling Types	Space heating	Ventilation & circulation	Domestic hot water (DHW)	Indoor lighting	Outdoor lighting	Holiday lighting	Cooking appliances	Refrigerator	Freezer	Dishwasher
1980 & newer non-electrically heated single detached homes	19,773	11,737	46,057	14,306	3,801	282	11,115	15,631	10,505	1,671

Technology Screening

A summary of the technology screening results is provided in Exhibit 25R. For each of the measures, the exhibit shows:

- The name of the measure
- The cost basis[1] for the CCE (cost of conserved energy) that is shown, e.g., full versus incremental
- The measure's average CCE when applied to all sub sectors.

Measures analyzed on the basis of full cost have been placed towards the top of the exhibit below because they are qualitatively different from the measures that pass only on an incremental basis. A measure that passes on a full-cost basis can be applied immediately, even if the piece of equipment it replaces or improves is currently working properly. That means the rate at which the measure can be implemented as a utility DSM measure is limited by market and program constraints. A measure that passes only on an incremental basis, on the other hand, is limited by the rate of natural replacement (due to failure or obsolescence) or purchase of the piece of equipment it replaces.

Exhibit 25R Residential Sector Energy-efficiency Technology Measures, Screening Results[2]

Measure Name	Basis (Full/ Incremental)	Average CCE (¢/kWh)	
		Existing Homes	New Homes
DHW Pipe Insulation	Full	0.20	0.25
Ultra Low-Flow Showerheads	Full	0.71	1.01
Hot Tub Pump Timers	Full	0.82	0.87
Insulating Hot Tub Covers	Full	1.29	1.36
LED Lamps	Full	1.44	1.44
PAR LED Lamps	Full	1.72	1.72
LED Lamps - Outdoor	Full	1.79	1.79
Timers for Electric Car Warmers	Full	2.21	2.22
Smart Learning Thermostats	Full	2.81	3.25
Solar Spa Pre-heat	Full	3.05	3.21
Programmable Thermostats (Baseboard Heating)	Full	3.13	3.52
Heat Pump Spa Heaters	Full	3.72	3.90
Motion Detectors for Outdoor Lighting	Full	4.38	4.38
Motion Detectors for Indoor Lighting	Full	4.61	4.61
Timer/Thermostat for Block Heaters	Full	5.05	5.00
Attic Insulation	Full	5.48	-
Outdoor Temperature Reset	Full	5.59	6.47
DHW Tank Insulation	Full	6.10	8.00
Basement (Foundation) Insulation	Full	6.27	-
LED Holiday Lighting (Outdoor)	Full	7.39	6.31
LEED Certified Apartment Buildings	Full		6.90
Spot/Task Lighting	Full	7.55	7.55
Air Leakage Sealing and Insulation (Old Homes)	Full	7.55	-

[1] See Step 3 in Section 7.2 of the 2011 Yukon Residential Report for a complete description.
[2] Average CCE does not include program costs.

Updates to Yukon Electricity CPR 2011

Measure Name	Basis (Full/ Incremental)	Average CCE (¢/kWh)	
		Existing Homes	New Homes
Smart Power Bars (Computers and Peripherals)	Full	7.59	7.72
Ductless Mini-Split Systems	Full	8.62	8.77
Air Sealing/Weather Stripping/Caulking	Full	8.88	-
Zone Heating	Full	9.38	10.85
Cold Climate Air Source Heat Pumps	Full	9.42	10.54
DHW Recirculation Systems (e.g. Metlund D'MAND)	Full	10.79	14.56
Wastewater Heat Recovery Systems	Full	11.25	14.51
Smart Power Bars (Televisions and Home Entertainment)	Full	13.35	12.96
Wall Insulation	Full	13.27	-
Crawlspace Insulation	Full	14.87	-
SuperGreen Homes (EGH rating of 85)	Full		16.05
DHW Piping Optimization	Full	18.37	16.19
Slab Insulation (Unfinished Basements)	Full	16.53	-
Solar Pre-heated Make-Up Air Systems (e.g., SolarWall®)	Full	18.60	20.80
High-efficiency Spa Pumps	Full	19.33	20.38
Timers for Electric Battery Blankets	Full	24.39	24.13
Near-zero/Net-zero Energy Homes	Full		26.09
LED Holiday Lighting (Indoor)	Full	27.58	27.58
Timers for Outdoor Lighting	Full	59.01	59.01
High-Efficiency Furnace Blower Motors (ECPM)	Full/Incr.	18.52	13.63
High-Efficiency (ENERGY STAR) Clothes Washers	Full/Incr.	15.44	15.67
Ground Source Heat Pumps (Closed Loop)	Full/Incr.	24.45	26.96
High-Efficiency (ENERGY STAR) Refrigerators	Incr.	5.60	5.80
Triple-glazed Windows	Incr.	14.65	6.78
Future Improvements to Electronics	Incr.	10.60	10.55
High-Efficiency (ENERGY STAR) Dishwashers	Incr.	11.23	14.88
High-Efficiency (ENERGY STAR) Freezers	Incr.	11.29	11.71
Quadruple-glazed Windows	Incr.	21.29	12.74
Efficient Fluorescent Fixtures (Replace T12s with T8s)	Incr.	12.80	12.80
Energy Efficient (ENERGY STAR) Printers and Faxes	Incr.	14.84	15.10
Optimizing of Glazing for Passive Solar Heating	Incr.	18.29	55.34
High-efficiency Heat Recovery Ventilators (HRVs)	Incr.	18.86	21.31
Energy Efficient (ENERGY STAR) Televisions	Incr.	21.83	21.83
Convection Ovens - Electric	Incr.	41.25	52.52
ENERGY STAR Ceiling Fans	Incr.	162.54	162.54
High-Efficiency Cooktops (Induction)	Incr.	421.30	536.44

Energy-efficiency Supply Curves

A supply curve was constructed based on the approximate Economic Potential savings associated with the above measures. The following approach was followed:

- Measures are introduced in sequence to show incremental impact and cost
- Sequence was determined by listing first the items that reduce the electrical load, then those that meet residual load with the most efficient technology
- Items appear in order, beginning with those that have the lowest average CCE

Exhibit 35R shows the measures included in the supply curve and Exhibit 36R shows the supply curve for Yukon as a whole in the 2030 milestone year. Since the 2035 results are based off of an extrapolation of 2030 results without any further achievable workshop consultations, the penetration and participation values for all measures were held constant over this period. Therefore, the 2030 supply curve results are presented below as this milestone year has the most reliable data.

Exhibit 35R Summary of Residential Sector Energy-Efficiency Measures, 2030

Ref #	Measure	Economic Potential Savings (MWh/yr.)	Accumulated CCE ($)	Weighted Average CCE (¢/kWh)
1	DHW Pipe Insulation	258	546	0.2
2	Showerheads	544	3,845	0.7
3	Hot Tub Pump Timers	194	1,596	0.8
4	Hot Tub Covers	16	213	1.3
5	LED Lamps	1,957	28,278	1.4
6	LED Lamps - Outdoor	497	8,876	1.8
7	Car Warmer Timers	119	2,221	1.9
8	Smart Learning Thermostats	904	23,453	2.6
9	Prog. Thermostats	347	10,267	3.0
10	Solar Spa Pre-heat	63	1,933	3.0
11	Heat Pump Spa Heaters	222	8,268	3.7
12	Pulse start metal halide sentinel lights	101	3,819	3.8
13	Block Heater Timers	952	40,858	4.3
14	Motion Detectors - Outdoor	11	476	4.4
15	Motion Detectors - Indoor	29	1,321	4.6
16	Basement Insulation	110	5,668	5.2
17	Attic Insulation	1,094	56,691	5.2
18	ENERGY STAR Refrigerators	1,190	64,763	5.4
19	Outdoor Temp Reset	1,435	78,438	5.5
20	DHW Tank Insulation	328	21,304	6.5
21	LEED Apartments	1,869	127,306	6.8
22	Sealing & Insul. - Old Homes	995	68,997	6.9

Updates to Yukon Electricity CPR 2011

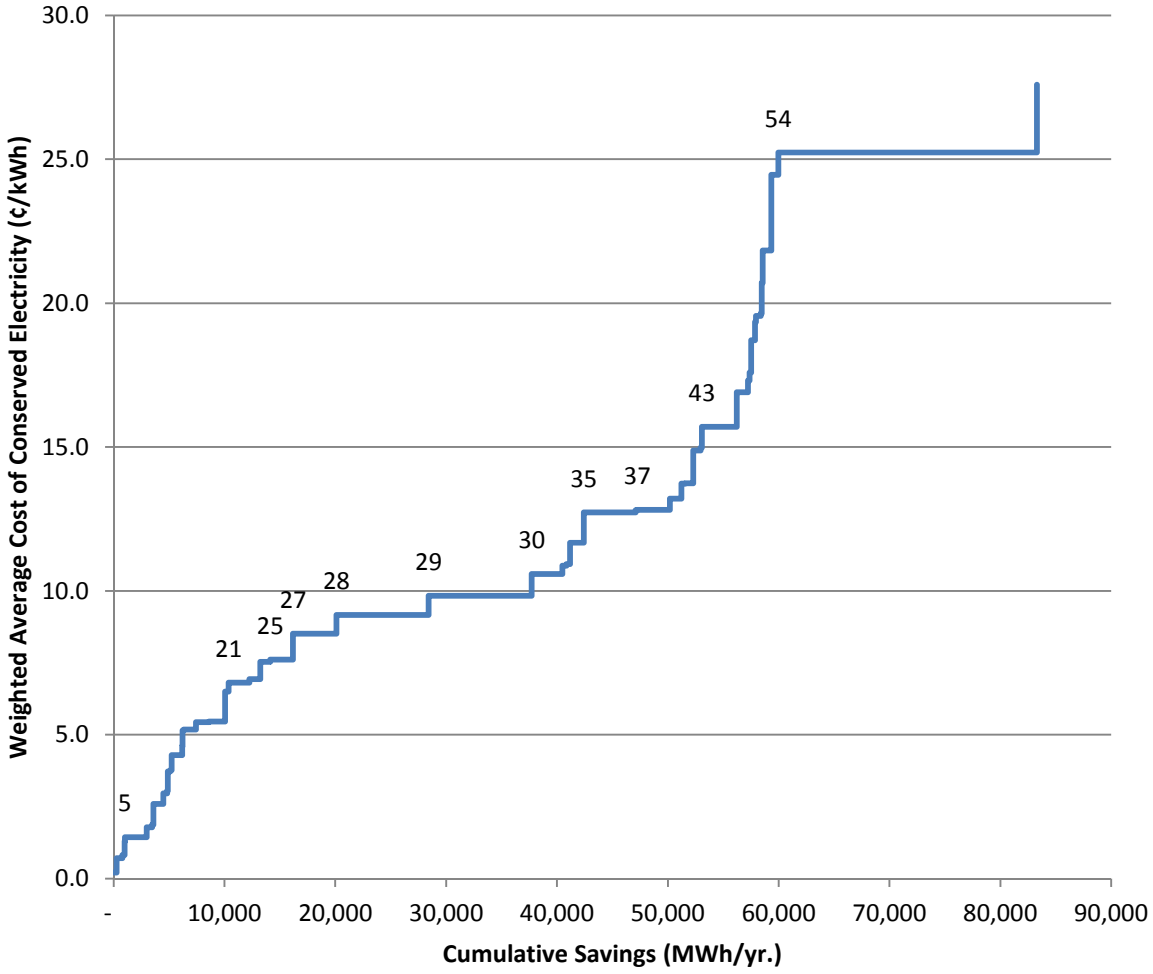
Exhibit 36R Energy-efficiency Supply Curve, Residential Sector, 2030



Summary of Potential Electric Energy Savings

Exhibit 54R and Exhibit 58R present the residential achievable potential results for the total hydro grid connected Yukon service territory by technology and milestone year.

The Achievable Potential is defined as the proportion of the savings identified in the Economic Potential that could realistically be achieved within the study period. The achievable potential recognizes that it is difficult to induce customers to purchase and install all the electrical efficiency technologies that are economically feasible. The results are presented as a range, defined as lower and upper. The rate at which customers accept and purchase energy-efficiency products will be influenced by the level of financial incentives, information and other measures put in place by YEC.

The most significant savings in the Achievable Potential come from the following measures:

- Cold temperature heat pumps, which account for 24% of the upper Achievable Potential savings in 2035 and 20% of the lower Achievable Potential savings in 2035
- Zone heating systems, which account for 13% of the upper Achievable Potential savings in 2035 and 10% of the lower Achievable Potential savings in 2035
- ENERGY STAR clothes washers, which account for 9% of the upper Achievable Potential savings in 2035 and 13% of the lower Achievable Potential savings in 2035
- High-performance new homes, which account for 7% of the upper Achievable Potential savings in 2035 and 14% of the lower Achievable Potential savings in 2035
- Ductless mini-split systems, which account for 7% of the upper Achievable Potential savings in 2035 and 6% of the lower Achievable Potential savings in 2035
- LEED certified apartment buildings, which account for 4% of the upper Achievable Potential savings in 2035 and 4% of the lower Achievable Potential savings in 2035
- LED Lamps, which account for 3% of the upper Achievable Potential savings in 2035 and 4% of the lower Achievable Potential savings in 2035

There are numerous other smaller measures that contribute to the overall Achievable Potential results.

Summary of Electric Peak Load Reductions: Electric Energy Measures

Exhibits 62R and 65R show the demand reductions associated with each residential sector electric energy savings measure in 2030. The 2030 results are presented in Exhibits 62R and 65R place of the 2035 results as they are more reliable results. With the absence of new achievable potential workshops, the results from 2035 were extrapolated from 2030 results with penetration and participation rates held constant. The results by milestone year are presented for the upper and lower achievable peak period 1 reductions in exhibits 62-2R and 65-2R respectively.

Most measures contribute to the peak demand reductions approximately in proportion to their electric energy savings. There are some notable exceptions. Block heaters are used at times that coincide closely with the utility peak, so their demand reduction would be disproportionate to their share of the electricity consumption savings. The potential reduction from block heater timers is even more significant than this would suggest, however, because the timer measure changes the load shape by moving the consumption almost entirely off the utility peak. Block heater timers offer the second largest potential for reducing peak demand in the Residential sector.

In contrast, the central heat pump and ductless mini-split systems, which both offer considerable electric energy savings potential, provide no reduction in peak electrical demand. This is because the utility peak occurs during the coldest period of the heating season, when these systems cease to operate as heat pumps and make use of their electric resistance backup heating elements.

Summary of Electric Peak Load Reductions: Capacity Measures

Exhibits 41R and 42R show the economic demand reductions associated with each residential sector peak load reduction measure in 2015. Exhibit 41R shows the name of the measure, the cost basis for the CEPR that the shown (full versus incremental) and the measure's average CEPR. The following approach was taken in updating these exhibits from the 2011 study:

- The discount rate was updated to 3.38% from 7.5%, thus impacting the CEPR values.
- The applicable dwellings count was updated from the 2010 base year to the new 2015 milestone year data, thus impacting the dwelling saturation and MW reduction for each capacity measure.
- Costing assumptions for each measure were left unchanged from the 2011 CPR study.

Measures analyzed on the basis of full cost have been placed towards the top of Exhibit 41R as they are qualitatively different from the measures that pass only on an incremental basis. A measure that passes on a full-cost basis can be applied immediately, while incremental measures presume the adoption of other technologies as a condition of their cost effectiveness (e.g., facility network gateways).

Exhibit 42R shows a list of the capacity electric peak load reduction measures grouped by applicable end use category. This exhibit shows the measure name, dwelling saturation, applicable count in 2015, average demand reduction and average CEPR. Note that since there was no threshold established for maximum cost effective CEPR, all measures are listed and there are no exclusions based on cost effectiveness.

Exhibit 41R Residential Sector Electric Peak Load Reduction Measures, Screening Results

Measure Name	Basis (Full/Incremental)	CEPR Ranges ($/kW)
One-way switch for engine block heater	Full	$55 - $68
Electric central thermal storage	Full	$109 - $111
One-way switch for pools and spas	Full	$77 - $82
One-way switch for water heating control	Full	$105 - $117
Electric room thermal storage for supplemental heat	Full	$96 - $99
One-way switch for plug loads	Full	$172 - $234
One-way switch for lighting control	Full	$270 - $300
One-way switch for engine block heater	Incremental	$48 - $60
One-way switch for pools and spas	Incremental	$37 - $39
One-way switch for plug loads	Incremental	$51 - $69
One-way switch for lighting control	Incremental	$80 - $89
One-way switch for water heating control	Incremental	$77 - $86

Exhibit 42R Total Applicable Dwelling Types and MW Impact by Measure

Electric Peak Reduction Measures	Dwelling Saturation	Applicable Count 2015	Avg MW	Avg CEPR $/kW/yr.
Space Heating				
One-way switch for engine block heater - utility load control – stand-alone	52%	7,897	1.5	$55 - $68
One-way switch for engine block heater - utility load control - incremental	52%	7,897	1.5	$48 - $60
Electric thermal storage (central)	13%	1,982	6.8	$109 - $111
Electric thermal storage (room/supplemental)	9.3%	1,418	1.7	$96 - $99
Electric Water Heating				
One-way switch-based utility load control – stand-alone	68%	10,267	2.7	$105 - $117
One-way switch-based utility load control - incremental	68%	10,267	2.7	$77 - $86
Lighting				
One-way switch-based utility load control - stand-alone	95%	14,379	1.2	$270 - $300
One-way switch-based utility load control - incremental	95%	14,379	1.2	$80 - $89
Plug Loads				
One-way switch-based utility load control - stand-alone	95%	14,379	1.0	$172 - $234
One-way switch-based utility load control – incremental	95%	14,379	1.0	$51 - $69
Electric Pools and Spas				
One-way switch-based utility load control - stand-alone	6.3%	949	0.6	$77 - $82
One-way switch-based utility load control – incremental	6.3%	949	0.6	$37 - $39

Summary of Lower Achievable Electric Peak Load Reductions: Capacity Measures

Exhibit 42-2R below shows the residential lower achievable demand reduction for peak period 1 and the average full cost CEPR value by end use category for each milestone year until 2035. The demand curve showing the lower achievable demand with EE measures only versus the lower achievable demand with both EE and capacity measures is shown in Exhibit 42-3R. The following approach was taken in developing these exhibits:

- The demand for each end use category after EE measures are applied was used as the baseline demand from which peak reductions occur due to capacity measures
- A lower achievable potential of 5% was assumed for all capacity measures, and was linearly extrapolated to all milestone years from a starting uptake of 0% in 2015 (due to lack of utility programs) up to a maximum of 5% in the year 2035.

Note that results of the achievable reduction due to capacity measures presented below are based upon the *lower* achievable potential and are subject to variation as they are highly jurisdiction-specific and dependent upon the structure of the utility programs. It is recommended that additional research be conducted in order to account for these limitations.

Exhibit 42-2R Lower Achievable Potential Peak Load Reductions by End Use (MW) – Capacity Measures

	2020	2025	2030	2035	Average CEPR ($/kW/yr.)
Space Heating	0.10	0.21	0.31	0.41	$100
Electric Water Heating	0.03	0.07	0.10	0.14	$111
Lighting	0.02	0.03	0.04	0.06	$285
Plug Loads	0.01	0.03	0.04	0.05	$203
Electric Pools and Spas	0.01	0.01	0.02	0.03	$80
TOTAL	**0.17**	**0.35**	**0.52**	**0.69**	

Exhibit 42-3R Lower Achievable Potential Demand (MW) – EE Measures only vs. EE & Capacity Measures

	2015	2020	2025	2030	2035
Demand with Lower Achievable EE Measures Applied (MW)	37.56	39.90	42.04	42.64	43.47
Lower Achievable Potential Demand (MW)	37.56	39.73	41.69	42.12	42.78

3.2 Commercial Results

Base Year

This section presents the results of the analysis of electricity consumption for the Base Year 2014. Electricity consumption is measured at the customer's point-of-use and does not include line losses.

Exhibit 10C presents total commercial sector hydro grid electricity consumption by sub sector and end use.

Base Year Electricity Use by Sub Sector

Other General Service Buildings account for the largest share of electricity use within the building sub sectors (19%), followed by Office (15%), and Education, Warehouse/Wholesale and Non-food Retail at 9% each.

Non-buildings account for 12% of Base Year Commercial sector hydro grid electricity use.

Base Year Electricity Use by End Use

Lighting is the largest Commercial sector end use, accounting for approximately 37% of total Commercial sector hydro grid electricity use. Indoor lighting, which consists of general, architectural and high-bay lighting, accounts for approximately 34%, while outdoor lighting accounts for the remaining 3%.

Space heating is the second largest end use, accounting for 14% of Commercial sector hydro grid electricity use, followed by refrigeration (9%), HVAC fans & pumps (8%), and computer equipment (6%). Cooking equipment, domestic water heating and a number of smaller end uses account for the remaining Commercial sector hydro grid electricity use.

Non-building loads are treated as both an end use and sub sector in this analysis. These loads account for 12% of Commercial sector end use hydro grid electricity consumption. Energy consumption for street lighting and block heaters is broken out separately as well.

Updates to Yukon Electricity CPR 2011

Technology Screening

A summary of the technology screening results is provided in Exhibit 25C. For each of the measures, the exhibit shows:

- The name of the measure
- The cost basis[3] for the CCE that is shown, e.g., full versus incremental
- The measure's average CCE when applied to all sub sectors.

Measures analyzed on the basis of full cost have been placed towards the top of the exhibit below because they are qualitatively different from the measures that pass only on an incremental basis. A measure that passes on a full-cost basis can be applied immediately, even if the piece of equipment it replaces or improves is currently working properly. That means the rate at which the measure can be implemented as a utility DSM measure is limited by market and program constraints. A measure that passes only on an incremental basis, on the other hand, is limited by the rate of natural replacement (due to failure or obsolescence) or purchase of the piece of equipment it replaces.

Exhibit 25C Commercial Sector Energy-efficiency Technology Measures, Screening Results[4] - Hydro Region

Measure Name	Basis (Full/[5] Incremental)	Average CCE (¢/kWh)
Low Flow Faucets	Full	0.22
Lighting Controls (Outdoor)	Full	0.39
Low Flow Showerheads	Full	0.48
Demand-Controlled Kitchen Ventilation	Full	0.64
Domestic Hot Water Tank Insulation	Full	1.72

Occupancy Controls	Full	4.74
Drainwater Heat Recovery	Full	4.85
LED Fluorescent Fixtures	Full	5.77
Ceramic Metal Halide Lamps	Full	6.04

[3] See Step 3 in Section 7.2 for a complete description.
[4] Average CCE does not include program costs.
[5] Due to the high avoided cost of new supply in Yukon many measures pass at full cost. The CCEs for energy-efficient equipment upgrades at time of failure (incremental) are typically significantly lower.

Energy-efficiency Supply Curves

A supply curve was constructed based on the approximate Economic Potential savings associated with the above measures. The following approach was followed:

- Measures are introduced in sequence to show incremental impact and cost
- Sequence was determined by listing first the items that reduce the electrical load, then those that meet residual load with the most efficient technology
- Items appear in order, beginning with those that have the lowest average CCE

Exhibit 35C shows the measures included in the supply curve and Exhibit 36C shows the supply curve for Yukon as a whole in the 2030 milestone year. Since the 2035 results are based off of an extrapolation of 2030 results without any further achievable workshop consultations, the penetration and participation values for all measures were held constant over this period. Therefore, the 2030 supply curve results are presented below as this milestone year has the most reliable data.

Exhibit 35C Summary of Commercial Sector Energy-efficiency Measures, 2030

Ref #	Measure	Economic Potential Savings (MWh/yr.)	Cost of Savings ($)	Weighted Average CCE (¢/kWh)

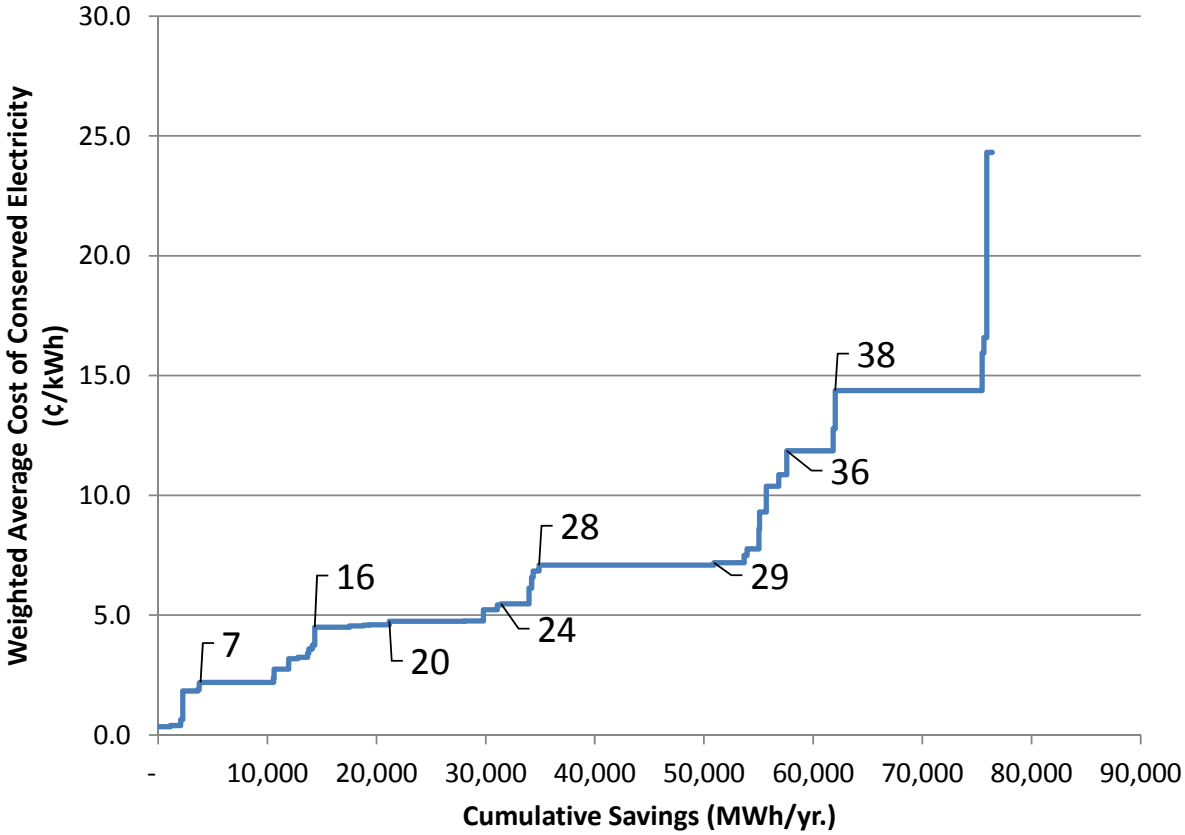
Exhibit 36C Energy-efficiency Supply Curve, Commercial Sector, 2030



Summary of Potential Electric Energy Savings

Exhibits 54C and 58C present the achievable potential results for the total hydro grid connected Yukon service territory by technology and milestone year.[6] The most significant savings in the Achievable Potential come from the following measures:

- Building recommissioning, which accounts for 16% of the upper Achievable Potential savings in 2035 and 15% of the lower Achievable Potential savings in 2035
- LED fluorescent fixtures, which account for 14% of the upper Achievable Potential savings in 2035 and 12% of the lower Achievable Potential savings in 2035
- LED high bay fixtures, which account for 11% of the upper Achievable Potential savings in 2035 and 9% of the lower Achievable Potential savings in 2035
- High performance new buildings (whole building – 60% more efficient than current), which account for 9% of the upper Achievable Potential savings in 2035 and 11% of the lower Achievable Potential savings in 2035
- High efficiency refrigeration measures (both full and incremental cost), which account for 8% of the upper Achievable Potential savings in 2035 and 15% of the lower Achievable Potential savings in 2035
- ENERGY STAR computers, which account for 5% of the upper Achievable Potential savings in 2035 and 7% of the lower Achievable Potential savings in 2035
- LED wallpack outdoor fixtures, which account for 4% of the upper Achievable Potential savings in 2035 and 4% of the lower Achievable Potential savings in 2035

There are numerous other smaller measures that contribute to the overall Achievable Potential results.

[6] Note that these exhibits were not present in the original commercial sector report. However, they are equivalent to Exhibits 54 and 58 in the original residential sector report.

Summary of Electric Peak Load Reductions: Electric Energy Measures

Exhibits 62C and 65C show the demand reductions associated with each electric energy savings measure in 2030. The 2030 results are presented in place of the 2035 results as they are more reliable results. With the absence of new achievable potential workshops, the results from 2035 were extrapolated from 2030 results with penetration and participation rates held constant. Most measures contribute to the peak demand reductions approximately in proportion to their electric energy savings. The results by milestone year are presented for the upper and lower achievable peak period 1 reductions in exhibits 62-2C and 65-2C respectively.

Summary of Electric Peak Load Reductions: Capacity Measures

Exhibits 40C and 41C show the economic demand reductions associated with each commercial sector peak load reduction measure in 2015. Exhibit 40C shows the name of the measure, the cost basis for the CEPR that the shown (full versus incremental) and the measure's average CEPR. The following approach was taken in updating these exhibits from the 2011 study:

- The discount rate was updated to 3.38% from 7.5%, thus impacting the CEPR values.
- The applicable count was updated from the 2010 base year to the new 2015 milestone year data, thus impacting the MW reduction for each capacity measure.
- Costing assumptions for each measure were left unchanged from the 2011 CPR study.

Measures analyzed on the basis of full cost have been placed towards the top of Exhibit 40C as they are qualitatively different from the measures that pass only on an incremental basis. A measure that passes on a full-cost basis can be applied immediately, while incremental measures presume the adoption of other technologies as a condition of their cost effectiveness (e.g., facility network gateways).

Exhibit 41C shows a list of the capacity electric peak load reduction measures grouped by applicable end use category. This exhibit shows the measure name, applicable count in 2015, average demand reduction and average CEPR. Note that since there was no threshold established for maximum cost effective CEPR, all measures are listed and there are no exclusions based on cost effectiveness.

Exhibit 40C Commercial Sector Capacity Reduction Measures, Screening Results

Measure Name	Basis (Full/Incremental)	CEPR Ranges ($/kW)
Engine block heater switch-timer	Full	$36 - $45
Lighting switch load control	Full	$19 - $21
Multiple whole facility elevator/HVAC switches	Full	$41
Electric heat switch control for Hotels	Full	$60 - $68
Electric water heater control switches	Full	$49 - $55
Multiple whole facility refrigeration switches	Full	$56
Multiple whole facility plug load switches	Full	$31 - $42
Electric thermal storage room units	Full	$142 - $159
Multiple whole facility elevator/HVAC switches	Incremental	$34
Electric heat switch control for Hotels	Incremental	$46 - $52
Multiple whole facility refrigeration switches	Incremental	$42
Electric water heater control switches	Incremental	$36 - $41
Multiple whole facility plug load switches	Incremental	$18 - $25

Exhibit 41C Economic Potential Electric Capacity measures and MW Impact

Electric Peak Reduction Measures	Applicable Count 2015	Avg. kW/unit	Avg kW	Avg CEPR $/kW/yr.
Space Heating				
One-way switch for engine block heater - utility load control – stand-alone (assumes 10,000 units)	1,395	0.17 - 0.22	271	$36 - $45
Electric thermal storage (10% of Hotel/Health Offices)	792	0.73 - 0.82	617	$142 - $159
One-way switch for control (Hotels) – stand alone	74	5.15 - 5.77	404	$60 - $68
One-way switch for control (Hotels) - incremental	74	5.15 - 5.77	404	$46 - $52

One-way switch-based utility load control – incremental	925	0.52 - 0.59	514	$36 - $41
Lighting				
One-way switch-based utility load control – stand alone	1,344	1.6 - 1.77	2,267	$19 - $21
One-way switch-based utility load control - incremental	1,344	1.6 - 1.77	2,267	$19 - $21
Plug Loads				
One-way switch-based utility load control – stand alone	823	0.72 - 0.97	694	$31 - $42
One-way switch-based utility load control – incremental	823	0.72 - 0.97	694	$18 - $25
Other Loads				
One-way switch-based Refrigeration – stand alone	75	1.75	131	$56
One-way switch-based Refrigeration – incremental	75	1.75	131	$42
One-way switch-based Elevators & HVAC Fans – stand alone	60	5.25	315	$41
One-way switch-based Elevators & HVAC Fans – incremental	60	5.25	315	$34

Summary of Lower Achievable Electric Peak Load Reductions: Capacity Measures

Exhibit 41-2C below shows the lower achievable demand reduction for peak period 1 and the average full cost CEPR value by end use category for each milestone year until 2035. The demand curve showing the lower achievable demand with EE measures only versus the lower achievable demand with both EE & capacity measures is show in Exhibit 41-3C. The following approach was taken in developing these exhibits:

- The demand for each end use category after EE measures are applied was used as the baseline demand from which peak reductions occur due to capacity measures
- A lower achievable potential of 5% was assumed for all capacity measures, and was linearly extrapolated to all milestone years from a starting uptake of 0% in 2015 (due to lack of utility support) up to a maximum of 5% in the year 2035.

Note that results of the achievable reduction due to capacity measures presented below are based upon the *lower* achievable potential and are subject to variation as they are highly jurisdiction-specific and dependent upon the structure of the utility programs. It is recommended that additional research be conducted in order to account for these limitations.

Exhibit 41-2C Lower Achievable Potential Peak Load Reductions by End Use (MW) – Capacity Measures

	2020	2025	2030	2035	Average CEPR ($/kW/yr.)
Space Heating	0.02	0.03	0.05	0.06	$100
Electric Water Heating	0.01	0.01	0.02	0.03	$52
Lighting	0.03	0.06	0.09	0.11	$20
Plug Loads	0.01	0.02	0.03	0.03	$37
Refrigeration	0.00	0.00	0.00	0.01	$56
Elevators & HVAC Fans	0.00	0.01	0.01	0.02	$41
TOTAL	**0.07**	**0.13**	**0.20**	**0.26**	

Exhibit 41-3C Lower Achievable Potential Demand (MW) – EE Measures only vs. EE & Capacity Measures

	2015	2020	2025	2030	2035
Demand with Lower Achievable EE Measures Applied (MW)	27.32	28.14	28.84	28.23	27.68
Lower Achievable Potential Demand (MW)	27.32	28.07	28.70	28.03	27.42

3.3 Discussion

Cost of Conserved Energy (CCE)

The CCE values in this study do not account for program costs. In addition, parameters that affect the NTG (net-to-gross) ratio (e.g. free-ridership, spillover, etc.) are highly dependent on the design of programs and other jurisdiction-specific features. Since the CCE values for the study do not assume a NTG ratio (i.e. distortion effects, such as free ridership, are ignored since they are program constructs), the CCE values are closer to being gross values.

However, the reference case assumes natural efficiency. This means that the reference case incorporates assumptions for changes to the penetration of energy efficiency measures in absence of utility support over the timeframe of the study. As such, the measure savings values are closer to being net of free ridership.

ICF expects that the CCE can be used as a proxy of utility program costs for YEC, since only a portion of the measure costs are covered by the utility. A recent study by the Lawrence Berkeley National Lab (LBNL) assessed the total cost of electric energy efficiency programs and the relative investments by program administrators versus program participants. Investments by program participants were net of incentives and/or rebates by utilities. The study found that the cost per unit savings varied significantly by jurisdiction and program type, as did the relative investment by program administrators versus participants. However, the study found that, on average, “program administrators and participants split the cost of saving electricity almost

exactly in half".[7] Since the CCE includes all measure costs and the average utility incentive for many energy efficiency programs is no more than 30% of measure costs, the CCE is a reasonable proxy of overall utility program costs for implementing energy efficiency; especially in a jurisdiction with a relatively small number of customers.

An ACEEE study, which focuses on utility costs (program spending) per unit savings and includes only electric DSM programs, is a useful point of reference as well.[8] This study profiled 14 leading EE program administrators in the US and a total of 107 program years. The study found that the levelized cost of saved energy (LCSE) ranged between 1 and 8 cents/kWh and the median was $0.035/kWh for their sample (i.e. all values in $USD). YEC would be expected to be on the higher end of this range based on the size of your jurisdiction and the fact that DSM programs are fairly new.

Achievable Potential

As noted earlier in this memo, the achievable potential results are presented as a range, defined as lower and upper. This is because any estimate of Achievable Potential over a long-term period is necessarily subject to uncertainty.

The lower Achievable Potential assumes Yukon market conditions that are similar to those contained in the Reference Case. That is, the customers' awareness of energy-efficiency options and their motivation levels remain similar to those in the recent past, technology improvements continue at historical levels, and new energy performance standards continue as per current known schedules. It also assumes that the ability of the Yukon utilities and government to influence customers' decisions towards increased investments in energy-efficiency options remains roughly in line with previous company DSM experience.

The upper Achievable Potential assumes Yukon market conditions that aggressively support investment in energy efficiency. For example, this scenario assumes that real energy prices increase over the study period. It also assumes that federal and territorial government actions to mitigate climate change result in increased levels of complementary energy-efficiency initiatives. The upper Achievable Potential typically does not reach Economic Potential levels; this recognizes that some portion of the market is typically constrained by barriers that cannot realistically be affected by DSM programs within the study period.

It should also be emphasized that the estimation of Achievable Potential is not synonymous with either the setting of specific program targets or with program design. While both are closely linked to the discussion of Achievable Potential, they involve more detailed analysis that is beyond the scope of this study. Nonetheless, ICF is aware that achievable potential results are often used to guide targets in some jurisdictions. The lower Achievable Potential often represents a "business-as-usual" scenario in many jurisdictions, while it may represent a more aggressive target in jurisdictions with less DSM experience, such as Yukon.

Executive Summary

The Yukon Energy Corporation ("YEC") has commissioned Midgard Consulting Incorporated ("Midgard") and its team of sub-consultants to complete a Transmission Options Evaluation of eleven potential Yukon transmission line corridors. The assignment scope comprises:

- Detailed transmission corridor optimization (Section 2)
- Estimate of capital expenditures ("CAPEX") (Section 3)
- Estimate of operating expenditures ("OPEX") (Section 4)
- Calculation of power transfer capacities (Section 5)
- Overview of transmission corridor development schedules (Section 6)
- Assessment of corridor risks (Section 7)

Figure 1 below illustrates the eleven routes of interest on a map of the Yukon.

Figure 1: Map of Studied Routes

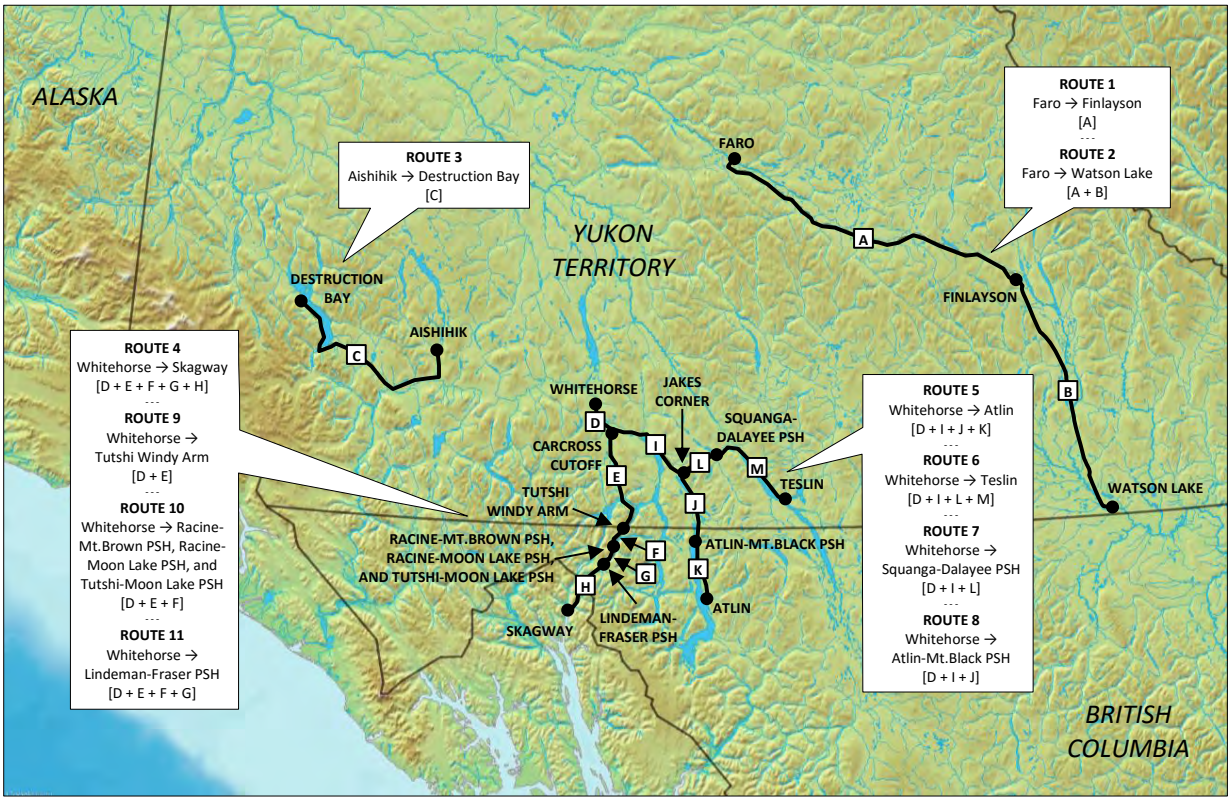

Table 1 below provides a high level summary of the study results for each transmission option, listing the line voltage, line length, maximum reliable transfer capacity, estimated CAPEX, estimated annual OPEX, and earliest In-Service-Date ("ISD").

Vancouver BC, Canada
V6E 4A4

The estimated CAPEX and OPEX costs shown in Table 1 represent a Class 5 estimate (-50%/+100% range of cost accuracy) as set out in Standard 17R-97 of the Association of the Advancement of Cost Engineering.

Table 1: Summary of Results (Costs Stated in $2016)

#	Transmission Route	Voltage	Length	Reliable Transfer Capacity[1]	CAPEX	OPEX	Earliest Possible ISD
1	Faro → Finlayson	138 kV	233 km	84 MW	$221M	$351k/yr	Jan 2021
2	Faro → Watson Lake	230 kV	414 km	190 MW	$597M	$613k/yr	Sep 2022
3	Aishihik → Destruction Bay	138 kV	157 km	122 MW	$167M	$217k/yr	Jul 2020
		230 kV		484 MW	$241M		
4	Whitehorse → Skagway	138 kV	170 km	114 MW	$166M	$285k/yr	Oct 2020
		230 kV		443 MW	$251M		
5	Whitehorse → Atlin	138 kV	172 km	97 MW	$158M	$236k/yr	Oct 2020
6	Whitehorse → Teslin	138 kV	174 km	95 MW	$165M	$239k/yr	Oct 2020
7	Whitehorse → Squanga-Dalayee PSH	138 kV	105 km	134 MW	$100M	$143k/yr	Dec 2019
8	Whitehorse → Atlin-Mt.Black PSH	138 kV	127 km	131 MW	$119M	$174k/yr	May 2020
9	Whitehorse → Tutshi Windy Arm	138 kV	96 km	135 MW	$94M	$143k/yr	Nov 2019
10	Whitehorse → Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH	138 kV	112 km	132 MW	$108M	$168k/yr	Jan 2020
11	Whitehorse → Lindeman-Fraser PSH	138 kV	129 km	129 MW	$125M	$200k/yr	Jun 2020

[1] These values represent the most restricted transfer capacity that is expected in either summer or winter. Thermally limited transmission options may demonstrate a higher Winter Capacity. See Table 8 for more details.

1 Introduction

The Yukon Energy Corporation ("YEC") has commissioned Midgard Consulting Incorporated ("Midgard") and its sub-consultant, J.D. Mollard and Associates (2010) Limited ("JDMA") to evaluate eleven potential Yukon transmission line options.

1) **Midgard Consulting Incorporated ("Midgard"):** Midgard has been providing consulting services to the electrical power and utility industry since 2009, specializing in utility resource planning, renewable generation development, transmission & distribution planning and design, and providing expert strategic services including business case development, project due diligence & financing, system modelling and regulatory support.
2) **J.D. Mollard and Associates (2010) Limited ("JDMA"):** JDMA is a private consulting firm of professional engineers, geoscientists, geographers, and environmental scientists based in Regina, Saskatchewan, Canada. The company has a long tradition of excellence in applied civil and geological engineering, geology, hydrogeology, geography, biology, remote sensing, GIS, terrain analysis, and environmental studies.

The scope of work includes evaluating and optimizing the transmission corridors, estimating capital expenditures ("CAPEX"), estimating operating expenditures ("OPEX"), calculating the maximum reliable power transfer capacities, preparing high-level transmission development schedules, and assessing development risks for each of the identified transmission options.

Table 2 lists the eleven transmission line options evaluated in this report.

Table 2: Overview of Transmission Options

#	Transmission Option	Voltage	Length
1	Faro → Finlayson	138 kV	233 km
2	Faro → Watson Lake	230 kV	414 km
3	Aishihik → Destruction Bay	138 & 230 kV	157 km
4	Whitehorse → Skagway	138 & 230 kV	170 km
5	Whitehorse → Atlin	138 kV	172 km
6	Whitehorse → Teslin	138 kV	174 km
7	Whitehorse → Squanga-Dalayee PSH	138 kV	105 km
8	Whitehorse → Atlin-Mt.Black PSH	138 kV	127 km

V6E 4A4

The following assumptions were utilized in preparing this report:

1) The line voltage for each transmission option was defined by YEC in the scope of work.
2) 34.5 kV distribution underbuild has been incorporated on portions of several routes, including:
    a. Whitehorse → Teslin
    b. Whitehorse → Carcross
    c. Aishihik → Haines Junction
3) The following standard phase conductor and bundling selections have been used throughout:
    a. 138 kV Options: Single 397.5 MCM[2] Ibis ACSR conductor
    b. 230 KV Options: Double Bundle[3] 477 MCM Hawk ACSR conductor

[2] MCM = Thousand circular mils. A circular mil is the cross-sectional area of a wire with a 1/1000 inch diameter (approximately 0.0005 mm^2)

[3] Double bundle 477 MCM Hawk has been selected to mitigate corona inception at 230 kV. In this conductor bundling configuration, each phase comprises two separate Hawk conductors.

2 Corridor Routing & Descriptions

JDMA, with input from Midgard and YEC, carried out route analysis and refinement for the transmission corridors of interest. JDMA completed the corridors evaluations using ESRI ArcGIS and MicroImages TNT MIPS, with data sourced from various territorial, provincial, and national sources (for a detailed breakdown of data sourcing, please see Section 2.1 of JDMA's report attached in Appendix C). The general methodology of route selection was as follows:

- Transmission line span length between poles/structures/towers targeted to be 200 to 230 m with longer spans as needed
- Where practical, the transmission line corridor was placed adjacent to roadways
- The target corridor width of 500m, but narrowed to less than 500 m when necessary to avoid major terrain constrictions adjacent to the corridor (e.g.: next to a steep slope, river, etc.)
- Avoided crossing privately held land wherever possible
- Where practical, line deflections were kept to <15° to avoid more complex and costly structures

In addition to these specific criteria, JDMA also considered surficial geology and surface materials, terrain and slope, total length, as well as stream and wetland crossings to help identify potentially feasible corridors. The full JDMA study is attached in Appendix C. Figure 2 shows all of the transmission routes considered.

Table 3 provides a brief overview of the analyzed routes.

Table 3: Description of Studied Routes

#	Transmission Route	Description of Route
1	Faro ↓ Finlayson	▪ **Start:** Town of Faro ▪ **End:** Finlayson Project Interconnection ▪ **Length:** 233 km ▪ Follows the "Faro → Watson Lake" route from Faro for 233 km until reaching the Finlayson project interconnection point.
2	Faro ↓ Watson Lake	▪ **Start:** Town of Faro ▪ **End:** Town of Watson Lake ▪ **Length:** 414 km ▪ Parallels the Pelley River for 56 km at the north end and then follows Highway 4 (Robert Campbell Highway) to Watson Lake. ▪ Crosses several major rivers at the south end, including the Frances and Liard Rivers.
3	Aishihik ↓ Destruction Bay	▪ **Start:** Aishihik Generating Station ▪ **End:** Town of Destruction Bay ▪ **Length:** 157 km ▪ From Aishihik the corridor heads south to Canyon, paralleling existing access and transmission used for the Aishihik project. ▪ From Canyon the corridor generally follows Highway 1 westwards (Alaska Highway) to Destruction Bay. ▪ The corridor detours off of Highway 1 at the Slims River crossing to take advantage of a narrower river crossing location further upstream, but even this upstream location may involve a crossing span of up to 500 m. ▪ After crossing Slims River, the corridor continues to follow Highway 1 to Destruction Bay, making use of an abandoned pipeline right-of-way. ▪ 49 km of 34.5 kV distribution underbuild is included from Aishihik to Haines Junction
4	Whitehorse ↓ Skagway	▪ **Start:** Whitehorse Generating Station ▪ **End:** Town of Skagway, AK ▪ **Length:** 170 km ▪ From the Whitehorse Generating Station the corridor follows Highway 1 southeast for 17 km to Carcross Cutoff (the junction of Highways 1 and 2). ▪ From Carcross Cutoff the corridor follows Highway 2 southwards through the town of Carcross for 77 km to the BC-Yukon border. ▪ Once in BC the corridor continues along Highway 2 for an additional 56 km to the BC-Alaska border. ▪ Once in Alaska the corridor continues along the same highway (now named Highway 98) for an additional 21 km to Skagway, Alaska. ▪ 68 km of 34.5 kV distribution underbuild is included from Whitehorse to Carcross

#	Transmission Route	Description of Route
5	Whitehorse ↓ Atlin	▪ **Start:** Whitehorse Generating Station ▪ **End:** Town of Atlin, BC ▪ **Length:** 172 km ▪ From the Whitehorse Generating Station the corridor follows Highway 1 southeast for 17 km to Carcross Cutoff. ▪ The corridor then follows Highway 1 eastwards for 62 km to Jakes Corner where Highway 1 meets Highway 8. On this stretch the corridor crosses the Yukon River, a span of approximately 250 m. ▪ From Jakes Corner the corridor turns south and follows Highway 7 for 42 km to the BC-Yukon border. ▪ Once in BC the corridor continues along Highway 7 for an additional 50 km to Atlin, BC. ▪ 79 km of 34.5 kV distribution underbuild is included from Whitehorse to Jakes Corner
6	Whitehorse ↓ Teslin	▪ **Start:** Whitehorse Generating Station ▪ **End:** Town of Teslin ▪ **Length:** 174 km ▪ From the Whitehorse Generating Station the corridor follows Highway 1/2 southeast for 17 km to Carcross Cutoff (the junction of Highways 1 and 2). ▪ The corridor then follows Highway 1 eastwards for 62 km to Jakes Corner, where Highway 1 meets Highway 8. On this stretch the corridor crosses the Yukon River, a span of approximately 250 m. ▪ From Jakes Corner the corridor follows Highway 1 eastwards for 95 km to Teslin, crossing the Teslin River (a span of approximately 400 m) and passing through the communities of Johnson's Crossing, Brooks Brook, and Teslin Lake. ▪ 34.5 kV distribution underbuild is included for the entire corridor (174 km)
7	Whitehorse ↓ Squanga-Dalayee PSH	▪ **Start:** Whitehorse Generating Station ▪ **End:** Squanga-Dalayee PSH Project Interconnection ▪ **Length:** 105 km ▪ From the Whitehorse Generating Station the corridor follows Highway 1/2 southeast for 17 km to Carcross Cutoff (the junction of Highways 1 and 2). ▪ The corridor then follows Highway 1 eastwards for 62 km to Jakes Corner, where Highway 1 meets Highway 8. On this stretch the corridor crosses the Yukon River, a span of approximately 250 m. ▪ From Jakes Corner the corridor follows Highway 1 eastwards for 26 km to the Squanga-Dalayee PSH interconnection point. ▪ 34.5 kV distribution underbuild is included for the entire corridor (105 km)

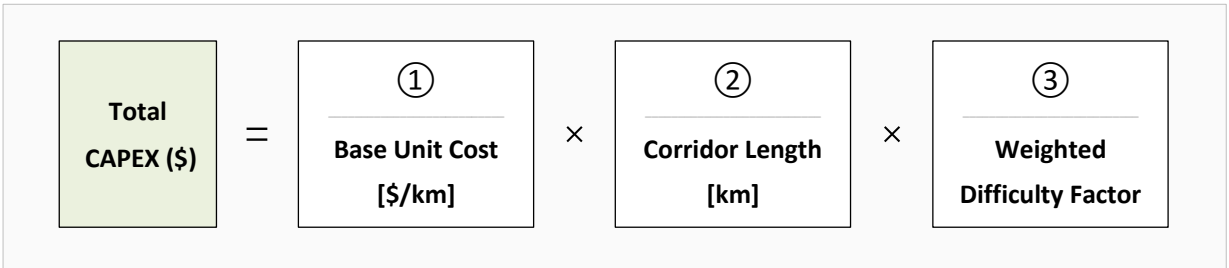
3 CAPEX Analysis

Midgard created a parametric model to estimate the all-in CAPEX required to implement each transmission line routing option. Midgard's costs represent total, all-in costs for the transmission lines, which includes owner's costs, development costs, stakeholder engagement costs, land costs, planning and engineering costs, construction costs, contractor profit margins, material costs, and commissioning costs. The CAPEX estimates do not include any provisions for new substations or substation related costs (e.g.: new bays, new breakers, or new bus work).

3.1 CAPEX Estimation Methodology

The factor-based CAPEX model is defined by the following logic (see Figure 3):

Figure 3: Midgard Parametric CAPEX Model



The following descriptions provide more information on each component of the parametric CAPEX model:

- **Component ① - Base Unit Costs:** Drawing upon both public and proprietary industry transmission project cost information, an average per kilometer project costs for the studied voltage classes (138 kV and 230 kV) was established. The source data covers a wide range of transmission projects (16 x 138 kV projects and 17 x 230 kV projects) and represents a reasonable estimate of the expected "base case" unit costs for both 138 kV and 230 kV voltages.
- **Component ② - Corridor Length:** The corridor length for each of the transmission line routes was extracted from the detailed corridor analysis.
- **Component ③ - Weighted Difficulty Factor:** Weighted Difficulty Factors are calculated based on the terrain information from the detailed corridor analysis. The corridor-specific difficulty factors are based on a variety of inputs that uniquely differentiate each route based on the expected difficulty of project execution. Factors considered include: vegetation cover, water features, surficial geology, permafrost, terrain slope, existing access, human settlements, land use and remoteness.

In addition to the factor-based workup of project costs (detailed above), sub-sections of several routes (Whitehorse → Teslin, Whitehorse → Carcross, and Aishihik → Haines Junction) include a provision for 34.5 kV distribution underbuild. Since the Base Unit Costs do not include allowance for distribution underbuild, an additional adder was included for the route segments requiring underbuild. It is worth noting

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

that distribution underbuild cost is dependent on a variety of factors that have not yet been determined (e.g.: conductor type, number of taps/services, etc.), and therefore a consistent underbuild costs per kilometer was used. The following ranges are indicative of the incremental costs that could be expected to add distribution underbuild on different transmission line configurations:

1) Short spans, single pole structures, light distribution conductor: $80,000 per km
2) Short spans, single pole structures, heavy distribution conductor: $100,000 per km
3) Long spans, H-frame structures: $120,000 to $150,000 per km

Midgard considers that a $100,000 per km adder is a reasonable high-level allowance for the incremental all-in costs of adding 34.5 kV underbuild to the selected transmission route segments.

The level of accuracy of the factor-based CAPEX model is Class 5 as per standard 17R-97 by the Association of the Advancement of Cost Engineering, which represents a -50% / +100% range of accuracy.

3.2 CAPEX Results

Table 4 below provides the tabular details of each of the eleven transmission corridors (including voltage, length, and the amount of 34.5 kV distribution underbuild) as well as the estimated total CAPEX and estimated CAPEX per km.

Table 4: Summary of CAPEX Results (Costs Stated in $2016)

#	Transmission Route	Voltage	Length	34.5 kV Underbuild	CAPEX [Total]	CAPEX [Per KM]
1	Faro → Finlayson	138 KV	233 km	None	$221M	$0.95M/km
2	Faro → Watson Lake	230 kV	414 km	None	$597M	$1.44M/km
3	Aishihik → Destruction Bay	138 kV	157 km	49 km	$167M	$1.07M/km
		230 kV			$241M	$1.54M/km
4	Whitehorse → Skagway	138 kV	170 km	68 km	$166M	$0.98M/km
		230 kV			$251M	$1.48M/km
5	Whitehorse → Atlin	138 kV	172 km	79 km	$158M	$0.91M/km
6	Whitehorse → Teslin	138 kV	174 km	174 km	$165M	$0.95M/km
7	Whitehorse → Squanga-Dalayee PSH	138 KV	105 km	105 km	$100M	$0.96M/km
8	Whitehorse → Atlin-Mt.Black PSH	138 KV	127 km	79 km	$119M	$0.94M/km
9	Whitehorse → Tutshi Windy Arm	138 KV	96 km	68 km	$94M	$0.98M/km
10	Whitehorse → Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH	138 KV	112 km	68 km	$108M	$0.97M/km
11	Whitehorse → Lindeman-Fraser PSH	138 KV	129 km	68 km	$125M	$0.97M/km

3.3 CAPEX Benchmarking Analysis

In addition to the above CAPEX estimates, Midgard has also completed a benchmarking exercise against several YEC cost numbers in the Yukon. The two data sets being compared are:

1) **The 138 kV Routes from This Report:** The 138 kV lines (10 in total) considered in this *Transmission Options Evaluation* are based on the average costs (plus some factor modification, see Section 3.1) of 16 recent projects across the Yukon, Alberta, and British Columbia.
2) **YEC Projects of Interest:** A 138 kV route cost workup for the Stewart-Keno Transmission Project provided by YEC on July 8, 2016.

A benchmarking comparison (on a $2016/km basis) of the two data sets is presented in Table 5 below.

Table 5: Benchmarking Results (Costs Stated in $2016)

Data Set	#	Cost Range ($2016)	Items Included in Cost Estimate
Transmission Options Evaluation 138 kV Results	10 Lines	$0.85M → $1.04M/km	Complete, All-In Costs (including project contingency, land costs, First Nation costs, development costs, permitting costs, engineering costs, salvage costs, and owner's overhead/admin costs, but not including distribution underbuild costs)
YEC Stewart-Keno Transmission Project Estimate	1 Line	$0.53M/km	Construction Cost Only

As seen in the table above, the results of this *Transmission Options Evaluation* are higher than YEC's Stewart-Keno Transmission Project. Midgard believes this difference is primarily due to the *Transmission Options Evaluation* costs being represented as **total, all-in** costs as opposed construction-only costs (an "apples-to-oranges" comparison). Some of the cost items missing from YEC's Stewart-Keno Transmission Project estimate include:

1) **Project Contingency:** A contingency is a budget allocation to compensate for unforeseen costs. Unforeseen costs can manifest in many forms, including weather induced delays, unplanned soil conditions, or changes in labour market rates.
2) **Land Costs:** Land costs can include Right-of-Way acquisition, long term land leases, settlements with private land owners, relocation costs, remediation efforts, and habitat compensation offsets.
3) **First Nation Costs:** First Nation costs can include consultation efforts, compensation packages (impact benefit agreements), granting equity in projects, etc.

Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com

828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

4) **Development Costs:** Development costs cover all early stage conceptual studies, preliminary engineering efforts, and environmental studies.
5) **Permitting Costs:** Permitting costs can include highway crossing permits, access permits, river crossing permits, aerodrome permits, pipeline crossing permits, etc.
6) **Engineering Costs:** Detailed engineering to design and issue the construction package for the transmission line.
7) **Salvage Costs:** Salvage costs includes any modification or removal of existing infrastructure to accommodate a new transmission line. For example, the removal of an old transmission line or wrecking out old distribution circuits.
8) **Owner's Overhead & Admin Costs:** Utility overhead includes the project's portion of all utility overhead. Utility overhead includes administration, office space, staffing costs, etc.

Typically the eight non-construction costs listed above can make up 30% to 50% of total, all-in project costs for a transmission line. Considering this fact, the benchmarking results do show overlap between the two sets of cost estimates.

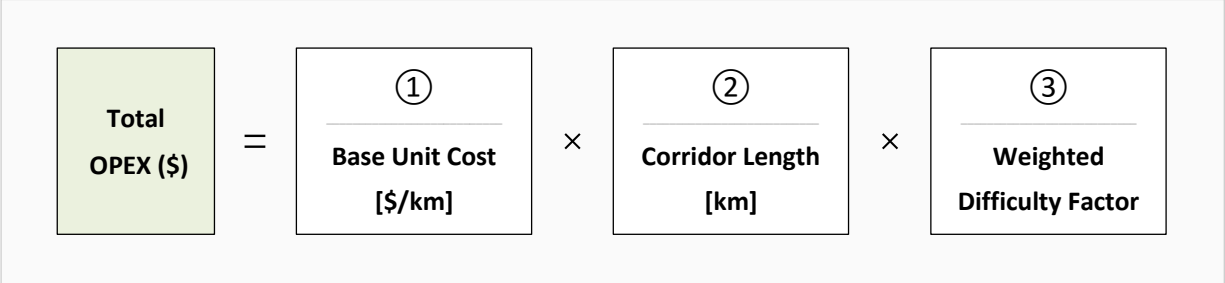
4 OPEX Analysis

Midgard calculated the annual OPEX required to maintain each transmission line option by drawing upon the average per unit costs of operating the existing YEC transmission system. Similar to the CAPEX modeling, the estimated OPEX costs represent the total all-in cost of transmission operations.

4.1 OPEX Estimation Methodology

The OPEX model is defined by the following logic (see Figure 4):

Figure 4: Midgard OPEX Model



The following descriptions provide more information on each component used in the calculations:

- **Component ① - Base Unit Cost:** The YEC 2012-2013 General Rate Application was used as the source for YEC's total transmission operational costs. The proposed OPEX cost estimate for YEC in 2013 was $1,293,000 (extracted from Table 3.6 on page 3-8 of "Supporting Documents: Tab 3 – Revenue Requirement"), which is comprised of labour costs, brushing costs, and other non-labour costs. This 2013 estimate was normalized to a $/km value using the total line length of the existing YEC transmission system. Finally, the resulting per unit operational costs were inflation-adjusted to give results in 2016 Canadian dollars.
- **Component ② - Corridor Length:** The corridor length for each of the transmission line routes was extracted from the detailed corridor analysis.
- **Component ③ - Weighted Difficulty Factor:** Weighted Difficulty Factors are calculated based on the terrain information from the detailed corridor analysis. The corridor-specific difficulty factors are based on four inputs that uniquely differentiate each route based on the expected difficulty of operations. Factors considered include: permafrost, remoteness, terrain slope, and an adder for projects that extend outside the Yukon jurisdiction. The factors were applied in a manner such that some routes had increased operating costs (above the Base Unit Cost) and some had decreased operating costs (below the Base Unit Cost). This approach was chosen as the Base Unit Costs are already representative of the different factors that influence Yukon operating costs, and that it is reasonable to assume the new routes under consideration would more or less average to a similar operating cost (some being higher than average, some being lower).

5 Power Transfer Capacity Analysis

In order to estimate the maximum reliable power transfer capacity of each transmission line option, a steady state power system analysis was performed using the Siemens PSS®E power system simulation software. The maximum reliable power transfer tells you how much electricity can be safely sent through the transmission line and is a useful characteristic to determine the most appropriate voltage and conductor type for planning purposes. The potential transmission lines studied in this *Transmission Options Evaluation* could be used for a variety of purposes, including serving electricity to remove communities, interconnecting mining operations to the Yukon grid, and/or interconnecting new power generations projects to the Yukon grid.

The power transfer capacity limit for each transmission option was determined by calculating the expected conductor temperature and the voltage magnitudes and angles at the line terminals and one or more intermediate points across a range of power transfers. For any given line option the capacity limiting parameter may be the absolute voltage magnitude (voltage constraint), the voltage angle separation between line terminals (angular constraint), or reaching the temperature limit of the conductor (thermal constraint). Since public access is not available for the power system models used by YEC, simplifying assumptions based on publicly available information were utilized to approximate the Yukon electrical system as part of a simplified model. Additional detail regarding the simulation set-up can be found in Appendix A.

It is important to state that the methodology used to calculate the maximum reliable power transfer capacity remains preliminary in this *Transmission Options Evaluation* for the purposes of informing YEC's long term planning efforts. As the projects are further considered, modified, and iterated towards actual implementation, the requirements and ultimate use of these proposed transmission lines will become more concrete. Once the transmission line projects are in a later stage of development, a more comprehensive suite of system analyses (including transient and voltage stability studies covering a broad set of present and future system forecast load cases) would be necessary.

5.1 Assumptions

5.1.1 General

Some of the basic assumptions adopted for this study are as follows:

1) Swing Bus: A Swing Bus is a simulated generator bus that is used to balance power system loads and generators during system studies. The Swing Bus either absorbs surplus power or generates power to balance total power generation and consumption when solving system simulations. In the context of this study, the Swing Bus represents the cumulative Yukon grid, and the amount of power the Swing Bus absorbs represents the power transferred by the transmission line.

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

2) Yukon Loads: Yukon communities that are already electrified (e.g.: Tagish, Carcross, Ross River, etc.) were assumed to remain connected via their existing electrical grid connections (i.e. they were not transferred from their existing grid connection to the potential transmission lines). Midgard reviewed a series of future mining loads[4], but determined that they would not be supplied by any of the eleven transmission corridors. All other electrical load values were provided by YEC.
3) Power Transferred to the Swing Bus = [Total generation along the new transmission line] – [Total loads along the new transmission line] - [Transmission line losses]
4) Voltage Stability: Steady state voltage stability implies maintaining voltage levels within 90% and 110% of the prescribed operating voltage (138 kV or 230 kV).
5) Angular Stability: Steady state angular stability is assumed to be achieved by maintaining a voltage angle difference of less than 33° between the generating end and the receiving end.

5.1.2 Operating Conditions

The following assumptions were made in order to model transmission line behaviour:

1) Wind Speed: 2 ft/s (0.61 m/s)
2) Winter Ambient Temperature: -10°C
3) Summer Ambient Temperature: +35°C
4) Altitude: Detailed in Table 7.

Table 7: Altitude of Transmission Line Terminal Locations

Location	Altitude (m)
Whitehorse	655
Faro	670
Aishihik	920
Mayo	504
Pelly Crossing	570
Destruction Bay	815
Watson Lake	685
Teslin	690

Location	Altitude (m)
Finlayson Lake	934
Squanga-Dalayee	778
Atlin	696
Tutshi Windy Arm	715
Racine	900
Lindeman	900
Skagway	0

5.1.3 Conductor Type

Conductor selection assumptions:

1) 138 kV Corridors: Single 397.5 MCM Ibis ACSR conductor
2) 230 KV Corridors: Double Bundle 477 MCM Hawk ACSR conductor

[4] Victoria Gold, Brewery Creek, Alexco Bellekeno and Carmacks Copper are the potential mines that may be operational in the future.

Vancouver BC, Canada
V6E 4A4

5.2 Methodology

The following methodology was applied to determine the maximum reliable transfer capacity for each Transmission Option:

1) STEP 1: A steady state power flow model is developed for the PSS®E software using the following inputs:
    a. Transmission line information (resistance, reactance, charging susceptance, and thermal rating)
    b. Generation and load information
    c. Operating voltage
2) STEP 2: A full Newton-Raphson simulation is performed assuming a flat start condition utilizing an assumed base power transfer level.
3) STEP 3: The bus voltage, the voltage angle, and the conductor temperature are monitored to determine if they remain within their limiting conditions. The limiting conditions are as follows:
    a. Bus Voltage: Lower limit is 90% of the operating voltage, and the upper limit is 110% of the operating voltage
    b. Voltage Angle: The upper limit for sending & receiving end voltage angle separation is 33°
    c. Thermal Rating: The limits are dependent on the type of conductor, operating voltage and conditions such as line orientation, elevation, ambient temperature and wind speed.
4) STEP 4: If there are no violations of the monitored key parameters, the process is repeated from Step 2 at an incrementally higher line transfer capacity.
5) STEP 5: The simulation is stopped and the transmission line maximum power transfer limit (recorded as power flow into the swing bus end of the system) is identified when any one of the monitored parameters reaches a limiting value.

5.3 Route Characteristics and Transfer Capacity Results

Maximum power transfer capacity results are tabulated in Table 8 below. Table 8 lists the voltage class, conductor type, line length, size and location of loads, the maximum summer power transfer rate, the maximum winter power transfer rate, and the limiting condition for each of the evaluated transmission options.

Table 8: Electrical Description of Routes & Power Transfer Results

#	Option	Description	Results
1	Faro ↓ Finlayson	▪ Voltage: 138 kV ▪ Conductor Type: Ibis 397.5 MCM (Single Bundle) ▪ Total Line Length: 233 km ▪ Loads Modeled: o No Intermediate loads	Max Power Transfer: **84 MW** Limiting Factor: Voltage Angle Limit

6 Project Scheduling

High-level project schedules have been estimated for each of the transmission project options evaluated in this report. Each project schedule is broken down into the following general activity phases[5]:

1) Phase 1: Preliminary Engineering and Cost Estimation
2) Phase 2: Permitting
3) Phase 3: Detailed Design
4) Phase 4: Procurement and Logistics
5) Phase 5: Tendering and Construction
6) Phase 6: Commissioning

The schedule estimates draw upon recent Yukon transmission project results[6] and are augmented with Midgard's knowledge of recently completed and ongoing transmission project developments in nearby jurisdictions. The following subsections describe the project schedule phases listed above, and the assumptions related to each respective phase.

6.1 Phase-By-Phase Discussion

6.1.1 Phase 1: Preliminary Engineering and Cost Estimates

The Preliminary Engineering and Cost Estimates phase includes allowance for the required pre-feasibility and feasibility design, and cost estimation activities required to support business case decisions.

The duration of preliminary engineering and cost estimate studies will be strongly influenced by the total length of the specific transmission line being considered, but the relationship between duration and line length is not linear. For the purpose of this report a minimum duration of at least 3 months has been assumed for short projects, and a maximum duration of 12 months has been assumed for transmission projects over 200 km in length (based on a range of time durations extracted from recent transmission line builds).

The study results from the preliminary engineering activities will feed into YESAB and YUB permit applications.

[5] The scheduling estimates included in this report account for technical components only and do not include the time required for First Nation and stakeholder consultation activities. In reality, all First Nations and stakeholders will be consulted and engaged with throughout project development (from early stage development through to project completion and operation).

[6] YESSA Project Proposal, Oct 2015: Stewart – Keno 138 kV Transmission Project and YESAB Project Proposal - Carmacks – Stewart/Minto Spur Transmission Project, Chapter 5

MIDGARD
Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

6.1.2 Phase 2: Permitting

The Permitting phase activities include preparing and filing the documents necessary to obtain environmental approvals from YESAB and regulatory permits from YUB.

Based upon the permitting duration allowance for the Carmacks – Stewart/Minto Transmission project and the Stewart Keno Transmission project, a minimum permitting duration of 13 months has been assumed. Assuming that there are no extraordinary issues identified during the permitting phase, a maximum permitting duration of 18 months is used for transmission options ranging from 150 km to 200 km, and for transmission options over 200 km the permitting duration is capped at 20 months (based on a range of time durations extracted from recent transmission line builds).

Issues that arise during the permitting phase may require line re-routing or other facility modifications to enable the necessary permits to be obtained. Any required modifications to the feasibility phase designs will cascade into the detailed design stage activities, and may extend expected timelines for permitting activities and all other project phases.

6.1.3 Phase 3: Detailed Design Engineering

The detailed design engineering phase builds on the results of the preliminary engineering and cost estimates, with further refinements being implemented throughout the permitting process as required to address any YESAB and YUB permit conditions.

The detailed design effort typically has a non-linear relationship to the line length. Certain design activities have a minimum duration even for very short lines, and significant external engineering resources are typically brought on for longer transmission projects, thereby mitigating the overall duration of detailed design activities. For the purpose of this report the estimated duration of detailed design engineering activities has been capped at 12 months for transmission projects over 200 km long (based on a range of time durations extracted from recent transmission line builds).

6.1.4 Phase 4: Procurement and Logistics

The procurement process for long lead-time equipment (e.g.: transformers) and bulk materials such as poles and conductor is often initiated prior to the issuance of final permits in order to avoid extended delays to construction start after the required permits have been obtained. Although the overall project duration can be shortened in this way, there is a risk of stranded investment if the project does not receive approval.

Similar to the design activities discussed above, the duration of procurement activities is not linearly proportional to line length. For the purpose of this report, procurement activities are assumed to last 16 months for lines 100 - 200 km long, and are capped at 20 months for lines longer than 200 km (based on a range of time durations extracted from recent transmission line builds).

Midgard Consulting Inc
+1 (604) 298 4997
midgard-consulting.com
828 – 1130 West Pender St.
Vancouver BC, Canada
V6E 4A4

6.1.5 Phase 5: Tendering and Construction

In most cases, construction activities cannot begin until after the necessary permits and licenses have been obtained, although construction tendering can be initiated prior to receiving permits (with the assumption of the associated incremental risk).

Transmission line construction activities include right-of-way brushing and clearing, access road development, foundation and anchor installation, structure assembly and erection, conductor stringing, sagging and clipping in. Construction activities must be carried out in consideration of environmental restrictions, such as avoiding bird nesting seasons and not entering or disturbing streams except during approved fish windows. Most construction activities in wet or permafrost areas must be completed during the winter season to take advantage of frozen conditions to reduce damage to soils and wetlands and to enable access to structure sites using standard vehicles.

6.1.6 Phase 6: Commissioning

A duration of 3 months has been assumed for commissioning the transmission line for all the transmission options considered in this report (based on a range of time durations extracted from recent transmission line builds). It is assumed that line review and commissioning preparation activities will actually be ongoing during the construction phase, so the incremental duration of commissioning activities post-construction will not be proportional to overall line length.

6.2 Schedule Results

Table 9 below contains the total timeline (from preliminary engineering through to commissioning) of each of the transmission routes of interest as well as a stated In-Service Date, assuming the initial activities are started today. A more detailed phase-by-phase Gantt chart for each transmission route option is included in Appendix B.

Table 9: Schedule Highlights

#	Transmission Route	Total Timeline	Earliest Possible ISD
1	Faro → Finlayson	52 Months	Jan 2021
2	Faro → Watson Lake	72 Months	Sep 2022
3	Aishihik → Destruction Bay	46 Months	Jul 2020
4	Whitehorse → Skagway	49 Months	Oct 2020
5	Whitehorse → Atlin	49 Months	Oct 2020
6	Whitehorse → Teslin	49 Months	Oct 2020

#	Transmission Route	Total Timeline	Earliest Possible ISD
9	Whitehorse → Tutshi Windy Arm	38 Months	Nov 2019
10	Whitehorse → Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH	40 Months	Jan 2020
11	Whitehorse → Lindeman-Fraser PSH	45 Months	Jun 2020

With regards to project lifespans, the typical asset life for transmission lines can be expected to range from 40 to 45 years. However, with proper and regular maintenance, line life can be extended. YEC amortizes transmission line assets over a 55 year period.

7 Risk Assessment

Potential risks must be identified and assessed whenever planning, budgeting, and scheduling any new transmission line projects. Different risks may be encountered during each phase of transmission project development, and the relative priority of risks will likely change between the different project phases.

7.1 Defining Risk Metrics

The first step in risk assessment involves creating a risk register that comprehensively identifies the risks that may credibly be encountered when developing an individual project (or portfolio of projects). Some risks are generic to transmission projects built anywhere, some apply to projects built within a particular geographical setting and climatic zone, and some risks are specific to the selected routing. Most of the projects discussed in this report are potentially exposed to a common set of risks that would be generally applicable to projects built anywhere in the Yukon.

Once the risks applicable to a particular project have been identified the probability and consequence of each risk is estimated. In this analysis, probabilities are assigned on a scale of 1 to 5, where 1 indicates a low probability (the risk is unlikely to happen on the project being evaluated) and 5 indicates a high probability (the risk will almost certainly be realized at some point during the project). Similarly, consequences are assigned a rating of 1 to 5 where 1 indicates a small consequence should the risk be incurred (minor cost impact or very brief schedule delay) and 5 indicates a significant consequence (major cost overruns, extended schedule delays, severe or widespread environmental or safety impacts).

Each risk is assigned a rank based upon the product of the probability and consequence of that risk:

- 1 to 5 = Low Risk (L)
- 6 to 10 = Moderate Risk (M)
- 11 to 15 = High Risk (H)
- 16 to 20 = Very High Risk (V)
- 21 to 25 = Extreme Risk (X)

7.2 Universal Risks (Affecting All Routes)

The first risk matrix shown below (Table 10) identifies and ranks risks to which all Yukon transmission line projects may be exposed. Each risk is identified as a development phase risk, a construction phase risk, and/or an operational phase risk. Some risks can impact more than one project phase.

In addition, the risk matrix also includes a “Potential Mitigation” column that lists some mitigation options identified by Midgard.

Table 10: Universal Risks (Affecting All Routes)

#	Risk Description	Risk Rank	Potential Mitigation
1	Risk: Meteorological –Extended Extreme Cold ▪ Construction delays ▪ Labour inefficiency ▪ Crew standby costs ▪ Additional mob & de-mob costs for extended extreme cold periods Affects: Construction	**Prob:** 5 **Conseq.:** 2 **Rank:** M	▪ Schedule activities potentially impacted by extreme cold temperatures during spring, summer or fall ▪ Allow adequate schedule float for anticipated extreme cold days
2	Risk: Meteorological – Extreme Snow ▪ Construction delays ▪ Labour inefficiency ▪ Standby costs ▪ Additional mob & de-mob costs ▪ Additional snow clearing costs ▪ Operational impacts can include structure & conductor damage, inadequate clearance over roads, railways and pathways Affects: Construction, Operations	**Prob:** 3 **Conseq.:** 2 **Rank:** M	▪ Schedule construction activities in heavy snow-prone areas during summer ▪ Allow adequate schedule float for an appropriate number of anticipated extreme snow days ▪ Allow adequate safety factor when designing clearances above ground and obstacles
3	Risk: Meteorological – Extreme Wind ▪ Construction delays, especially if high winds occur during structure erection or stringing activities ▪ Operational impacts can include structure failure, contact between phases and transmission structure or guys, phase contact with trees or buildings, trees falling into line, forest fire ignition Affects: Construction, Operations	**Prob:** 3 **Conseq.:** 2 **Rank:** M	▪ Allow adequate schedule float for anticipated extreme wind days ▪ Allow for phase blow-out in RoW widths ▪ Clear all danger trees that could fall into line
4	Risk: Geotechnical – Permafrost ▪ Additional foundation costs ▪ Sub-optimal span lengths required to avoid placing structures in permafrost (in areas with discontinuous permafrost) ▪ Operational risk if foundations accelerate permafrost melting and structure fails Affects: Construction, Operations	**Prob:** 4 **Conseq.:** 3 **Rank:** H	▪ Avoid or span over permafrost areas to the greatest extent possible ▪ Utilize permafrost-friendly foundation designs
5	Risk: Geotechnical – Exposed Bedrock ▪ High foundation and guying costs (e.g.: grouted rock anchors, blasting) Affects: Construction	**Prob:** 3 **Conseq.:** 3 **Rank:** M	▪ Select centreline route to maximize opportunities to site structures in acceptable overburden ▪ Select structure types adaptable to cost effective use of rock foundations and anchors

#	Risk Description	Risk Rank	Potential Mitigation
6	Risk: Geotechnical – Steep Sideslopes ▪ Difficult and costly foundation and structure erection ▪ Operational Risk of snow creep damaging structures sited on steep sideslopes in heavy snow zones ▪ Risk of snow avalanche damage ▪ Risk of slope instability/landslides, exacerbated by foundation excavation and access road construction Affects: Construction, Operations	**Prob:** 3 **Conseq.:** 3 **Rank:** M	▪ Avoid routing on steep sideslopes if possible ▪ Avoid placing structures in avalanche chutes or on unstable slopes ▪ Utilize existing access roads wherever possible ▪ Locate structures as close as possible to existing access roads ▪ Utilize snow creep resistant foundations and structure bases on steep slopes in heavy snow loading areas ▪ Utilize upslope avalanche guards or deflectors where necessary & practical
7	Risk: Geotechnical – Floodplains ▪ Expensive foundations ▪ Operational risk of flood damage or destruction of structures and resulting extended outages ▪ Construction difficult or impossible during freshet/snowmelt season Affects: Construction, Operations	**Prob:** 3 **Conseq.:** 3 **Rank:** M	▪ Avoid placing structures within floodplains to the greatest extent possible ▪ Schedule floodplain construction during late summer/fall/winter ▪ Use heavy rip-rap protection (large rock armour) for structures that must be placed in floodplains
8	Risk: Social – Permitting in Reserve Blocks ▪ Consultation with First Nations potentially impacted by new facilities in traditional lands or near communities ▪ Schedule delays or routing adjustments if route agreement is not achieved Affects: Development, Construction, Operations	**Prob:** 4 **Conseq.:** 4 **Rank:** V	▪ Begin comprehensive outreach activities with affected FN communities early
9	Risk: Social – Permitting near Urban Areas ▪ Avoiding populated areas may involve more complex line routing ▪ Possible cost increases due to additional route length, additional deflection structures, more difficult access roads ▪ Schedule delays if consultation does not achieve route agreement with landowners Affects: Development, Construction	**Prob:** 3 **Conseq.:** 4 **Rank:** H	▪ Where possible select routes that avoid densely populated areas ▪ Avoid siting structures close to residences

#	Risk Description	Risk Rank	Potential Mitigation
10	Risk: Social – Permitting in Scenic Areas ▪ Siting routes parallel to scenic highways increases risk of obstructing viewscapes or impacting sight lines due to RoW clearing Affects: Development, Construction	**Prob:** 3 **Conseq.:** 3 **Rank:** M	▪ Avoid locating structures between scenic viewpoint areas and scenic vistas ▪ Align RoW to minimize visual impact of transmission RoW cutlines through forested areas impact viewscapes

7.3 Route Specific Risks

In addition to the universal risks identified above, project-specific risk matrices have been developed for the following routes:

- Faro → Finlayson / Watson Lake (see Table 11)
- Aishihik → Destruction Bay (see Table 12)
- Whitehorse → Skagway / Tutshi Windy Arm / Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH / Lindeman-Fraser PSH (see Table 13)
- Whitehorse → Atlin / Atlin-Mt.Black PSH (see Table 14)
- Whitehorse → Teslin / Squanga-Dalayee PSH (see Table 15)

Table 11: Route Specific Risks for Faro → Finlayson / Watson Lake

#	Risk Description	Risk Rank	Potential Mitigation
1	Risk: Logistics – Very Large Projects located in Remote Area with little local capacity ▪ Challenging to setup and supply camps ▪ Transportation and storage of very large amounts of construction materials in remote area ▪ Difficult to stage construction for such a long linear project in this region Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 2 **Rank:** M	▪ Logistics and camp planning at very early project stage ▪ Allow adequate schedule float to address logistical challenges

Table 12: Route Specific Risks for Aishihik → Destruction Bay

#	Risk Description	Risk Rank	Potential Mitigation
1	Risk: Geotechnical – Floodplains ▪ Extensive Floodplain where Slims River previously discharged into south end of Kluane Lake Affects: Construction, Operations	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Route line near Hwy 1 and cross the dried up Slims River at the narrow point between two well-treed and relatively stable alluvial fans

V6E 4A4

#	Risk Description	Risk Rank	Potential Mitigation
2	Risk: Social – Permitting within Kluane National Park ▪ Proposed centerline lays within Kluane National Park ▪ Siting within the Park will likely impose moderate to severe restrictions on permitting, construction and operations Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Initiate routing discussions with Parks Canada and other stakeholders at very early stage ▪ If route through Park cannot be permitted, considering routing line on strip of non-park lands between Hwy 1 and Kluane Lake – note that scenic viewscape of lake will be impacted
3	Risk: Geotechnical – Permafrost ▪ Aishihik corridor features extensive areas of discontinuous permafrost, probably impossible to avoid placing a large number of structures into permafrost Affects: Construction, Operations	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Avoid or span over permafrost areas to the greatest extent possible ▪ Utilize permafrost-friendly foundation designs

Table 13: Route Specific Risks for Whitehorse → Skagway / Tutshi Windy Arm / Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH / Lindeman-Fraser PSH

#	Risk Description	Risk Rank	Potential Mitigation
1	Risk: Geotechnical – Exposed Bedrock ▪ Bedrock is unavoidable over substantial portions of this route, especially sections south of Tutshi Lake and in the White Pass area Affects: Construction	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Select centreline route to maximize opportunities to site structures in acceptable overburden ▪ Select structure types adaptable to cost effective use of rock foundations and anchors
2	Risk: Geotechnical – Steep Sideslopes ▪ Difficult to avoid building on sideslopes above the highway in the segments parallel with Tagish and Tutshi Lakes ▪ Risk is compounded since this is also an area of extreme snow loads and avalanches Affects: Construction, Operations	**Prob:** 5 **Conseq.:** 5 **Rank:** X	▪ Build on lake side of highway (may not be possible due to scenic highway restrictions) ▪ Install underground beside highway (very costly alternative)
3	Risk: Social – Permitting near Populated Areas ▪ Suburban residential development from Whitehorse to Carcross Cutoff ▪ Routing must pass through Carcross to cross narrows between Bennett Lake and Nares Lake Affects: Development	**Prob:** 3 **Conseq.:** 4 **Rank:** H	▪ Re-route south of developed area from Whitehorse to Carcross Cutoff ▪ Follow railway through Carcross

#	Risk Description	Risk Rank	Potential Mitigation
4	Risk: Social – Permitting in scenic areas ▪ Whitehorse to Skagway is a national scenic route ▪ Particular areas of special concern include Emerald Lake (between Carcross Cutoff and Carcross), the narrows at Carcross, along the shores of Tagish and Tutshi Lakes, and across White Pass Affects: Development	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Avoid locating structures between scenic viewpoint areas and scenic vistas ▪ Align RoW to minimize visual impact of transmission RoW cutlines through forested areas impact viewscapes
5	Risk: Social – Permitting near National Parks ▪ Skagway to White Pass segment abuts the Klondike Gold Rush US National Historical Park ▪ Schedule delays or routing adjustments if route agreement is not achieved Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Assess any special construction or operational requirements, such as low-profile structures, specialized paints or non-specular conductors, limited construction windows and operating access constraints ▪ Begin permitting activities early
6	Risk: Political – Yukon/BC Border Crossing ▪ Permitting must satisfy BC regulations ▪ May trigger studies and require approval by BC Hydro ▪ May require YEC to apply for status as a BC utility Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 4 **Rank:** V	▪ Initiate discussions with BC Government, BC Hydro and BC Utilities Commission to determine applicable regulations and approval & permitting requirements
7	Risk: Political – Canada/United States Border Crossing ▪ Will require permits from Canadian National Energy Board and US Federal Energy Regulation Commission ▪ International powerline crossings require a US Presidential Permit ▪ Will likely require additional approvals from State of Alaska and Municipality of Skagway Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 5 **Rank:** X	▪ Initiate discussions with all Canadian and US entities to determine applicable regulations and permitting requirements

#	Risk Description	Risk Rank	Potential Mitigation
8	Risk: Social, Geotechnical, Technical – Termination at Whitehorse Riverside ▪ Constrained access into open bay at Riverside substation ▪ Will require crossing under or relocating an existing 138 kV line ▪ Difficult access from south bank requires crossing Yukon River at a very congested location ▪ Two existing hydroelectric facilities, intake canal, tailrace canal and main stem of Yukon River Affects: Construction	**Prob:** 5 **Conseq.:** 3 **Rank:** H	▪ Relocate one of the existing 138 kV lines to the open north bay position ▪ Possibly double circuit existing 138 kV line located between the intake and tailrace canals ▪ Taking the new line underground/underwater at the river crossing may be an option (although very costly)

Table 14: Route Specific Risks for Whitehorse → Atlin / Atlin-Mt.Black PSH

#	Risk Description	Risk Rank	Potential Mitigation
1	Risk: Social – Permitting near Populated Areas ▪ Dense suburban residential development from Whitehorse to Carcross Cutoff Affects: Development, Construction	**Prob:** 3 **Conseq.:** 3 **Rank:** M	▪ Re-route south of developed area from Whitehorse to Carcross Cutoff
2	Risk: Social – Permitting in Reserve Blocks and First Nations traditional lands within BC ▪ BC has specific Provincial FN consultation requirements Affects: Development, Construction, Operations	**Prob:** 4 **Conseq.:** 4 **Rank:** V	▪ Assess BC-specific consultation requirements ▪ Begin comprehensive outreach activities with affected FN communities early
3	Risk: Political – Yukon/BC Border Crossing ▪ Permitting must satisfy BC regulations ▪ May trigger studies and require approval by BC Hydro ▪ May require YEC to apply for status as a BC utility Affects: Development, Construction, Operations	**Prob:** 5 **Conseq.:** 4 **Rank:** V	▪ Initiate discussions with BC Government, BC Hydro and BC Utilities Commission to determine applicable regulations and approval & permitting requirements

8 Summary & Conclusions

This *Transmission Options Evaluation* report included several components:

- Detailed transmission corridor optimization (Section 2)
- Estimate of CAPEX (Section 3)
- Estimate of OPEX (Section 4)
- Calculation of power transfer capacities (Section 5)
- Overview of transmission corridor development schedules (Section 6)
- Assessment of corridor risks (Section 7)

Table 16 below provides a tabular summary of this report's findings. For each potential transmission route, the line voltage, line length, max transfer capacity, estimated CAPEX, estimated OPEX, and earliest In-Service-Date ("ISD") is stated.

Table 16: Summary of Results (Costs Stated in $2016)

#	Transmission Route	Voltage	Length	Transfer Capacity[7]	CAPEX[8]	OPEX[8]	Earliest ISD
1	Faro → Finlayson	138 kV	233 km	84 MW	$221M	$351k/yr	Jan 2021
2	Faro → Watson Lake	230 kV	414 km	190 MW	$597M	$613k/yr	Sep 2022
3	Aishihik → Destruction Bay	138 kV	157 km	122 MW	$167M	$217k/yr	Jul 2020
		230 kV		484 MW	$241M		
4	Whitehorse → Skagway	138 kV	170 km	114 MW	$166M	$285k/yr	Oct 2020
		230 kV		443 MW	$251M		
5	Whitehorse → Atlin	138 kV	172 km	97 MW	$158M	$236k/yr	Oct 2020
6	Whitehorse → Teslin	138 kV	174 km	95 MW	$165M	$239k/yr	Oct 2020
7	Whitehorse → Squanga-Dalayee PSH	138 kV	105 km	134 MW	$100M	$143k/yr	Dec 2019
8	Whitehorse → Atlin-Mt.Black PSH	138 kV	127 km	131 MW	$119M	$174k/yr	May 2020
9	Whitehorse → Tutshi Windy Arm	138 kV	96 km	135 MW	$94M	$143k/yr	Nov 2019
10	Whitehorse → Racine-Mt.Brown PSH, Racine-Moon Lake PSH, and Tutshi-Moon Lake PSH	138 kV	112 km	132 MW	$108M	$168k/yr	Jan 2020
11	Whitehorse → Lindeman-Fraser PSH	138 kV	129 km	129 MW	$125M	$200k/yr	Jun 2020

[7] These values represent the most restricted transfer capacity that would be expected in either summer or winter. Thermally limited transmission options may demonstrate a higher Winter Capacity. See Table 8 for more details.

[8] All cost information is stated in $2016 and is considered a Class 5 estimate as per standard 17R-97 by the Association of the Advancement of Cost Engineering, which represents a +100% / -50% range of accuracy.

Appendix A:

PSSE Simulation Details

Appendix A: PSS®E Simulation Details

A simple PSS®E model was built and simulations were carried out to estimate the power transfer capability along the transmission line each of the transmission option being studied. This appendix provides the more in-depth details of the PSS®E modeling effort.

The voltage is maintained between a nominal range of 1.1 per unit to 0.9 per unit at all buses, and the maximum Sending End to Receiving End voltage angle difference is taken to be 33° to avoid angular instability for minor system perturbations. The term "*Transmission Line Capacity*" in the following tables represent available capacity at the Swing Bus after deducting intermediate loads (if connected) and peak transmission losses.

A.1 Conductor Characteristics

Table A-1 lists the conductor characteristics for the 138 kV and 230 kV transmission options.

Table A-1: Conductor Characteristics

Voltage Class (kV)	Conductor Type	GMR (ft.)	External Diameter (In)	Bundle	Phase Spacing (m)	Conductor Spacing (In)
138	Ibis 397.5 MCM	0.0264'	0.783"	1	4.6 m	N/A
230	Hawk 477 MCM	0.0289'	0.858"	2	6.7 m	18"

Assuming a wind speed of 2 ft/s and a maximum conductor temperature of 100°C, the thermal MVA rating of the conductors at different locations, for an ambient temperature of -10°C in winter and 35°C in summer is listed in the Table A-2 below.

Table A-2: Conductor Thermal Rating

Location	Altitude (ft)	Double Bundle 230 kV Hawk 477 MCM Thermal Rating (MVA)		Single Bundle 138 kV Ibis 397.5 MCM Thermal Rating (MVA)	
		@ -10°C	@ 35°C	@ -10°C	@ 35°C
Whitehorse	2149	765	575	204	153
Aishihik	3018	758	569	202	152
Destruction Bay	2674	761	571	203	153
Faro	2198	765	575	204	153
Watson Lake	2247	764	574	204	153
Teslin	2264	764	574	204	153
Mayo	1653	769	578	205	154
Pelly Crossing	1870	767	577	205	154

A.2 Route 1: Faro → Finlayson (138 kV)

Key physical parameters are listed in Table A-3.

Table A-3: Physical Parameters – Faro → Finlayson (138 kV)

Parameter	Value
From:	Faro
To:	Finlayson
Distance:	233 km
Transmission Voltage:	138 kV
Transmission Conductor:	Ibis 397.5 MCM
Conductor Thermal Rating:	202 MVA in Winter 152 MVA in Summer

A.2.1 Transmission Line Characteristics

Using a 100 MVA system base and 138 kV line voltage, Table A-4 was tabulated based on Table A-1 and tower structure assumptions for phase spacing.

Table A-4: Transmission Line Characteristics – Faro → Finlayson (138 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Faro	Voltage Test 1	58.2	0.0540260634	0.1496790132	0.0367760150
Voltage Test 1	Voltage Test 2	58.2	0.0540260634	0.1496790132	0.0367760150
Voltage Test 2	Voltage Test 3	58.2	0.0540260634	0.1496790132	0.0367760150
Voltage Test 3	Finlayson	58.2	0.0540260634	0.1496790132	0.0367760150

A.2.2 PSSE Simulation

Table A-5 lists the generation and load parameters for all buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-5 and Figure A-1 shows that the Yukon system can receive 84 MW of power through the 138 kV transmission line between Faro and Finlayson, when an imaginary generator at Finlayson generates its maximum power while maintaining acceptable system conditions.

Figure A-1: PSS®E Single Line Diagram – Faro → Finlayson (138 kV)

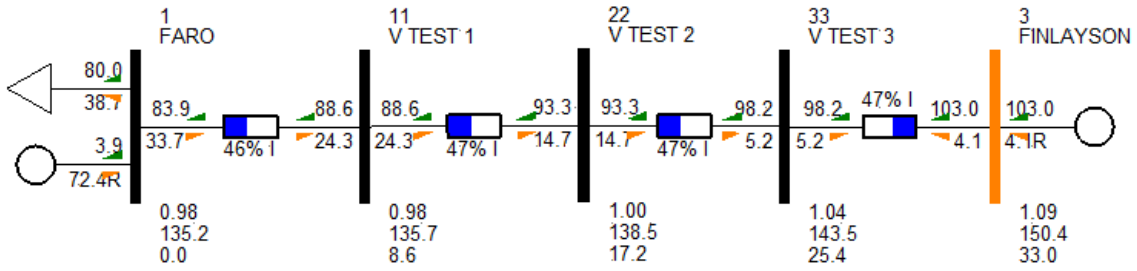

Table A-5: PSS®E Results – Faro → Finlayson (138 kV)

Location	Pgen (MW)	Qgen (MVAr)	Pload (MW)	Qload (MVAr)	Voltage (p.u.)	Voltage Angle (degrees)
Faro	-3.9	72.4	80	38.7	0.98	0.0
Voltage Test 1	-	-	-	-	0.98	8.6
Voltage Test 2	-	-	-	-	1.00	17.2
Voltage Test 3	-	-	-	-	1.04	25.4
Finlayson	103.0	4.1	-	-	1.09	33.0

A.2.3 Results

Analysis results are listed in Table A-6.

Table A-6: Analysis Results – Faro → Finlayson (138 kV)

Parameter	Value
Line Capacity:	84 MW
Limiting Issue:	33° Voltage Angle

A.3 Route 2: Faro → Watson Lake (230 kV)

A.3.1 Transmission Line Characteristics

Key physical parameters are listed in Table A-7.

Table A-7: Physical Parameters – Faro → Watson Lake (230 kV)

Parameter	Value
From:	Faro
To:	Watson Lake
Distance:	414 km
Transmission Voltage:	230 kV
Transmission Conductor:	Hawk 477 MCM
Conductor Thermal Rating:	764 MVA in Winter 564 MVA in Summer

Using a 100 MVA system base and 230 kV line voltage, Table A-8 was tabulated based on Table A-1 and tower structure assumptions for phase spacing. Voltage Test 1, Voltage test 2 and Voltage Test 3 are hypothetical test buses to measure midpoint line parameters.

Table A-8: Transmission Line Characteristics – Faro → Watson Lake (230 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Faro	Voltage Test 1	103.5	0.007358071	0.071937675	0.24036989
Voltage Test 1	Voltage Test 2	103.5	0.007358071	0.071937675	0.24036989
Voltage Test 2	Voltage Test 3	103.5	0.007358071	0.071937675	0.24036989
Voltage Test 3	Watson Lake	103.5	0.007358071	0.071937675	0.24036989

A.3.2 PSSE Simulation

Table A-9 lists the generation and load parameters for all the buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-9 and Figure A-2 shows that the Yukon system can receive 190 MW of power through the 230 kV transmission line between Faro and Watson Lake, when an imaginary generator at Watson Lake generates its maximum power while maintaining acceptable system conditions.

Figure A-2: PSS®E Single Line Diagram – Faro → Watson Lake (230 kV)

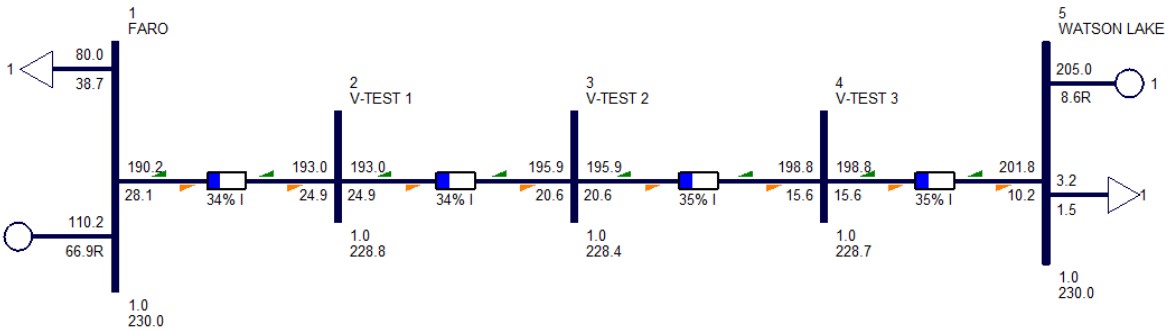

Table A-9: PSS®E Results – Faro → Watson Lake (230 kV)

Location	Pgen (MW)	Qgen (MVAr)	Pload (MW)	Qload (MVAr)	Voltage (p.u.)	Voltage Angle (degrees)
Faro	-110.2	66.9	80	38.7458	1.000	0.000
Voltage Test 1	-	-	-	-	0.995	8.080
Voltage Test 2	-	-	-	-	0.993	16.310
Voltage Test 3	-	-	-	-	0.994	24.660
Watson Lake	205.0	-8.6	3.2	1.6	1.000	33.040

A.3.3 Results

Analysis results are listed in Table A-10.

Table A-10: Analysis Results – Faro → Watson Lake (230 kV)

Parameter	Value
Line Capacity:	190 MW
Limiting Issue:	33° Voltage Angle

A.4 Route 3: Aishihik → Destruction Bay (230 kV)

A.4.1 Transmission Line Characteristics

Key physical parameters are listed in Table A-11.

Table A-11: Physical Parameters – Aishihik → Destruction Bay (230 kV)

Parameter	Value
From:	Aishihik
To:	Destruction Bay
Distance:	157 km
Transmission Voltage:	230 kV
Transmission Conductor:	Hawk 477 MCM
Conductor Thermal Rating:	758 MVA in winter 569 MVA in summer

Using a 100 MVA system base and 230 kV line voltage, Table A-12 was tabulated based on Table A-1 and tower structure assumptions for phase spacing.

Table A-12: Transmission Line Characteristics – Aishihik → Destruction Bay (230 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Aishihik	Voltage Test 1	78.6	0.005559094	0.054280891	0.181035243
Voltage Test 1	Destruction Bay	78.6	0.005559094	0.054280891	0.181035243

A.4.2 PSSE Simulation

Table A-13 lists the generation and load parameters for all buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-13 and Figure A-3 shows that the Yukon system can receive 484 MW of power through the 230 kV transmission line between Aishihik and Destruction Bay, when an imaginary generator at Destruction Bay generates its maximum power while maintaining acceptable system conditions.

Figure A-3: PSS®E Single Line Diagram – Aishihik → Destruction Bay (230 kV)

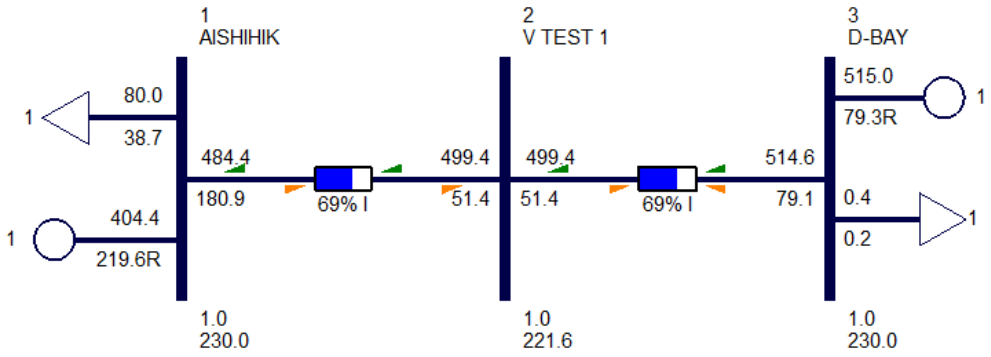

Table A-13: PSS®E Results – Aishihik → Destruction Bay (230 kV)

Location	Pgen (MW)	Qgen (MVAr)	Pload (MW)	Qload (MVAr)	Voltage (p.u.)	Voltage Angle (degrees)
Aishihik	-404.4	219.6	80	38.7458	1.000	0.000
Voltage Test 1	-	-	-	-	0.964	16.490
Destruction Bay	515.0	79.3	0.415	0.2	1.000	33.040

A.4.3 Results

Analysis results are listed in Table A-14.

Table A-14: Analysis Results – Aishihik → Destruction Bay (230 kV)

Parameter	Value
Line Capacity:	484 MW
Limiting Issue:	33° Voltage Angle

A.5 Route 3: Aishihik → Destruction Bay (138 kV)

A.5.1 Transmission Line Characteristics

Key physical parameters are listed in Table A-15.

Table A-15: Physical Parameters – Aishihik → Destruction Bay (138 kV)

Parameter	Value
From:	Aishihik
To:	Destruction Bay
Distance:	157 km
Transmission Voltage:	138 kV
Transmission Conductor:	Ibis 397.5 MCM
Conductor Thermal Rating:	202 MVA in Winter 152 MVA in Summer

Using a 100 MVA system base and 138 kV line voltage, Table A-16 was tabulated based on Table A-1 and tower structure assumptions for phase spacing.

Table A-16: Transmission Line Characteristics – Aishihik → Destruction Bay (138 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Aishihik	Voltage Test 1	52.4	0.04937811	0.13553595	0.03293529
Voltage Test 1	Voltage Test 2	52.4	0.04937811	0.13553595	0.03293529
Voltage Test 2	Destruction Bay	52.4	0.04937811	0.13553595	0.03293529

A.5.2 PSSE Simulation

Table A-17 lists the generation and load parameters for all buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-17 and Figure A-4 shows that the Yukon system can receive 122 MW of power through the 138 kV transmission line between Aishihik and Destruction Bay, when an imaginary generator at Destruction Bay generates its maximum power while maintaining acceptable system conditions.

Figure A-4: PSS®E Single Line Diagram – Aishihik → Destruction Bay (138 kV)

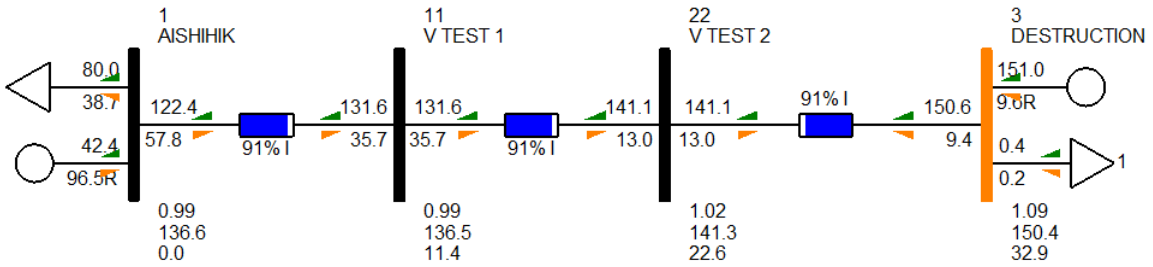

Table A-17: PSS®E Results – Aishihik → Destruction Bay (138 kV)

Location	Pgen (MW)	Qgen (MVAr)	Pload (MW)	Qload (MVAr)	Voltage (p.u.)	Voltage Angle (degrees)
Aishihik	-42.4	96.5	80.0	38.7	0.99	0.0
Voltage Test 1	-	-	-	-	0.99	11.4
Voltage Test 2	-	-	-	-	1.02	22.6

A.5.3 Results

Analysis results are listed in Table A-18.

Table A-18: Analysis Results – Aishihik → Destruction Bay (138 kV)

Parameter	Value
Line Capacity:	122 MW
Limiting Issue:	33° Voltage Angle

A.6 Route 4: Whitehorse → Skagway (230 kV)

A.6.1 Transmission Line Characteristics

Key physical parameters are listed in Table A-19.

Table A-19: Physical Parameters – Whitehorse → Skagway (230 kV)

Parameter	Value
From:	Whitehorse
To:	Skagway
Distance:	170 km
Transmission Voltage:	230 kV
Transmission Conductor:	Hawk 477 MCM
Conductor Thermal Rating:	765 MVA in Winter 575 MVA in Summer

Using a 100 MVA system base and 230 kV line voltage, Table A-20 was tabulated based on Table A-1 and tower structure assumptions for phase spacing.

Table A-20: Transmission Line Characteristics – Whitehorse → Skagway (230 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Whitehorse	Voltage Test 1	84.8	0.006071923	0.059307501	0.197893825
Voltage Test 1	Skagway	84.8	0.006071923	0.059307501	0.197893825

A.6.2 PSSE Simulation

Table A-21 lists the generation and load parameters for all buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-21 and Figure A-5 shows that the Yukon system can receive 443 MW of power through the 230 kV transmission line between Whitehorse and Skagway, when an imaginary generator at Skagway generates its maximum power while maintaining acceptable system conditions.

Figure A-5: PSS®E Single Line Diagram – Whitehorse → Skagway (230 kV)

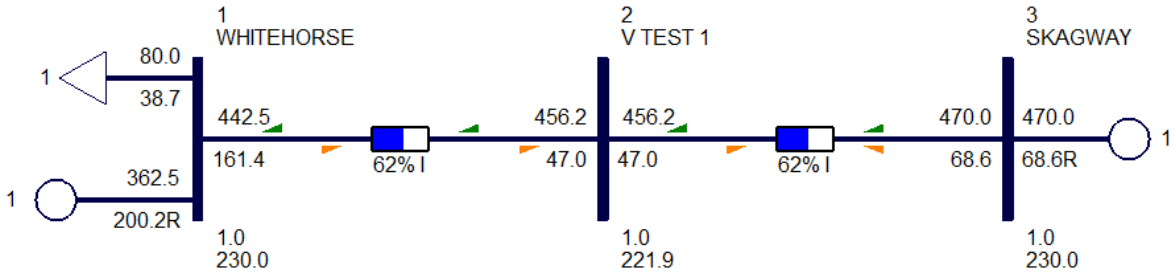

Table A-21: PSS®E Results – Whitehorse → Skagway (230 kV)

Location	Pgen (MW)	Qgen (MVAr)	Pload (MW)	Qload (MVAr)	Voltage (p.u.)	Voltage Angle (degrees)
Whitehorse	-362.5	200.2	80	38.7458	1.000	0.000

Conductor Thermal Rating:	152 MVA in Winter 202 MVA in Summer

A.14.1 Transmission Line Characteristics

Using a 100 MVA system base and 138 kV line voltage, Table A-56 was tabulated based on Table A-1 and tower structure assumptions for phase spacing.

Table A-56: Transmission Line Characteristics – Whitehorse → Lindeman-Fraser PSH (138 kV)

From	To	Distance (km)	Resistance R (p.u.)	Reactance X (p.u.)	Charging B (p.u.)
Whitehorse	Voltage Test 1	64.6	0.061776554	0.169164012	0.040989919
Voltage Test 1	Lindeman-Fraser PSH	64.6	0.061776554	0.169164012	0.040989919

A.14.2 PSSE Simulation

Table A-57 and Table A-58 list the generation and load parameters for all buses considered in the power flow simulation. For simplicity, all loads are assumed to have a power factor of 0.9, and each generator is capable of producing at 0.9 power factor lagging or leading.

Table A-57/Table A-58 and Figure A-17/Figure A-18 show that the Yukon system can receive 147 MW in winter and 129 MW in summer through the 138 kV transmission line between Whitehorse and Lindeman-Fraser PSH, when an imaginary generator at Lindeman-Fraser PSH generates its maximum power while maintaining acceptable system conditions.

1 Introduction

1.1 Scope of work

Midgard Consulting Inc. (MC) asked J.D. Mollard and Associates (2010) Limited (JDMA) to conduct a desktop identification and evaluation of transmission line corridors for a number of endpoint locations within the Yukon Territory, BC and Alaska. MC specified that the transmission line corridors be approximately 500 m wide with the flexibility to narrow or widen the corridors locally to accommodate routing constraints. Transmission line corridor routing and characterization was conducted at a high level and ground truthing was not included in the scope of work. MC requested that the width of the transmission line corridors be 500 m.

1.2 Study areas

MC provided six (6) new endpoint pairs for transmission line corridor identification in May 2016 in addition to the previous eight (8) endpoint pairs that MC provided in April 2015. The six new endpoint pairs and original eight endpoint pairs are listed in Table 1. The corridor lengths listed in Table 1 are based on JDMA's analysis of the final corridor lengths as they have been described in this report. The location of the six new endpoint pairs and eight previous endpoint pairs are shown in Figure 1.

Table 1: Transmission Line Corridors Evaluated

Transmission Line Name	Length (km)
Aishihik to Destruction Bay	157
Whitehorse to Carcross Cutoff	17
Carcross Cutoff to Jakes Corner	62
Jakes Corner to Teslin	95
Jakes Corner to Atlin	92
Carcross Cutoff to Skagway	154
Faro to Watson Lake	414
Two Mile Canyon	112
Fraser Falls	48
Granite Canyon	15
Slate Rapids	9
False Canyon	7
Middle Canyon	6
Hoole Canyon	2

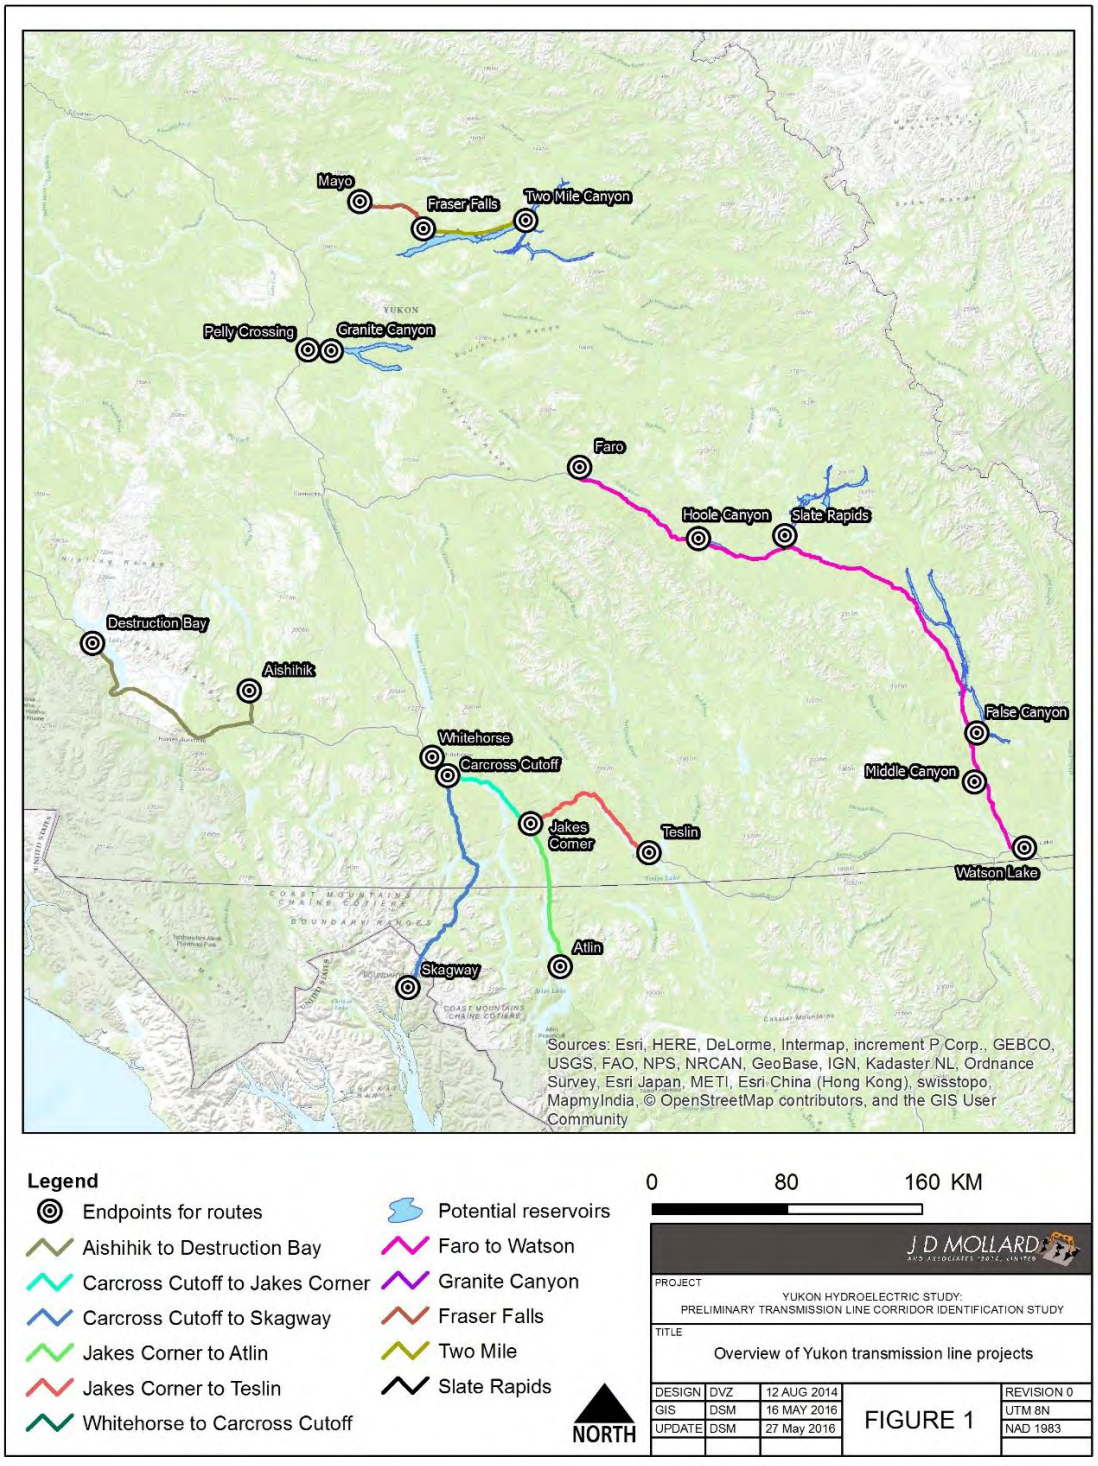

Figure 1: Overview map

2 Methodology

The transmission line corridor identification was done at a high level, and as such no detailed data sources were used in the analyses (e.g., air photographs, high resolution satellite, LiDAR). All evaluation of corridors was completed using ESRI ArcGIS and MicroImages TNT MIPS. Data were obtained from various territorial, provincial and national sources to aid in the evaluation of the routes.

MC provided the following criteria to JDMA for transmission line corridor identification:

- Transmission line span length will be approximately 200-230 m with longer spans possible in special cases,
- Where practical, place the transmission line corridor adjacent to roadways for maintenance and construction access,
- Where practical, narrow the corridor to less than 500 m to avoid major terrain constrictions adjacent to the corridor (e.g. next to a steep slope, river, etc.),
- Avoid crossing privately held land,
- Deflections up to 15° will not require special structures.

In addition to these specific criteria, JDMA also considered surficial geology and surface materials, terrain and slope, total length, as well as stream and wetland crossings to help in identifying feasible corridors.

In the case of the Jakes Corner to Atlin connection, one of the endpoints is located in BC. In the case of Carcross Cutoff to Skagway connection, one endpoint is in Alaska, requiring this corridor to pass through parts of Yukon, BC and Alaska. In these cases, the corridors were segmented for analysis based on territory, province, or state because different datasets exist for Yukon, BC and Alaska. This results in data being presented for nine (9) new corridor segments in Table 3 and the original eight (8) corridors in Table 4. The Faro to Watson Lake corridor in Table 4 was segmented based on the tap locations that extend along it.

2.1 Data sources

JDMA obtained base data for this project from free open-source files found on Government of Yukon, Government of Canada, Government of BC, and United States Geological Survey (USGS) web pages.

The data used in this study include both physical and cultural data. Geospatial data sources used in this study are listed in Table 2.

The above data were downloaded from the following links:

- SPOT, CDEM, rivers, waterbodies, and road network data were obtained from http://ftp2.cits.rncan.gc.ca/pub/,
- SRTM, NLCD data were obtained from http://earthexplorer.usgs.gov/
- Alaska road network were obtained from http://www.asgdc.state.ak.us/
- Yukon surficial geology data were obtained from http://www.geology.gov.yk.ca/digital_surficial_data.html
- Atlin surficial geology data were obtained from http://www.empr.gov.bc.ca/Pages/default.aspx
- Skagway surficial geology were obtained from http://www.dggs.alaska.gov/pubs/id/93
- Permafrost data were obtained from http://permafrost.gov.yk.ca/data/arcgis/
- Yukon municipal boundaries, First Nations Settlement lands, land parcels, land use, utility data and other base data were obtained from ftp://ftp.geomaticsyukon.ca/GeoYukon/.
- BC land parcels, land use, and other base data were obtained from https://apps.gov.bc.ca/pub/dwds/addProducts.do?orderId=1651722.

The data sources listed above were used as screening tools and to derive the statistics presented in Table 3 and Table 4. It should be noted that these data sources have limitations related to scale and the amount of ground truthing that was done in local areas. Within the study areas JDMA conducted a limited quality control check on these data sources through visual examination of the data in comparison to features discernible in the SPOT satellite imagery. At the locations checked, it was found that the data were generally consistent with features visible in the satellite imagery.

The wetland datasets are derived from the LCC-2000 national landcover data set and NLCD-2001 US landcover dataset. Wetlands are categorized as treed, shrub, or herb. These classes represent the dominant vegetation type for each wetland. In comparing the wetland boundaries to satellite imagery it appears that the wetland file may underrepresent the actual number of wetlands in the study areas. The LCC-2000/NLCD-2001 dataset was primarily interpreted from classified Landsat imagery with little to no ground truthing. Wetlands that may have gone unclassified are likely mostly included in the forest land cover classes where wetlands may be masked by the forest canopy.

The forest classes in the LCC-2000 dataset are classified according to crown closure. This provides information on forest density. The boundaries between dense canopy, open canopy, sparse canopy forests are discernible in the SPOT satellite imagery.

Riparian zones were calculated by taking all stream courses, water bodies, and wetlands identified in the CanVec, LCC-2000, and NLCD-2001 datasets and applying a 15 m buffer around them. Non-vegetated land classes were omitted from this buffer and the remaining area is considered the riparian zone. Therefore, riparian zone defined in this way represents a vegetated buffer around waterbodies and wetlands.

Major stream crossings were identified from the CanVec water body layer. Any stream that had both river banks represented, as opposed to being represented by a single line was considered to be a major stream.

Surficial geology maps were obtained primarily at a scale of 1:100,000 and 1:250,000. These two datasets were merged to provide surficial geology coverage across all of the study areas with the smaller scale dataset being used only where larger scale data are not available. For corridor segments located in BC and Alaska, surficial geology data only exist for small areas near Atlin and Skagway. For those areas in BC and Alaska where mapping does not exist, JDMA provided surficial geology mapping. The primary material unit attribute was used to identify the surficial geology within the corridor. When identifying thin-drift-over-bedrock, the surficial geology dataset was interpreted to identify those areas where bedrock was a secondary unit and the depth of the primary unit was veneer (<1 m thick).

Slopes were calculated from the CDEM and SRTM dataset. Slope calculations were performed in ArcGIS. The slope calculation in Table 3 considers all slopes regardless of aspect.

First Nations lands, settled lands, and land uses were taken from base data available from GeoYukon for Yukon datasets and from GeoBC for BC datasets. These data exist as several data layers and these data

layers were merged to provide a summary of all of the land uses that are crossed by the corridors. Alaska datasets could not be located.

The road layers were taken from the National Road Network – Yukon/BC and US DOT - Alaska. Paved roads were identified from the road surface attribute. Improved gravel roads were identified from the road surface attribute and road type attribute. These are roads that have a gravelled surface and are designated as either collector, or highway class roads. All other roads are included in the trail or resource road category and included various smaller gravelled roads, dirt roads and roads with an unknown surface type.

2.2 Corridor Identification

After all of the geospatial imagery was compiled JDMA began identifying corridors for each of the connections that were identified by MC for this study. The various datasets were overlaid on the imagery in the GIS and routes were identified. Routes were drawn as single lines which would later become the basis for the final 500 m corridors. The imagery and the digital elevation data were incorporated in TNT MIPS which allows the user to view the imagery in 3D. This provided a view of the terrain, land cover (vegetation) and land use and helped to refine the routes in places where these may be limiting factors.

500 m corridors were generated from the centreline routes that were mapped. The corridors were then offset from the centreline in places to take advantage of more than one centreline option within the same corridor, to centre the corridor on a roadway, or to minimize hazardous or other undesirable terrain. In places where the transmission line corridor was wider than adjacent terrain constraints, the corridor was narrowed to only cover those areas where it would be practical to construct and maintain a transmission line. In a few areas the corridor was widened beyond 500 m to allow for consideration of multiple alternatives that are more than 500 m apart.

3 Results

Statistics were collected and compiled for each corridor and are summarized in Table 3 and Table 4. These tables break down the routes according to many factors including corridor length, surficial geology, slopes, environmental concerns, First Nations lands, incidence of land parcels / land uses crossed, and other infrastructure crossings. These categories provide a high level view of the types of terrain and land uses that are to be expected within each corridor. The following subsections describe some of the distinctive characteristics of the transmission line corridors. Base data comparable to that available in the Yukon were not found or provided for corridor segments that extend into BC and Alaska. Because of this, the route comparison table is broken down based upon territory, province, and state. Where data are unavailable the table entry was marked “No Data”.

The corridors **Slate Rapids to False Canyon**, **Jakes Corner to Atlin (BC)**, and **Jakes Corner to Teslin** were broken down into sections with endpoints specified by the client. These sections are split up in the tables below and in the figures in Appendix A.

Corridor maps for each of the endpoint pairs are included in Appendix A.

3.1 Aishihik to Destruction Bay

The Aishihik to Destruction Bay corridor is 157 km long. The corridor follows the Alaska Highway (Highway #1) between Destruction Bay and Canyon where it deflects north to the Aishihik Generating Station. In its western portion, the corridor is located adjacent to Kluane Lake between Destruction Bay and Silver City, except for a 15 km segment where it follows the Slims River Valley upstream to a

suggested crossing of the Slims River. On the west side of Kluane Lake the corridor parallels an old pipeline right-of-way that appears to be abandoned.

The dominant terrain unit within the Aishihik to Destruction Bay corridor is classified as morainal. The next dominant unit is classified as fluvial terrain and mainly occurs where the corridor crosses creeks and alluvial fans on the west and east sides of Kluane Lake. There are also minor amounts of organic terrain located within this corridor. In total the corridor crosses 30 hectares of organic terrain. Organic terrain is considered poor for routing a transmission line due to the likelihood of a high water table and compressive soils. Slopes along this route are generally quite gentle. Extensive areas of lacustrine terrain occur locally south of Kloo Lake, near Haines Junction and adjacent to the Aishihik and Desadeash rivers in the eastern portion of the corridor. There are only a few instances of slopes being steeper than 15°. These areas primarily occur near the mouth of the Slims River, where the low flat fluvial landscape narrows and bedrock slopes form a pinch point. In this area there is very little exposed bedrock as the lower bedrock slopes are covered by colluvium. This corridor crosses 1,164 hectares of extensive discontinuous permafrost.

The crossing of the Slims River is one of the most significant constraints along this corridor. The Slims River is a large river that discharges into Kluane Lake. Locating the transmission line adjacent to the Alaska Highway across the floodplain is not considered a good option because of susceptibility to flooding and scour, poor foundations and aesthetic impacts along the scenic Alaska Highway. As a result, the corridor has been located farther up the valley where two side-valley alluvial fans will provide the crossing with the shortest span. These fans are well treed and appear to be relatively stable. This crossing span may be up to 500 m depending on final structure locations. Other major constraints on this route may be the land uses located adjacent to and offset from the Alaska Highway on the west side of Kluane Lake. Steep slopes and evidence of debris flows and rock avalanches in this area also require further evaluation. Several gravel pits, campgrounds, and other land uses were identified along the corridor as well, in addition to two (2) airstrips. The corridor has been routed so that it should be possible to maintain adequate clearance from the runways.

3.2 Whitehorse to Carcross Cutoff

The Whitehorse to Carcross Cutoff corridor is 17 km long and mainly located in the City of Whitehorse. The corridor width was reduced to 150 m in the urban area due to the constricted nature of development in this area. The Whitehorse corridor originates at the Whitehorse Dam and the primary corridor option follows the Alaska/Klondike highways (Highway #1/2) south of the city to the junction of the Alaska and Klondike highways.

The main surficial material within this corridor is fluvial sediment, followed by anthropogenic features because much of this route goes through urban areas. The slopes on this route are all below 15° owing to dominance the gently sloping fluvial terrain.

There are many rural residences listed along this route that would have to be considered in selection of a final route centreline. These residences are primarily located immediately adjacent to roadways.

Transmission line development could be located either directly next to the road or farther from the road behind these residences.

An alternative corridor that might be considered to avoid the built up urban area is a 500 m corridor that crosses the Alaska/Klondike Highway 4.7 km south of the Whitehorse Dam and passes south of the developed areas. This corridor could terminate either south or east of Carcross Crossing depending on where it extends to. The terrain along this corridor is quite flat and appears to be free of development.

3.3 Carcross Cutoff to Jakes Corner

The Carcross Cutoff to Jakes Corner corridor is 62 km long and originates in Carcross Cutoff. It follows the Alaska Highway eastwards towards Jakes Corner. The corridor crosses the Yukon River at a location that would require an approximately 250 m span. It then parallels Marsh Lake before turning towards Jakes Corner.

The dominant terrain unit within the Carcross Cutoff to Jakes Corner corridor is fluvial terrain. The next most dominant terrain type is moraine followed by bedrock. The corridor follows the base of several mountains. These locations are characterized by more frequent bedrock exposures and steeper slopes. Throughout most of the corridor the slopes are below 15° but in some isolated areas the slopes exceed 15°.

There are many developments and land uses along the Alaska Highway including gravel pits, industrial developments, and utilities.

3.4 Jakes Corner to Teslin

The Jakes Corner to Teslin corridor is 95 km in length. It begins at Jakes Corner and follows the Alaska Highway northeast to Johnsons Crossing where it turns southeast to Teslin. The corridor crosses the Teslin River at a location that will require a span of approximately 400 m. The corridor passes through the communities of Johnsons Crossing, Brooks Brook, and Teslin Lake in addition to the communities that are located at its two end points.

The terrain along this corridor is relatively flat with most of the slopes below 15°. The dominant terrain unit is morainal and the next most common unit is fluvial terrain. There are several land uses in the corridor with the most prevalent being gravel pits located along the highways. There are two airstrips along the corridor. The corridor has been routed to allow for a centreline selection that provides adequate clearance from the runways. Even so, the separation distance at the Teslin airstrip will need to be confirmed given the location of the transmission line termination point and the orientation of the airstrip.

As an alternative to crossing the Teslin River at Johnsons Landing, JDMA has identified a second corridor option that is slightly shorter in length and has a shorter span across the river. The terrain and material types appear to be similar to the Johnsons Landing crossing location but the route alignment does require the corridor to depart from the highway adjacent location for a distance of approximately 1.5 km.

3.5 Jakes Corner to Atlin (YK, BC)

The Jakes Corner to Atlin corridor is 92 km long and connects Jakes Corner to Atlin, BC. Jakes Corner is north of Atlin and the corridor is mainly oriented north-south. The corridor follows Highway #7 and is adjacent to Little Atlin Lake and Atlin Lake. Approximately 42 km of the corridor is located in the Yukon with the remaining 50 km located in BC.

The main terrain unit in the corridor is fluvial terrain followed by lacustrine terrain. The lacustrine units primarily occur adjacent to Atlin Lake where the road and corridor are located next to the lake. In this area, several mountain slopes constrain the corridor to a zone between Atlin Lake and the steep mountain slopes. In addition to fluvial and lacustrine terrain some exposed bedrock and organic terrain are mapped within the corridor.

No major land uses are affected by this corridor; however, there are several gravel pits within the corridor. The British Columbia portion of the corridor lacks the same amount/type of land use data that are available for the Yukon. As a result, there is no land use land data available for the BC segment of the corridor.

3.6 Carcross Cutoff to Skagway (YK, BC, AK)

The Carcross Cutoff to Skagway corridor is 154 km long and extends across parts of Yukon, British Columbia, and Alaska. The Yukon section is 77 km, the British Columbia section is 56 km, and Alaska section is 21 km. The corridor runs mostly north-south from Carcross Crossing in the Yukon to Skagway on the Taiya Inlet, in Alaska. The corridor passes by several communities as it parallels the Klondike Highway all the way to Skagway. The corridor passes by and follows adjacent to Nares Lake, Tutshi Lake, Shallow Lake, Bernard Lake, and Summit Lake.

The main terrain unit in the corridor is bedrock. The second most common unit is moraine. This corridor has the steepest slopes of any of the corridors. Lacustrine terrain occurs locally south of Cowley Lake and in several short segments north of Carcross. There are many stretches of corridor where the slopes are greater than 15° reaching greater than 30° in some locations. Many of these steep slopes are bedrock terrain with varying thicknesses of colluvium depending on slope steepness and the proximity of the corridor to the base of the slope. In these areas the corridor was narrowed to only include the lower parts of the slopes. In many parts of this corridor the transmission line will need to be placed on the mountain side of the road because there is inadequate space on the lakeward side. In some locations the road is cut into the side of the mountain with a near vertical blasted or cut face adjacent to the road. In these cases it will be necessary to locate the transmission line higher on the slope, above the steep blasted or cut face. This situation will make construction and maintenance more challenging and costly.

Land uses within this corridor include many rural residences, gravel pits, parks and campgrounds. The British Columbia and Alaska portions of the corridor lack the same amount/type of land use data that are available for the Yukon. As a result, there is no land use land data available for the BC and Alaska segments of the corridor.

3.7 Faro to Watson Lake

The Faro to Watson Lake corridor is 414.1 km long, following the Robert Campbell Highway (Highway #4) corridor between the communities of Faro and Watson Lake. At the north end this corridor parallels the Pelly River for a distance of approximately 56 km between the communities of Faro and Ross River. In many places, the Faro to Ross River transmission line is also located within or near the corridor proposed for the Faro-Watson Lake transmission line. At the southern end the proposed corridor crosses several larger rivers including the Frances and Liard rivers.

The dominant terrain unit along the Faro to Watson lake corridor is classified as moraine (12,901 Ha). The next dominant unit is classified as fluvial (4,791 Ha). The fluvial unit is encountered where the corridor is located near several river channels located in the Faro-Watson Lake study area. Morainal and fluvial terrains are generally favourable for transmission line construction. Less favourable is organic terrain which covers approximately 2,547 Ha of the corridor. Organic terrain is generally less favourable for transmission line construction and maintenance due to higher water table, compressive soils, and a greater likelihood of permafrost-affected soils. Slopes along this route are generally quite low with only a few scattered instances of slopes being steeper than 15°.

Other possible constraints within the corridor are the land uses adjacent to and offset from the Robert Campbell Highway. These include a large number of gravel pits, some campgrounds, and other land uses that appear in available GIS datasets. In addition, there are two stream crossings that are approximately 250 m wide. There are also at least five, and possibly six, airports near the corridor. Even so, the corridor has been routed so that adequate clearance has been maintained from these airports.

Apart from a few short exceptions, the Robert Campbell Highway is located within the Faro to Watson Lake transmission line corridor making it possible to locate the transmission line near the highway in most locations. Near Faro, the corridor also encompasses an existing distribution line that links the communities of Faro and Ross River. The corridor is situated so that potential centrelines can take advantage of either being adjacent to the highway or parallel to the existing distribution line. It appears as though there is a wide right-of-way for the distribution line and existing access trails from the Robert Campbell Highway to the transmission line right-of-way. Near Watson Lake, the corridor goes south around Watson Lake before terminating at its end location within the community of Watson Lake. Going north around the lake decreases the overall length of the route but would result in the transmission line being in close proximity to the Watson Lake airport and passing through an area with more existing infrastructure.

3.8 Two Mile Canyon and Fraser Falls

The Two Mile Canyon and Fraser Falls corridors both originate at the Mayo substation near the community of Mayo. From the substation a common corridor extends east to the Fraser Falls site. From there the remainder of the Two Mile Canyon corridor continues for an additional 65 km to the Two Mile Canyon site. Both corridors are located mainly north of the Stewart River. Two possible alternative sections have been identified south of the river; one is located from the Mayo substation to the Fraser Falls site. A second southern alternative section approaches the Two Mile Canyon site from a river crossing about 25 km to the west.

The termination point suggested by MC for the Fraser Falls site is located on the west side of Stewart River at the proposed Fraser Falls hydroelectric site. However, the proposed transmission line corridor approaches the site from the east side of the river. With this layout the transmission line would have to cross the river at this site. This would not be a problem because the proposed hydroelectric station is located at a narrowing of the river and the proposed corridor represents a preferred location to cross the Stewart River. Cross the Stewart River at other locations would involve span lengths of >300 m from bank to bank plus crossing a wide floodplain that is subject to flooding and possible permafrost conditions.

Farther east, the Two Mile Canyon corridor crosses the river near the Two Mile Canyon site where the river channel is approximately 225 m wide. In the event that the Fraser Falls hydroelectric project is built, a span of approximately 725 m would be required to cross the reservoir at this location.

The main terrain type crossed by the Fraser Falls and Two Mile Canyon corridors is moraine on the lower valley slopes and upland adjacent to the Stewart River floodplain. In some upland areas the morainal sediment (till) may form a relatively thin and discontinuous cover over the underlying bedrock. Toward the east end of the Two Mile Canyon corridor the corridor crosses fluvial and lacustrine terrain on lower-lying terraces adjacent to the Stewart River floodplain. Although these terrain types may be more susceptible to a higher water table and permafrost-affected conditions, they cannot be avoided when crossing the Stewart River to reach the Two-Mile Canyon site. For this reason, a possible alternative crossing has been identified approximately 25 km west where the terrain is more favourable. However, this alternative would also require a span of approximately 725 m across the Fraser Falls reservoir with access from a narrow peninsula that may be subject to bank erosion. (Assuming both the Fraser Falls and Two-Mile Canyon projects are built.)

Except for the area immediately around Mayo, there is no infrastructure development in the Two Mile Canyon / Fraser Falls area. As such the major constraints on these routes are terrain related. There are a high number of steep slopes in this area (i.e., > 15°) and there are areas prone to ground ice in permafrost making construction, operation and maintenance challenging.

3.9 Granite Canyon

The Granite Canyon corridor is 14.6 km in length. Its west endpoint appears to be a tap from an existing transmission line that parallels the Klondike Highway (Highway #2). The east endpoint is a potential hydroelectric site on the Pelly River.

The terrain along this corridor is a low relief aeolian plain. The only other terrain unit identified in the area is a small area classified as fluvial terrain located adjacent to the Pelly River. Almost the entire length of this corridor is located on Category B (surface rights) First Nations Settlement land belonging to the Selkirk First Nations. The other designated land in the study area is a Land Disposition classified as *utility* at the eastern end of the corridor. This designation may be related to the hydroelectric potential at this site. Should a transmission line be built here it will require crossing over the Klondike Highway in order to tap the transmission line which is located on the west side of the highway.

3.10 Slate Rapids

The Slate Rapids corridor is 9.2 km long and extends from the Slate Rapids site on the Ross River to the proposed Faro to Watson Lake corridor. The Slate Rapids corridor deflects around a large low-lying area classified as organic terrain and follows a low ridge adjacent to the Ross River. Big Campbell Creek enters the Ross River near the south end of the corridor where an alluvial fan has formed. Therefore, the tap location has been located east of the fan.

The majority of the corridor is located on First Nations Category A and Category B land belonging to the Ross River Dena Council. There are no other designated land uses within the Slate Rapids study area.

3.11 False Canyon

The False Canyon corridor is 7.4 km long and extends from the Faro to Watson Lake corridor to the False Canyon site on the Frances River. Almost the entire length of this corridor is 200 m wide being confined to the lower slope between the Frances River to the east and the adjacent steeper slope and more rugged upland to the west. The corridor widens to 500 m near the tap location in the Faro to Watson Lake corridor.

A gravel pit is located near the tap location. However, most of the gravel pit is outside the corridor leaving sufficient room within the corridor to avoid crossing the gravel pit.

The tap point in the Faro to Watson Lake corridor is located on First Nations Category B land belonging to the Liard First Nation.

3.12 Middle Canyon

The Middle Canyon corridor is 6.2 km long from a potential hydroelectric site on the Frances River to the tap location in the Faro to Watson Lake corridor. The dominant terrain in the corridor is moraine and the slopes within corridor are gentle. The corridor is 500 m-wide over its entire length and there are no designated land uses in this area including no First Nations Settlement lands.

3.13 Hoole Canyon

The Hoole Canyon corridor is 1.7km long and connects the potential hydroelectric site on the Ross River to the tap location in the Faro to Watson Lake corridor. The primary terrain within the corridor is moraine, but also includes small amounts of fluvial and organic terrain. The majority of this corridor is on slopes that are less than 5°. There are no land uses or First Nations Settlement lands within the corridor.

4 Summary

JDMA has identified transmission line corridors for fourteen (14) potential routes identified by Midgard Consultants. A high level desktop study was carried out using readily available satellite imagery and GIS data sources. No detailed analysis was done using air photos and no ground-truthing or other field work has been carried out. While attempts have been made to identify major routing constraints, the possibility remains that site specific land use or terrain issues may exist that are not detectable with the

data resolution used in this study. Therefore, JDMA recommends more detailed analysis should be completed for each of these corridors including detailed air photo analysis, acquisition of high resolution satellite imagery and LiDAR data and field reconnaissance should further development of these corridors be considered.

Having said that, the corridors identified here are believed to represent viable routing options and the data presented provides a reasonable basis for a high level evaluation of the feasibility of constructing and maintaining a transmission line to each of the potential hydroelectric sites that have been included in this study.

5 Deliverables

The following products accompany this final report:

1) Route comparison spreadsheet in Excel format
2) Fourteen (14) corridor shapefiles – 1 for each corridor

These GIS products were created in ESRI ArcMap V.10.4

6 Signatures

Shayne MacDonald, B.Sc.

Lynden Penner, M.Sc., P.Eng., P.Geo.

MEMORANDUM

To: Marc-Andre Lavigne, Yukon Energy Corporation

From: Sunil Bhatti, P.Eng.

Date: 1 November 2016

Subject: Transmission Options Evaluation – 69 kV Transmission Line Options Addendum

---

- Midgard Consulting Incorporated ("Midgard") was commissioned to calculate the capital cost and average losses incurred to serve a load of 8 MW for two 69 kV transmission lines:
  - Atlin → Jake's Corner
  - Whitehorse → Atlin
- The results of this exercise are summarized in Table 1 below

Table 1: 69 kV Transmission Line Option Evaluation Summary

Transmission Route	Voltage Class	Line Length	Reliable Transfer Capacity	Line Losses (at 8 MW Load)	Capital Cost	Operating Cost	Earliest Possible ISD
Atlin → Jake's Corner	69 kV	93 km	38 MW	0.4 MW	$54.2 M	$129 k / Year	Jan 2020
Whitehorse → Atlin	69 kV	172 km	21 MW	0.6 MW	$104 M	$236 k / Year	Oct 2020

Note: Whitehorse → Atlin line losses were achieved using a 2 MVAr shunt capacitor on the load bus.

Cost Assumptions

Capital Cost

- Midgard was unable to find cost data for recently-constructed 69 kV transmission lines in western Canada, and therefore was unable to use the costing methodology applied in the Transmission Options Evaluation report
- The 69 kV voltage class is no longer a common voltage class for new transmission lines; at transmission levels, utilities seem to opt for 138 kV instead
- 69 kV line cost estimate was derived by marking down the cost components of 138 kV lines:
  - Materials & Shipping cost for 69 kV were 50% of that of 138 kV
  - Engineering, Construction & Salvage for 69 kV were 75% of 138 kV
  - Land & Access for 69 kV were 66% of 138 kV

Operating Cost & Schedule

- Operating cost & schedule calculated in accordance with methodology used in Transmission Options Evaluation

PSSE Simulation Details & Criteria

Table 2: Conductor Characteristics

Voltage Class	Conductor Type	Geometric Mean Radius	External Diameter	Conductors per Bundle	Phase Spacing	Conductor Temperature
69 kV	Partridge 266.8	0.0217 ft	0.642 in	1	1.35 m	100 °C

Table 3: Reliable Transfer Capacity Limit Modelling Criteria

Voltage Angle Limit:	Not to exceed 33 degrees
Thermal Limit:	Not studied
VAR Limits:	Not applied
Reliable Transfer Limit Calculation:	Real power injected into load bus

Table 4: Average Losses Modelling Criteria

Load Size:	8.89 MVA (8 MW at 0.9 power factor)
Bus Voltage Limits:	0.95 to 1.05 per unit
Average Loss Type:	Considered real power losses only
Average Loss Calculation:	Real power injected into generator bus less real power injected into load bus
Generator Power Factor:	Power factor >= 1.0
Shunt Compensation:	Minimized requirement for shunt compensation (to reduce capital cost)

Appendix 6.1
Liquefied Natural Gas: Potential Supply Options

Introduction

In May, 2016, as inputs to the pending 2016 Resource Plan, YEC undertook a 20 year forecast of future Liquefied Natural Gas (LNG) prices. This forecast included conservative assumptions with respect to the non-commodity components of delivered LNG. That is, the forecast assumed that the source of, and transportation routes of its LNG feedstock would remain relatively unchanged.

To augment the May work, YEC has now reviewed other possible LNG delivery options, which may achieve costs savings relative to the current forecast assumptions.

The approximate current $22/GJ cost of LNG delivered to YEC (Whitehorse) can be broken down as follows[1]:

LNG Cost Component

Transportation and Tanker Charge:	62%
Commodity Charge:	16%
Gas Charge:	22%
Total:	100%

These cost categories are detailed as follows:

- Transportation: this covers the cost of LNG delivery, from liquefaction plant to YEC, including the Tanker Charge, which is the rental fee for the LNG shipping vessel.
- Commodity Charge: This is the charge to convert natural gas to LNG using a refrigeration/liquefaction process; and
- Gas Charge: is the cost of the natural gas that is the LNG feedstock.

In estimating a possible future change in the above costs, YEC has reviewed potential options in each of the cost categories above.

Transportation Charge

The Transportation Charge should be highly correlated to the distance travelled, as it is composed of cost of labour (driver), the rental time for the vehicle, and the cost of the vehicle fuel (diesel). Larger loads and shorter distances should result in savings. Distances, driving time and status can be seen below in Table 1.

[1] This breakdown was obtained from delivered LNG invoices (2015- early 2016); the source data is commercially sensitive.

Table 1. Existing and Potential Sources of LNG

Location	Distance	Driving time	Status
Dawson Creek, BC (AltaGas)	1,460 km	16 hours	Existing
Delta, BC (Tilbury Island)	2,390 km	25 hours	Existing
Fort Nelson, BC (KT Energy)	988 km	11 hours	Potential

YEC's current source of LNG is Delta British Columbia (Tilbury Island). Dawson Creek is the location of the existing AltaGas LNG facility, which has announced plans to expand by over 30% to over 100 m^3/d. Dawson Creek is located in the heart of the Montney gas field, one of the largest, most prolific and most cost-competitive gas plays in North America. There is currently no LNG Facility in Fort Nelson, but in early 2016 KT Energy announced the potential for smaller-scale modular facilities in the region. Fort Nelson is situated in the Horn River gas supply basin, a major current and potential source of natural gas supply.

As transportation costs are highly correlated with the distance travelled, a more northerly LNG supply source should result in significant savings. Larger shipments than the current 60m^3 volume should result in cost savings. A number of different delivery options was reviewed, up to 90m^3 per load, a 50% increase in delivered LNG per shipment.

Commodity Charge

The two largest cost components for LNG production are capital cost recovery for the liquefaction plant, and the fuel cost for undertaking the chilling/liquefaction process. Natural gas is almost always used as the energy source for the LNG process, with approximately 7% of the input gas being consumed in the process. This is in large, efficient plants, with a higher percentage of gas consumed as fuel in smaller facilities. A very limited number of liquefaction plants use electricity to run the refrigeration process, but electricity is generally a more expensive source of energy than natural gas. The commodity charge is highly related to the efficiency of the liquefaction plant, with the cost of gas to LNG conversion being equivalent to $4/GJ and above. YEC has no information to indicate that with respect to this charge category, the Dawson Creek or a Fort Nelson LNG facility would be more efficient and more cost effective than its current supplier. Generally, the larger and older (depreciated) the LNG facility, the lower the liquefaction cost.

Gas Charge

Typically, the closer to the wellhead the natural gas supply, the less expensive, due to lower pipeline tolls. This makes North Eastern British Columbia sourced natural gas inherently less expensive that gas sourced further south. An analysis of natural gas prices at the Station 2 and Sumas market hubs indicates an approximate $0.50/GJ difference, with the northern hub having a lower average price. This differential is consistent with the transportation cost between the markets (pipeline tolls). Logistically and economically it would make more sense to produce LNG in the north, as opposed to shipping the gas to the south and then trucking LNG north, thereby incurring transportation charges in both directions. The "Optimized Supply" LNG price scenario described following assumes that natural gas is sourced at Station 2, taking advantage of the lower cost of gas closer to the supply in northeast BC.

Summary

The transportation charge represents the significant potential source of future cost savings, due to the potential for economies of scale (larger delivery vessels), and shorter delivery distances between Whitehorse and the source of the natural gas feedstock. YEC is conservative with respect to estimating cost savings due to larger vessels, as it has not fully reviewed the challenges in single larger LNG shipments. Before deliveries from larger containers should be counted on, shipping constraints (physical due to bridges and axle loadings, and local bylaws) should be thoroughly researched.

Based on currently available information, YEC estimates an $8/GJ overall LNG cost reduction due to sourcing LNG from Dawson Creek. This saving assumption is mostly due to reduced shipping distances, but also due to larger ($80m^3$) shipping vessels.

YEC recommends that it initiate negotiations with alternative suppliers of LNG, in order to firm-up these price estimates, and potentially realize these savings.

Figure 1 following shows a breakdown of forecast LNG costs in the key scenarios studied, for the first year of delivery. Fuel cost refers to the cost of the natural gas feedstock at the LNG liquefaction plant. Table 2 shows the content of Figure 1 as numerical values.

Figure 2 following shows the cost of LNG under the "Status Quo" assumptions, specifically current $60m^3$ LNG shipments, sourced from Tilbury Island - for each of the three underlying natural gas scenarios: Base, Low and High. The "Optimized Supply" scenarios are based on larger $80m^3$ shipments and LNG sourced from Dawson Creek - for each of the same 3 underlying natural gas price forecasts. Table 3 shows the content of Figure 2 as numerical values.

Figure 3 is a simplification of Figure 2, in that only the three LNG price scenarios that are used in further analysis are shown: the Base, High and Optimized scenarios. The Base scenario assumes Status Quo shipment volumes and the current Tilbury Island LNG source. The High scenario includes the same Status Quo assumptions as the Base scenario, but with the high gas price forecast. The Optimized Supply scenario selected assumes the Base gas price forecast but with $80m^3$ shipments and LNG sourced from Dawson Creek. These 3 selected forecasts were used as LNG fuel input costs in YEC's portfolio analysis, as discussed in Chapter 8. Table 4 shows the content of Figure 3 as numerical values.

Figure 1: Delivered LNG Price for Different Trailer Size and Fuel Source (2016 $CA/GJ)

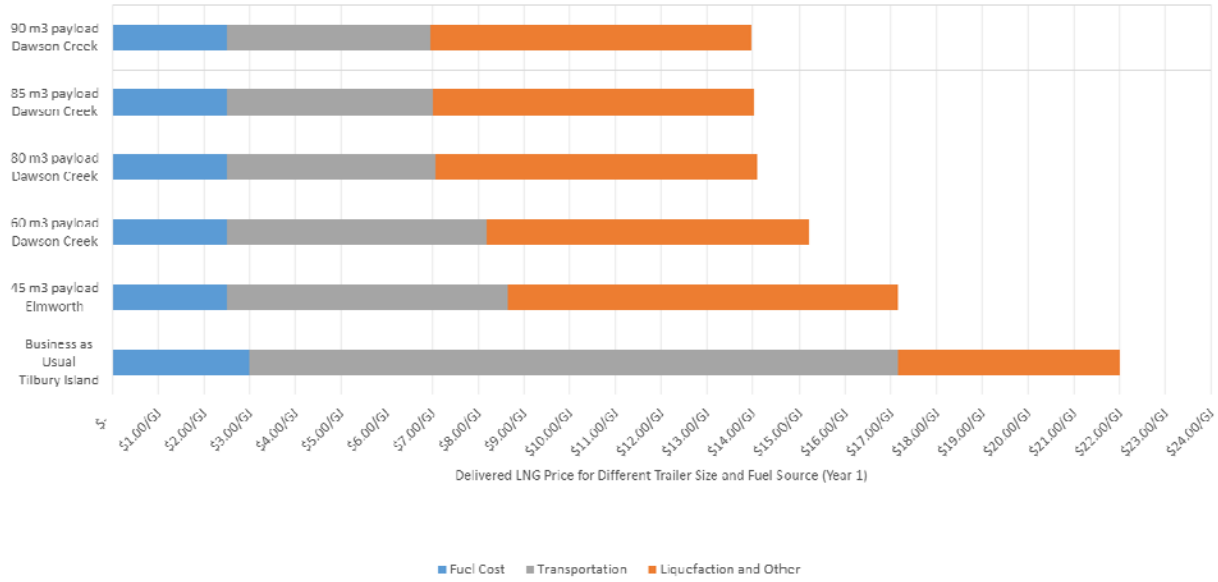

Table 2: Delivered LNG Price for different Trailer Size and Fuel Source (2016 $CA/GJ)

Scenario	Transportation	Liquefaction and Other	Fuel Cost
Business as Usual Tilbury Island	$14.15/GJ	$4.85/GJ	$3.00/GJ
45 m^3 payload Elmworth	$6.15/GJ	$8.50/GJ	$2.50/GJ
60 m^3 payload Dawson Creek	$5.68/GJ	$7.03/GJ	$2.50/GJ
80 m^3 payload Dawson Creek	$4.57/GJ	$7.03/GJ	$2.50/GJ
85 m^3 payload Dawson Creek	$4.50/GJ	$7.03/GJ	$2.50/GJ
90 m^3 payload Dawson Creek	$4.45/GJ	$7.03/GJ	$2.50/GJ

Summary

The social cost of carbon (SCC) is a monetary value that indicates the net harm of human CO2 emissions from burning coal, oil and natural gas (fossil fuels). The SCC is usually measured in dollars per tonne of CO2 ($/tCO2). The Yukon Energy Corporation seeks a value for the SCC that it might use to guide energy investments and other planning and policy decisions.

While there are many reasons why estimates of the SCC can diverge significantly, two stand out. The first is that the SCC must include harm to what are sometimes called the earth's unmanaged systems, for which we cannot readily attribute monetary values. Reduced output from agriculture, forestry and fisheries will result in monetary losses that can be tabulated. In contrast, the extinction of a non-commercial species, such as the polar bear, or the destruction of a major ecosystem, like the Amazon rainforest, is not directly linked to lost market products. The efforts of researchers to address this uncertainty has led to a steady rise in the SCC value used by, for example, the US Environmental Protection Agency, and to its conclusion that its SCC estimates are likely still biased downward. The second major reason for diversity is that some SCC estimates place little value on low probability catastrophic outcomes, such as runaway methane release in the Arctic, collapse of the West Antarctic Ice Sheet, and reversal of the Gulf Stream. More recent SCC estimates attempt to somehow incorporate these potential costs, but there is great uncertainty about what values to use.

The US EPA uses a wide range of values for the SCC when assessing its proposed regulations, such as vehicle or coal plant emissions standards. Because it does not apply a single SCC value, some regulations may be pursued even if not justified according to the lowest values.

In Canada, governments have not used the SCC in such a transparent manner. Instead, four provincial governments are enacting explicit carbon pricing (via a carbon tax, or the price of tradable permits in a cap-and-trade system) covering over 30 million Canadians. These carbon prices are $15 to $30 /tCO2, with provisions in three cases to rise at 5% plus inflation.

At the same time, Canadian provincial governments have enacted other policies that direct crown corporations and in some cases private corporations to shift toward lower emission technologies, especially in electricity generation. It is possible to compute the 'implicit' carbon price for these policies, which is the level of carbon tax that would have been needed to get the same outcome. These implicit carbon prices are in the range of $100 /tCO2 or higher.

Background

The social cost of carbon (SCC) is a monetary value that indicates the net harm of human CO2 emissions from burning coal, oil and natural gas (fossil fuels). The SCC is usually measured in dollars per tonne of CO2 ($/tCO2), but sometimes dollars per tonne of carbon ($/tC).

The harms human CO2 emissions cause to people, the economy and the environment are called 'externality costs' if they are not included ('internalized') in the prices of goods and services that cause these emissions. These harms result from rising CO2 concentrations in the atmosphere and oceans. In the atmosphere, the CO2 raises global temperatures resulting in desertification in some regions, more extreme weather events (floods, droughts, heat waves, hurricanes), rising sea levels (from accelerated melting of glaciers and ice sheets), accelerated species extinction (from rapid ecosystem change), and reduced net global economic output (though some regions may initially experience net benefits from modest levels of warming). In the oceans, the rising CO2 concentration causes acidification, which reduces biological productivity and economic output.

Yukon Energy Corporation seeks to adopt one value, or a range of values, for the SCC that it might use to guide energy investments and other planning and policy decisions. This briefing document explains the SCC concept and how experts estimate its value. It then provide various estimated SCC values, and comments on their significance and potential applicability to Yukon Energy, notably by providing examples of how other governments, corporations and agencies use the SCC and related concepts.

The Challenge of Estimating the Social Cost of Carbon

For over two decades, William Nordhaus of Yale University has played a leading role in the estimation of the SCC.[1] Because the initial stages of global warming may increase agricultural productivity in colder regions of North America and Eurasia, he notes that the SCC should be computed as a 'net' value, in which the benefits of global warming are subtracted from the costs.

When estimating these costs, Nordhaus divides the earth into managed and unmanaged systems.[2] Managed systems are resources that humans use to produce market products. Examples are ocean fish stocks, agricultural land, and commercial forests. If carbon emissions affect the productivity of these systems, one can estimate the cost as the lost market output. Likewise, one can estimate the cost of defensive expenditures caused by CO2 emissions, such as higher dykes, storm protection and more air conditioning.

The bigger challenge is to estimate a monetary value for damage to the mostly unmanaged systems of the earth. An example would be a loss of arctic ice leading to extinction of a non-commercial species, such as the polar bear, or the destruction of a major ecosystem, like the Amazon rainforest. Because these values are not directly linked to market products, estimating

[1] Nordhaus, W., "An optimal transition path for controlling greenhouse gases," Science, Vol.258, Nov. 1992.
[2] Nordhaus, W., The Climate Casino: Risk, Uncertainty and Economics for a Warming World, Yale, 2013.

the monetary loss to humanity is fraught with uncertainty. Some uncertain values are simply omitted, which biases downwards the SCC estimate. For this reason, the US Environmental Protection Agency (EPA) qualifies its own SCC estimate with, "However, given current modelling and data limitations, it does not include all important damages."[3] And this leads Nordhaus to conclude, "So, if anything, the uncertainties point to a more rather than less forceful policy – and one starting sooner rather than later – to slow climate change."[4]

Another big challenge for the SCC is to estimate a monetary value for low probability, catastrophic outcomes whose probability increases as temperatures rise, examples being runaway methane release in the Arctic, collapse of the West Antarctic Ice Sheet, and reversal of the Gulf Stream. Marty Weitzman of Harvard has argued for a decade that SCC estimates need to somehow incorporate these potential harms ('known unknowns'), as well as somehow considering as-yet unimaginable outcomes ('unknown unknowns').[5] As noted below, some researchers have tried to incorporate into the SCC at least some values for known potential damages from the low probability, catastrophic outcomes which seriously concern scientists.

Estimates of the social cost of carbon

Some jurisdictions monitor the SCC estimates of the US EPA, which are updated on a regular basis to incorporate research advances – with the caveat noted above that the estimates are nonetheless biased downwards. The following table shows the range of SCC estimates (in real 2007 $US) for a 3% discount rate for the next 20 years. Note that in all cases, researchers show the SCC to rise over time. This presents an 'optimal path' that minimizes the costs and maximizes the benefits of reducing CO2 emissions. The diversity in estimates is due to a range of values for key assumptions: notabley the forecasts of CO2 concentrations in the absence of efforts to reduce emissions, the impacts of those concentrations on the global atmosphere-land-ocean system, and the costs of reducing emissions. The range gets even wider if one uses a 5% discount rate, which leads to very low SCC estimates in the present and future.

US EPA (2007 $US)	2015	2035
Lowest estimate	$36	$55
Highest estimate	$105	$168

Source: US EPA, 2016, http://www3.epa.gov/climatechange/EPAactivities/economics/scc.html

[3] US EPA, Social Cost of Carbon, 2016. http://www3.epa.gov/climatechange/EPAactivities/economics/scc.html
[4] Nordhaus, W., "Why the global warming skeptics are wrong." New York Review of Books, 2012
[5] Weitzman, M., "Fat-tailed uncertainty in the economics of catastrophic climate change," Review of Environmental Economics and Policy, 2011.

When assessing its proposed regulations, such as vehicle or coal plant standards, the US EPA uses a wide range of values for the SCC. It does not select a single value from which to make decisions. Rather it simply records how each level of regulation performs under the different SCC values, including values that it notes are likely to be strongly biased downwards as in the case of a 5% discount rate.

Aside from the EPA, some researchers have responded to the challenge of unincorporated effects by estimating, by some means, the potential costs and probabilities of catastrophic outcomes. The next table shows the latest estimates provided by Simon Dietz and Nicholas Stern of the London School of Economics, using the same model as Nordhaus, but with some inclusion of low probability, catastrophic outcomes.[6] (Note that these values are in 2015 $US, while the EPA estimates in the previous table are in 2007 $US.)

Dietz & Stern (2015 $US)	2015	2035
Lowest estimate	$32	$82
Highest estimate	$103	$260

Source: Dietz and Stern, 2015.

As both tables show, the SCC estimates in each year cover a wide range. This presents a dilemma for policy-makers who seek to internalize the SCC into private and public decision-making in their jurisdiction. Even if they recognize the great uncertainty, they need to pick one or a few values if they intend to 'internalize' the externality of CO2 emissions.

Carbon pricing and the social cost of carbon

Economists argue that the prices of fossil fuels should be increased by the SCC value according to the CO2 emissions from fossil fuels – 'carbon pricing'. To reflect their different carbon intensities, the price of coal per unit of energy would increase by more than that of oil, which would increase by more than that of natural gas.

Carbon pricing via carbon taxes

The simplest and most transparent method of carbon pricing is by levying a carbon tax on coal, oil and natural gas. Experts widely agree that British Columbia's carbon tax, implemented in 2008, is a model example because of its consistency and comprehensiveness.[7] It is applied to

[6] Dietz, S. and N. Stern, "Endogenous growth, convexity of damage, and climate risk: How Nordhaus' framework supports deep cuts in carbon emissions," The Economic Journal, 2015.
[7] Murray, B. and N. Rivers, "British Columbia's revenue-neutral carbon tax: a review of the latest 'grand experiment' in environmental policy." Energy Policy, 2015.

fossil fuel combustion in virtually all sectors of the economy. At $30, the tax increases the price of gasoline by 7 cents per litre, with comparable effects on the price of coal and natural gas.

While there are other jurisdictions around the world with carbon taxes, the tax level tends to vary within each jurisdiction in order to prevent significant cost increases for carbon-intensive, trade-exposed sectors. Thus, Alberta's intended carbon tax, to be applied in 2017, will be the same as BC's for gasoline used in vehicles, natural gas used in buildings, and natural gas and coal used in electricity generation, but will be lower on average for these fuels when used in oil sands production facilities, refineries and petrochemical plants.

In keeping with the economists' argument that the carbon price should rise over time, Alberta's tax is slated to grow 5% annually over the rate of inflation. BC's tax increased $5 annually from 2008 to 2012, but is currently frozen at $30.

Carbon pricing via tradable permit prices in cap-and-trade systems

A second method for carbon pricing is to establish a jurisdiction-wide cap on CO2 emissions, and then allocate tradable permits that each year sum to the level of the cap – called 'cap-and-trade.' The market price of the tradable permits has the same effect as a carbon tax. If gasoline retailers must purchase permits at $30 / tCO2 for the carbon content in their gasoline, they will pass on this extra cost to consumers at a rate of 7 cents per litre.

In the case of cap-and-trade, however, the carbon price is uncertain because it depends on the cost of CO2 emission reductions in all sectors of the economy, which are not precisely known by government when it sets the cap. To remove some of this uncertainty, many jurisdictions with cap-and-trade systems now set a minimum price for the permits. In the joint cap-and-trade system of Quebec and California, for example, the minimum price for permits purchased and sold in Quebec was $10 (Cdn) in 2013, and set to increase 5% annually plus inflation. As of 2015, the permit trading price in Quebec has never been more than a few dollars above the minimum price.

Ontario is slated to soon join the Quebec-California system.[8] If this occurs by 2018, explicit emissions pricing will be the norm in Canada. Of a current national population of 36 million, 22 million (Quebec and Ontario) will have a minimum carbon price of almost $15 /tCO2 (depending on the cap-and-trade permit market at that time) and 8.5 million (BC and Alberta) will have a carbon tax of $30 /tCO2.

Implicit carbon prices

Emissions pricing is but one policy option for reducing CO2 emissions. Governments can also regulate private industry or give explicit directions to state-owned corporations and various public agencies. This approach has led to far more CO2 emission reductions in Canada and most other jurisdictions concerned about GHG emissions.

The most significant climate policy in Canada thus far was Ontario's closure of its coal-fired power plants, which it achieved between 2004 and 2014. This one policy reduced annual CO2 emissions by 25 megatonnes (MT). In 2007, BC passed a 'clean electricity' requirement that

[8] Manitoba's government has also expressed its intent to join Quebec and Ontario, although it has not yet progressed down this path to a significant extent.

forced BC Hydro to cancel contracts for two private coal-fired power plants and its own plans for a large natural gas plant, reducing expected annual CO2 emissions in 2020 by 11-17 MT. In comparison, BC's carbon tax is estimated to reduce 2020 annual emissions by 3-5 MT.

From regulations and investment directives like these it is possible to calculate an 'implicit carbon price.' This is the carbon price that would be required to cause the same amount of emissions reduction in the sector in question. For example, it has been calculated that BC's electricity regulation had an implicit carbon price of $90 to $210 /tCO2, depending on assumptions of the cost of energy storage (for wind and run-of-river power) and natural gas in the future.[9] Crude estimates of Ontario's coal phase-out policy suggest that its implicit carbon cost was $100 to $150 /tCO2. Also, the Saskatchewan government subsidized the installation of carbon capture and storage technology at its Boundary Dam coal-fired power plant, and the cost has been estimated at more than $100 /tCO2 reduced, which may be acceptable since there may be future benefits from the development of this new technology. Finally, in announcing its new climate policy, Alberta noted that in addition to implementing a $30 carbon tax it would require an accelerated reduction in coal-fired power, which would include payments for wind power up to an implicit carbon price of $90 /tCO2.[10]

Social cost of carbon as a guide to regulations and investments

The following table summarizes the evidence on explicit and implicit carbon pricing in Canada. It shows, firstly, that real-world explicit carbon prices are either below estimated SCC values, or at least not slated to rise at the rate that would track them into the future. Secondly, it shows that seemingly high, real-world implicit carbon prices, resulting from regulations and public investment decisions, are much closer to the estimated SCC values into the future, given that these decisions about electricity generation investment are multi-decade commitments.

2018 carbon price ($ / tCO2)	Explicit carbon price	Implicit carbon price
Quebec	**≈$15**	**?**
Ontario	**≈$15**	**$100-$150 (coal plant phase-out)**
BC	**$30**	**$90-$210 (clean electricity requirement)**
Alberta	**$30**	**$90 (coal plants to wind)**

[9] Rhodes, K. and M. Jaccard, "A tale of two climate policies: political economy of British Columbia's carbon tax and clean electricity standard." Canadian Public Policy, 2013.
[10] Government of Alberta, "Climate Leadership Plan," 2015.

It is uncertain if estimates of the SCC guided any of the explicit or implicit pricing policies recently applied by Canadian provinces. Some research suggests that political acceptability is the most important factor in determining the type and stringency of climate policy.[11] This may explain why Canadian implicit prices exceed explicit prices. The cost of the carbon tax in BC is obvious to everyone who buys gasoline, since it is indicated on the pumps, whereas only an energy analyst would know the much higher cost of the clean electricity requirement. Thus, politicians who sincerely want to reduce CO2 emissions seem willing to use both the explicit and the implicit carbon pricing methods, but the latter has been applied at higher levels that might be more consistent with current estimates of the SCC trajectory over the next couple of decades.

The use of the SCC to guide policies in the US, at least at the federal level, is more direct and transparent. The EPA must show that any of its regulations pass a cost-benefit test, which includes monetized values for all externalities. Thus, the EPA value for the SCC was used in the latest EPA revisions to US vehicle efficiency and emissions regulations. Likewise, the EPA's new proposed coal plant emission regulation – currently in the comment and review phase – is justified in a cost-benefit analysis that uses the SCC estimate.

Thus, the SCC can provide a 'shadow price' for determining the stringency of government regulations. It can also be used by industry. Many corporations claim that they use an internal 'shadow price' for CO2 emissions in determining the level of energy efficiency and fuel choice in large and small investments.

Informing energy-climate policy in the Yukon

Over the next few years, as part of Canada's federal-provincial climate policy collaboration, the Yukon government might choose to implement a carbon tax, as in BC and soon Alberta, or a cap-and-trade system, as in Quebec and soon Ontario. But, regardless of this decision, the Yukon Energy Corporation has the immediate opportunity to apply a shadow carbon price to guide its investment and operation decisions, decisions that may have carbon emission implications for years and even decades to come.

The challenge is to decide which price to use as its shadow carbon price. Yukon Energy could test any decision against the range of EPA estimates for the SCC. But this range is so wide that it is not that helpful. Yukon Energy could take a precautionary approach, using the EPA's highest SCC values. Or it could be guided by the carbon prices that are explicit or implicit in decisions and policies in other Canadian jurisdictions.

If Yukon Energy were to use the explicit carbon price in other parts of Canada as a guide, the carbon prices in Quebec, Ontario, Alberta and BC will range from $15 to $30 in 2018, rising thereafter. These explicit prices are at the low end of EPA and more recent estimates of the SCC. But the benefit is that they will be applied to almost all CO2 emissions in these provinces, not just the emissions and investment decisions of public corporations and agencies. And all of these

[11] Rhodes, K., Axsen, J. and M. Jaccard, "Does effective climate policy require well-informed citizen support?" Global Environmental Change, 2014.

jurisdictions, with the exception of BC, have scheduled their carbon prices to rise annually.

If Yukon Energy were to use the implicit carbon prices in other parts of Canada as a guide, crown corporations and provincial governments in Ontario, BC, Saskatchewan and soon Alberta are accepting much higher prices to guide energy-related investment and planning, and in setting regulations that affect private investment decisions in renewable electricity generation. Thus, it would be consistent with these other jurisdictions for Yukon Energy to use a value in the neighbourhood of $100 /tCO2. This price reflects government decisions as diverse as Saskatchewan Power's investment in carbon capture and storage, Ontario Power's closure of its coal plants and replacement with low- and zero-emission alternatives, the BC government's clean electricity regulation favouring renewable electricity, and Alberta's recent policy announcement for wind to play a significant role in the accelerated closure of its coal plants.

Table 9: Low Industrial Activity with Minto Closing Early and Eagle Gold Project Portfolio Summary

Resource Option	Installed Capacity [MW]
2018	
Demand Side Management	1.5
2019	
Thermal - 3rd NG Engine at Whitehorse	4.4
2020	
4 MW Battery - Takhini Substation	4.0
Aishihik Uprate	1.3
Whitehorse Uprate	1.7
Southern Lake Enhancement Storage Project	0.0
2021	
Thermal Diesel - Takhini Substation	20.0
2022	
Mayo Hydro Refurbishment	2.3
Mayo Lake Enhancement Storage Project	0.0
2023	
Drury Creek Small Hydro	8.1
Grand Total	43.3

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 298.6	
Optimization Results (Present Value)		
Fixed Costs	$ 130.2	[A]
Variable Costs	$ 49.1	[B]
Total Costs	$ 179.4	[C] = [A] + [B]

This portfolio generates an average of 99.3% renewable energy over the 20 year planning period, under average water assumptions.

Table 12: Medium Industrial Activity Portfolio Summary

Resource Option	Installed Capacity [MW]
2018	
Demand Side Management	1.9
2019	
Thermal - 3rd NG Engine at Whitehorse	4.4
2020	
4 MW Battery - Takhini Substation	4.0
Aishihik Uprate	1.3
Whitehorse Uprate	1.7
Southern Lake Enhancement Storage Project	0.0
2021	
Thermal Diesel - Takhini Substation	20.0
2022	
Mayo Hydro Refurbishment	2.3
Mayo Lake Enhancement Storage Project	0.0
2025	
Drury Creek Small Hydro	8.1
Grand Total	43.7

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 298.6	
Present Value		
Fixed Costs	$ 122.7	[A]
Variable Costs	$ 74.4	[B]
Total Costs	$ 197.1	[C] = [A] + [B]

This portfolio generates an average of 98.1% renewable energy over the 20 year planning period, under average water assumptions.

Table 15: High Industrial Activity with Capped Intermittent and Committed Resources Portfolio Summary

Resource Option	Installed Capacity [MW]
2018	
Demand Side Management	2.2
2019	
Thermal - 3rd NG Engine at Whitehorse	4.4
2020	
4 MW Battery - Takhini Substation	4.0
Aishihik Uprate	1.3
Whitehorse Uprate	1.7
Southern Lake Enhancement Storage Project	0.0
2021	
Thermal Diesel - Takhini Substation	20.0
2022	
Mayo Hydro Refurbishment	2.3
Mayo Lake Enhancement Storage Project	0.0
Wind - Miller's Ridge	20.0
2023	
Small Hydro - Drury Creek	8.1
2026	
Thermal Diesel - Takhini Substation	10.0
Grand Total	74.0

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 414.0	
Optimization Results (Present Value)		
Fixed Costs	$ 150.9	[A]
Variable Costs	$ 294.8	[B]
Total Costs	$ 445.7	[C] = [A] + [B]

This portfolio generates an average of 91.9% renewable energy over the 20 year planning period, under average water assumptions.

Table 24: Medium Industrial Activity with 20-Year GWP Portfolio Summary

Resource Option	Installed Capacity [MW]
2018	
Demand Side Management	1.9
2019	
Thermal - 3rd NG Engine at Whitehorse	4.4
2020	
4 MW Battery - Takhini Substation	4.0
Aishihik Uprate	1.3
Whitehorse Uprate	1.7
Southern Lake Enhancement Storage Project	0.0
2021	
Thermal Diesel - Takhini Substation	20.0
2022	
Mayo Hydro Refurbishment	2.3
Mayo Lake Enhancement Storage Project	0.0
2025	
Drury Creek Small Hydro	8.1
Grand Total	43.7

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 298.6	
Present Value		
Fixed Costs	$ 122.7	[A]
Variable Costs	$ 74.6	[B]
Total Costs	$ 197.3	[C] = [A] + [B]

This portfolio generates 98.1% energy under average water assumptions.

Mayo Hydro Refurbishment	2.3
2026	
Thermal Diesel - Takhini Substation	10.0
Grand Total	44.9

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 207.4	
Present Value		
Fixed Costs	$ 96.9	[A]
Variable Costs	$ 37.7	[B]
Total Costs	$ 134.6	[C] = [A] + [B]

This portfolio generates 99.8% energy under average water assumptions.

Table 33: Low Industrial Activity with Medium Diesel and Low LNG Price Portfolio Summary

Resource Option	Installed Capacity [MW]
2018	
Demand Side Management	1.3
2019	
Thermal - 3rd NG Engine at Whitehorse	4.4
2020	
4 MW Battery - Takhini Substation	4.0
Whitehorse Uprate	1.7
2021	
Thermal Diesel - Takhini Substation	20.0
2022	
Aishihik Uprate	1.3
Mayo Hydro Refurbishment	2.3
2026	
Thermal Diesel - Takhini Substation	10.0
Grand Total	45.0

Cost Components	Cost [2016 $Millions]	Comment
Portfolio Capital Cost	$ 207.4	
Present Value		
Fixed Costs	$ 97.6	[A]
Variable Costs	$ 37.4	[B]
Total Costs	$ 135.0	[C] = [A] + [B]

This portfolio generates 99.8% energy under average water assumptions.
