2006 Resource Plan

YUKON ENERGY CORPORATION

20-YEAR RESOURCE PLAN: 2006-2025

January, 2006

and

SUPPLEMENTAL MATERIALS

May, 2006

YUKON ENERGY CORPORATION SUBMISSION
20 YEAR RESOURCE PLAN

SUMMARY OF PROPOSED ACTIONS

INTRODUCTION

Yukon Energy's 20 Year Resource Plan Submission addresses major electrical generation and transmission requirements in Yukon during the 2006 to 2025 period, with emphasis on:

a) near term projects that will require Yukon Energy commitments before the year 2009 with costs of $3 million or more, and
b) planning activities that Yukon Energy may be required to carry out in order to start construction on other projects before 2016 to meet the needs of potential major industrial customers or other major potential developments in Yukon.

In response to past commitments, the 20-Year Resource Plan Submission is expected to provide the Yukon Utilities Board (YUB) with the opportunity to review near term generation or transmission projects that Yukon Energy proposes to commit before 2009 with costs of $3 million or more, including projects based on revised planning criteria now adopted by Yukon Energy. The last Resource Plan, which was submitted for review by the YUB in 1992, covered 1992-2001 and was prepared by Yukon Energy and Yukon Electrical Company Limited (YECL).

The Submission also proposes Yukon Energy planning activities to protect Yukon Energy's ability to start construction on other major generation and transmission projects before 2016 to meet the needs of potential major industrial development opportunities.

This summary reviews the following:

- Resource Planning for Yukon Power Systems (to provide context for this Submission).
- New Capacity Criteria (reviews a key factor affecting proposed actions in this Submission).
- Proposed Near Term Actions (summary of actions proposed for commitment before 2009).
- Proposed Actions Relating to Industrial Development Scenarios and Opportunities (summary of proposed planning activities to protect possible commitments beyond 2009 and before 2016).

RESOURCE PLANNING FOR YUKON POWER SYSTEMS

The distinct and independent power systems in the Yukon are each served by separate source(s) of generation, and include: the Whitehorse Aishihik Faro (WAF) grid; the Mayo Dawson (MD) grid; the diesel community of Watson Lake; and a number of smaller isolated diesel communities (Beaver Creek, Destruction Bay, Pelly Crossing, Swift River and Old Crow).

Yukon Energy's generation on the WAF and MD systems accounts for 112.4 MW of the 127.4 MW of installed and currently rated capacity in Yukon. The YECL generation accounts for the balance, or for 15.0 MW of installed and rated capacity.

Yukon Energy's extensive hydro generation, as well as most of its related transmission facilities, were previously developed in response to major industrial mine developments. Today, these hydro systems are the key factor causing Yukon power costs to be lower than those found in Alaska or the Northwest Territories. Without such hydro facilities, Yukon utilities probably would have relied almost entirely on diesel generation with its associated higher costs.

The Yukon economy, and Yukon's electrical loads and systems have changed substantially since the 1992 Resource Plan review by the YUB. Highlights relevant to the current Resource Plan include:

- Due to closure of the Faro mine, no reopening of the UKHM mine, and no new mines yet having emerged on the WAF and MD systems, there is today a substantial surplus of hydro energy on these grids.
- Yukon Energy's response to these conditions has included greatly increased secondary sales and development of the Mayo Dawson Transmission Line.
- Yukon Energy's three water licences have been renewed.

As the major generator and transmitter of electrical power in the Yukon region, Yukon Energy plans for the capacity and energy requirements of Yukoners, particularly those supplied on the WAF and MD grids.

- **Capacity requirement** planning focuses on the highest or peak megawatt (MW) generation capability (capacity) required on each system during each year, including sufficient generation reserve capability (based on the system's capacity planning criteria) to address unplanned outages.
- **Energy requirement** planning focuses on the number of kilowatt hours (kW.h) of electricity that are required to be generated on each system.

The Resource Plan reviews WAF and MD system capability to supply loads today and into the future under various time horizons, industrial load development scenarios, and resource supply options.

- **Immediate need for new WAF generation capacity:** Forecast load growth, pending retirement (absent substantial Life Extension investment) of three Mirrlees diesel units (11.4 MW) located in YEC's Whitehorse diesel plant, and new capacity criteria adopted by Yukon Energy together create an immediate need for new WAF generation capacity to serve peak winter load requirements in the near term through to 2012.
- **Potential new mines prior to 2009:** Potential new industrial developments prior to 2009 at the Minto and Carmacks Copper mines may also absorb the WAF hydro energy surplus, support transmission extension of the WAF grid from Carmacks to at least Pelly Crossing, and create opportunity to interconnect the WAF and MD grids.
- **Diverse range of other possible industrial development scenarios and opportunities**: Planning activities to proceed with other energy-focused generation projects beyond 2009 and before 2016 are being driven by the potential needs of a diverse range of possible industrial development scenarios and opportunities, including various possible mines and the Alaska Highway Natural Gas Pipeline project.
- **Potential supply resource options for a construction start within the next 10 years**: Supply resource options potentially relevant for a construction start within the next 10 years vary widely depending on the potential industrial developments considered, and include a range of different hydro and diesel generation possibilities as well as transmission, and possibly coal and/or natural gas-fired generation.
- **Balance required**: Readiness and timing to supply new major industrial loads needs to be balanced with understanding of the long predevelopment timelines and considerable costs, uncertainties and risks associated with planning specific power resource options.

Varying levels of technical and costing assessments have been carried out to screen options, including in some instances investigations advanced to the project feasibility stage. The Resource Plan process identifies preferred projects for which YEC can then commit when appropriate to proceed with more detailed project-specific pre-decision planning.

This Submission includes near term projects at different stages of pre-decision planning. No final decision has yet been made to implement these projects. In some instances, environmental approvals have already been secured - in other instances, however, the necessary applications for such approvals have yet to be made. Final design, costing and tendering tend to be a final stage to be carried out prior to final Yukon Energy decisions to proceed with construction/implementation.

NEW CAPACITY CRITERIA

After an extensive review of its system capacity planning criteria, Yukon Energy has adopted new capacity planning criteria. System capacity planning criteria are the sets of rules used to determine how much generation is required on the various Yukon systems and when additions to generation capacity are required.[1]

Background on Evolution of Capacity Planning

Planning of a utility system must provide both for system growth and for operation after a component failure. Utility systems across North America vary greatly in size and complexity but the ability of each system to maintain service is compared by using established and recognized criteria.

The criteria used by the Northern Canada Power Commission (NCPC) prior to 1987 were developed to indicate the amount of firm generating capacity required to cover relatively small isolated systems, and were consistent with utility planning standards of that era. NCPC had started with a multiple of small isolated systems, some of which continued, but others had grown to the point where multiple sources were interconnected.

Yukon Energy (and its then manager, YECL), as the operator succeeding NCPC for the Yukon, initially followed the practice of NCPC. It was quickly found that the continuing small isolated installations were reasonably covered by the NCPC criteria but that the larger systems with multiple sources needed more detailed analysis to be secure:

- The small systems were considered to be adequately protected if the generating capacity with the largest single unit out of service was at least 110% of the anticipated peak load.
- For the larger "grid" systems, it became necessary to consider not only the possible loss of a single generator (in the case of WAF, a single "wheel" at Aishihik), but also the likelihood that at least one of the major WAF diesels would be unavailable at the same time. Consequently, the Resource Plan in 1992 introduced recognition of the diesel-related effect on Yukon Energy's ability to serve any particular WAF load by adding a "10% of installed diesel" reserve on top of the Aishihik hydro reserve.

Under the original NCPC capacity planning criteria and the capacity planning criteria reviewed in the 1992 Resource Plan, the transmission system availability was not taken into consideration.

[1] For the purposes of system planning, all "firm" customer load requirements at the time of system maximum load or peak (e.g., winter peak on WAF) are considered when assessing each system's capacity planning requirements. Yukon Energy's policy requires that secondary energy service be interrupted when surplus hydro resources are not available, and therefore no bulk electrical supply capabilities are planned to supply secondary energy service.

In contrast to these earlier Yukon capacity planning criteria, integrated utilities today typically use a statistical approach to evaluate the potential interruption of service for any customer. This is often evaluated as the Loss of Load Expectation (LOLE) and it is measured in hours per year[2]. Most Canadian utilities apply an LOLE range from one to two hours per year as their capacity planning criteria standard. Further, where relevant, certain utilities today have incorporated transmission into this probability assessment when generation reliability is directly and materially affected by transmission.

Certain utilities have also adopted additional tests along with the LOLE criteria. For example, recently the Northwest Territories Power Corporation (NWT Power Corporation) has incorporated into its system capacity planning criteria a second test which is applied in parallel with LOLE criteria to ensure that customers are protected against failure of any single system component.

In summary, throughout various integrated utilities it is apparent that capacity planning criteria have evolved gradually into more defined ratios as systems have grown larger and more complicated. Furthermore, where relevant, transmission reliability is also being addressed today where it directly affects generation reliability.

Recent Yukon Energy Review of Capacity Planning Criteria

Yukon Energy recently completed an extensive review of its capacity planning criteria and, amongst other things, has examined the LOLE approach, testing it against the operating history of its WAF system. This review was undertaken in consultation with reliability experts from the University of Saskatchewan (under the direction of Dr. Roy Billinton[3]). Dr Billinton and his colleague were retained in late 2004 to review Yukon Energy's then established capacity planning criteria (i.e., the criteria as reviewed in the 1992 Resource Plan), including studying and determining the probabilities inherent in that criteria.

In contrast with statistical approaches such as LOLE, Yukon Energy's capacity criteria reviewed in the 1992 Resource Plan are "deterministic" in that a specific test was adopted for each system as a proxy intended to ensure adequate capacity. Yukon's criteria dealt with the concept of a "reserve" rather than actually assessing the likelihood (or probability) that the generation available will be insufficient to supply the load at any given point in time. Without reference to a specific probability of interruption, the adequacy of Yukon Energy's capacity criteria as reviewed in the 1992 Resource Plan cannot be readily compared today with criteria adopted in other jurisdictions for integrated systems.

[2] Other terms are also used to describe the probabilistic measures, such as the BC Hydro criteria of Loss of Load Probability (LOLP) or Newfoundland and Labrador Hydro's Loss of Load Hours (LOLH).

[3] The same experts advised NWT Power Corporation in the development of the Snare-Yellowknife system planning criteria which criteria received approval from NWT Power Corporation and its regulator in 2004.

The recent work by Dr. Billinton addressed this issue with regard to WAF. It indicated that Yukon Energy's capacity criteria as reviewed in the 1992 Resource Plan provided excellent capacity reliability, based on LOLE, for residential and commercial WAF customers in 1996/97 when the Faro mine was operating. Today, however, in terms of the maximum peak load that can be supported, Dr. Billinton's work indicated that WAF generation is not adequate to supply the peak allowed under that same criteria within any reasonable LOLE reliability standard adopted elsewhere in Canada. The primary reasons for this conclusion are that the WAF system has substantial hydro generation availability that is directly affected by certain transmission, and further that the WAF system also has been trending to an increasing probability of longer outages as it expands (particularly with expansion of residential and commercial loads and major reductions in industrial load).

As a result of this recent review, Yukon Energy has now incorporated the LOLE approach, with recognition of transmission reliability where relevant, into its system planning criteria to better protect all of its firm customers from generation-related outages.

At the same time, Yukon Energy has recognized that the LOLE function is an average that does not indicate how long any particular outage will last, and that any extended outage on WAF or the Mayo Dawson grid during the winter peak could be extremely serious for affected residential and commercial customers. Yukon Energy has addressed this concern by incorporating a second test as part of its capacity planning criteria, known as the N-1 standard[4] which ensures sufficient system capability to continue to serve firm residential and commercial customers when a failure occurs to the single largest system component. As an example, the biggest loss of generation on WAF today at winter peak would be 30 MW following a failure of the Aishihik transmission line; this loss would be far greater than the loss during winter peak of the biggest generator (which currently is a 15 MW generator at Aishihik).[5]

New Capacity Planning Criteria

The following new capacity planning criteria have been adopted by Yukon Energy:

1. **WAF and MD System-wide capacity planning criteria:** Each grid system (WAF and MD) will be planned not to exceed a Loss of Load Expectation (or LOLE) of 2 hours/year.
2. **Emergency (or "N-1") WAF and MD system capacity planning criteria:** Each grid system

[4] A test described as "surviving the first failure" or "operating in the N-1 condition where "N" is the normal system complement.

[5] The largest single unit on the WAF system today is WH 4, one of the hydro units at Whitehorse. However, as Whitehorse has 4 hydro units (WH1 at 5.8 MW, WH2 at 5.8 MW, WH3 at 8.4 MW and WH4 at 20 MW), but only 24 MW of firm flows in winter in drought conditions, a loss of WH4 would only effectively reduce the available capacity by 4 MW (as the other 3 units would still be available); this loss at winter peak would therefore be smaller than the loss of 15 MW via one of the units at Aishihik.

(WAF and MD) will be planned to be able to carry the forecast peak winter loads (excluding major industrial loads) under the largest single contingency (known as "N-1"). The N-1 criterion determines system capacity assuming the loss of the system's single largest generating or transmission-related generation source.

3. **WAF and MD "community" criteria:** For communities on the WAF or MD grids, any location with a load large enough to justify a diesel unit of about 1 MW or more will be considered as a preferred location for new diesel units if that community does not already have back-up from another source (e.g., having an existing diesel unit). The new diesel units would provide grid support, and in times of line failures would provide local generation for the communities where they are located.

For isolated diesel communities no change has been made for the capacity planning criteria (Yukon Energy will maintain the past criteria of being able to meet 110% of the community peak with the largest unit out of service).

PROPOSED NEAR TERM ACTIONS

Four separate major investments are proposed for Yukon Energy generation and transmission commitment before 2009, three with anticipated costs of $3 million or more. These proposed major projects will address near term requirements and opportunities to 2012 and together will provide over 21 MW of new WAF firm winter capacity by 2012 (i.e., enough new firm capacity to meet WAF capacity shortfalls that would otherwise be expected by 2012 of 18.7 MW under the Base Case forecast and 21.5 MW under the Base Case forecasts plus the Minto and Carmacks Copper mine loads). The four major proposed projects are reviewed below, along with contingency provisions and other proposed actions before 2012:

1. **Aishihik 3rd Turbine Project:** This project, which was initially reviewed in the 1992 YUB Resource Plan hearing, will provide 7 MW of added peaking capability[6] and about 5.4 GW.h/yr of long-term average hydro energy supply at the existing Aishihik generation station at a capital cost of about $7 million (2005$). Under Base Case loads without any new industrial developments, this project is expected to be economic within the planning period to 2025 based solely on its diesel operating cost saving benefits for the WAF grid, including displacement of peaking and then baseload diesel as WAF loads increase. Yukon Territorial Water Board and environmental approvals for the project were received in the new Aishihik Water Licence.
    a) Accordingly, this project will proceed with final planning activities to enable a final decision during 2007 to start construction for in-service by October 2009.

[6] Without twinning of the Aishihik Transmission Line, none of this added Aishihik capacity is recognized under the N-1 WAF capacity planning criteria, and only 0.6 MW is recognized under the LOLE WAF capacity planning criteria.

b) If Marsh Lake Fall/Winter Storage is developed without any additional non-industrial load growth or new industrial loads emerging, the final decision to start construction is proposed to be deferred until late 2009 for in-service in 2011 or 2012.

2. **Marsh Lake Fall / Winter Storage licence revision:** This project, which was not reviewed in the 1992 Resource Plan hearing, will increase the firm winter capacity of the Whitehorse Rapids hydro facility by about 1.6 MW and increase long-term average hydro energy from this facility by about 7.7 GW.h/year at a capital cost of no more than $1 million.[7] Yukon Energy will undertake the project planning activities, including consultation and environmental licensing, as required to seek amendment of the Whitehorse Rapids water licence to enable modified operation of Marsh Lake within its current lake levels to enhance fall/winter storage. Basically no new physical works are expected to be required for this project. Project approval is forecast by August 2007 (although provision is made in the event that the new Yukon environmental licencing regime requirements delays completion of the licence amendment to 2008). The effects of the proposed licence amendment are summarized as follows:
   a) **Remain within current lake level limits:** In all cases, the water levels with the amended licence will remain within the lake level limits currently experienced (i.e., the peak controlled level would be below the natural high water levels experienced in the lake).
   b) **Licence amendment changes the "controlled maximum" level:** The proposed amendment would change the licenced "controlled maximum" level that YEC can maintain upwards by about 1 foot; however, during uncontrolled periods of summer and fall (when YEC currently has no control over the lake and it is operating under an entirely natural regime), Marsh Lake has been known to peak at 2 feet above the YEC "controlled maximum" level. The effects of the proposed change are as follows depending on water conditions:
      i. **Non flood year operation other than a drought:** This project would allow Yukon Energy to reduce the amount of water it releases in non-flood years from August 15 to the end of September, to allow that water to be used instead during the peak winter generation period. No effect is to occur under these conditions in any year prior to August 15, other than under drought conditions (see below).
      ii. **Flood year operation:** During flood years, there would be no change in the flood levels experienced on Marsh Lake, and no change to operations would be made during August and September until after flood levels subside.
      iii. **During drought years:** Current licence provisions to help alleviate summer drought levels on Marsh Lake through "early closures" of the Lewes Dam would

7 This estimated capital cost is made up of the costs for licencing, any required mitigation works and any potential facility modifications.

remain, and would likely be adapted to alleviate further summer drought conditions to ensure the lake reached the full supply capacity level in each year.

3. **Carmacks-Stewart Transmission Line Project:** This project will fully interconnect the MD and WAF grids as well as facilitate WAF transmission access to potential new mine loads at Minto and Carmacks Copper, providing 5.6 MW of additional firm near term capacity and 15 GW.h/year of additional near term energy for WAF[8]. Development of this project, which is estimated to cost about $35 million (2005$), is subject to provision of Yukon Government funding to ensure that there is no net cost to Yukon Energy or Yukon ratepayers beyond what would be required for any other option to provide required capacity and energy. Based on external funding to assure no adverse impact on ratepayers from project development, planning activities will proceed with the Carmacks-Stewart project to enable a decision to proceed with construction early in 2007 for an in-service date in approximately late 2008.

4. **Mirrlees Life Extension Project**: Subject to confirmation of technical feasibility that is expected to be determined within the first quarter of 2006, the Mirrlees Life Extension Project will conclude final planning activities in 2006 in order to provide in-service during 2007 through to 2009 to provide an additional 14 MW of firm WAF winter capacity at a cost of up to $4.5 million (2005$).
    a) **First Mirrlees unit in service by October 2007:** By the summer of 2006 planning work and commitments for construction/implementation will begin on the first Mirrlees unit (5 MW) at a cost of up to $2.5 million (2005$)[9] in order that in-service will occur before October 2007.
    b) **Other two Mirrlees units by October 2008 and 2009**: Life Extension for the other two Mirrlees units will proceed thereafter for expected in-service in 2008 and 2009, subject to review of the experience gained from Life Extension of the first unit and the possible Yukon Energy consideration of replacing the third Mirrlees unit (4 MW) with a larger capacity new diesel unit (e.g., 8 MW or 11 MW unit).[10]

[8] Added capacity and energy supplied to WAF by this interconnection are subject to MD loads, and will decline as MD loads increase. Reopening of the UKHM mine or other new industrial developments on MD, for example, would reduce MD surplus capacity and hydro energy available to WAF. In contrast, potential additional enhancements at the existing Mayo hydro facility or other new generation opportunities in the MD area could enhance overall WAF/MD power supply in the event of Carmacks-Stewart Transmission line development.

[9] This cost includes a "teardown" level of overhaul and the common diesel plant upgrade work necessary to undertake the Mirrrlees Life Extension Project.

[10] In the event that Mirrlees Life Extension proceeds but the Carmacks-Stewart Transmission Line is not developed in the near term, replacing the third Mirrlees unit with an 11 MW new diesel would more than replace the capacity that otherwise would have been provided by the Carmacks-Stewart Transmission Project.

5. **If Mirrlees Life Extension is not technically feasible, implement diesel replacement/expansion and/or other project options as appropriate:** Without the Mirrlees Life Extension option providing 14 MW of firm capacity, the key near term choice is between the option involving Whitehorse Diesel Replacement/Expansion (capability for three units with combined capacity of up to at least 33 MW) versus the Aishihik 2nd Transmission Line (providing 22 MW under N-1 criteria and about 14.4 MW with LOLE criteria).[11]

   Although the expected capacity shortfall can technically be met with the Aishihik-related option, this is not expected to be the lowest cost option to 2012 under Base Case loads and also this is not the lowest cost long-term option under higher loads including mines. The Aishihik-related option also exposes the WAF grid to near term and growing capacity shortfalls until it is completed.

   Accordingly, the Diesel Replacement/Expansion option will be implemented as follows in the event that Mirrlees Life Extension is not technically feasible[12]:

   a) **Base Case Loads**: **First Diesel Unit (8 to 11 MW) needs to be installed by October 2007:** Yukon Energy will need under these circumstances to proceed with final planning work on this project by summer 2006, including orders for the necessary engine unit (with cancellation provisions) in order that the unit can be installed by October 2007 at a capital cost (2005$) of up to about $7.2 million (8 MW) or $8.8 million (11 MW). This will include updating any common diesel plant systems necessary for connection of a new unit.
   b) **Other Diesel Units**: Once the first unit is committed, it is expected that up to two additional diesel units (depending on the unit size selected) will be implemented thereafter as required for in-service before 2012.

6. **Ongoing monitoring of existing customer load forecasts and new industrial development opportunities:** In order to facilitate ongoing assessment of generation and transmission options and requirements, Yukon Energy monitoring of annual customer class load trends (peak capacity and seasonal energy) on each grid is required. In addition, Yukon Energy will continue to monitor directly with developers and government specific new industrial

[11] In this context, the Aishihik-related option has been examined for possible implementation assuming that it is feasible to commit development of the Aishihik 2nd Transmission Line by 2009 at the latest; under this option, material near term capacity shortfalls would still occur until the Aishihik 2nd Transmission Line was in service.

[12] Diesel Replacement/Enhancement will also be the option pursued as required in the event that other major projects do not proceed as proposed, e.g., the Carmacks-Stewart Transmission Line Project (which is assumed to provide 5.6 MW by late 2008) and/or the Marsh Lake Fall/Winter Storage (which is assumed to provide 1.6 MW by fall 2007 or 2008). In the event that mine loads are connected to WAF without completion of the Carmacks-Stewart Transmission, Yukon Energy will review the feasibility of the Aishihik 2nd Transmission Line project.

development opportunities for grid power service, including assessment of any mine site power contribution to the supply of reliable grid peak capacity.

7. **Other Small Enhancement Projects:** Continued routine utility investment is recommended in assessing and proceeding with projects to enhance existing facilities at a cost less than $3 million. This includes:

    - study of the hydrology of the Southern Lakes, and potentially pursuing small water control structures in this region (new generating stations to manage water plus generate hydro power would, if proposed in the future, exceed $3 million);
    - continued pursuit of opportunities to cost-effectively rewind or re-runner existing hydro generating units at Whitehorse and Aishihik; and,
    - assessing need and timing for a potential 1 MW diesel unit installation at Carcross/Tagish (likely by YECL).

PROPOSED ACTIONS RELATING TO INDUSTRIAL DEVELOPMENT SCENARIOS AND OPPORTUNITIES

Yukon Energy proposes planning activities as set out below to address a wide range of potential industrial development scenarios beyond the near term, and to protect future opportunities to commit development of additional generation and transmission projects before 2016 in a timely and cost-effective way in the event that one or more of these industrial development scenarios materialize.

Planning activities are organized by industrial development load scenario, identifying proposals as to how to approach each load scenario should it arise. “Pre-commitment” activities are also addressed which encompass planning activities Yukon Energy proposes to carry out prior to any certainty or commitment on the part of potential new industrial loads.

Proposed Activities Regarding Scenario 1: A 10 MW WAF Industrial Scenario

This industrial development scenario (which provides for near term development and operation between 2007 and 2018 of the Minto and Carmacks Copper mines) supports commitment of modest existing hydro enhancements, but does not support commitment of any new hydro site development before 2016 unless mine loads of at least 10 MW are sustained well beyond 2016. Consideration of the smallest hydro site options (1-4 MW) could potentially be supported in the event that 10 MW mine load development extends through to at least 2020. In this context, the following planning activities are recommended in the event these mine loads are seriously being considered for development prior to 2016:

- **WAF hydro system enhancements:** If not already committed pursuant to Chapter 4 near-term recommendations, planning should then proceed to commit the Aishihik 3rd Turbine, the

Marsh Lake Fall/Winter Storage and any other feasible existing hydro enhancements indicated to date by the Aishihik Diversion assessments, the Southern Lakes hydrology work, and existing WAF hydro plant upgrade assessments.

  - If not already committed, Aishihik Diversions and Atlin Storage should then be advanced to Level 2 studies, including system-wide water and load dispatch modeling, to quantify the energy benefits under this scenario.
  - Ongoing assessment of the Southern Lakes should be completed to identify additional water control or small hydro opportunities to enhance Whitehorse Rapids output.

- **Mayo hydro system enhancements:** If the Carmacks to Stewart transmission line is developed to interconnect the WAF and MD grids, assess and develop as appropriate feasible enhancements at the existing Mayo hydro facility, including enhanced peaking capability.
- **New WAF hydro site development:** If industrial and overall load development commitment is such that both new capacity and baseload diesel generation energy are required through to at least 2020 (and there is no clear indication of more major industrial development scenarios emerging during the 20 year planning period), planning activities should be carried out to enable commitment of a very small hydro site development (1-4 MW, 5-30 GW.h/year) [13] able to provide new capacity and displace diesel energy.
  - Based on current information, this would indicate that the hydro site at Drury should at that time be advanced to full Level 3 studies that include consideration of variations that maximize capacity.
  - Possible consideration might also be given to Level 2 studies for Squanga as a utility project or IPP, and/or for Morley, as potential alternatives for comparison to Drury.
  - Consideration must include means to mitigate downside risks should industrial loads close prematurely.
  - Actual development in each or these cases will involve investments greater than $3 million, or long-term contract commitments in excess of $3 million present value to IPPs, and therefore YUB review will be sought prior to project commitment.
- **Other activities re: DSM:** If loads of this scale and duration develop, further consideration will be given to DSM programming focused primarily on reduction of system peak demand.

Proposed Activities Regarding Scenario 2: A 25 MW WAF Industrial Scenario

If industrial loads are committed on WAF before 2016 for development of more than 10 MW (70 GW.h/year) but less than about 20-25 MW (comparable to the Faro mine) for a period through to at least 2025, planning activities should be carried out to enable commitment before 2016 to develop new hydro site resources to provide approximately 50 GW.h per year to WAF.

[13] Present estimates of the costs are $12-$47 million generation capital cost (2005$) with potential generation planning costs of $1.2-$4.7 million prior to a decision to proceed with construction.

For potential hydro projects, key options to be considered at such time as greater load certainty develops regarding this level and duration of industrial load are as follows:

- **WAF hydro system enhancements:** If not already committed pursuant to Chapter 4 near-term recommendations, planning should proceed to commit the Aishihik 3rd Turbine, the Marsh Lake Fall/Winter Storage and any other feasible existing hydro enhancements indicated to date by the Aishihik Diversion assessments, the Southern Lakes hydrology work, and existing WAF hydro plant upgrade assessments (see proposals for Scenario 1).
- **Mayo hydro system enhancements:** If the Carmacks to Stewart transmission is developed to interconnect the WAF and MD grids, assess and develop as appropriate feasible enhancements at the existing Mayo hydro facility (including any feasible enhanced peaking capability).
- **New hydro site development:** If industrial and overall load development commitment on WAF before 2016 is such that WAF baseload diesel generation energy of more than 10 MW (70 GW.h/year) is then required through to at least 2025, and there is no clear indication of more major industrial development scenarios establishing new WAF industrial loads in excess of about 20 MW (about 125 GW.h/year) emerging during the 20 year planning period and extending beyond 2025, planning activities should then be carried out to enable commitment of a small hydro site development (7-10 MW, about 50 GW.h/year[14]) able to provide diesel displacing energy to WAF.
  - New hydro options focused on Yukon-based projects, if available, would be the preference.
  - However, given limited attractive projects in this size range identified in Yukon to date, further Level 1 and 2 activity should be undertaken if timing permits in areas within 50 km of existing 138 kV WAF transmission focused initially on scans of the various inventory studies completed by NCPC or others.
  - Sites in BC, including Moon Lake and Tutshi[15], should have Level 2 studies updated in preparation for this possible load scenario, particularly focusing on the costs and risks associated with interprovincial licencing requirements and water rentals. Level 3 studies should then proceed if warranted.
- **Coal supply possibilities:** In the event that the loads of this scale develop and coal also becomes available from developed Yukon sources, coal generation technology should be reviewed in the event that timing permits to determine the potential for an economic and environmentally sound coal development at sizes below 20 MW, sized as appropriate to fit the industrial loads being developed at that time.

[14] Present estimates of the costs are $50-$100 million generation capital cost (2005$) with potential generation planning costs of $5-$10 million prior to a decision to proceed with construction.

[15] No further work should proceed on Surprise Lake so long as the community continues its plans to develop micro-hydro at the site.

- **Other activities re: DSM and wind:** If loads of this scale and duration develop, further consideration will be given to DSM programming focused on both the reduction of system peak demand and energy conservation, and development of new wind generation (if attractive sites near established utility grids can be identified).

Actual development of new hydro sites (or any other new generation site) in each case will involve investments greater than $3 million, so YUB review will be sought prior to project commitment. In addition, for larger scale developments, planning and feasibility work may exceed the $3 million level, so there is the potential for YUB review at this earlier stage as well.

Proposed Activities Regarding Scenario 3: A 40 MW WAF Industrial Scenario

If industrial loads are committed on WAF before 2016 of more than about 20-25 MW (150 or more GW.h/year) for a period through to at least 2030, resulting in forecast baseload WAF diesel generation energy of more than about 150 GW.h/year to be required until at least 2030, then planning activities can reasonably proceed to consider commitments before 2016 to develop new hydro site or coal generation resources of 20-30 MW to provide 130-150 GW.h per year of long-term energy (20 or more years) to WAF.

- **Load uncertainties and low probabilities today:** The industrial loads required to reach the above levels at this time involve significant uncertainties and low probabilities.
- **New medium scale hydro site development (20-30 MW, 130-150 GW.h/year):** The development of generation and transmission to serve these loads, based on currently identified potential hydro sites (Primrose and Finlayson), would involve substantial generation capital costs ($179-$191 million (2005$)), excluding transmission, as well as very large planning costs (about $20 million) prior to a decision to proceed with construction. Such costs are likely at or beyond the limits of YEC's current financial capabilities and involve material costs and risks related to investments in feasibility and planning long before final decisions to proceed can occur or plants brought on-line.
- **Coal supply thermal generation possibilities:** Coal resource options of this scale could involve far less capital than comparable new hydro sites, provided that coal supply as such was otherwise available from developed Yukon sources. The scale at 20 MW (144 GW.h/year[16]), however, is still very small for coal thermal technology and would require careful Level 2 and 3 screening and feasibility assessments to confirm its potential feasibility.

For potential generation projects related to the above scales, it is not apparent today that there is sufficient likelihood of this major development scenario arising to justify major investment at this time in planning and

[16] The present estimate of the costs are $ 61 million thermal plant capital cost (2005$), excluding transmission or coal resource development costs, with potential generation planning costs of $6 million or more prior to a decision to proceed with construction.

feasibility studies for medium new hydro or small coal plants. Accordingly, no specific planning activities are recommended at this time.

Coal options for thermal generation must be environmentally sound to be considered. The feasibility of coal generation will depend in part on the cost of employing state of the art technologies to reduce emissions, as well as on the availability of coal supply from developed Yukon sources and the occurrence of very large industrial mine developments that can be connected economically to the grids.

Future decisions with respect to the level of effort and expense in this area will reflect YEC's ongoing assessment of the probabilities of the required loads developing. For projects of this scale, even early planning and feasibility work (at least on hydro sites) will exceed the $3 million level, in which case YUB review will be sought before proceeding with specific planning commitments of $3 million or more.

Proposed Activities Regarding Scenario 4: A 120 to 360 MW WAF Pipeline Scenario

The Scenario 4 pipeline loads at this time involves significant uncertainties as regards timing and magnitudes. However, given the implications of this industrial development for all aspects of Yukon power utility activities, and its clear possibility to come into service within the 20-year period for the current Resource Plan, one key activity recommended for the near-term regarding Scenario 4 involves continued active monitoring of this development as well as active planning to identify and assess all potential related material impacts, options and opportunities, including:

- Power supply options for the pipeline for compression (focusing initially on short listing and assessing at Level 1 knowledge large scale hydro site options and related transmission requirements).
- More modest power supply opportunities focused on compressor station "station service" loads.
- Options to use natural gas for power generation to serve cost effectively other incremental industrial loads.

The development of generation and transmission to serve these pipeline loads is likely well beyond the limits of YEC's current financial capabilities, as well as involving material costs and risks related to investments in feasibility and planning long before final decisions to proceed can occur or plants brought on-line. Accordingly, prior to carrying out any planning activities beyond Level 1 assessment of any specific site or technology specific studies, it is proposed that Yukon Energy identify and assess options that would address this constraint, e.g., joint venturing with others, and/or options to secure external government or other financing.

Proposed "Pre-commitment" activities

Prior to any certainty developing regarding any specific industrial scenario that may arise, it is proposed that Yukon Energy remain focused on certain key planning activities to ensure protection of the options to address new load requirements. Yukon Energy proposes the following activities in this regard:

- **Monitoring of Industrial load developments:** Yukon Energy will continue to monitor closely potential load development and related spin-off residential and commercial impacts, including necessary discussions with mineral exploration companies active in Yukon, key officials in Yukon government working with mines and other industrial developments and relevant industry associations. Separately, YEC will maintain ongoing monitoring of potential Alaska Highway pipeline developments and factors that may impact electrical loads in Yukon (including potential for electrical compression).
- **Southern Lakes hydrology assessments:** Continued assessment and studies of the hydrology of the southern lakes area, including identification of potential for water control structures to enhance output of Whitehorse Rapids, as well as potential hydro generation sites.
- **Other existing hydro facility enhancements:** Continued focus on projects to enhance output of existing hydro generation facilities at Aishihik, Whitehorse and in certain cases, Mayo. This includes full Level 3 and 4 studies on the Aishihik 3rd turbine and updating Level 2 studies on Aishihik diversions. Where suitable, activities should be carried out in conjunction with other normal Supply Side Enhancement planning by Yukon Energy, such as re-runnering.
- **Level 1 and 2 assessments to identify preferred 5-30 MW scale Yukon hydro sites**: There is an option to invest in further surveying the potential of other Yukon based hydro generation sites to try to identify good sites in the 5-10 MW range (within about 50 km of existing high voltage transmission) and to advance credible candidates in the 5-30 MW range through Level 2 assessments (including ongoing monitoring of hydrology) in order to identify more clearly preferred sites to develop for possible loads within this range. However, this activity is costly and may require assessment of a number of sites. No activities in this regard are recommended today; however, in the event that at least one large industrial load (such as Red Mountain or Division Mountain) proceeds to advanced licencing and likely commitment stages, it is proposed that this initial work should proceed quickly to determine if the sites identified to date are indeed the best candidates or if there are other Yukon-based sites that should be seriously considered, and to identify specific projects for Level 3 feasibility assessments.
- **Ongoing monitoring of hydrology**: Active hydrology monitoring will proceed where feasible for all hydro sites likely to be serious candidates for future development within the 20 year planning period. The monitoring may be periodic (seasonal flow information, current cost of $1,000 per year per site) up to a full-time recording station (at a current cost of $30,000 (initial costs) plus ongoing costs of between $10,000 to $15,000 per year).

TABLE OF CONTENTS

CHAPTER 1 - INTRODUCTION

1.0 INTRODUCTION 1-1
1.1 PURPOSE OF THE SUBMISSION 1-1
1.2 SCOPE OF SUBMISSION 1-2
1.3 RESOURCE PLANNING FRAMEWORK 1-3
1.3.1 Power Capacity and Energy in Yukon 1-4
1.3.2 Basic Planning Process 1-6
1.3.3 Resource Plan and Specific Capital Project Decisions 1-8
1.4 CURRENT YUKON SITUATION COMPARED WITH 1992 1-9
1.5 SUBMISSION OVERVIEW 1-13

CHAPTER 2 – BACKGROUND ON YUKON POWER SYSTEMS

2.0 BACKGROUND ON YUKON POWER SYSTEMS 2-1
2.1 OVERVIEW OF GENERATION FACILITIES AND TRANSMISSION IN YUKON 2-1
2.1.1 Generation in Yukon 2-3
2.1.2 Transmission in Yukon 2-7
2.2 OUTCOMES FROM THE 1992 REVIEW 2-8
2.3 MAJOR EVENTS AFFECTING POWER SYSTEMS SINCE 1992 2-13
2.3.1 Closure of the Faro Mine 2-13
2.3.2 The Growth of Secondary Sales 2-14
2.3.3 Shift to Direct Management 2-14
2.3.4 Whitehorse Rapids Generating Station Fire Rebuilding Project 2-15
2.3.5 Renewal of Water Licences at Whitehorse, Mayo and Aishihik 2-15
2.3.6 Mayo-Dawson Transmission Line 2-16
2.3.7 System Upgrades and Changes 2-17
2.4 BULK ELECTRICAL SUPPLY PLANNING SINCE 1992 2-17
2.4.1 Ongoing Yukon Energy Infrastructure Planning Process 2-18
2.4.2 BC Hydro Inventory of Potential Future Hydro Supply Options 2-18
2.4.3 Bulk Electrical Supply Infrastructure Condition Assessment Work 2-18
2.4.4 Generation Capacity Planning Criteria Review 2-18
2.4.5 Demand Side Management and the Energy Solutions Centre 2-19

CHAPTER 3 – SYSTEM CAPABILITY

3.0 SYSTEM CAPABILITY 3-1
3.1 CURRENT FACILITIES CONDITION ASSESSMENT 3-1
3.1.1 Yukon Energy's Response to Condition Assessments 3-2
3.1.2 Condition Assessment Findings Relevant to Resource Planning 3-5

3.2 CAPACITY AND ENERGY OUTPUT OF EXISTING FACILITIES 3-6
3.2.1 Whitehorse Rapids Hydro Firm Capacity 3-7
3.2.2 Aishihik Hydro Capacity and Energy 3-9
3.2.3 Mayo Hydro Capacity 3-10
3.2.4 Whitehorse Diesel Capacity 3-10
3.2.5 Fish Lake Hydro (YECL) Capacity 3-11
3.3 CAPACITY PLANNING CRITERIA REVIEW 3-11
3.3.1 Background and Overview on the Evolution of Capacity Planning 3-12
3.3.2 Yukon Energy's Previous Capacity Planning Criteria (prior to late 2005) 3-14
3.3.3 Previous Yukon Criteria Compared with Criteria for Other Jurisdictions 3-17
3.3.4 New Criteria Adopted by Yukon Energy 3-20
3.3.5 Rationale for Adopting a Two-Part Criteria on WAF and MD 3-21
3.3.6 Implications of the Adopted Criteria 3-23
3.4 SUMMARY: REVISED CAPACITY PLANNING CRITERIA 3-25

CHAPTER 4 – NEAR TERM REQUIREMENTS

4.0 NEAR TERM REQUIREMENTS 4-1
4.1 PLANNING APPROACH AND TIMELINE 4-1
4.2 REQUIREMENTS 4-3
4.2.1 Basis for Non-Industrial Load Forecasts 4-4
4.2.2 Basis for Near Term Industrial Load Forecasts 4-7
4.2.3 Near Term WAF Load –
Cases Analyzed Based on Non-Industrial and Industrial Requirements 4-7
4.2.4 Base Case Requirements 4-8
4.2.5 Low Sensitivity Case 4-10
4.2.6 Base Case with Mine Loads 4-12
4.2.7 High Sensitivity Case Including Mines 4-14
4.3 OPTIONS 4-16
4.3.1 Overview of "Opportunity" Project Options 4-17
4.3.2 Aishihik 3rd Turbine 4-19
4.3.3 Marsh Lake Fall/Winter Storage 4-20

1.0 INTRODUCTION

Yukon Energy Corporation's ("YEC" or "Yukon Energy") 20-Year Resource Plan Submission addresses major generation and transmission requirements in Yukon during the period 2006 to 2025. The last Resource Plan, which was submitted for review by the Yukon Utilities Board ("YUB") in 1992, covered 1992-2001 and was prepared by YEC and Yukon Electrical Company Limited ("YECL").

This chapter sets out the purpose, scope, framework, and approach and outline of the 20-Year Resource Plan Submission. The sections for this chapter are as follows:

- Section 1.1: Purpose of the Submission
- Section 1.2: Scope of the Submission
- Section 1.3: Resource Planning Framework
- Section 1.4: Current Yukon Situation Compared with 1992
- Section 1.5: Submission Overview

1.1 PURPOSE OF THE SUBMISSION

The Resource Plan Submission provides Yukon Energy's 20-Year Resource Plan with respect to major electrical generation and transmission requirements during the 2006 to 2025 period, with emphasis on:

a) near term projects that will require YEC commitments before the year 2009 with costs of $3 million or more, and
b) planning activities that YEC may be required to carry out in order to start construction on other projects before 2016 to meet the needs of potential major industrial customers or other major potential developments in Yukon.

Yukon Energy is committed to seek YUB review, prior to construction, of any new capital project costing $3 million or more. Yukon Energy's December 2004 Application to the YUB regarding 2005 Required Revenues and Related Matters also committed Yukon Energy to bring forward to the YUB new or revised capacity planning criteria in advance of capital investment in new generation for capacity reasons. Accordingly, the 20-Year Resource Plan Submission is expected to provide the YUB with the opportunity to review near term generation or transmission projects costing $3 million or more, including projects that are required based on revised capacity planning criteria now adopted by Yukon Energy.

The Submission also proposes Yukon Energy planning activities within the next 10 years to protect YEC's ability to start construction on other major generation and transmission projects before 2016 to meet the

needs of potential major industrial development opportunities. In some circumstances, to identify and protect power resource options related to industrial development opportunities, some of these planning commitments will need to be made on some form of contingent basis in advance of resolving various major uncertainties.

1.2 SCOPE OF SUBMISSION

The planning and development of new transmission and generation projects requires a forward looking perspective regarding major objectives, options, policies and planning activities. The Resource Plan Submission identifies generation and transmission issues and options facing Yukon Energy in both the near term (i.e., prior to 2009), and within the next 10 to 20 years. The Submission also provides an overview of the development and composition of Yukon's power systems; an update on Yukon Energy's capital planning process since the last Resource Plan submitted in 1992; and the context today for bulk electrical supply ("BES") planning by Yukon Energy.

With regard to near term generation and transmission projects of $3 million or more included in the Plan for construction start within the next three years (i.e., by 2009), Yukon Energy has examined:

- the necessity of the proposed spending commitments, their expected effects on overall utility costs and electricity rates, and (to the extent currently known) their physical and engineering characteristics and their economic consequences;
- the capability and condition of existing generation and transmission facilities, taking into account appropriate capacity planning criteria;
- forecast load requirements for electricity and the need for spending commitments to meet these forecast requirements;
- all reasonable alternative near term options and developed proposals based on reasonable grounds; and
- the potential risks of each option.

During the planning process, Yukon Energy reviewed the studies and activities that have taken place before and after 1992. Major initiatives carried out in the past few years include a review the condition of existing assets, and an examination of the adequacy of the current capacity planning criteria. Additional technical project-specific feasibility or planning studies have generally not been carried out since 1992, beyond developments actually undertaken such as the Mayo Dawson Transmission Line Project. Yukon Energy also completed an initial review of a potential Carmacks-Stewart Transmission

Line in 2002; a review of a potential Atlin Transmission Line in 2003; and a Small Hydro Assessment in 2004.

Major near term projects addressed in the Submission for construction start prior to 2009 are the result of the adoption in late 2005 of revised capacity planning criteria. Studies are ongoing with regard to leading near term major project options. The Submission proceeds on the basis of current information regarding these near term options, setting out the conditions relevant to proceeding with any specific option. Updates will be provided during the review of the Submission to the extent that relevant new information is forthcoming from ongoing studies on these projects.

Longer term opportunities addressed in the Submission are contingent on the extent to which new industrial developments do in fact move forward during the next 10 to 20 years. The Submission identifies representative scenarios related to possible future industrial development, and the planning activities appropriate for Yukon Energy to identify and protect relevant generation and transmission options that may need to be developed with respect to these scenarios.

1.3 RESOURCE PLANNING FRAMEWORK

In Yukon, electric power resource planning focuses separately on each electric power system. The Whitehorse-Aishihik-Faro ("WAF") grid, and the Mayo-Dawson ("MD") grid are typically planned as separate systems, as are each of the isolated diesel-served communities.

The basic electric power resource planning model addresses separately each system's generation **capacity** (MW [megawatts], particularly at the time of system winter peak) and its **energy** generation kW.h or MW.h [kilowatt hours or megawatt hours] over the full year). An overview of power capacity and energy in Yukon is provided below (Section 1.3.1).

The basic resource planning process in the Submission is then reviewed (Section 1.3.2), including the following elements (in the following sequence) which the Submission examines separately as required for capacity and energy on both the WAF and MD systems:

1. **System Capability** – existing system capability over the next 20 years, based on the condition of existing facilities, firm capability of these facilities at the time of winter peak, and capacity planning criteria for each system that define generation capacity (MW) adequacy and load carrying capability;

2. **System Requirements** – capacity and energy requirements forecast over the next 20 years (and beyond) for each system in order to assess the loads that may need to be met under different industrial development scenarios;

3. **New Facility Requirements** – the capability of installed plant on each system over the next 20 years compared to forecast system requirements (to establish forecast requirements for new facilities under each load scenario);

4. **Options** – resource options to meet new facility requirements for each load scenario on each system;

5. **Assessment of Options** – resource options are assessed and/or screened, to the extent feasible today, based on consideration of technical feasibility (including timing), cost efficiency, reliability and risk.

1.3.1 Power Capacity and Energy in Yukon

As the main generator and transmitter of electrical power in the Yukon region, Yukon Energy focuses on serving and planning for the capacity and energy requirements of Yukoners, particularly those supplied on the WAF and MD grids. An overview of power capacity and energy in Yukon is provided below.

Capacity: The capacity requirement on a power system in any year is the highest or peak generation capability (MW) required during the year. This required capability reflects both the operating generation capability needed to serve the peak loads on the system (including provision for system losses over and above customer loads) plus the provision of sufficient generation reserve capability to address unplanned generation outages (based on the system's capacity planning criteria).

Capacity requirements on Yukon systems typically drive the need to develop a specific MW amount of new generation facilities within a certain time period. The type of generation selected, however, may depend on forecast energy requirements[1].

[1] Diesel generating units have low capital costs, and very high operating costs; accordingly, diesel units are typically well-suited to meeting capacity needs during system peaks and as reserve capacity, rather than being run to provide sustained energy on a regular basis throughout the year. Conversely, hydro generating plants have relatively high capital costs and very low operating costs; as a result, sustained operation of such facilities over an extended time period in a year can often yield lower unit costs for energy generation than would occur with diesel generation units.

In Yukon, the peak power requirement is typically in the winter. For example, during the winter of 2004/05, the WAF system peak occurred on Wednesday January 12th, 2005, when the temperature reached -44.5 degrees Celsius. The WAF system integrated hourly peak for generation on that day was 56.4 MW.

The capacity capability of generation facilities can vary depending on the time of year. For example, the winter peak in Yukon occurs on the WAF grid when the capability of the Whitehorse Hydro Plant is reduced due to lower water flows. For a hydro asset, the amount of electricity that the asset can generate is determined in part by the volume of water moving through the plant. The amount of water flowing through the Whitehorse Plant in the winter months under normal or low flow water regimes is typically lower than in the summer months. Accordingly, given that there is very little reservoir storage to retain water for the winter, the Whitehorse Plant firm capacity in the four coldest winter months (about 24 MW) is well below its peak capacity in the summer months (40 MW).

The capacity planning criteria applied on each Yukon system in the past, as reviewed and recommended by the YUB in 1992, in effect provide a requirement for "reserve generation capacity" equal to the capacity needed to meet forecast winter peak load with the loss of the single largest winter generation unit (on WAF, this is one 15 MW hydro unit at Aishihik) plus the loss of 10% of the installed diesel capacity[2]. In light of changes since 1992, it became timely to review the adequacy of the current capacity planning criteria for the WAF and MD systems.

Energy: The annual energy requirement on a power system is the number of kilowatt hours of electricity that are required to be generated.

Generation requirements are higher than the sales to customers as a result of system losses between the generation plant and the customers as well as generation station service power requirements. Yukon Energy must generate enough electricity to serve its load, and to account for the associated line and other system losses. Between 2000 and 2004, Yukon Energy's energy losses overall required generation averaging 8% more than YEC's sales to its customers.

Yukon's existing diesel generation facilities on each system typically are sufficient to provide a reliable supply of firm energy to meet system loads, even under low flow conditions for the hydro generation

[2] On isolated systems, this is worded so as to require the diesel plant installed, less the largest unit, to be 110% of the forecast peak.

facilities. The prime energy-related issue when assessing new facilities in Yukon therefore relates to the opportunity to displace diesel generation with less costly energy supply alternatives.

Energy requirements in Yukon may establish the economic opportunity for certain types of new generation or even transmission facilities. If sufficient energy is required on a sustained basis, past Yukon experience has shown that opportunities may emerge to develop new hydro or transmission facilities (with access to surplus or cost competitive hydro generation) to displace what would otherwise be served by diesel generation. These opportunities arise because hydro plants have relatively high capital costs and very low operating costs; as a result, sustained operation of such facilities over an extended time period in a year can often yield lower unit costs for energy generation than would occur with diesel generation units[3].

Current surplus hydro generation capability on both the WAF and MD systems limit opportunities today for developing new lower cost generation on these systems. The Resource Plan identifies the future growth conditions required before the current surplus hydro would be fully utilized and new opportunities may emerge to displace diesel generation on these systems.

1.3.2 Basic Planning Process

The basic planning process that Yukon Energy undertook to develop its 20 Year Resource Plan included the following elements:

1. **System Capability:** Existing system capability over the next 20 years was assessed, based on the condition of existing facilities, firm capability of these facilities at the time of winter peak, and capacity planning criteria for each system that define generation capacity (MW) adequacy and load carrying capability.
    a) **Condition assessments of existing facilities:** Yukon Energy commissioned assessments of its existing facilities to determine their condition and their remaining life. The prime focus for the Resource Plan from these assessments is the potential timing for retirement of any generation or transmission facilities during the next 20 years.

[3] Conversely, diesel units have low capital costs and very high operating costs; accordingly, diesel units are typically well-suited to meeting capacity needs during relatively brief system peak periods, rather than being run to provide sustained energy on a regular basis throughout the year. Diesel units, however, can be cost effective for sustained operation in many specific situations, e.g., Yukon experience demonstrates instances involving isolation from a grid and/or viable energy options, small scale of requirements, or short term time periods for requirements.

b) **Firm capability of existing facilities:** The ability of these facilities to provide capacity and energy was reviewed, particularly at system peak periods in winter. This included planned retirements and age-related derates.

c) **Capacity planning criteria review:** Capacity planning criteria were thoroughly reviewed for each system. These criteria establish the "reserve" capacity (MW) capability that must be planned over and above the capacity needed to supply forecast system winter peak load when each facility is operating at its respective capability (e.g., the reserve needed to cover reasonable contingencies regarding potential generation and transmission or BES unit failures). Yukon Energy has adopted revised capacity planning criteria as a result of this review.

2. **System Requirements Forecasts:** Capacity and energy requirements were forecast over the next 20 years (and beyond) for each system in order to assess the loads that may need to be met under different industrial development scenarios. For Yukon, a key historic driver has been opening and closing of major industrial loads (new or existing mines) and planning for each system must therefore address different industrial load scenarios. Generation and transmission are designed, built and operated on each system to provide reliable supply of both capacity and energy to meet forecast non-industrial and industrial requirements:

   a) **Capacity requirement forecasts:** These forecasts address the peak facility power requirements (MW) at the specific time of the system annual peak load in winter, including the provision of sufficient generation reserve capability to meet the capacity planning criteria.

   b) **Energy requirement forecasts:** These forecasts address the energy requirements (kW.h) over the full year; and, where relevant, seasonal energy requirements.

3. **Forecast New Facility Requirements:** The capability of installed plant on each system over the next 20 years was compared to forecast system requirements (to establish forecast requirements for new facilities under each load scenario):

   a) **New capacity requirements:** New capacity requirements reflect the extent to which forecast MW requirements at the time of system peak in winter (including provision to meet capacity planning criteria for reserve capability) exceed the forecast system capability of existing plant (i.e., reliable MW of capacity from what is installed today, less those units that are retired over time). Given the short duration of peak capacity needs in any year, capital cost minimization will typically be a key factor in selecting new facility options required solely to meet new capacity needs.

b) **New energy opportunities:** To the extent that such requirements affect the choice for new facilities, new energy requirements in Yukon typically reflect cost effective opportunities to displace either existing or new diesel fuel energy generation.

4. **Resource Options:** Supply side options to meet new capacity and/or energy requirements on each system include: enhancing existing generation facilities; extending the life of existing generation facilities; developing new generation plants (diesel, hydro, coal, wind, biomass, etc); and/or developing new transmission facilities connecting existing and/or new resources to load centres. Demand side options also exist, including conservation, load management, and customer efficiency improvements.

5. **Assessment of Resource Options:** Available options to meet new capacity and/or energy requirements on each system are assessed and/or screened based on consideration of technical feasibility (including timing), cost efficiency, reliability, and risk.

1.3.3 Resource Plan and Specific Capital Project Decisions

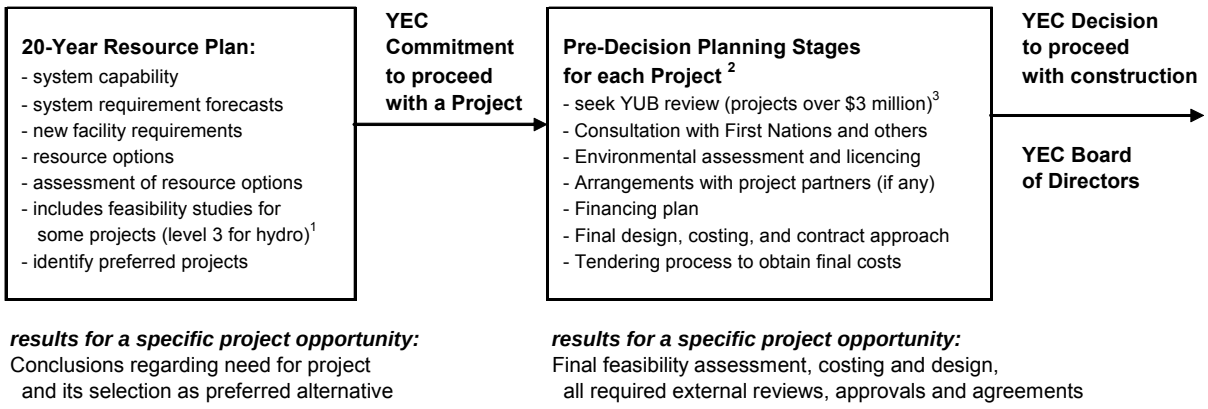
Figure 1.1: 20-Year Resource Plan and Decisions on Specific Projects reviews the relationship between the 20-Year Resource Plan process and activities leading to final Yukon Energy construction decisions on specific project opportunities identified by the Resource Plan.

The structure and framework of the 20-Year Resource Plan reflect overall broad capabilities and requirements for each system, options to fulfill requirements and/or capture opportunities identified for new facilities, and comparisons/assessments between the options. In assessing specific resource options under the Resource Plan, Yukon Energy carries out varying levels of technical and costing assessments to enable screening of options, including in some instances investigations advanced to the project feasibility stage. The Resource Plan process in this manner identifies preferred projects for which YEC can then commit to proceed with more detailed project-specific pre-decision planning.

Figure 1.1 identifies pre-decision planning stages that Yukon Energy carries out, as needed, for each preferred project identified by the Resource Plan process prior to any final decision to proceed with construction or implementation. Pre-decision planning for each project reflects specific requirements for that project, including anticipated regulatory review and/or approval needs, consultation requirements, any arrangements needed with other parties, final design and costing needs, and timing needs for bringing the project into service.

This Submission includes near term projects at different stages of pre-decision planning. No final decision has yet been made to implement these projects. In some instances, environmental approvals have already been secured – in other instances; however, the necessary applications for such approvals have yet to be made. Final design, costing and tendering tend to be a final stage to be carried out prior to final Yukon Energy decisions to proceed with construction/implementation.

Figure 1.1:
20-Year Resource Plan and Decisions on Specific Projects



1 - In large projects (e.g., over $30 million), project feasibility stages can exceed $3 million and YEC would then seek YUB review prior to commitment to these stages.
2 - For individual projects, these planning stages will proceed in different sequences and with different timing. For projects over $3 million,Yukon Energy is committed to seek YUB review prior to a decision by the YEC Board to proceed with construction.
3 - An OIC under the Yukon Utilities Act can direct the YUB to review a YEC submission on need and justification for a project and to report on its findings to the Commissioner in Executive Council. This type of YUB review would be separate and distinct from a normal YUB review of project rate base costs as required for a Yukon Energy revenue requirements and rate application.

1.4 CURRENT YUKON SITUATION COMPARED WITH 1992

The last Resource Plan that was submitted to the YUB in 1992 was filed jointly by Yukon Energy and Yukon Electrical Company Limited, and reflected a situation very different from that facing the Yukon today. At that time, the Faro mine was in operation, the WAF system was consuming significant diesel fuel throughout each year, and there were substantial uncertainties regarding the life of the Faro mine load (about 25 MW and up to 180 GWh/yr). The submission also covered the potential opening of new mines; extensive planning studies previously carried out on Demand Side Management ("DSM"); various hydro supply development options; and possible transmission developments. There were no projects being requested in the near term, and the applicability of nearly all projects hinged on which mine load "scenario" was going to arise, and the risks associated with the load. In the end, due to substantial

downside risk related to existing loads, the 1992 Resource Plan did not propose any near or long term projects for development.

The Yukon economy, and Yukon's electricity loads and systems have changed substantially since the 1992 review. Due to the closure of the Faro mine, no reopening of the United Keno Hill Mine ("UKHM"), and no new mines yet having emerged, there is currently a surplus of hydro energy available on the WAF and MD grids. Potential new industrial developments during the next several years may absorb the WAF hydro energy surplus. However, forecast load growth even without new industrial loads, pending retirement of existing diesel generation and the adoption of new capacity planning criteria indicate an immediate need in any event to provide new WAF generation capacity to serve winter peak load requirements even through the WAF hydro energy surplus could remain for most of the current 20 year planning period.

Beyond near term needs and opportunities, current planning issues must be addressed regarding other potential future major industrial loads and developments during the next 10 to 20 years, including the Alaska Highway Natural Gas Pipeline project. Potential industrial loads need to be considered, and the identification, definition and "protection" of appropriate resource options is required to ensure that Yukon Energy is able to meet new loads when relevant on a timely basis if and when they develop.

Supply side options potentially relevant for a construction start within the next 10 years vary widely depending on the potential industrial developments considered, and include a range of different hydro possibilities as well as coal-fired generation and potentially natural gas-fired generation.

Lead times required to plan, approve and develop major new power supply projects, as well as the material planning costs associated with pre-construction activities required to keep these options available on a timely basis, underline the relevance of the current Resource Plan review.

Yukon Energy has organized generation and transmission project options by different load situations and resource needs. As shown in *Figure 1.2 Load Situation, Resource Needs and Project Options*, the resource needs (capacity or energy) are the primary driver in evaluating the appropriateness of an option for a given scenario. New industrial loads of less than 10 MW typically give rise to capacity-focused options, while new industrial loads above 10 MW may create opportunities for energy-focused options,

driven in part by specific opportunities to enhance existing hydro systems and in part by Yukon Energy's revised capacity planning criteria. Changes in Yukon power systems, significant load growth in the Whitehorse area and the potential retirement of three diesel units at Whitehorse prompted a re-examination of these planning criteria. Yukon Energy believes that its revised criteria better reflect the Yukon electrical grids' reliability requirements today.

- **Potential near term major project options** include opportunities, projects and major capacity shortfall projects as noted in Figure 1.1. These near term project opportunities and options are examined in the context of a range of possible load situations (see Figure 1.2).
- **Opportunities projects** include enhancements to existing hydro facilities at Whitehorse and Aishihik as well as possible access to government infrastructure funding to develop a Transmission Line from Carmacks to Stewart Crossing connecting the WAF and MD systems.
- **Major capacity shortfall project options** address major new WAF system capacity needs in the context of current surplus hydro energy on both the WAF and MD systems.

As outlined in Figure 1.2, planning activities to proceed with other generation or transmission projects beyond 2009 and before 2016 are being driven by the potential needs of a diverse range of possible major industrial customers (such as various possible major new mines) or other major potential industrial developments (i.e., Alaska Highway Pipeline project), and the energy requirements and/or opportunities related to such industrial developments. The Submission examines these opportunities in the context of the different possible load situations outlined in Figure 1.2, the significant uncertainties associated with such load possibilities, and the lead times and other needs associated with Yukon Energy protecting appropriate resource options related to these different loads.

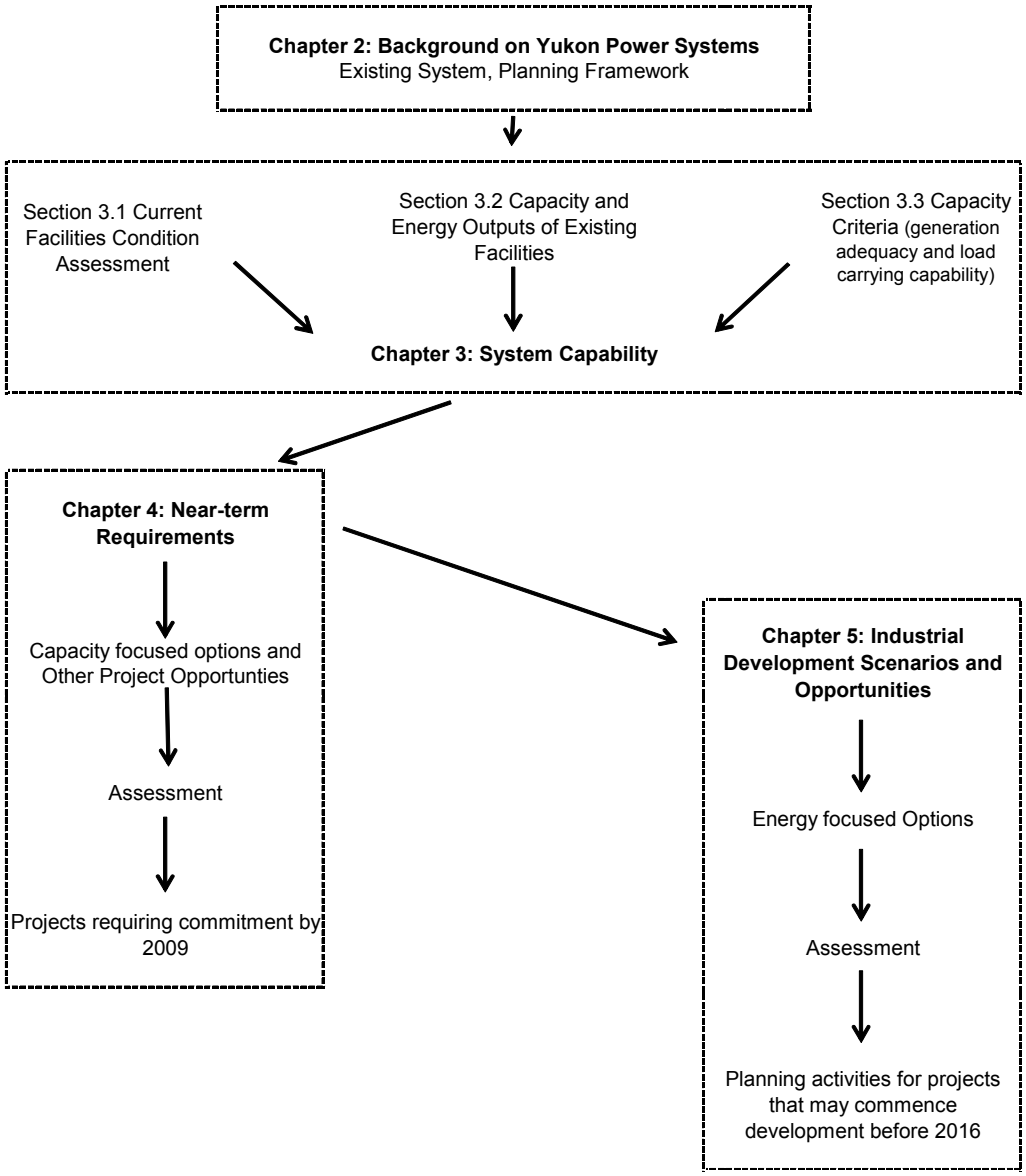
Figure 1.2:
Load Situation, Resource Needs and Supply Options 2006-2025

Load Situation (WAF Scenarios)	Resource Needs	Well Defined Project Options	Relatively Undefined Project Options
Scenario 4: **A 120 to 360 MW Alaska Highway Natural Gas Pipeline Scenario**	Large Energy (223 to 894 GW.h/yr, starting at earliest in 2012-2015 time period)		• Granite (80 MW, 660 GW.h/yr up to perhaps 254 MW) • Hoole (40 MW, 275 GW.h/yr) • Fraser Falls (100 MW, 613 GW.h/yr up to perhaps 450 MW) • Yukon River (multiple sites including Rink Rapid, Eagles Nest and Five Fingers, 75-240 MW) • Two Mile Canyon on Hess (53 MW, 280 GW.h/yr), Slate (42 MW, 266 GW.h/yr) • Natural Gas (to be determined)
Scenario 3: **A 40 MW WAF Industrial Scenario: Substantial Mining Industry Development in Excess of the Faro Mine** (more intense mine development than Scenario 2)	More Energy (max about 250 to 300 GW.h/yr during life of mine projects) Following mine closures, energy requirements at 56 GW.h or less		• Primrose (28 MW, 141 GW.h/yr) • Finlayson (17 MW, 129 GW.h/yr) • Coal (previously studied at 20 MW, about 144 GW.h/yr, up to 50 MW or larger, no credible smaller concept developed to date)
Scenario 2: **A 25 MW WAF Industrial Scenario: Multiple Major Developments Comparable to Faro Mine** (similar to Faro Mine, could comprise multiple mines, such as Minto, Carmacks Copper plus Red Mountain or Division Mountain coal)	Smaller Energy (max about 100 GW.h/yr for life of mine projects) Following mine closures, energy requirements at 35 GW.h or less	• Drury (2.6 MW up to perhaps 5.2 MW, 23 GW.h/yr)	• Moon (8.5 MW, 50 GW.h/yr) • Mayo B (10 MW, 48 GW.h/yr) • Aishihik Diversions (maximum 24 GW.h) • Tutshi (7.5 MW, 51 GW.h) • various other hydro (Orchay, Morley, Lapie,Squanga) • Surprise (8.5 MW, 50 GW.h/yr; removed by other proposals)
Scenario 1: **A 10 MW WAF Industrial Scenario: Combined Industrial load up to about 10 MW** (focus on Minto and Carmacks Copper mines [9-11 MW, about 60 GW.h/yr], 8-12 years)	Capacity focus - absorb current WAF surplus hydro while both mines operate (21 to 27 MW shortfall by 2012, base case and high load sensitivity)	Minor added capacity over and above base case (diesel or other options noted below)	
Base Case: **Existing Non-Industrial Loads** (new capacity planning critieria, retirement of 11.4 MW of Whitehorse diesel capability (3 Mirlees units))	Capacity shortfall focus - WAF surplus hydro likely until near end of 20 (Base Case shortfall by 2012 at 19 MW; range 15 to 24 MW)	**Major Capacity Shortfall Projects** • WH Diesel Replacement/Expansion Project (15-24 MW by 2012 wihout new industrial loads) • Mirrlees Life Extension Project (14 MW) • Aishihik 2nd Trans. Line (up to 22 MW, 0 GW.h/yr) **Opportunity Projects** • Aishihik 3rd Turbine (7 MW, 5.4 GW.h/yr) • Marsh Lake Fall/Winter Storage (1.6 MW, 7.7 GW.h/yr) • WAF-MD Interconnect (about 6 MW, 15 GW.h/yr, decreasing as MD load grows)	• Atlin Lake Top Storage (2.0 MW, 9 GW.h/yr) • Aishihik Supply Side Enhancements (about 6 MW potential) • Other Southern Lakes (to be determined)

1.5 SUBMISSION OVERVIEW

Figure 1.3: Submission Overview provides an overview of the organization and the interconnections that are present in the document.

Figure 1.3:
Submission Overview



The document is composed of five chapters:

Chapter One: Introduction provides the framework for the Submission.

Chapter Two: Background on Yukon Power Systems provides background information. The chapter includes an overview of the Yukon power system; the outcomes from the 1992 review; major events affecting power systems since 1992; and bulk power planning since 1992.

Chapter Three: System Capability provides information on the capability of the Yukon systems to meet the electricity needs of Yukoners, and addresses a review of system capacity planning criteria and the revised criteria that Yukon Energy has adopted.

Figure 1.3: Depicts the three sections of Chapter Three. These sections are separate, but each contributes in determining the adequacy of the system.

Section 3.1: Current Facilities Condition Assessment provides information on Yukon Energy's generation, substation and transmission assets. The second section of the chapter,

Section 3.2: Capacity and Energy Outputs of Existing Facilities focuses on implications of changes to major facility output since 1992, either from age, enhancement, or licencing conditions. The third section of the chapter,

Section 3.3: Capacity Planning Criteria Review, provides information on Yukon Energy's previous capacity criteria, the Company's 2005 review of its capacity criteria, and its adoption of revised criteria.

The next two chapters of the Plan reflect differentiation of (a) the near term requirements, and (b) longer term industrial development scenarios and opportunities.

Chapter Four: Near Term Requirements reviews major projects currently in the pre-decision planning stage (Figure 1.1) that Yukon Energy proposes to commit for construction or implementation prior to 2009, focusing on near term opportunities with regard to enhancing existing Yukon Energy facilities as well as near term projects which Yukon Energy is required to address under the revised capacity planning criteria. Proposed actions by Yukon Energy are identified regarding major projects that require final commitment decisions prior to 2009.

Chapter Five: Industrial Development Scenarios and Opportunities identifies and assesses on a preliminary basis major energy focused project possibilities during the 20 year planning period beyond 2009 and before 2016 in response to different industrial development scenarios. Proposed actions by

Yukon Energy are identified regarding planning activities that Yukon Energy may be required to carry out to start construction on such projects before 2016, including actions to ensure that YEC protects its ability to deal with these industrial development loads and opportunities should they arise. No project options examined in Chapter 5 are yet at the pre-decision stage of project planning (as reviewed in Figure 1.1).

2.0 BACKGROUND ON YUKON POWER SYSTEMS

The chapter provides background on current Yukon power systems, primarily encompassing the two integrated grids and generation facilities and transmission owned by Yukon Energy.

The sections for this chapter are as follows:

- Section 2.1: Overview of Generation Facilities and Transmission
- Section 2.2: Outcomes from the 1992 Review
- Section 2.3: Major Events Affecting Power Systems Since 1992
- Section 2.4: Bulk Electrical Supply Planning Since 1992

2.1 OVERVIEW OF GENERATION FACILITIES AND TRANSMISSION IN YUKON

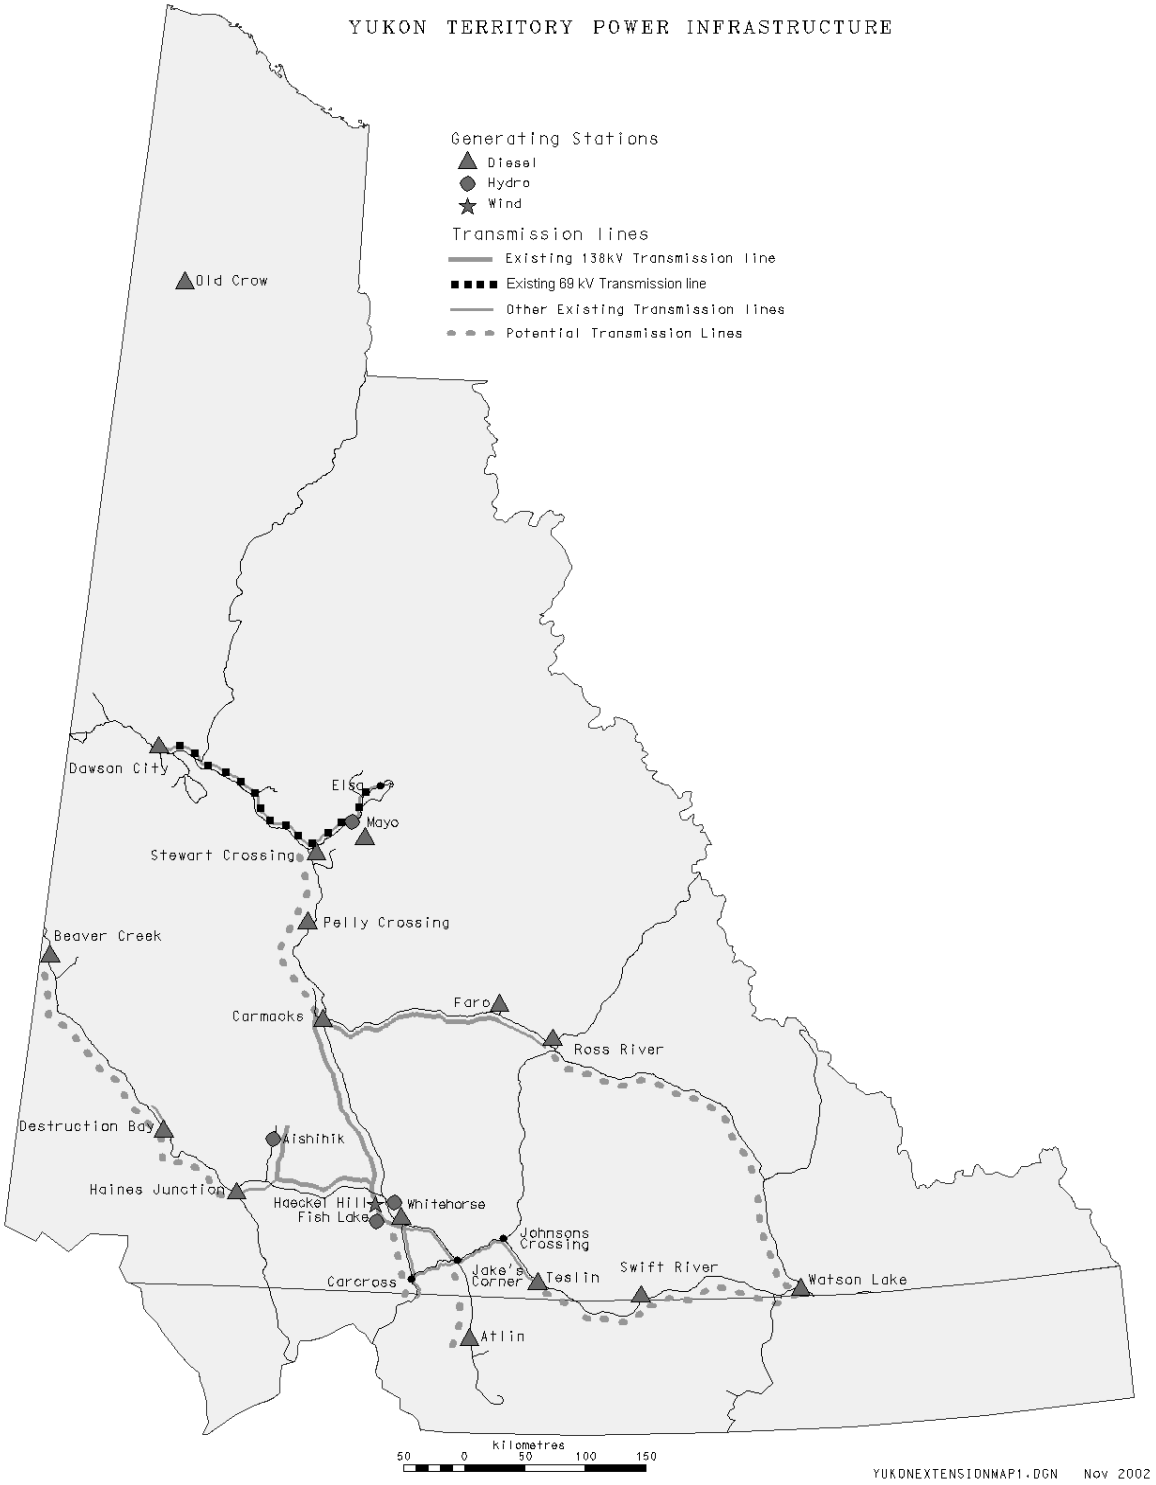
Yukon Energy is the main BES provider, or main generator and transmitter of electrical energy in Yukon. Yukon Energy currently accounts for 90% of annual Yukon power generation, and operates two independent transmission grids – the WAF and the MD.

The power systems identified in this Resource Plan are distinct and independent systems, each being served by its own source(s) of generation. The power systems in the Yukon include: the WAF grid; the MD grid; the diesel community of Watson Lake; and a number of smaller isolated diesel communities (Beaver Creek, Destruction Bay, Pelly Crossing, Swift River and Old Crow). The Yukon power systems are shown in *Figure 2.1: Map of Yukon Territory Power Infrastructure*.

Yukon Energy currently serves approximately 1700 retail customers, or 11%, of Yukon's customers directly. The retail customers that are served directly include residential and commercial classes. The majority of these customers are located in and around Dawson City, Mayo and Faro.

Yukon Energy's wholesale customer, YECL, distributes power to the other 89% of Yukon's retail customers. The bulk of Yukon Energy's sales are composed of firm wholesale sales to YECL on the WAF grid. YECL maintains and operates its distribution lines independent of Yukon Energy.

Figure 2.1:
Map of Yukon Territory Power Infrastructure



Hydro generation from the Aishihik and Whitehorse stations supply the WAF communities of: Carmacks, Carcross, Haines Junction, Teslin, Whitehorse, Ross River, Tagish, Deep Creek, Takhini River Sub and Marsh Lake through wholesale sales to YECL. The WAF communities of Champagne, Faro, Johnsons Crossing and Braeburn are served directly by Yukon Energy.

Hydro generation from the Mayo Generating station is supplied by Yukon Energy to the Town of Mayo, the City of Dawson, as well as to loads along the Mayo-Dawson transmission line route (the North Klondike Highway loads), as well as on a wholesale basis to YECL for service to Stewart Crossing, Elsa, and Keno.

Hydro generation stations on the Yukon grids are supplemented as necessary by a small amount of diesel for peaking or maintenance purposes, and on the WAF grid, by wind generation. The absence of power grid interconnections with other neighbouring jurisdictions prevents export of surplus generation or import of competitive supplies, and is one of the key factors distinguishing Yukon's situation from that prevailing in most southern jurisdictions in Canada.

2.1.1 Generation in Yukon

Yukon Energy's systems account for 112.4 MW of the 127.4 MW of installed capacity in Yukon. The YECL systems account for the balance, or for 15.0 MW of installed capacity.

The generation assets currently owned by both Yukon Energy and YECL are shown in *Table 2.1: Generation Capacity in Yukon – YEC and YECL in 2005*.

Table 2.1:
Generation Capacity in Yukon – YEC and YECL in 2005

Yukon Energy Generation Assets (in MW installed & currently rating)			**YECL Generation Assets** (in MW installed)		
Hydro Facilities			Hydro Facilities		
Whitehorse	WAF	40.0	Fish Lake	WAF	1.3
Aishihik	WAF	30.0	Base Load Diesel Facilities		
Mayo	MD	5.4	Old Crow	Isolated	0.7
Total Hydro		75.4	Pelly Crossing	Isolated	0.7
			Beaver Creek	Isolated	0.9
Wind Facilities			Destruction Bay	Isolated	0.9
Haeckel Hill	WAF	0.8	Swift River	Isolated	0.3
			Watson Lake	Watson Lake	5.0
Diesel Facilities			Back-up Diesel Facilities		
Whitehorse	WAF	22.4	Carmacks	WAF	1.3
Faro	WAF	5.3	Teslin	WAF	1.3
Dawson	MD	5.0	Haines Junction	WAF	1.3
Mayo	MD	2.0	Stewart Crossing	MD	0.3
Mobile Diesel		1.5	Ross River	WAF	1.0
Total Diesel		36.2	Total Diesel		13.7
TOTAL YUKON ENERGY		112.4	TOTAL YECL		15.0
TOTAL YUKON GENERATION		**127.4** **(YEC + YECL)**			

Yukon Energy's extensive hydro generation and transmission facilities and the resulting significant reduction in overall reliance on diesel generation are the key factor causing Yukon power costs to typically be lower than those found in Alaska or the Northwest Territories ("NWT"). Without such hydro facilities, Yukon utilities probably would have relied almost entirely on diesel generation with its associated higher costs[1].

[1] See Cabinet Commission on Energy, Technical Background Paper on Electrical Rates and Relief, 1997. Chart 1 in this paper reviewed Residential power bills in North America in 1996. The paper (pages 6-7) reviewed factors affecting northern power costs (e.g., lower population and customer densities, reliance on diesel generation, and the absence of power grid connections with other jurisdictions), and concluded that the lower power costs in Yukon reflect YEC's extensive hydro generating facilities (e.g., YEC hydro generation provided from 70 to 90% of all Yukon power generation each year from 1987 through to 1997). The paper noted that production or generation costs represented almost 70% of all Yukon power costs forecast for 1997 in the 1996/97 GRA.

Figure 2.2:
Yukon Total Power Generation 1967 – 1997

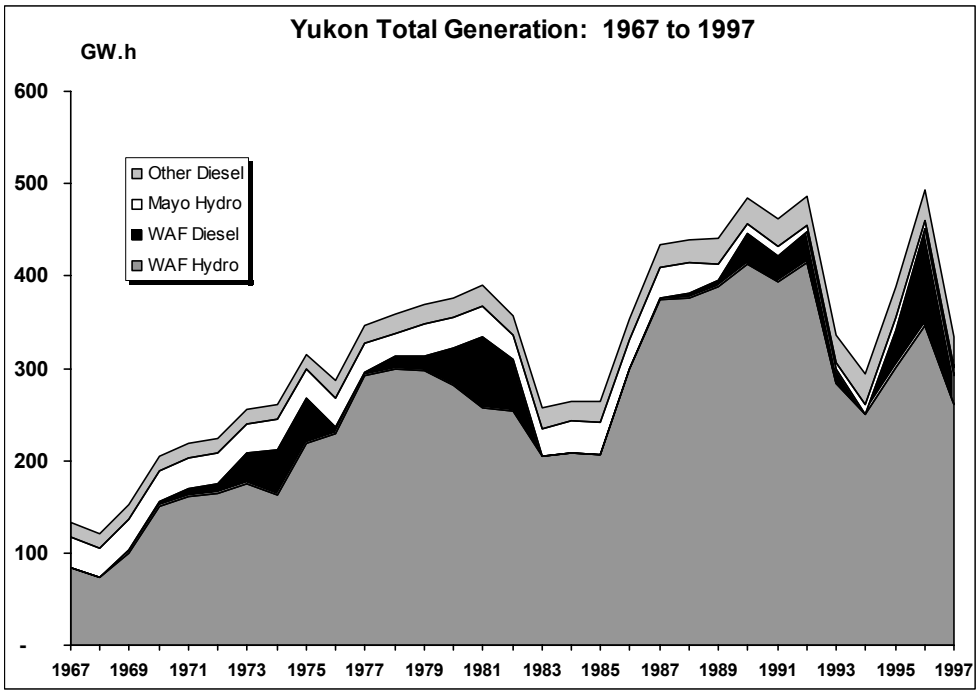


Figure 2.2: Yukon Total Power Generation: 1967-1997 highlights the overall importance of Northern Canada Power Commission ("NCPC")/YEC hydro generation in Yukon and the evolution of this capability from the late 1960's (after the first two hydro units were installed at Whitehorse Rapids) until the mid 1980s. This figure also demonstrates the relatively minor effect overall for Yukon related to diesel generation required outside the WAF and Mayo areas[2].

Hydro generation in Yukon was developed in the past by the NCPC in response to load developments in the Yukon, particularly mine-related loads at Faro, Keno, and Whitehorse. Yukon Energy acquired these hydro assets in 1987 as a result of the NCPC transfer.

- In 1952, NCPC built the Mayo Hydro facility to supply power to Mayo and UKHM in Elsa and Keno.

[2] Completion of the MD transmission line in 2002 materially further reduced diesel generation requirements in Yukon (by displacing diesel generation at Dawson). Figure 2.2 requires access to YECL generation data, which is not available after the years noted in the figure.

- In 1958, NCPC built the first two turbines at Whitehorse Rapids to supply the rapidly growing demand for power in Whitehorse.
- A third turbine was added to the Whitehorse Rapids plant by NCPC in 1969, along with the 138 kV transmission line from Whitehorse to Faro, as a consequence of an agreement between Cyprus Anvil Mining Corporation and Government of Canada to build a mining facility at Faro.
- In response to the Faro mine's power requirements and the opportunity to cost effectively displace diesel generation, the Aishihik hydro plant was developed by NCPC between 1973 and 1975, and the Whitehorse fourth hydro turbine generator was developed between 1982 and 1984.

Figure 2.3: YEC WAF Generation 1967 – 2004 details historic generation on the WAF grid. The majority of WAF generation has been hydro generation. During periods when the Faro mine was in operation there was also ongoing material diesel generation.

Figure 2.3:
YEC WAF Generation 1967 – 2004

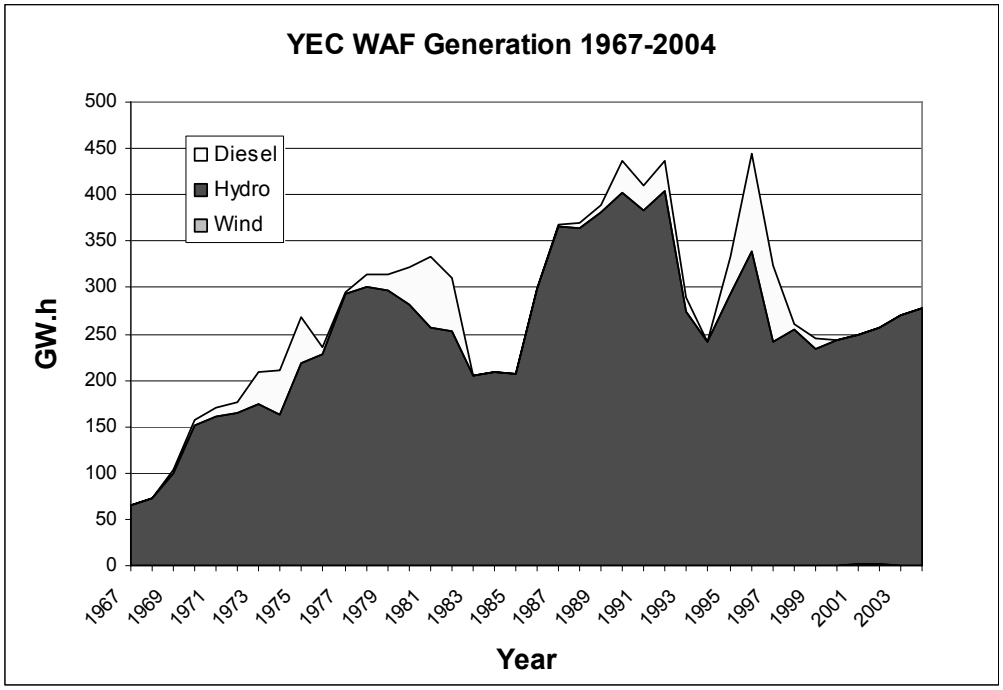

Figure 2.4: YEC Generation on MD 1980 to 2004 details historic generation in the communities that now form the MD grid. Until the UKHM closure in 1989, there was substantial hydro generation being used

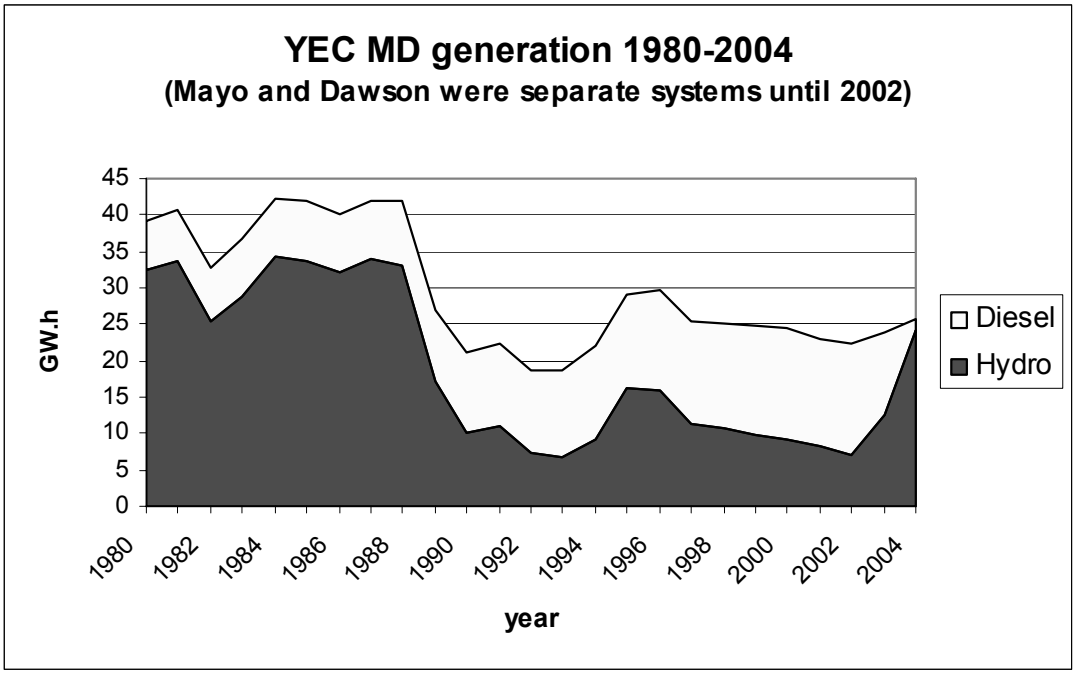
(primarily at UKHM). Prior to completion of the Mayo-Dawson Transmission Line project in 2002, Dawson was a diesel served community; with completion of the MD grid, hydro generation has become the main source of generation for all MD grid communities. By 2004, only 6% of MD generation was by diesel.

Figure 2.4:
Generation on MD, 1980 – 2004



2.1.2 Transmission in Yukon

Yukon Energy owns and operates the WAF and MD transmission systems in Yukon of 69 kV or higher, as well as certain lower voltage lines; certain lower voltage lines (25 to 34.5 kV) are also owned and operated by YECL. The WAF and MD grids, and the other lines in Yukon are identified in *Figure 2.1: Map of Yukon Territory Power Infrastructure*.

The WAF and MD transmission lines are characterized as transmission lines because the lines transmit power from one community to another. However, due to the lower voltage, some of these transmission lines would be considered to be sub-transmission or distribution lines on a larger system.

WAF transmission is primarily a 510 kilometre 138 kV line that extends from Aishihik east to Whitehorse, north to Carmacks, and then east to Faro. Separate lower voltage lines connect other communities, comprising a 25 kV line (YEC) to Haines Junction, a 25 kV line (YEC) from Faro to Ross River, and a 34.5 kV system (YECL) southeast from Whitehorse to Teslin, Carcross, Tagish, Marsh Lake, Jakes Corner and Johnsons Crossing.

The MD grid is composed of a 223 kilometer 69 kV transmission line extending from the Town of Mayo to the City of Dawson, and connecting Stewart Crossing. A separate 69 kV transmission line connects to Keno and Elsa, northeast of Mayo.

2.2 OUTCOMES FROM THE 1992 REVIEW

Order-in-Council 1992/092 directed the YUB to review Yukon Energy and YECL (the "Companies") major capital projects and contract commitment proposals required for non-diesel fuel generation, transmission and DSM to 1997. The 1992 Resource Plan submission prepared by the Companies was jointly submitted to the YUB, and provided the first opportunity since the NCPC transfer in 1987 to review long-range major capital planning options for Yukon power systems.

The 1992 Submission Overview provided a snapshot of an ongoing dynamic resource planning process, and proposed a set of ongoing demand and supply work plan elements for the 1992 to 2001 period rather than the development of a single resource option.

The YUB conducted a public hearing in October, 1992 to review the 1992 Resource Plan, and submitted a report (the "Capital Hearing Report") with recommendations to the Commissioner in Executive Council on December 7, 1992 (Review of the Capital Resource Plans of YEC and YECL. Yukon Energy and YECL subsequently provided comments on the YUB's forty-eight recommendations in Section 5.3 of the 1993/94 General Rate Application ("GRA") Submission. Some of the notable recommendations are detailed below, along with responses by the Companies (as filed in the 1993/94 GRA), and updates on each recommendation:

A Framework for Capital Programs to be Pursued: The YUB's Recommendations 1 and 2 stated that the Capital Hearing Report provided a framework for future capital projects, and that the capital resource plan should be reviewed as part of general rate applications, or as directed by the Board. The Companies agreed.

Yukon Energy and YECL provided updates to the YUB on capital planning activities as part of the jointly filed 1993/94 and 1996/97 general rate applications. Yukon Energy provided updated information on capital projects in *Section 5 of the 2005 Required Revenues and Related Matters Application*. The current Resource Plan Submission provides a further and more detailed update for the YUB.

Market Risks: The Companies agreed with Recommendations 3 and 4 that stated the significant market risk associated with the closure of the Faro Mine should be considered in assessing the Companies' Resource Plan and in determining the need for new facilities.

After the closure of the Faro Mine in 1998, there has been a significant WAF hydro surplus. As a result, there has not been a need for new facilities to address mining loads in Yukon. However, there are now new mining opportunities on the horizon for Yukon.

Potential mining loads are discussed in *Chapter Five: Industrial Development Scenarios and Opportunities*. Yukon Energy's assessment of new facilities in the context of mining loads takes into account the related risks.

Load Forecasts and Demand Side Management: The Board recommended that the low and base case scenarios should be considered in assessing the need for DSM (Recommendation 5).

The Companies agreed that DSM initiatives should not be based on the high case scenarios. Since the closure of the Faro Mine, there has been a hydro surplus, and the "high" case that the Board considered in 1992 does not exist at the present time (i.e., there is no industrial customer in Yukon today).

The Board also supported aggressive DSM activities to the extent that it can be demonstrated that the activities result in lower costs to consumers than alternate supply options (Recommendation 22). The Companies agreed that DSM activities should only be pursued where they are more economic than supply-side investments.

There is currently a hydro energy surplus in Yukon. The incremental cost to produce hydro generated electricity is virtually zero, and therefore there has not been a need on the WAF and MD systems to reduce energy use. As a result, both supply-side and demand-side conservation initiatives have not been a key focus for Yukon Energy since 1997.

In terms of managing the demand (customer consumption) on the system, the focus for Yukon Energy since the Faro Mine closure in 1998 has been primarily on developing interruptible energy sales opportunities on the WAF and MD systems (see *Section 2.3.2: The Growth of Secondary Sales*).

Recent DSM activities have been undertaken by the Energy Solutions Centre ("ESC")[3] . DSM options that reduce the load on the WAF system at the very immediate peak times (i.e., reduce the capacity requirement of the Yukon system) have the potential to provide value to Yukoners today. Programs that have been developed and tested by Yukon Energy and ESC since 1992 are explored in greater detail in *Section 2.4: Bulk Power Planning Since 1992*.

Load Factoring: The Board's Recommendation 11 recommended that the Companies perform studies and tests to determine the potential to use load factoring to increase the capacity relied on at the Whitehorse Rapids Hydro Plant.

The Companies continued to experiment with load factoring between 1992 and the 1993/94 GRA. The Companies maintained in the 1993/94 GRA that enhanced load factoring would not result in a firm capacity rating above 24 MW for Whitehorse during non-drought years. This item is further discussed in *Chapter 3*.

Load Forecasts and Use Per Customer: The YUB recommended a more rigorous approach to estimating residential and general service use per customer (Recommendations 7 and 8).

Yukon Energy and YECL did review the historical use per customer during the 1993/94 GRA. The average use per customer was expected to stay relatively constant. Consequently the driver in the load growth forecasts was the number of customers.

In the 1993/94 General Rate Application the Companies agreed to explore opportunities to carry out research pertaining to use per customer with the Yukon Government and others, and to document current electric heating use characteristics on the WAF system.

[3] The Energy Solutions Centre was under the management of the Yukon Development Corporation. On February 5th, 2005, the Yukon Territorial Government ("YTG") announced its plan to transfer management from YDC to YTG. Release #05-23, "New Model for Energy Solutions Centre to Improve Accountability", Online: http://www.gov.uk.ca/news/2005/05-23.html.

Yukon Energy and YECL also examined use per residential customer in the 1996/97 GRA. The Companies identified a trend of declining use per customer, and reflected this trend in the sales forecast. The decline in use per customer was attributed to a reduction in electric heat. The Companies suggested that higher electricity rates in the mid-1990s had encouraged conversions from electric heating.

Yukon Energy has factored a use per customer variable into its current load forecasting methodology for its retail customers. Yukon Energy's current load forecasts have two components: a measure of the increase in the number of customers; and a measure to reflect changes in the average use per customer. Yukon Energy's load forecast methodology is explained in greater detail in *Section 4.2.1: Non-Industrial Load Forecasts*. Due to its limited retail customer load, Yukon Energy does not have the data or analysis to weather normalize its past sales or forecasts for its own retail customers. Yukon Energy is not able to carry out analysis on customer numbers or use per customer on YECL's current retail customers.

Aishihik 3rd Turbine: The Board recommended in Recommendation 37 that the Companies pursue approval for the construction of the third turbine at Aishihik, given that it is economically, technically and environmentally feasible. The Board asked the Companies to "report back to the Board before commencing construction" and indicated that "the Companies should pursue installation of the maximum capacity that is economically, technically and environmentally feasible".

As of the 1993/94 GRA, the Companies were delaying activity on the third Turbine due to the closure of the Faro Mine at that time; similarly, active consideration of developing this project was once again delayed after the Faro Mine closures in 1997 and 1998. The third Turbine, however, remained a component of the Yukon Energy application for Aishihik relicencing throughout the period.

Yukon Energy received its renewed water licence at Aishihik in 2002 (which extends to December 31, 2019), including the environmental approval to install a third Turbine of up to 7 MW. Based on the current Resource Plan, Yukon Energy is now proceeding with the next steps in the Aishihik third Turbine project, including updated costing of the 7 MW installation and confirmation of hydrology.

Supply Options: In Recommendation 36 the Board stated that before pursuing construction of "large projects" (defined as projects with a cost of more than $5 million), preference should be given to DSM, small utility owned projects and Independent Power Producers ("IPP") that are cost effective for consumers.

In the 1993/94 GRA the Companies agreed with this option, providing that these options are cost effective for consumers. Yukon Energy's last internal large-scale Resource Planning exercise took place in 1996. In September, 1996, Yukon Energy requested Expressions of Interest from qualified parties interested in providing technologies, investments and/or partnerships to establish new generation facilities in Yukon to displace diesel generation. During that planning process, IPP projects were considered.

Independent Power Producers: The Companies agreed with the Board's Recommendation 45 that IPP's should be encouraged in Yukon, provided that there are no negative rate impacts on consumers. The Board recommended (Recommendation 47) that the Minister direct the Board to hold a hearing with respect to IPP policy and to develop a firm IPP policy for Yukon.

A hearing was not held. However, as noted above, Yukon Energy did solicit IPP proposals for development in 1996.

Feasibility Studies: Recommendation 39 stated that the Companies should not proceed with any feasibility studies for Drury Creek, Morley River, Lapie River and Orchay River, other than developing long-term hydrological data.

Yukon Energy has collected hydrological data, but has not proceeded with feasibility studies.

Coal: The Companies agreed with the Board's Recommendation 42 that studies of coal-fired generation should be limited to a review of coal technology, particularly with respect with plants under 20 MW.

Yukon Energy has not proceeded with any detailed study of coal technology. However, when Expressions of Interest were requested in 1996, three respondents focused on coal-based thermal generation for the WAF system. As a result of the closure of the Faro mine in 1997 and again in 1998, no projects were developed as a result of the call for Expressions of Interest.

Mayo-Dawson Transmission Line: The Companies agreed with Recommendation 42 that no further studies should be conducted on this transmission line unless demand changed sufficient to warrant a review of the project.

Escalating fuel costs and load growth subsequently led Yukon Energy to update its studies and ultimately commit to proceeding with the MD project in 2001 (including receiving the approval of the Minister). The

Line commenced operation in September of 2003, and has offset diesel generation and reduced fuel costs for Yukon Energy. For more information of the MD Transmission Line, see *Section 2.3.6: Mayo-Dawson Transmission Line*.

Wind: Recommendation 43 stated that research and development work should continue to be pursued with respect to wind generation. The 1993/94 GRA included the purchase and installation of a wind turbine on Haeckel Hill.

Yukon Energy has installed two research and development wind turbines at Haeckel Hill with a combined generating capacity of 800 kW.

2.3 MAJOR EVENTS AFFECTING POWER SYSTEMS SINCE 1992

There have been a number of significant changes to the Yukon system since 1992. The most notable of these changes include: closure of the Faro Mine; the increase in Secondary Energy sales; Yukon Energy's shift to direct management; the Whitehorse Rapids Generating Station fire rebuilding project; renewal of Yukon Energy's three water licences; and the construction of the MD Transmission Line. These events are outlined below.

2.3.1 Closure of the Faro Mine

After decades of operation on the WAF grid, including a number of closures and re-openings, the Faro Mine closed in 1998. This mine closure followed the 1989 closure of the United Keno Hill Mine ("UKHM"), which had been served by the Mayo hydro plant. As a result of the Faro Mine closure, there are currently no major industrial customers being served in Yukon. Major industrial customers are defined by Order-in-Council 1995/90 as, "a customer engaged in manufacturing, processing, or mining, whose peak demand for electricity exceeds 1 MW, but it does not include an isolated industrial customer[4]."

Overall generation and diesel usage declined after the Faro Mine's closures in 1983 and 1993, 1997 and again after its final closure in 1998. When the Faro Mine was in operation, all of Yukon's hydro generation was absorbed by the system, and diesel generation was required on an ongoing basis. Since the final closure of the Faro Mine in 1998, there has been a hydro energy surplus on WAF.

[4] Rate Policy Directive, Order-in-Council 1995/90, May 29, 1995.

2.3.2 The Growth of Secondary Sales

Secondary Energy has been available from time to time to General Service or Industrial customers based on the availability of surplus hydro since before the NCPC transfer. Rate Schedule 32 – Secondary Energy, provides Yukon Energy with an opportunity to sell excess low-cost hydro power when it is available, but can interrupt secondary sales customers when it is likely that the utility will be required to generate electricity with diesel. There are now approximately 25 retail customers who together receive more than 20 GW.h of electricity under Rate Schedule 32. These customers use the electricity to displace fuel oil, and in some cases, propane.

The current Secondary Energy rate was approved in YUB Board Order 2005-12 at 66.7% of the equivalent energy price of fuel oil. The rate is adjusted quarterly to reflect ongoing market price adjustments for fuel oil.

Secondary sales have grown from 3,917 MW.h in 2000, to a forecast 20,613 MW.h for 2005. The recent growth in secondary sales can be attributed to the surplus in hydro energy on the WAF grid since the closure of the Faro Mine in 1998. Surplus hydro generation on the MD grid is also stimulating secondary sales on that system.

At today's rates, Secondary Energy sales are very beneficial, and help to pay for the fixed costs of the system (more than $1 million in revenues annually). However, although Secondary Energy are available from existing system assets, the generation system is not planned to provide service to secondary customers. For the purposes of planning the system for capacity requirements or energy projects, Secondary service is not included as required load to be served (however, in some cases the ability to enhance sales of secondary power can provided added economic benefits from certain projects).

2.3.3 Shift to Direct Management

On January 1st, 1998, Yukon Energy assumed full management and operation of its generation, transmission and distribution infrastructure and services. This includes direct responsibility for activities related to planning the Yukon integrated generation and transmission systems today.

Prior to 1998, Yukon Energy's assets had been managed by Canadian Utilities, a subsidiary of ATCO, which is YECL's parent company. Yukon Energy's billing service is the only service that is still provided by an ATCO company.

Yukon Energy and YECL are both regulated by the YUB. YECL was an active intervenor in the spring 2005 YUB hearing on Yukon Energy's *2005 Required Revenues and Related Matters* application. This was the first comprehensive revenue requirement submission that either had made to the YUB since the shift to direct management.

2.3.4 Whitehorse Rapids Generating Station Fire Rebuilding Project

On October 30, 1997, a fire started in the pump room of the Whitehorse Rapids generating station. The fire destroyed the generating station building, the system control centre, the Yukon Energy Corporate office, the switchgear, and caused superficial damage to hydro generators 1, 2 and 3. Even with the damage sustained by Yukon Energy, electrical service was not interrupted during the fire.

Yukon Energy filed insurance claims under its insurance provisions, and received a favourable settlement. The fire destroyed assets with a rate base of $2,280,000. A total of $11,604,000 of new assets were placed in service to replace the assets destroyed or damaged during the fire. A total of $1,799,000 in betterments were also completed. Yukon Development Corporation ("YDC") paid for $1 million of these costs. The balance of $799,000 was put into rate base.

The insurance claim resulted in a net benefit to ratepayers. Aging assets were replaced at essentially no cost to ratepayers. There was also a resulting insurance gain of $744,000.

2.3.5 Renewal of Water Licences at Whitehorse, Mayo and Aishihik

Yukon Energy is required to have water licences for the hydroelectric facilities that it owns and operates in Whitehorse, Mayo and Aishihik (near Haines Junction, Yukon). Water licences in the Yukon are issued for a period up to, but not exceeding 25 years. All of the water licences for these three facilities expired since the 1992 Resource Plan filing, and renewal of each licence has been obtained.

Whitehorse: The Whitehorse Water Use Licence (HY99-010) expired in 2000, and was renewed for 25 years (expires in 2025). It combines two prior licences, Marsh Lake and Whitehorse Rapids. The renewal of the licence was sought on the basis of no relevant changes being made to its terms and conditions, and included only administrative changes. The licence renewal was granted by the Yukon Territorial Water Board ("YTWB") on this basis. Dam safety monitoring requirements were formalized in the new licence. This was consistent with Yukon Energy practices and current Canadian Dam Safety Guidelines.

Mayo: Mayo Water Use Licence (HY99-012) expired in 2000, and was renewed for 25 years (expires in 2025). Similar to the Whitehorse facility, the renewal of the licence was sought on the basis of no

relevant changes being made to its terms and conditions, and included only administrative changes, and the licence renewal was granted by the YTWB on this basis. Dam safety monitoring requirements were formalized in the new licence, which was consistent with Yukon Energy practices and current Canadian Dam Safety Guidelines.

Aishihik: Relicencing of the Aishihik hydroelectric facility took place over a number of years. It involved four amendments to the 1978 licence. A new licence with a Fisheries Act Authorization was issued in 2002 upon expiry of the 1978 licence. Yukon Energy had sought a new licence, and a 17-year licence was granted. Similar to Whitehorse and Mayo, the dam safety requirements in the licence are normal modern utility standards that would need to be completed whether a requirement of the licence or not. The renewal of the licence called for ongoing heritage payments, the construction of a boat launch at the north end of the lake, and an annual fish monitoring program.

New terms of the 17-year licence provide for a conditional seven-foot operating range subject to the terms of the Department of Fisheries and Oceans ("DFO") Fish Act Authorization, and allow for the installation of a third turbine not exceeding 7 MW (subject to the requirement for YTWB approval of an operating plan when the third turbine is installed). Additional details on the Aishihik Licence renewal were provided in Interrogatory Response YUB-YEC-1-55 in Yukon Energy's 2005 Required Revenues and Related Matters Application.

2.3.6 Mayo-Dawson Transmission Line

The MD Transmission Line Project came into service in September of 2003. The MD project was the first large-scale transmission infrastructure development project undertaken by Yukon Energy since the NCPC transfer in 1987. The 223 kilometre 69 kV transmission line links Mayo, a community with surplus hydro, with Dawson, a community that was previously served solely by diesel generation. The transmission line now supplies almost all of Dawson's energy requirements. The line also provides hydro power to YECL at Stewart Crossing, which was previously served with diesel generation, as well as various locations along the North Klondike Highway that were not previously served by utility power.

The costs of the MD Transmission line were projected to be $35.6 million as of the end of 2005. A total of $5.8 million of this amount was provided by Yukon Development Corporation at no cost to ratepayers. YDC has also provided flexible debt financing to Yukon Energy. This financing ensures that ratepayers

will be protected so that they are not paying, in any year, more than they would have paid had Dawson remained on diesel fuel generation[5].

2.3.7 System Upgrades and Changes

In addition to the completion of the MDTransmission Line project, and relicensing of its three hydro plants, Yukon Energy has undertaken additional system upgrades since the submission of the 1992 Resource Plan. Recent Upgrades include:

- Aishihik Unit #1 Rewind in 2003 (cost $1.2 million)
- Mayo Hydro Unit #1 and Unit #2 Capacity Increase in 2002 (cost $1 million)
- Addition of Wind Turbine #2 in 2000 (cost $2 million)

Yukon Energy has also been able to extend the service life of its three Mirrlees Blackstone base load diesel units located in its Whitehorse diesel plant (diesel units WD1, WD2 and WD3). WD3 is currently scheduled for retirement in 2007; WD2 is currently scheduled for retirement in 2009; and WD1 is currently scheduled for retirement in 2011. The 1992 Resource Plan had scheduled the retirement of WD1, WD2, and WD3 in 1998, 1998, and 2000 respectively. By 1996 the retirement was extended. After the Faro Mine closed, these units provided required reserve capacity for the system.

Since the Faro Mine closure in 1998, a 5 MW diesel unit was retired at Faro. Two diesel units with a combined capacity of 2 MW were moved to Mayo, and a 1.3 MW unit was removed from Faro to act as a mobile unit. The result is a decrease in the Faro diesel plant size from 13.6 MW to 5.3 MW.; in addition, two diesel units with a combined capacity of 1.3 MW were retired from Mayo.

2.4 BULK ELECTRICAL SUPPLY PLANNING SINCE 1992

Yukon Energy has been engaged in a number of power planning activities since the 1992 Resource Plan submission. In addition to the submission of the current plan, Yukon Energy has provided updates to the YUB in its rate and revenue application submissions. Yukon Energy's planning has included: developing an inventory of future supply options with YDC and BC Hydro; condition assessment work of its key generation and transmission assets; a review of the WAF and MD capacity criteria review; and work with ESC on DSM. Yukon Energy's significant power planning activities since 1992 are outlined in the following sub-sections.

[5] YUB Board Order 2005-12 approved $29.046 of the costs of the MD Transmission Line for inclusion into YEC's ratebase, net of the $5.75 million contribution by YDC ($0.05 million of the amount provided by YDC was an interest-free advance, not a contribution) and about $0.8 million being disallowed (amounts YEC cannot charge to ratepayers).

2.4.1 Ongoing Yukon Energy Infrastructure Planning Process

Infrastructure updates were provided as part of Yukon Energy's GRAs to the YUB in 1993/94, 1996/97, and in the *2005 Required Revenues and Related Matters* Application. These updates were in response to the YUB's Recommendation 2 from the 1992 Resource Plan hearing. The YUB recommended that the Companies' capital resource plan should be reviewed on an ongoing basis as part of general rate applications, or as directed by the Board.

2.4.2 BC Hydro Inventory of Potential Future Hydro Supply Options

YDC commissioned BC Hydro to work with YEC to conduct a Small Hydro Resource Study in 2002. The study included a review and assessment on existing information on hydro sites located in Yukon and relevant projects located in northern British Columbia. BC Hydro summarized over 200 sites which has provided Yukon Energy with a consolidated source for information on potential project options. The area studied included the WAF and MD transmission corridors, roughly 50 kilometres from the grids or highways. On WAF the study was extended from the current gird to Watson Lake along the Alaska Highway area.

2.4.3 Bulk Electrical Supply Infrastructure Condition Assessment Work

Yukon Energy commissioned three recent condition assessment studies. Acres International was commissioned to assess Yukon Energy's key transmission assets, while BC Hydro was commissioned to complete two studies: a study of Yukon Energy's key generating assets, and a study of selected substation assets. In May of 2004, BC Hydro completed its *Condition Assessment of Selected Yukon Energy Generating Assets*. BC Hydro's second report, *Condition Assessment of Selected Yukon Energy Corporation Substation Assets* was completed by BC Hydro in June of 2004. The Acres International report, *Assessment of Transmission Lines for Yukon Energy Corporation* was completed in December of 2003. A more thorough review of the findings from the condition assessments can be found in this Plan in *Section 3.1: Current Facilities Condition Assessment*.

Most of the assets examined by Acres International and BC Hydro were found to be in good to relatively good condition, and were expected to have operating lives of 20 additional years or more. The main exception is the Whitehorse Mirrlees diesel engines, which are further discussed in *Chapters 3 and 4*.

2.4.4 Generation Capacity Planning Criteria Review

There have been changes to the Yukon systems since the last detailed Yukon Utilities Board review of bulk system planning in 1992 as well as in the 1993/94 and 1996/97 GRAs including: closure of the Faro

Mine; growth in Whitehorse area loads; the interconnection of Mayo-Dawson; and the need to address the near term retirements of the Whitehorse Mirrlees engines. In combination, the above factors raised concerns regarding the ability of the assets in the Whitehorse area to serve the city in the event that the Aishihik Line was out of service for a substantial period during the winter peak. As a result, Yukon Energy undertook a review of the Capacity Planning Criteria.

For the Whitehorse area capacity, one specific issue was to determine how to approach the pending retirement of 14 MW of nameplate capacity for three Whitehorse Mirrlees diesel (WD) units (WD1, WD2 and WD3). Reviewing the adequacy of capacity planning criteria is a prudent first step prior to making (or rejecting the need to make) any such new capital investments.

NWT Power Corporation recently undertook a similar review of their Yellowknife grid. NWT Power Corporation commissioned a study of their capacity planning criteria by Dr. Billinton from the University of Saskatchewan. The NWT Power Corporation received approval from its regulator for its revised capacity planning criteria in November of 2004.

Yukon Energy retained Drs. Billinton and Karki from the University of Saskatchewan to study the key areas and characteristics of the Yukon systems (focused on WAF) relevant for a review of the required firm capacity planning criteria. As part of the capacity criteria review, Yukon Energy worked with Drs. Billinton and Karki to develop recommendations on capacity planning criteria for the Yukon systems. The conclusions from that work are detailed in *Section 3.3: Capacity Planning Criteria Review*.

2.4.5 Demand Side Management and the Energy Solutions Centre

Section 2.2: Outcomes from the 1992 Review touched on Yukon Energy's approach to DSM. When the Faro Mine was in operation, hydro generation was fully utilized and Yukon Energy actively pursued DSM opportunities in order to save diesel generation costs. The Faro Mine closures shifted Yukon Energy's focus away from DSM due to surplus diesel generation costs. After the final closure of the Faro Mine in 1998, the focus on DSM activities decreased greatly. The key activities from the 1992 to 1998 are outlined below.

DSM From 1992 to 1998

Smart Home on Wheels Community Tour: In 1992 the Companies developed a Smart Home on Wheels Community Tour to educate Yukon residents and retailers outside of Whitehorse of the benefits of Power Smart products. This program was intended to parallel the impact of The Power Smart Idea

Shop which was located in Whitehorse. Between October 26 and December 14, 1992, the Tour visited the communities of: Burwash Landing, Beaver Creek, Carmacks, Pelly Crossing, Teslin, Haines Junction, Mayo, Stewart Crossing, Dawson City, Carcross, Tagish, Watson Lake, Ross River and Faro. Fifteen presentations were made to local schools, and over 500 people visited the trailer. A survey was completed by the majority of visitors to the trailer, and 99% of respondents indicated that they learned something new about energy management. A further 85% identified steps that they planned to take to reduce energy consumption.

Home Smart: In March 1993 Phase one of the Home Smart program was completed. The program provided subsidies on six energy-saving and energy efficient products, including: outdoor timers, water saver kits, water tank wraps and pipe insulation, power cord savers, compact fluorescent light bulbs and compact fluorescent hardware fixtures. The program was retail focused, and 59 Yukon retailers participated by carrying Power Smart products, information displays and information.

Energy Management Working Group: On November 1st, 1996, Yukon Energy and YECL submitted a Final Report to the Yukon Utilities Board on the activities of the Energy Management Working Group. The group was formed as per Item 4 of the 1996/97 GRA Settlement, as approved by the Board in Order 1996-7. The parties who participated in the process included:

- Utilities Consumers' Group
- Yukon Housing Corporation
- Yukon Energy/YECL
- Yukon Chamber of Mines
- Whitehorse Chamber of Commerce
- City of Whitehorse
- The Government of Yukon

The Report identified work in progress that Yukon Energy and YECL set to achieve within the 1996/97 GRA period. The activities noted were:

- Education to the general public via bill stuffers, trade shows, etc.
- Opportunity assessments completed for customers on request
- An Opportunity Assessment was completed for Anvil Range Mining Corporation and paid for by Yukon Energy
- Opportunity Assessments were completed by YECL for the City of Whitehorse and Town of Haines Junction to train their employees

- YECL committed to investigate and study programmable electric hot water controllers to shift the peak load
- Yukon Energy planning a "Opportunities Assessment" of their plants
- Studies on capacity enhancements were scheduled for 1997
- YECL committed to start a more aggressive energy management initiative with its major users
- Rebate programs for residential customers were scheduled for study in 1997

Demand Side Management Since 1998

Since the closure of the Faro Mine in 1998, there has been a hydro energy surplus. Consequently there has been minimal economic justification to pursue DSM initiatives for most Yukon assets. However, DSM programs have not been terminated.

Since 2000, management of DSM programs has been undertaken by the ESC. ESC is a service and program delivery agency for energy efficiency and green power programs for the Federal and Yukon governments. The programs run by ESC include electricity programs, and programs focussed on improving the energy efficiency of other energy sources, such as wood-burning. As reported by ESC, the ESC programs that specifically address electricity conservation include the following:

2002-2003 Fridge Exchange: A Pilot Project of Yukon Development Corporation and Natural Resources Canada: The program encouraged Yukoners to exchange fridges that were 10-years old or more, for new, and more energy efficient ENERGY STAR fridges. Yukoners were responsible for purchasing the new appliances, however incentives were given. The program resulted in the following savings:

- 58 reduced tonnes of CO2 generation
- 72 megawatt hours of savings
- $14,400 in avoided costs

Final Report to Climate Change Action Fund Public Education and Outreach, Completed June 2001: The program targeted 2,000 house call energy audits. A total of 1,457 homes were visited. The program focussed on low flow showers to reduce water heater use; water heater blankets; and higher efficiency bulbs. The program resulted in:

- 2,203 reduced tonnes of CO2 generation
- 2,938 megawatt hours of savings

"Six Pack" Parking Lot Controller Pilot Project: A 2003 study of Intelligent Parking Lot Controllers in six Whitehorse locations: This pilot project evaluated the use of a block heater conservation device that limited the number of hours that block heaters would be in use during the business day. The test year that was used for the analysis was a warmer than average year which reduced the savings realized during the year. The total savings realized were 6,426 KWh. However, the payback period for the equipment was very difficult to forecast.

Penguin Pilot Project: Assessing the acceptability of residential tank timers: Results and Evaluation report, December 2003: The pilot project evaluated timers on residential water heaters. The bulk of the water heaters in the pilot project were 40-gallon capacity, with two 3,000 watt elements. The pilot project included 50 hot water tanks, and had a combined load of 150 KW.

The GreenHog Handbook: The handbook was launched in March 2004 by ESC. The handbook solutions to reduce greenhouse gas emissions in the Yukon. The 50-page handbook includes information on climate change, practical tips and solutions for lowering greenhouse gas emissions, coupons for free and discount items, and a booster card for discounts on locally available products and services. This handbook provides a number of suggestions and detailed information, but it is difficult to calculate the greenhouse gas emissions reduced due to this program.

3.0 SYSTEM CAPABILITY

In order to begin an effective resource planning exercise, it is necessary to assess the capability of the existing system to supply loads today and into the future under various time horizons and scenarios. This includes assessing the condition of Yukon Energy's assets, their capability to provide capacity and energy to the system, and ensuring that an adequate capacity planning criteria for the system is in place. This chapter provides a review of the condition and output of Yukon Energy's assets, and Yukon Energy's new capacity planning criteria.

The sections for this chapter are as follows:

- Section 3.1 Current Facilities Condition Assessment
- Section 3.2 Capacity and Energy Output of Existing Facilities
- Section 3.3 Capacity Planning Criteria Review
- Section 3.4 Summary: Revised Capacity Planning Criteria

The condition assessment section contains a description of three recent condition assessment reports requisitioned by Yukon Energy, and the findings of the assessments.

The capacity and energy output of the existing facilities are reviewed in the second section, which focuses on implications of changes to major asset output since 1992, either from age, enhancement, or licencing conditions.

The capacity planning criteria review section provides an overview of Yukon Energy's past capacity criteria, and the new capacity criteria that was recently adopted. Yukon Energy's past criteria was developed by NCPC, adopted in 1987 when Yukon Energy acquired NCPC's assets, and modified slightly in 1992. Yukon Energy reviewed its capacity criteria in 2004-2005 to determine if the criteria still reflects the needs of the Yukon system, and concluded that changes are required as set out in Section 3.4.

3.1 CURRENT FACILITIES CONDITION ASSESSMENT

Yukon Energy has recently had independent assessments of its key generation, substation and transmission assets.

- In May of 2004, BC Hydro completed its *Condition Assessment of Selected Yukon Energy Generating Assets*. This assessment was focused on Whitehorse Hydro (Units WH1 through

WH4), Whitehorse Diesel (Units WD1 through WD7) and Aishihik Hydro (units AH1 and AH3). The condition assessment did not review the other diesel plants or the Mayo hydro facility.

- A *Condition Assessment of Selected Yukon Energy Corporation Substation Assets* was completed by BC Hydro in June of 2004. The focus of BC Hydro's assessment was on circuit breakers and transformers located at the substations at Aishihik, Takhini, MacIntyre, Whitehorse (all on WAF) plus Mayo.
- Acres International was commissioned to assess Yukon Energy's transmission assets. The Acres International report, *Assessment of Transmission Lines for Yukon Energy Corporation* was completed in December of 2003. The condition assessment by Acres International of Yukon Energy's transmission lines was of a significantly different type than the Generation and Substation assessments. In the Acres assessment, the primary item to be addressed was the expected remaining life of the transmission assets, based on a sampling of the WAF transmission lines.

The three reports were filed in YEC's 2005 Required Revenues and Related Matters Application as Interrogatory Response YUB-YEC-A52. BC Hydro and Acres International found Yukon Energy's assets to be in good to relatively good condition with a few notable exceptions:

- Whitehorse Diesel Units WD1, WD2 and WD3 were assessed to be at their "end of life" and either need to be retired, or require substantial investment;
- Mayo Substation transformer T1 needs to be replaced in the next five years; and
- A number of circuit breakers need to be replaced at various substations.

Other smaller projects for modernization or life extension were also recommended in the various condition assessments.

3.1.1 Yukon Energy's Response to Condition Assessments

As a result of the condition assessment documents, Yukon Energy developed short to medium term capital investment plans to address the bulk of the items identified by BC Hydro and Acres International. This Yukon Energy plan was provided in the 2005 Required Revenues and Related Matters Application and has been reviewed by the Yukon Utilities Board. To summarize:

- **BC Hydro Condition Assessment of Selected Yukon Energy Generation Assets:** As shown in the Table 3.1, the BC Hydro report recommended $2.454 million in work on these units. Yukon Energy's capital plan for these same units over the period 2004-2009 reflects overall approximately the same scope of work (also shown on Table 3.1). Yukon Energy's plan consists of $3.760 million. The reason for the $1.306 million variance is primarily

material costs associated with the WH1 and WH2 trunion bushing capital projects that were not forecast by BC Hydro for $824,000, plus a 2004 project for major capital work on WD5 for $201,000 that was already in progress when BC Hydro prepared their report (and therefore is not addressed in the BC Hydro recommendations).

- **BC Hydro Condition Assessment of Selected Yukon Energy Corporation Substation Assets:** In this report, BC Hydro reviewed a number of Yukon Energy's substations and recommends $921,000 in work over the "medium to long-term" at Appendix I of their report (also see Table 3.2). Yukon Energy's capital plan for 2004-2006 includes $880,000 to complete this work, including further detailed assessment of each of the recommendations. YEC intends to review other options before proceeding with circuit breaker replacements estimated at $210,000.
- **Acres International Assessment of Transmission Lines for Yukon Energy Corporation:** Although some token amounts were identified as being recommended as capital to be spent in the next five years ($43,000 per page 28), the majority of the report was not aimed at determining the appropriate capital investment in transmission line. Yukon Energy has incorporated the amounts identified by Acres International in its five year capital plans for transmission spending.

Table 3.1:
BC Hydro Generation Condition Assessment Recommended spending compared to YEC Budgeted Capital Planning 2004-2009 ($000s)[1]

BC Hydro 5 year Recommendation

	P125	P126	P127	AH0			
Unit Life Extension Mech	$152	$438	$84	$22			$696
Unit Life Extension Elect	$20		$40	$130			$190

Notes:
Only YEC plans that correlate to the BC Hydro report are shown here. Other work is planned for substations or components that BC Hydro did not assess.

3.1.2 Condition Assessment Findings Relevant to Resource Planning

The Condition Assessment findings indicate Yukon Energy's system is generally well suited to meeting the future WAF and MD system load requirements over the duration of the Resource Plan within the as-built capabilities of each the various units studied. Aside from new requirements related to load growth, the clear exception is the three Whitehorse Mirrlees diesel units, WD1, WD2, and WD3, located at the Whitehorse diesel plant.

It has been well known to Yukon Energy that the Mirrlees units were approaching retirement, and in fact earlier Yukon resource planning exercises (both 1992 and 1996) were based on these three units being retired prior to 2006. The units have been retained in-service due to the current system load, which has not required material running time for these three units during the 1993-1995 closure, or since the 1998 closure of the Faro mine and into the future until at least the current hydro surplus on the WAF system is consumed by firm load.

The issues and options relating to the requirement to retire the Mirrlees units are further addressed in *Chapter 4.*

3.2 CAPACITY AND ENERGY OUTPUT OF EXISTING FACILITIES

The generating assets in service are required to meet both capacity (instantaneous peak) and energy (annual and sometimes seasonal requirements) of the individual systems (WAF, MD, isolated). An overview of Yukon Energy's generating assets is set out in Table 3.3. On each of the WAF and MD grids, supply is also available from diesel and, in one case, hydro assets owned by YECL.

This section reviews the capability of key Yukon generation assets to meet capacity and energy requirements of the various systems.

The capacity ratings of Yukon Energy's assets reflect design or "nameplate" ratings, as adjusted in certain cases to reflect the real-world conditions with respect to the individual unit, or conditions that exist at the time of year when capacity requirements are highest (e.g., winter). Capacity ratings for resource planning also must reflect what can be relied upon in worst case conditions, in particular drought conditions for hydro units.

Energy ratings could similarly be developed to reflect reliable output in worst case conditions (such as a drought for hydro units). However, given the current surplus energy conditions on the two main Yukon systems, energy output is only addressed in this section with respect to Aishihik, which has been moderately affected by recent changes to the Water Licence under which it operates.

3.2.1 Whitehorse Rapids Hydro Firm Capacity

The largest generating station in Yukon is the Whitehorse Rapids hydro plant. The output of the plant at full river flow conditions in summer is 40 MW, or slightly above. However, during low flow (i.e., drought) winter periods, the plant's firm output that can be relied upon is well below this level.

Whitehorse hydro is supplied by the flows of the Yukon River. The plant is largely "run-of-the-river", but there is some modest flow control via a control structure at the outlet of Marsh Lake (the Lewes Dam). By managing the flow out of Marsh Lake in accordance with licence conditions, Yukon Energy can help sustain Yukon River flows into the winter periods when system load requirements are highest. Absent this control, the plant would have very low firm winter output. Although YEC has a modest level of flow control on the river, there is very limited ability during winter to use the Whitehorse Rapids plant for "load factoring" where the plant output might be materially varied on (say) a daily basis. In summary, "load factoring" types of fluctuation in downstream flows at this plant during winter conditions can cause ice break-up and ice jamming, and consequently flood low-lying areas of Whitehorse, as was reviewed in detail by the YUB at the 1992 Resource Plan hearing.

The Whitehorse Rapids reliable firm capacity rating during low winter flows was reviewed in 1992 and in follow-up at the 1993/94 GRA (as set out in Chapter 2). In short, at that time Yukon Energy and YECL provided evidence that during drought years, a managed drawdown of Marsh Lake over six months can provide 19 MW of consistent firm capacity under the lowest flows on record. However, Yukon Energy also indicated that in 80% of the years (i.e., non-drought years), the plant could reliably provide 24 MW or more during winter. In 1992, the Companies indicated that in drought years, if 24 MW of plant capacity was required, up to 5 MW of diesel may be able to be temporarily leased for the winter to maintain a 24 MW reliable level of capability at this plant (over and above the capability provided by the plant's existing diesel units). As a result, since that time the hydro units at this plant have been assigned a winter reliable capacity rating of 24 MW.

Yukon Energy has continued to refine its operation of the Whitehorse Rapids hydro plant, particularly in the period since the closure of the Faro mine. Based on these more recent reviews, Yukon Energy can now confirm that the drought-year capability of the Whitehorse Rapids plant is 24 MW under current load conditions. This is achieved largely by being able to maximize Marsh Lake outflows, starting November, at a stable level for the four coldest winter months, and at licenced minimum flows for the remaining two winter months (when capacity is less of a concern on the WAF system). In addition, Yukon Energy can manage Schwatka Lake levels to a small degree on a daily basis, drawing down the lake by about six inches during the day and allowing it to refill at night.

Consequently, Yukon Energy continues to use 24 MW as the firm capacity of the Whitehorse Rapids plant. Moreover, this full level is now achieved without the earlier concept of resorting to short-term leased diesel units during drought conditions.

3.2.2 Aishihik Hydro Capacity and Energy

Unlike Whitehorse Rapids, Aishihik hydro capacity output is not limited by water storage or droughts. This is because the multi-year Aishihik reservoir is large and quite flexible (with a seven foot restricted operating range under the renewed licence), and can be dispatched largely as needed by Yukon Energy to meet peak loads. For this reason, Aishihik's output can vary substantially during the day in winter as loads change (compared to Whitehorse hydro, which is a very stable daily output). Aishihik's output also varies materially on a seasonal basis, as summer use is minimized to allow the lake to re-fill for the coming winter.

The maximum capacity output of Aishihik hydro is 30 MW today, based on 2 – 15 MW units. For the reasons noted, this capability is available on a firm basis during winter low flow conditions.

Recent rewinds performed on AH1 indicate a potential to increase the rating on the units to 15.4 MW. However, rewind work has not yet been performed on AH2 (scheduled for 2006) and until this is completed and consequent coordinated testing done on the units, YEC will not be able to confirm the slight increase in capacity ratings. Future potential also exists to re-runner the Aishihik units to theoretically increase the mechanical capacity output by as much as 20%; however this initial indication requires significant further work to confirm that the electrical system and various physical components (such as wicket gates and turbine bearings) can handle the increase in output. This preliminary assessment work is ongoing.

In terms of annual energy capability, due to the multi-year characteristics of the Aishihik plant and how it is used, the long-term annual energy output of Aishihik is dependent upon a combination of (a) long term average flow conditions, (b) load requirements on WAF, and (c) the constraints relating to the facility's capacity and its water licence terms and conditions. For the purposes of this Resource Plan, Yukon Energy has retained the Aishihik long-term average output at 105 GW.h/year consistent with previous plans. As noted below, this capability is expected to increase slightly should sufficient major new industrial loads be placed on the system; however, under such increased load conditions, Aishihik's energy long term average capability is currently estimated to be about 3 GW.h/year lower than it would have been had the previous licence conditions (nine foot unrestricted operating range) been maintained.

- **Current WAF Load Conditions:** At present, given surplus hydro energy on WAF due to current load conditions, Aishihik Lake is being maintained in a substantially full condition near the top end of its licence limits, so any major increase in need to drawdown the lake (such as for major new loads) will allow high output for some time before the stored energy is

consumed (similarly, drought conditions at Aishihik today can be addressed by a period of drawdown to maintain long-term average generation levels despite low inflows). Under these conditions, the earlier long-term average energy capability does not appear to be materially affected by the new Water Licence terms and conditions.

- **Major Industrial Load Additions:** At such time as sufficient large new industrial load develops on WAF, similar to the Faro Mine loads in the past (or greater), it is to be expected that Aishihik Lake would tend over a few years to be drawn-down to within the mid-range of its licenced operating range. After such drawdown, Aishihik's long-term average annual energy output is expected to increase slightly above 105 GW.h/year and to reflect licence conditions. In the event that sufficiently higher WAF industrial loads occur, this long-term average energy capability is expected to be somewhat further increased, but also to be as much as 3 GW.h per year lower under the current seven foot restricted operating range than would be expected under the nine foot unrestricted operating range of the reservoir with the previous Water Licence.

3.2.3 Mayo Hydro Capacity

The capacity of the Mayo hydro plant has traditionally been listed as 5 MW based on 2-2.5 MW turbines. However, there has not been sufficient load on this system for many years to make use of this full capacity.

Due to the age of the units, in the last few years Yukon Energy has re-runnered and rewound the units which has enabled an increase in individual unit performance (now rated at 2.6 and 2.8 MW respectively). For planning purposes, Yukon Energy has assumed the combined 5.4 MW can be generated at the plant. It is important to note, however, that there is not sufficient load today to bring both units simultaneously up to full load to determine whether the full 5.4 MW can be achieved. This testing cannot occur until further load growth occurs on the Mayo-Dawson system. The increase in capacity is also forecast to increase the long-term average energy from 40 to 42 GW.h/yr.

3.2.4 Whitehorse Diesel Capacity

As noted in Section 3.1, there are immediate issues with respect to determining the future of the Whitehorse diesel plant in light of requirements to either retire or invest substantially in the Mirrlees diesel units WD1, WD2, and WD3.

In the interim, the three units are not in a condition that can sustain a Maximum Continuous Rating ("MCR") for planning purposes to the full nameplate ratings of these units. As a result, Yukon Energy has based its near-term planning on a "de-rated" MCR for these units of 4.2 MW (WD 2 and WD3, nameplate ratings of 5.15 MW) and 3.0 MW (WD1, nameplate rating of 3.92 MW).

Should some form of life extension project be undertaken on these units, that project would need to re-assess the ability to bring these units back up to the full nameplate MCR.

3.2.5 Fish Lake Hydro (YECL) Capacity

YECL maintains a small two unit hydro facility on the WAF system called Fish Lake, rated at 1.3 MW. Fish Lake hydro is neither dispatched nor monitored by Yukon Energy, and cannot be readily adjusted to match load conditions on a daily basis.

Fish Lake has traditionally been included in the Yukon planning process as firm capacity on the WAF system, at 1 MW. However, recent reports on the output of Fish Lake indicate winter flows cannot be relied upon to sustain outputs higher than about 400 kW, as was the case through the monthly averages during the winter of 2003/04 (December of that year dropped to a monthly average output of 389 kW), with many recent winters not recording average monthly outputs above about 600-700 kW.

Consistent with normal system planning practice of recognizing winter constraints, as is done for Yukon Energy's assets, the YECL Fish Lake facility are considered in this Resource Plan to be reliable firm winter capacity at a maximum of 400 kW.

3.3 CAPACITY PLANNING CRITERIA REVIEW

The Yukon system capacity planning criteria are the sets of rules used by YEC to determine how much firm generation capacity is required on the various Yukon systems and when additions to generation capacity are required. Criteria are applied separately for each power system in Yukon, e.g., the WAF system versus each isolated diesel system.

Changes to the Yukon systems since 1992, as well as the pending retirement of the three Mirrlees diesel units at Whitehorse, prompted a re-examination of the capacity planning criteria, focused particularly on WAF. As a result of this re-examination, Yukon Energy has adopted new capacity planning criteria.

Adequate firm generation capacity is one component of providing reliable power. Overall reliability of each BES system (generation and transmission) requires:

a) that there is adequate firm generation (and transmission) capacity installed on the system;
b) that the installed system be properly protected;
c) that the installed system be properly maintained (including brushing of transmission lines); and,
d) that the installed system is operated and dispatched in accordance with sound operating criteria.

In addition, the reliability of service to customers served on the distribution system will also include various factors relating to the reliability of that lower voltage system as well.

Standard utility reliability tests are intended to cover all of the recognized factors affecting system generation supply reliability including load factor growth both on a system and on each feeder, maintenance of equipment, regular and routine servicing and repair, assessing remaining life, planning for end of life replacement, removal of danger tress, and a range of other specific factors that affect reliability.

Capacity criteria in regards to long-term BES resource planning deals only with the first item in the above list of factors affecting BES system reliability; namely, that there be adequate firm generation and transmission capacity installed on each system.

In assessing capacity planning, it is recognized that Yukon Energy policy first interrupts secondary energy service that is to be supplied by surplus hydro resources, and that no BES capability is planned to supply secondary energy service. All remaining “firm” customer load requirements at the time of system maximum load or peak (e.g., winter peak on WAF) are considered when assessing each system’s capacity planning requirements.

3.3.1 Background and Overview on the Evolution of Capacity Planning

Planning of a utility system must provide both for system growth and for operation after a component failure. Systems vary greatly in size and complexity but the ability of each system to maintain service is compared by using established and recognized criteria.

In general, throughout various systems these planning criteria have evolved gradually into more defined ratios as systems have grown bigger and more complicated. Where relevant, transmission reliability has also been addressed where it directly affects generation reliability.

The criteria used by NCPC were developed to indicate the required amount of firm generating capacity to cover relatively small isolated systems, and were consistent with utility planning standards of that era. NCPC had started with a multiple of small isolated systems, some of which continue, but others had grown to the point where multiple sources were interconnected.

Yukon Energy (and its then manager, YECL), as the operator succeeding NCPC for the Yukon, initially followed the practice of NCPC. It was quickly found that the continuing small isolated installations were reasonably covered by the NCPC criteria but that the larger systems with multiple sources needed more detailed analysis to be secure:

- The small systems were considered to be adequately protected if the generating capacity with the largest single unit out of service was at least 110% of the anticipated peak load. This approach is continued today.
- For the larger "grid" systems, it becomes necessary to consider not only the possible loss of a single generator (in the case of WAF, a single "wheel" at Aishihik), but also the likelihood that at least one of the major WAF diesels would be unavailable at the same time. Consequently, the Resource Plan in 1992 introduced recognition of the diesel-related effect on Yukon Energy's ability to serve any particular WAF load by adding a "10% of installed diesel" reserve on top of the Aishihik hydro reserve.

Under the NCPC capacity planning criteria and the 1992 Resource Plan criteria, the transmission system availability was not considered at all.

In the meantime, other integrated utilities developed a statistical approach to the potential interruption of service for any customer. This is often evaluated as the Loss of Load Expectation ("LOLE") and it is measured in hours per year[2]. Most of the various Canadian utilities have come to apply an LOLE range from one to two hours per year as their capacity planning standards. Where relevant, certain utilities have incorporated transmission into this assessment where generation reliability is directly and materially affected by transmission. Specific recent experience with Northwest Territories Power Corporation has

[2] Other terms are also used to describe the probabilistic measures, such as the BC Hydro criteria of Loss of Load Probability ("LOLP") or Newfoundland and Labrador Hydro's Loss of Load Hours ("LOLH").

also applied, in parallel with LOLE criteria a second test to ensure that customers are protected against failure of any single system component.

Yukon Energy has recently examined the LOLE approach and tested it against the operating history of its WAF system. This review has shown that the WAF system has substantial hydro generation availability that is directly affected by certain transmission, and that the WAF system also has been trending to an increasing probability of longer outages as it expands (particularly with expansion of residential and commercial loads and major reductions in industrial load). Yukon Energy has therefore now incorporated the LOLE approach, with recognition of transmission reliability where relevant, into its system planning criteria to better protect all of its firm customers from generation-related outages.

At the same time, Yukon Energy has recognized that the LOLE function is an average that does not indicate how long any particular outage will last, and that any extended outage on its grid systems during the winter peak could be very adverse and serious, particularly for affected residential and commercial customers. Yukon Energy has addressed this concern by considering in parallel with LOLE a second test as part of its planning criteria, namely the effect of the failure of any individual bulk electrical system component and the ability of the system to continue to serve its firm residential and commercial customers without the failed component (i.e., a test described as "surviving the first failure" or "operating in the N-1 condition where "N" is the normal system complement). As an example, the biggest loss of generation on WAF today at winter peak would be 30 MW following a failure of the Aishihik transmission line; this loss would be far greater than the loss during winter peak of the biggest generator (which currently is a 15 MW generator at Aishihik)[3].

The previous criteria, the recent review and the revised criteria now adopted by Yukon Energy are each reviewed in more detail below.

3.3.2 Yukon Energy's Previous Capacity Planning Criteria (prior to late 2005)

The Yukon systems were previously planned with criteria (as reviewed in 1992) using a single formula for specifying its required firm generation capacity on each type of system. This deterministic criteria was outlined in the 1992 Resource Plan.

[3] The largest single unit on the WAF system is WH4, one of the hydro units at Whitehorse. However, as Whitehorse has four hydro units (WH1 at 5.8 MW, WH2 at 5.8 MW, WH3 at 8.4 MW and WH4 at 20 MW), but only 24 MW of firm flows in winter in drought conditions, a loss of WH4 would only effectively reduce the available capacity by 4 MW (as the other three units would still be available), which is smaller than the loss of 15 MW via one of the units at Aishihik.

- For **Isolated Diesel Communities**, the criteria required each system to have installed generation capacity sufficient to meet 110% of the forecast peak load with the largest generation unit out of service.
- For the **WAF grid**, the required system generation capacity was determined as follows:
  1. The installed generation system, less a "Generation Reserve Requirement", must be able to meet the forecast WAF winter peak loads. For simplicity, this approach was used to define the Maximum Allowable Peak Load ("MAPL") for the WAF system at any time, i.e., the installed capacity at that time less the applicable Generation Reserve Requirement.

  2. The Generation Reserve Requirement was the reserve needed to meet forecast winter peak load with the loss of the single largest winter unit (one of the Aishihik units at 15 MW) plus the loss of 10% of the installed diesel capacity.

- For **individual communities on the WAF grid**, there was no generation capacity planning criteria in place. In practice, communities over about 300 people other than Faro and Whitehorse typically have local diesel generation installed to serve a dual purpose: overall grid support similar to major diesel installations at Whitehorse or Faro, as well as local supply during transmission outages. This applied at Ross River, Carmacks, Haines Junction, and Teslin, but has not been traditionally applied at Carcross. It was also not applied at smaller centres below 300 people.

  With respect to Faro, there has traditionally been a major diesel plant well in excess of the town requirements, but below the requirements of the Faro mine. Today, Faro maintains a diesel plant of 5.3 MW, which serves as a major diesel anchor point for the grid as well as for local supply in the case of transmission outages.

  For Whitehorse, there were no criteria regarding generation capacity requirements. In practice, however, Whitehorse has traditionally had sufficient generation (hydro plus diesel) installed in the local area to supply the community in the case of major transmission outages. This condition has now changed with recent growth in Whitehorse and the pending retirement of the Mirrlees units.

- For the **MD grid**, there was previously no approved capacity planning criteria. Previously, the Mayo system criteria had been based on supplying 110% of the peak load with the hydro

units out of service. The separate Dawson system had been planned as an isolated diesel community (prior to the Mayo Dawson transmission development).

For both of the grid systems, the generation assets were included in the past capacity planning criteria calculation, but transmission assets were not considered. As a result, the possibility of transmission failure was not accounted for.

The MD Transmission Line was brought into service in 2002 to use surplus hydro at Mayo to offset diesel generation in Dawson City. The Dawson diesel plant is still in service in Dawson as back-up capacity well in excess of the community's peak loads (it had been installed to meet the Isolated system standard). There are also two diesel units in Mayo that together approximate the local Mayo firm peak loads. Consequently, the WAF grid was the focus during the examination of the capacity planning criteria.

Table 3.4 depicts the generating complement and Maximum Peak Load under the previous planning criteria for WAF. The result is that a WAF load of 68.7 MW can be allowed under these criteria without exceeding the calculated capability of the current generating units in service.

Table 3.4:
Current WAF Generating Complement and
Maximum Allowable Peak Load (MAPL)
under Previous Planning Criteria

Unit	Rating (MW)
Whitehorse Hydro (winter - for all units)	24.0
Whitehorse diesel #1	3.0
Whitehorse diesel #2	4.2
Whitehorse diesel #3	4.2
Whitehorse diesel #4	2.5
Whitehorse diesel #5	2.5
Whitehorse diesel #6	2.7
Whitehorse diesel #7	3.3
Faro diesel #3	1.0
Faro diesel #5	1.3
Faro diesel #7	3.0
Aishihik #1	15.0
Aishihik #2	15.0
Carmacks diesel (YECL)	1.3
Haines Junction diesel (YECL)	1.3
Teslin diesel (YECL)	1.3
Ross River diesel (YECL)	1.0
Fish Lake hydro (2 units - YECL)	0.4
Total	87.0
Less: 15 MW hydro Reserve	-15.0
Less: 10% Diesel Reserve	-3.3
Maximum Allowable Peak Load (MAPL)	68.7

3.3.3 Previous Yukon Criteria Compared with Criteria for Other Jurisdictions

Yukon Energy's previous capacity criteria do not identify any specific BES system capacity requirement that can be readily compared with criteria adopted in other jurisdictions for integrated systems. This was because the previous Yukon criteria only dealt with the concept of a "reserve" rather than actually assessing the likelihood (or probability) that the generation available will be insufficient to supply the load at any given point in time, which has been adopted by the majority of Canadian utilities. The previous Yukon criteria are described as "deterministic" in that a set test is adopted for each system as a proxy

intended to ensure adequate capacity – however, to assess the adequacy of this proxy, it was necessary to compare Yukon's situation with criteria adopted in other jurisdictions.

Reliability experts were hired from the University of Saskatchewan in 2004 (under the direction of Dr. Roy Billinton) to study and determine the probabilities inherent in the existing Yukon capacity planning criteria. NWT Power Corporation has used Dr. Billinton as an advisor in the development of their Snare-Yellowknife system planning criteria, and received approval from its regulator for their revised criteria in November of 2004.

The review confirmed that a comparison of Yukon's previous criteria with criteria typically adopted by major Canadian utilities cannot be readily undertaken. However, in terms of the maximum peak load that can be supported, the review indicated that WAF generation was not adequate to supply the 68.7 MW peak (as would be allowed under the existing criteria (see Table 3.4)) within any reasonable reliability standard adopted elsewhere in Canada[4].

Generation Adequacy (capacity) criteria in Canada today are typically derived by looking at the probability of an outage occurring due to having inadequate generation installed. This "probabilistic" approach looks at the likelihood of different load levels over the year and the likelihood of this load not being met due to unplanned outages of generation units or (in some limited cases) transmission facilities. The resulting criteria are expressed for a system as LOLE (stated as average number of hours or days per year that the BES system would be inadequate due to unplanned events) and Loss of Energy Expectation (LOEE, stated in MWh/yr of energy desired by customers that would go unserved). The review indicated that criteria commonly used in the NWT and southern Canada are LOLE between about one and two hours per year. If applied to the Yukon system (including consideration of constraints posed by the reliability of the Aishihik transmission line), the review indicated that such standards would only allow a maximum peak on the current WAF system of about 60.1 MW to 62.9 MW (compared to 68.7 MW under the previous criteria).

The review also indicated several key findings with regard to the previous WAF criteria, as follows:

[4] The work by Drs. Billinton and Karki reflects an evaluation of the WAF system with some minor overall differences from the capacity values indicated in Table 3.4. For example, Drs. Billinton and Karki did not consider Fish Lake as a reliable supply resource (the load data available was net of Fish Lake outputs, so the resource was effectively already accounted for in the loads) and used a higher assumed Haines Junction diesel output of 1.7 MW. Subsequent investigations indicate this assumed capacity for Haines Junction was too high. The net result, however, of these variations is minimal on the overall conclusions of the report.

1. **The WAF Deterministic Criteria was adequate in 1996/97** – The previous WAF capacity criteria provided excellent capacity reliability for residential and commercial customers in 1996/97 when the Faro Mine was in operation, with an LOLE of 0.008 hrs/year (based on the Faro Mine being the first customer to be interrupted). The reliability for industrial customers was considerably less at that time at about 9.4 hours per year. However, even in the event of a major shortage of WAF generation, the mine would still have typically received substantial supply from the Faro diesel plant (13.6 MW at that time).

2. **The WAF Deterministic Criteria is not adequate today based on LOLE** – The previous WAF capacity criteria provide poor capacity reliability today with an LOLE of about 5.9 hrs/yr at the peak load level allowed by the past criteria. The LOLE is considerably higher than it was in 1996, and also well above the normal range of one to two hours per year adopted by other Canadian utilities. Since there are currently no major industrial customers on WAF, this assessment in effect addresses the current capacity reliability for residential and commercial customers on WAF.

3. **Aishihik transmission line is key capacity constraint** – The transmission line from Takhini to Aishihik (L171 line) accounts for about 80% of the total LOLE today for WAF, and is thus the key WAF capacity constraint. This transmission line connects 31.3 MW of capacity to the Whitehorse area (as well as loads at Haines Junction). Were it not for this exposure to transmission outages, the LOLE would drop from 5.9 to 1.2 hours per year. The effect of considering the transmission line reliability is a reduction of 8.0 MW of load carrying capability at the two hours per year LOLE level.

4. **Previous criteria not adequate to track impacts of WD retirements** – The previous capacity criteria did not keep pace from a reliability standpoint with the planned retirement of Whitehorse capacity (WD1, WD2 and WD3). This is because retirement of 4.2 MW of diesel units at Whitehorse only reduced the MAPL by 3.8 MW (due to the 10% diesel reserve). The recent review however indicated that load carrying capability at an LOLE of two hours per year reduced by at least 4.2 MW upon a retirement of a unit of this type (in some cases slightly more than 4.2 MW).

In addition to LOLE generation criteria, some utilities (including NWT Power Corporation for its Yellowknife grid) also adopt a further emergency standard to ensure each major BES system can meet its peak winter loads with loss of its largest single transmission component (called “N-1” criteria). The

previous Yukon criteria do not address the N-1 emergency criteria for systems such as WAF because the transmission facility loss was not considered in the capacity planning criteria. The overall result was to potentially expose Whitehorse area customers in particular to loss of adequate generation if the Aishihik line suffers a sustained failure at the time of system peak. In practice, this risk exposure was not material so long as there was adequate generation (including diesel units) in the Whitehorse area to reliably supply this area's loads; however, this situation is changing through growth in Whitehorse area loads and pending retirement of diesel units at the Whitehorse Rapids Diesel plant.

3.3.4 New Criteria Adopted by Yukon Energy

The new capacity planning criteria now adopted by Yukon Energy are as follows:

1. **WAF and MD System-wide capacity planning criteria:** Each system (WAF and MD) should not exceed a LOLE of two hours per year. The two hour measure is the same as that adopted in NWT and is comparable to the lower end of standards commonly used in southern Canada (which are typically from one to two hours per year LOLE).

   Although determining the LOLE requires sophisticated computer modelling, in practice the LOLE approach can generally be applied on WAF by benchmarking the two hours per year LOLE to a WAF overall "load carrying capability" of 62.9 MW. In rough terms, this load carrying capability changes by about 1 MW for every MW of non-Aishihik line generation that is added or retired (e.g., a retirement of 4 MW from the Whitehorse diesel plant will reduce this load carrying capability by about 4 MW, vice versa for additions). The benchmarking is also based on a rough assumption that the load carrying capability would be increased by about 8.0 MW if the current Aishihik transmission line constraint was removed. This could be done by twinning the line (i.e., creating a second line to allow access to Aishihik generation resources in the event of failure of the existing line).

   For MD, this criteria is well exceeded today. MD is well below two hours/year LOLE and also satisfies an N-1 condition in all locations.

2. **Emergency (or "N-1") WAF and MD system capacity planning criteria:** Yukon's grids are small and isolated from major power grids, with single transmission lines connecting generation to load centres. Consequently, it was also determined to be appropriate to incorporate a standard to address the potential for sustained emergency conditions. In order to be able to address major emergencies, each system (WAF and MD) should be able to carry the forecast peak winter loads (excluding major industrial loads) under the largest single

contingency (known as "N-1"). The N-1 criterion determines system capacity assuming the loss of the system's single largest generating or transmission-related generation source. For the case of the WAF system, the largest possible loss would currently be the Aishihik line, which connects 31.3 MW of capacity (30 MW from Aishihik, and 1.3 MW of Haines Junction diesel).

This N-1 criteria on WAF equates to a current load carrying capability (non-industrial) of 55.7 MW (excluding Haines Junction load, as it would not need to be served from the Whitehorse end of the Aishihik transmission line in the event that transmission line is out of service).

3. **WAF and MD "community" criteria:** For communities on the WAF or MD grids, any location with a load large enough to justify a diesel unit of about 1 MW or more should be considered as a preferred location for new diesel units if that community does not already have back-up from another source (e.g., having an existing diesel unit). The new diesel units would provide grid support, and in times of line failures would provide local generation for the communities where they are located.

For isolated diesel communities no change has been adopted for the capacity planning criteria. Accordingly, the previous criteria is maintained for isolated diesel systems of being able to meet 110% of the community peak with the largest unit out of service.

3.3.5 Rationale for Adopting a Two-Part Criteria on WAF and MD

The two-part capacity planning criteria adopted by Yukon Energy for the WAF and MD systems is essentially the same as the capacity criteria approved by the regulator for the Yellowknife system[5]. This approach ensures that two different concerns are addressed on an ongoing basis.

The LOLE criteria provide an overall system measure that assesses the normal balance of the system including industrial loads, and the probabilities of experiencing outages due to having inadequate generation (and transmission) installed on the system. For Yukon, a standard approximately comparable to that used in Yellowknife (at about the lower end of planning standards used in southern jurisdictions in Canada), was viewed as reasonable. The LOLE standard in effect indicates the probability that the installed BES resources will be inadequate to supply the load for the total load on the system (including

[5] The only exception is that the Yellowknife N-1 criteria (called "minimum diesel") is slightly more stringent, in that 105% of the forecast winter peak loads must be carried under the N-1 condition, not simply 100% of the forecast peak as adopted by Yukon Energy.

industrial). In effect, it measures the balance between generation and loads (under normal probabilities of each system generating and key transmission units failing) and indicates how likely or unlikely it is that the balance will be unable to be maintained. This part of the criteria ensures that system capacity is planned on an ongoing basis to meet standards adopted and approved for other similar utilities in Canada.

However, the severity of a potential outage for non-industrial customers is not accounted for in the LOLE model. For example, despite an LOLE of two hours per year, it is entirely possible to have sustained outages (due to generation and transmission inadequacy, primarily related to the Aishihik line which is the largest single system constraint) for much longer than this under extreme winter conditions.

An emergency criteria was determined to be a necessary complement, given the potential seriousness of a sustained outage of the critical component of the system in winter (e.g., the Yukon system peak occurs in the coldest months of winter, when there is the least amount of sunlight to effect repairs such as to transmission facilities). This is to address the "surviving the first failure" consideration noted above (the N-1 test). YEC is incorporating this second level of testing into its capacity planning along with the LOLE criteria already described. As an example, the current biggest single winter generator on the WAF system is a single Aishihik wheel at 15 MW but the current biggest single potential loss of supply would be 30 MW following a failure on the Aishihik transmission line[6].

The N-1 criteria will not be extended to major industrial customer loads who typically maintain sufficient on-site diesel for their own emergency purposes (these customers would be informed that they would not receive full supply should the Aishihik line be out-of-service during the coldest days of winter).

Yukon Energy considered the NWT approach of requiring the system to meet the N-1 condition to a full 105% of forecast peak loads (slightly more stringent than a strict N-1) as a "safety factor for load forecast error"[7]. Given a WAF peak in 2005 of about 55.4 MW (excluding Haines Junction, which is not part of the N-1 criteria as it is on the western end of the Aishihik transmission line), such a "reserve" on WAF would equate to 2.8 MW. As the load today on WAF is only forecast to grow by about 1 MW per year (about 1.85%) and diesel capacity can be added relatively quickly if new capacity is seen to be required from unusual load growth, such a reserve for load forecast error was not considered necessary.

[6] The WAF system would also lose access to the 1.3 MW of generation installed at Haines Junction, but would similarly lose the need to supply the Haines Junction load from remaining WAF capacity (Haines Junction would be supplied by its own diesels) so there would be no impact on WAF of this additional loss.
[7] NWT Public Utilities Board Decision 14-2004, page 25.

The N-1 criteria will effectively govern the need for WAF system capacity requirements in the near term. However, this may not always be the case. As an example, if the Aishihik line was to be twinned, the N-1 condition would then only exclude 15 MW (the second largest single contingency on the WAF system is a loss of one Aishihik turbine) and it is likely that the LOLE condition would then govern the need for WAF system capacity. In addition, the LOLE condition may drive the need for new generation in the event of large new industrial loads, although these loads will have no impact on the N-1 criteria. It is important to ensure that ongoing capacity planning therefore addresses both concerns identified in the adopted two-part criteria approach.

3.3.6 Implications of the Adopted Criteria

The net effect of the new criteria adopted by Yukon Energy is a 2005 WAF system condition that is basically at the limits for all retail/wholesale loads (with approximately 300 kW of surplus in 2005). In short, any further wholesale or retail growth on WAF will be required to be met with new generation, as well as all future WAF system diesel unit retirements (see *Table 3.5, WAF Peak and Capacity Surplus (Shortfall) as Whitehorse Diesels are Retired (MW)*).

New capacity requirements of 18.7 MW are forecast for WAF for 2012 based on the adopted N-1 criteria as compared with only 12.5 MW based on the adopted LOLE criteria of two hours per year. Consequently the N-1 criteria has governed assessment today of new WAF capacity requirements. In contrast, the previous WAF criteria would indicate that no new WAF capacity would be required until 2010, and by 2012 only 5.5 MW of new capacity would be needed. These forecasts are based on current estimates of system load growth, excluding new industrial loads.

In contrast, MD generation under the new criteria adopted by Yukon Energy is well in excess of required levels in the absence of new major industrial loads. The same criteria can be applied to the MD system as capacity constraints arise on that system. However, at this point in time it is clear that MD is well below two hours per year LOLE and satisfies an N-1 condition in all locations.

Table 3.5:
WAF Peak and Capacity Surplus (Shortfall)
as Whitehorse Diesels are Retired (MW)

		Previous Criteria			LOLE Criteria			N- 1 Criteria		
Year	**Retirements**	**Peak (WAF wide, including loads served by Fish Lake)**	**Load Carrying Capability**	***Surplus / (shortfall)***	**Peak (WAF wide, including loads served by Fish Lake)**	**Load Carrying Capability 2 hours / year LOLE**	***Surplus / (shortfall)***	**Peak excluding Haines Junction (assumed to be 1 MW)**	**N – 1 criteria load carrying capability**	***Surplus / (shortfall)***
2005		56.4	68.7	*12.3*	56.4	62.9	*6.5*	55.4	55.7	*0.3*
2006		57.4	68.7	*11.3*	57.4	62.9	*5.5*	56.4	55.7	*(0.7)*
2007	WD3	58.5	64.9	*6.4*	58.5	58.7	*0.2*	57.5	51.5	*(6.0)*
2008		59.6	64.9	*5.4*	59.6	58.7	*(0.9)*	58.6	51.5	*(7.1)*
2009	WD2	60.6	61.1	*0.5*	60.6	54.5	*(6.1)*	59.6	47.3	*(12.3)*
2010		61.7	61.1	*(0.6)*	61.7	54.5	*(7.2)*	60.7	47.3	*(13.4)*
2011	WD1	62.9	58.4	*(4.4)*	62.9	51.5	*(11.4)*	61.9	44.3	*(17.6)*
2012		64.0	58.4	*(5.5)*	64.0	51.5	*(12.5)*	63.0	44.3	*(18.7)*

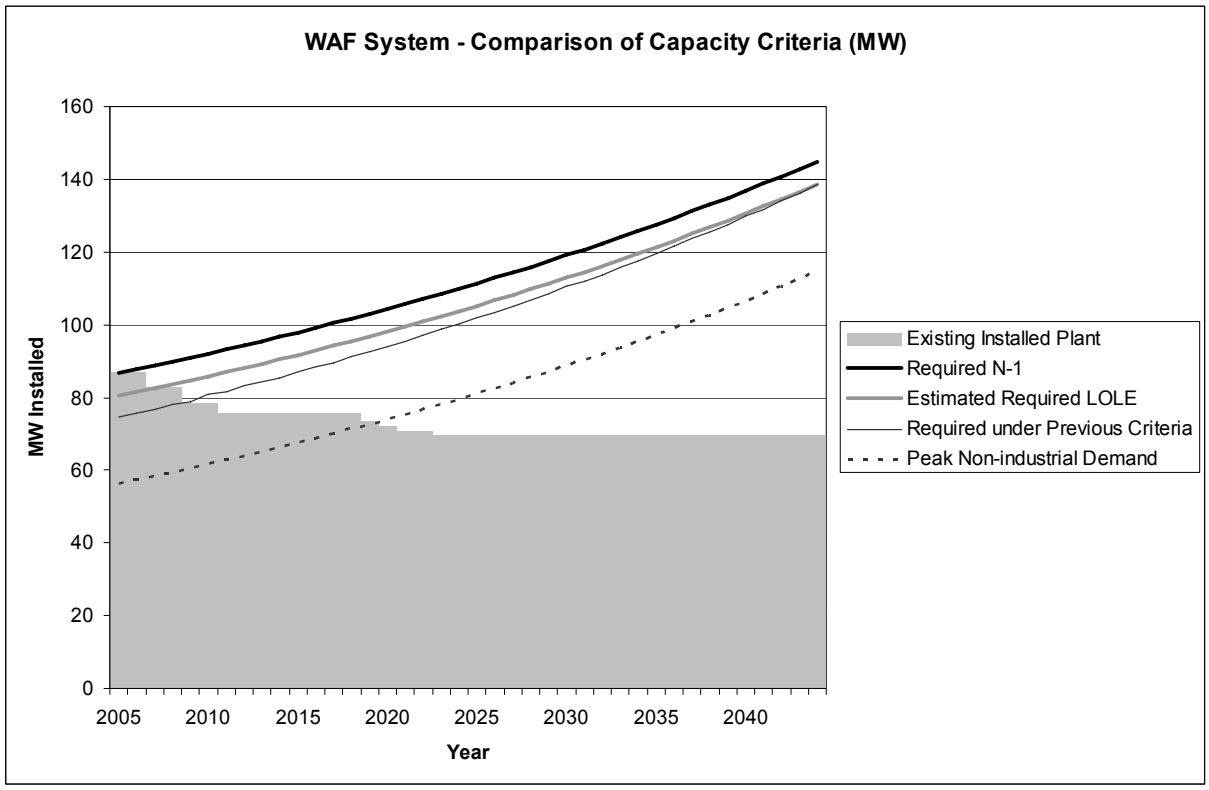
As long as the WAF system with the current Aishihik line (i.e., no twinning of this line) can meet the wholesale/retail peak under the N-1 criteria, up to 6-7 MW of major industrial loads can be served without driving new generation investment for capacity reasons.

Adoption of the revised planning criteria was required to plan and develop infrastructure in Yukon. The new criteria indicate a need to have WAF generation additions occurring in the next 12-24 months. This may drive a requirement for capital investment in excess of $3 million in the near-term.

Figure 3.1 WAF System – Comparison of Capacity Criteria depicts Yukon Energy's need for new capacity through to 2045 under the N-1, LOLE, and previous criteria. Forecast WAF peak load (non-industrial) is depicted by the dashed line. Required capacity is shown based on the forecast peak load and the three different capacity planning criteria examined in Table 3.5 – this analysis assumes continuation of the current WAF systems without any new investment (such as twinning of the Aishihik line) to remove of the current Aishihik transmission line constraint. Forecast existing installed plant reflects retirement assumptions as noted in Figure 3.1. In effect, the analysis assumes that all new capacity requirements are met with diesel installed at Whitehorse.

Of note is that even under the existing capacity planning criteria, the planned retirement of the Mirrlees combined with expected load growth over the next five to six years will require new capacity to be installed on the WAF system. However, with adoption of the new criteria noted above, this requirement will lead to the need for new capacity to address all planned Mirrlees retirements plus basically all load growth from 2005 forward.

Figure 3.1:
WAF System – Comparison of Capacity Criteria



3.4 SUMMARY: REVISED CAPACITY PLANNING CRITERIA

The following revised capacity planning criteria have been adopted by Yukon Energy:

1. **WAF and MD System-wide capacity planning criteria:** Each system (WAF and MD) will be planned not to exceed a Loss of Load Expectation (or LOLE) of two hours per year.

2. **Emergency (or "N-1") WAF and MD system capacity planning criteria:** Each grid system (WAF and MD) will be planned to be able to carry the forecast peak winter loads (excluding major industrial loads) under the largest single contingency (known as "N-1"). The N-1 criterion determines system capacity assuming the loss of the system's single largest generating or transmission-related generation source.

3. **WAF and MD "community" criteria:** For communities on the WAF or MD grids, any location with a load large enough to justify a diesel unit of about 1 MW or more will be considered as a preferred location for new diesel units if that community does not already

have back-up from another source (e.g., having an existing diesel unit). The new diesel units would provide grid support, and in times of line failures would provide local generation for the communities where they are located.

For isolated diesel communities no change has been adopted for the capacity planning criteria (which requires being able to meet 110% of the community peak with the largest unit out of service).

4.0 NEAR TERM REQUIREMENTS

"Near term" requirements address Yukon Energy generation and transmission commitments required before 2009 for major investments with anticipated costs of $3 million or more. Given the time needed for possible construction, the assessment examines possible in-service needs to meet loads out to 2012.

This chapter focuses on opportunities for enhancements to existing hydro stations as well as cost-effective resource supply alternatives capable of meeting the 15 to 27 MW of new capacity required within the defined near term period. The sections for this chapter are as follows:

- Section 4.1: Planning Approach and Timeline
- Section 4.2: Requirements
- Section 4.3: Options
- Section 4.4: Assessment
- Section 4.5: Proposed Actions

4.1 PLANNING APPROACH AND TIMELINE

Potential major investments in the near term for new generation or transmission relate to opportunities to enhance existing system assets, and to address WAF system capacity shortfalls. As reviewed in Section 4.2, the WAF shortfalls are forecast to be between 15 and 27 MW within the next five to six years. In contrast, with material surplus hydro generation on both the WAF and MD systems, there is no apparent near term requirement or opportunity for major new energy-related investments. There is a near term opportunity to extend the WAF grid to supply two possible new mines in the Carmacks to Pelly Crossing region using available surplus hydro generation (see *Section 4.2: Requirements*).

Near term opportunities in respect of existing hydro assets focus on both the Whitehorse and Aishihik generating stations. In each case, the projects have been reviewed over many years in different variations. These projects fit with similar initiatives in other jurisdictions such as BC Hydro's "Resource Smart" program focusing on means to provide additional energy or capacity "through physical or operational modifications to existing facilities", and similar Supply Side Enhancement programs at Manitoba Hydro.

In respect of capacity requirements, as reviewed below capacity shortfalls on WAF under the new capacity planning criteria begin to arise as soon as 2006, even before any Whitehorse diesel units are retired, and become sufficiently material in 2007 to require overall spending commitments exceeding the

$3 million level. Consequently, planning activities for the near term focus on supply options that are sufficiently well-defined to make commitments and begin the necessary licencing or construction activities by, at the latest, late 2006 to early 2007.

The planning approach for near term requirements follows the general planning approach set out in Chapter 1:

1. **System capability** (part of Section 4.2: Requirements) over the intended "near term" horizon (in this case, as explained above, to about 2012) is reviewed, particularly noting planned retirement of generating capacity.
2. **System capacity requirements** (part of Section 4.2: Requirements) are reviewed over the near term based on the new capacity planning criteria, focused on non-industrial load forecasts plus potential loads from reasonably well-defined industrial load options that might emerge in the near term; sensitivities are examined with regard to different possible load forecasts.
3. **Forecast New Facilities Requirements** (part of Section 4.2: Requirements) are reviewed over the near term based on system capacity requirements, opportunities to enhance existing hydro generation facilities and, in the event loads are sufficiently high, opportunities to displace diesel-based energy production.
4. **Resource Options** (Section 4.3: Options) are reviewed over the near term, focused on potential resources of sufficient definition, size and timing for in-service to meet the near term requirements for new facilities.
5. **Assessment of Resource Options** (Section 4.4: Assessment) are reviewed over the near term, focused on technical feasibility (including timing), cost efficiency, reliability, and risk (in particular, risks related to "markets" or future loads developing differently than indicated by forecasts today).

Key considerations with respect to system capability are reviewed in Chapter 3. Over the focused near term to about 2012, one key system capability issue relates in large part to the planned retirement of the three Mirrlees engines:

- **WD1:** A Mirrlees KV12, installed in 1968, currently rated at 3.0 MW MCR (nameplate 3.92 MW) with a planned retirement in 2011;
- **WD2:** A Mirrlees KV16 from 1968, currently rated at 4.2 MW MCR (nameplate 5.15 MW), with a planned retirement in 2009; and,
- **WD3:** A similar Mirrlees KV16 dating from 1970, currently rated at 4.2 MW MCR (nameplate 5.15 MW) with a planned retirement in 2007.

The three Mirrlees engines have been planned for retirement for many years, including as far back as the 1992 Resource Plan hearing (when they were planned to be retired in 1998, 1998 and 2000 respectively). By 1996, the planned retirement of these units had been extended by four years to reflect in part lower running hours during the 1993-1995 closure of the Faro mine, as well as maintaining their running hours at a very low level by maintaining the units at the bottom of the stacking order.

With the 1998 closure of the Faro mine, Yukon Energy was able to further extend the planned retirements to the current schedule (WD1 by 9 years, WD2 by 5 years and WD3 by 3 years) based on updated assessment of the relative condition of each unit, and continued minimal operation.

However, at the present time, it is clear that further delay of retirement of these units is not possible without material investment in major tear-down overhaul work. This is further confirmed by the BC Hydro Condition Assessment (see Section 2.1) which concluded that these units were at “end-of-life”. In addition, the Mirrlees are low-speed base load units (514 RPM) which are poorly suited to the current operating regime of stop-and-start operation. Finally, Yukon Energy and others who maintain Mirrlees engines of this vintage (including Northwest Territories Power Corporation) have substantial concern with the ongoing ability of the current owner of Mirrlees to provide ongoing parts and technical support.

Any further delay in planning for an orderly retirement or, if possible, major refurbishment of the Mirrlees units will in all likelihood substantially increase the risks of a major failure or inability of these units to supply reliable utility standard service when required.

4.2 REQUIREMENTS

Yukon requirements for new capacity or energy resources in the near term result from the combined effects of three factors within each system:

- forecast non-industrial load growth, particularly on WAF related most notably to growth in the Whitehorse area;
- potential opportunities to connect new major industrial mine loads, including via new transmission to supply potential mines in the Carmacks to Stewart Crossing area; and,
- changes in the capability of existing generation or transmission resources, including changes related to new capacity planning criteria and planned retirements.

As set out in detail in Section 4.3, there are only two material new near term resource supply opportunities and/or requirements on Yukon systems:

1. New firm WAF capacity required, due to WAF winter peak capacity exceeding the maximum loads allowed on the system under new capacity criteria (however, this system has no need for new firm energy capability due to ongoing surplus hydro energy generation of over 90 GW.h/yr, with about 21 GW.h/yr of this surplus being currently used to supply interruptible secondary sales).
2. Opportunities to enhance existing WAF hydro generating assets to increase energy and/or capacity outputs.

The MD system has surplus hydro energy generation of about 17 GW.h per year, and surplus winter peak capacity with existing hydro and diesel generation. Consequently, as reviewed in Section 3.3, the LOLE for the MD system is not likely to exceed 2.0 hrs per year for many years into the future, absent major new industrial loads on this system. The MD system also satisfies the N-1 capacity criteria at each end of the MD transmission line as well as at the community of Stewart Crossing.

With respect to WAF requirements, four near term load cases have been identified, and are set out in the following sections. Each section includes graphs depicting the capacity and energy requirements under each scenario as follows:

- **Forecast WAF generation capacity:** The MW capacity requirement at winter peak is indicated, showing separately the capacity to meet N-1 Requirement and the LOLE Requirement, as well as the projected winter peak generation load. The graphs also illustrate the capability to meet this requirement from existing capacity, net of scheduled retirements, and the forecast need for new required capacity. For the purposes of illustrating requirements, the new capacity is portrayed in these “requirements” graphs based on a consistent assumption that requirements will be met by new 4 MW diesel units.
- **Forecast WAF generation energy:** The MW.h per year from existing hydro and from diesel are indicated separately. The energy graphs also show any surplus supplied as Secondary interruptible energy up to the forecast maximum Secondary Load expected (maximum of 30 GW.h per year). The forecasts show the generation expected to occur, and therefore these graphs do not show the full surplus hydro energy generation capability (which in many cases materially exceeds forecast Secondary sales).

4.2.1 Basis for Non-Industrial Load Forecasts

Yukon Energy’s near term non-industrial load forecasts for WAF are shown in Table 4.1, and are reviewed in more detail below.

Table 4.1:
Near Term Non-Industrial Load Forecasts

Load Forecasts				
Population Increase	**Source**	**Increase in Use/Customer**	**Combined Percentage Increase**	**Sensitivity**
0.4%	Yukon Bureau of Statistics: Medium Growth Projection	0.5%	0.9%	Low
1.0%	City of Whitehorse Population Increase (4 year average)	0.5%	1.5%	Medium-Low
	Mid-point		1.85%	Medium
	Yukon Energy's 3-Year Average Recorded Increase in Consumption		2.2%	Medium-High
	Yukon Energy's Highest Annual Recorded Increase in Consumption		3.0%	High

Yukon Energy's long-term non-industrial load forecast is based on a review of sales over past periods (as far back as 1992 in some cases, but focused on the period since 1998 when the Faro mine last closed), readily available information on the Yukon economy and other relevant statistics, and in some cases review of load forecasting variables used by other Canadian utilities.

The Yukon landscape is such that forecasting long-term non-industrial loads with precision is considerably more difficult than in southern jurisdictions. Although electricity consumption in many cases follows trends typical of other places in Canada, the Yukon economy can be substantively impacted by single events that, in most cases, cannot be foreseen with any accuracy more than a very short period in advance of the event (this short period can be one to two years or less). Examples include the opening and closing of large resource projects, such as mines, and major changes to Government of Canada funding to the Yukon Government.

Since the 1992 Resource Plan, the most material change in the Yukon electricity load forecast landscape has been the closure of the Faro mine (previously 40% of Yukon's load). Not only did the closure reduce industrial loads by nearly 200 GW.h a year, but it also dramatically reduced the loads in communities local to the mine (such as Faro, which reduced from an average residential customer count of 478 in 1996 to an average of 189 in 2001) and also major centers such as Whitehorse (Yukon Energy wholesales to YECL declined from 232 GW.h in 1996 to 217 GW.h in 2001).

The 1998 Faro mine closure impacts appear to have been largely incorporated into the Yukon economy and population by 2001. During this 1998-2001 period, out-migration of about 10% of the Yukon's population occurred (over 3,000 people).

Since 2001, the Yukon's economy and electricity loads have begun to develop a more normalized pattern. This is most evident in YECL's native load (Yukon Energy's wholesales to YECL plus YECL's own WAF Fish Lake generation added back) which has been characterized by growth of about 2.2% per year (three year average from 2001-2004) with one year growth as high as 3% in 2004. As a normal level of growth in the major load centers in Yukon, this three year average growth rate is likely within a reasonable range of forecasts for the near term period in question. This reflects three factors:

1. **Population growth:** Population in the major load center of Whitehorse has been recently increasing by approximately 1% per year reflecting fertility and mortality rates, net in-migration to Yukon and net in-migration to Whitehorse from other places in Yukon (both of these net in-migration trends have been positive since 2001). From 2001 to 2004 the resulting Whitehorse growth rate was in excess of 1% per year. Growth in customer numbers is expected to be at about this same level if not slightly higher due to reduced average number of persons per household, reflecting normal Canadian trends.
2. **Use per residential customer:** Use per customer for residential customers is assumed to be increasing at about 0.5% per year. Changes in use per customer are typically small over time, with Canadian utilities typically forecasting similar uptrends over the next 20 years for non-heating loads. This uptrend reflects in part increased use of certain appliances (such as internet connected computers and other electronic devices) offset by modest efficiency improvements in certain appliance sectors (for example, fridges are now far more efficient than in past years, but the stock of fridges typically changes quite slowly so is only a modest incremental change each year).
3. **Use per commercial customer:** Use per customer for commercial customers is not expected to vary materially from trends seen for residential customers, although growth may be slightly higher reflecting the trend towards larger stores and facilities (such as the Argus properties).

Based on the above assessment, Yukon Energy has based long-term load forecasts on a **base case** of 1.5% (medium-low) to 2.2% (medium-high) growth per year with 1.85% growth per year as the mid-point. In order to ensure the impacts of potential extreme outcomes with respect to non-industrial loads are considered, load forecast uncertainty to a range of 3.0% annual growth (High Sensitivity) and 0.9%

annual growth (Low Sensitivity) have been considered where these extremes have the potential to materially change the recommendations for major new investments in power resources.

- The **high sensitivity** of 3.0% per year is based on the highest one year wholesale sales growth rate experienced by YEC (2004). This was a period of very high growth, but given that it is the very recent experience, it is necessary to consider the potential that this rate is representative of a major new evolution with respect to Yukon electrical load.
- The **low sensitivity** of 0.9% per year based on a very nominal growth which is the combination of strictly the growth in use per customer plus the Yukon Bureau of Statistics population forecast growth assuming no in-migration (0.4%). This is consistent with the Yukon experience of not having had any periods of sustained zero to negative growth in the non-industrial system (and reflecting the fact that today's loads are not predicated on any downside risks related to underlying industrial projects, as no major industrial customers are currently receiving service in Yukon).

4.2.2 Basis for Near Term Industrial Load Forecasts

In order to address the current expectation that two new industrial loads may proceed in the area north of Carmacks, two industrial load cases have been included in the near term analysis (a range of other still more optimistic industrial development scenarios are examined separately in Chapter 5):

1. **No new industrial load**, and
2. **Industrial loads consistent with Minto and Carmacks Copper both being developed in the near term,** or about 9-11 MW of new load (2-4 MW for Minto plus 7 MW for Carmacks Copper) and 64 GW.h of annual energy. These mine projects are not expected to be long-lived, at 12 years for Minto starting 2007 and 8.5 years for Carmacks Copper starting 2008 (although these starting dates may be delayed by other processes and development timelines).

4.2.3 Near Term WAF Load – Cases Analyzed Based on Non-Industrial and Industrial Requirements

Based on the above near term non-industrial and industrial load forecasts, four near term WAF load cases have been considered:

1. **Base Case:** The Base Case near term assumptions are based on non-industrial loads at the mid-point base case level (1.85% per year) and no new industrial loads.
2. **Low Sensitivity Case:** This case maintains non-industrial loads at the low sensitivity level (0.9% growth) and no new industrial loads.

3. **Base Case including Mines:** This case combines the Base Case assumption for non-industrial (1.85% growth) plus near term development of the Minto and Carmacks Copper loads at a combined 9 MW.
4. **High Sensitivity Case, including Mines:** As the largest near term growth scenario, this case combines the high sensitivity non-industrial load growth (3.0%) with near term development of the Minto and Carmacks Copper loads.

4.2.4 Base Case Requirements

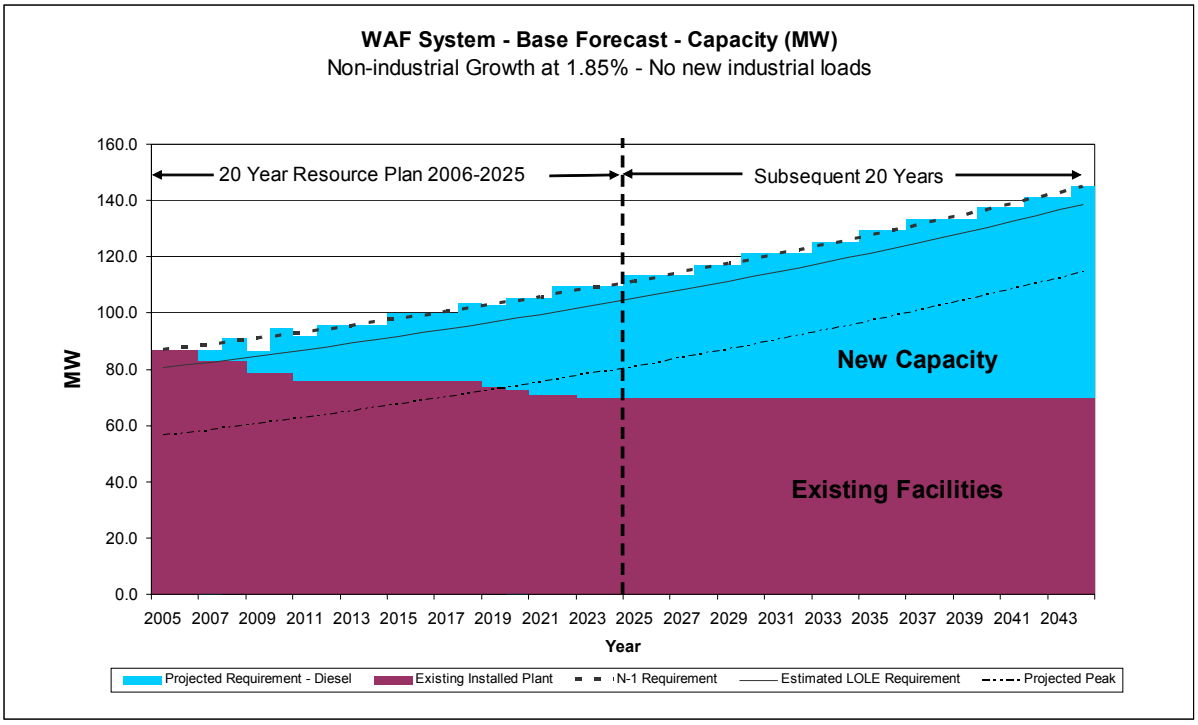
Under the Base Case, forecast loads exclude any major industrial customers. Non-industrial load growth is projected at 1.85% per year.

Capacity: Under the Base Case, there is a 0.7 MW capacity shortfall forecast for 2006, increasing to 18.7 MW by 2012 assuming that all three Mirrlees units (11.4 MW) have been retired by that time[1].

Figure 4.1 provides a 40 year horizon (20 years of Resource Plan plus the 20 subsequent years) and indicates the capability of the existing facilities with planned retirements as well as the requirement for new facilities to meet the proposed new planning criteria (LOLE and N-1, indicated by solid and dotted lines respectively). In this figure, five new 4 MW diesel generation units (or equivalent 20 MW) are assumed to be installed to meet the capacity shortfalls to 2012.

[1] Note that under the previous capacity criteria, the capacity shortfall in 2012 is 5.5 MW as noted in Section 3.3, and is entirely driven by the retirement of the 11.4 MW of current Mirrlees capacity.

Figure 4.1:
WAF Base Case Capacity Requirements

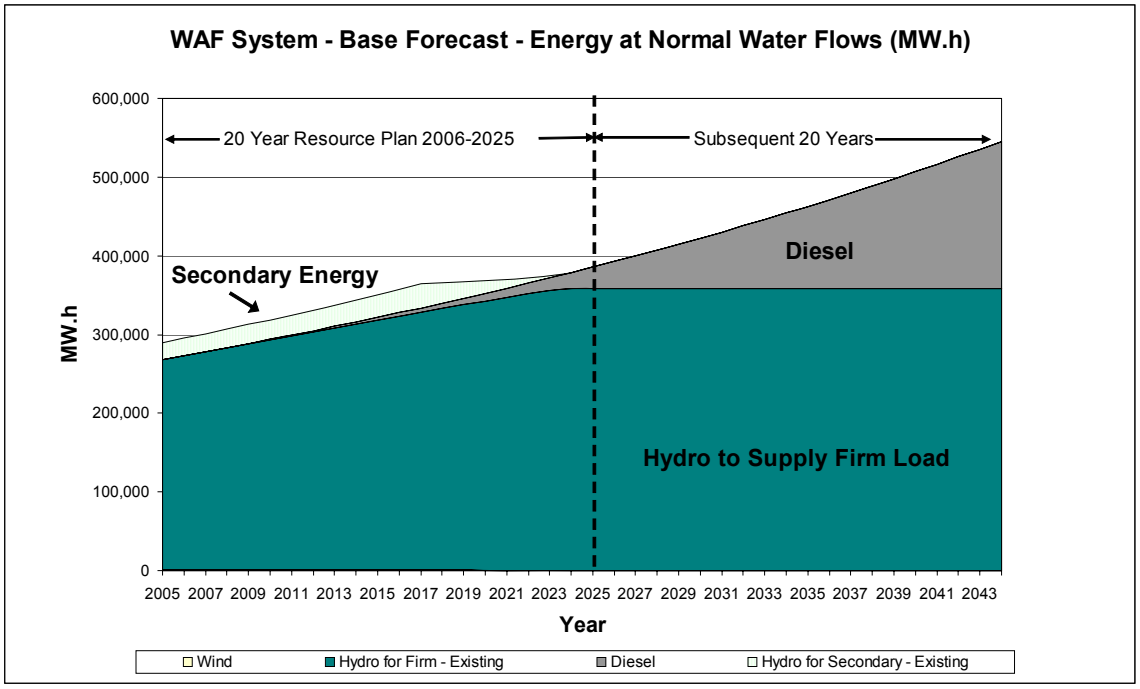


Energy: The Base Case analysis as reviewed in Figure 4.2 indicates that diesel generation is not required to supply sustained loads (e.g., loads in excess of average annual hydro energy generation) until at earliest the end of the 20 year forecast planning period. Some diesel generation is required for peaking purposes (i.e., brief time periods during the winter peak months), but these peaking diesel generation requirements remain below 10 GW.h per year until after 2020 (i.e., near the end of the 20-year planning period), increasing to about 28 GW.h/year in 2025. Figure 4.2 also indicates the potential energy available for supplying secondary power up to the expected maximum annual program subscription of 30 GW.h/year[2].

In summary, there is no opportunity under the Base Case near term forecast to develop new non-diesel generation to displace diesel fuel until near the end of the 20 year planning horizon.

[2] The analysis does not attempt to determine the secondary energy demanded that would go unserved due to short-term winter interruptions during periods of peaking diesel, i.e., the analysis determines only the annual impacts on energy available to service secondary loads. In reality, actual secondary sales would experience greater short term interruption as load growth increases the periods of peaking diesel operation during each year.

Figure 4.2:
WAF Base Case System Energy Requirements

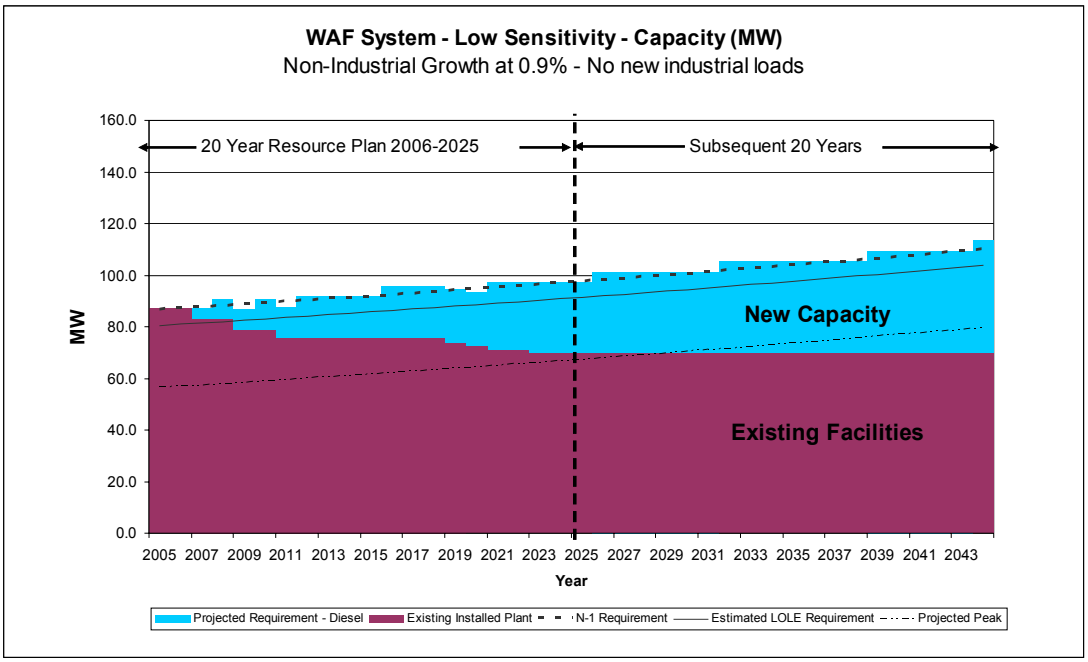


4.2.5 Low Sensitivity Case

The Low Sensitivity Case is based on non-industrial load growing at 0.9%/year and no new industrial loads.

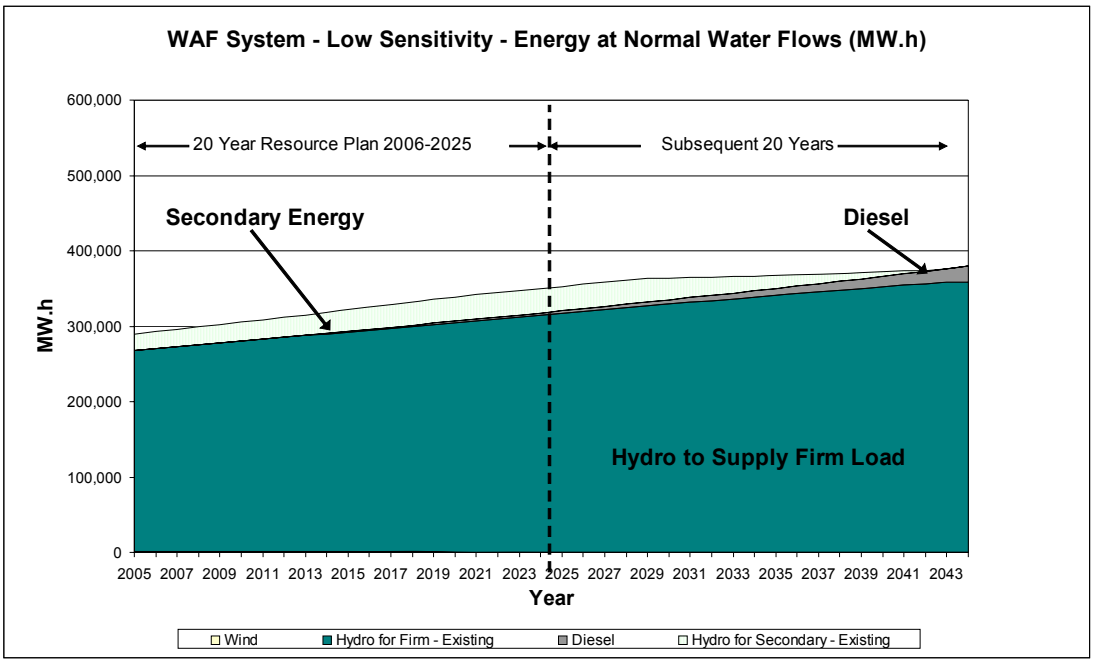
Capacity: Under this case, as reviewed in Figure 4.3, capacity shortfalls occur in 2006 of 0.2 MW with growing requirements thereafter driven primarily by retirement of diesel units (11.4 MW of retirements by 2011). The Low Sensitivity Case forecast indicates 14.7 MW of capacity shortfall by 2012. Figure 4.3 identifies a requirement by 2012 of four new 4 MW diesel units (16 MW).

Figure 4.3:
WAF Low Sensitivity Case Capacity Requirements



Energy: Under the Low Sensitivity Case (see Figure 4.4), as with the Base Case, there is no requirement for material diesel generation in the 20 year planning horizon.

Figure 4.4:
WAF Low Sensitivity Energy Requirements

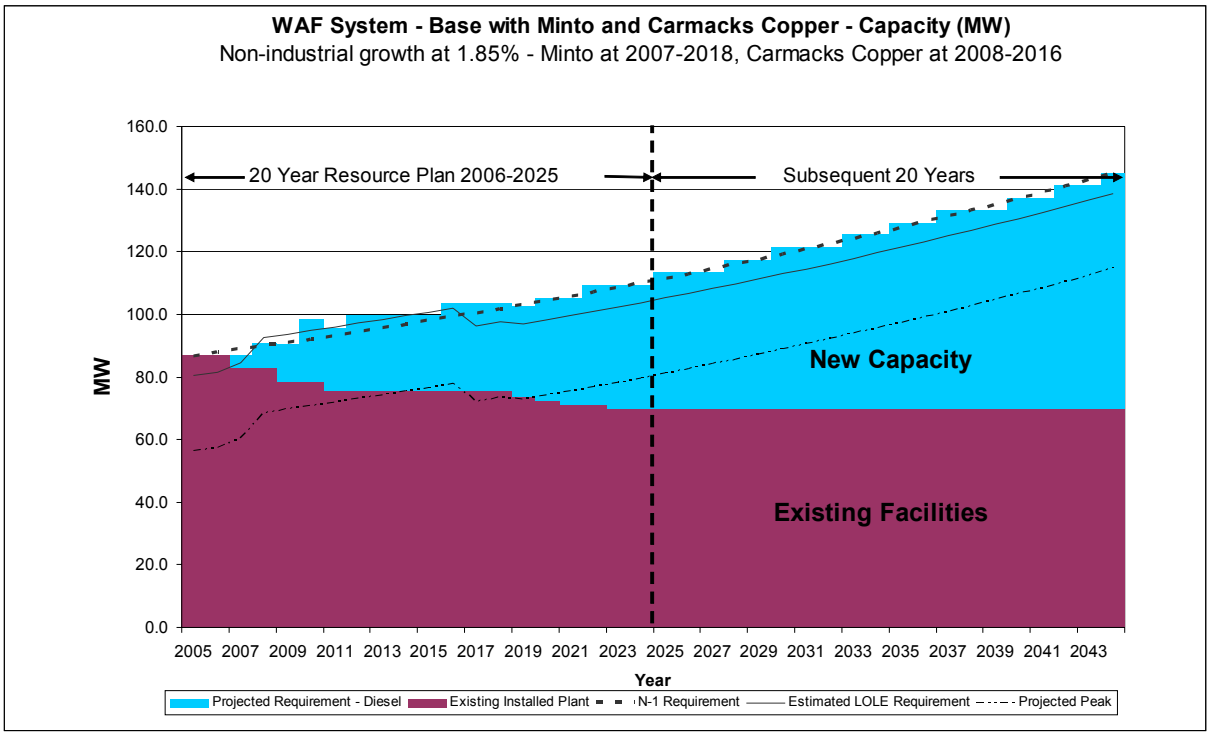


4.2.6 Base Case with Mine Loads

The Base Case with Minto and Carmacks Copper Mine loads includes the same non-industrial load growth of 1.85% from the Base Case, plus an assumed near term connection of the Minto and Carmacks Copper new mine loads to the WAF grid. This case presumes near term development of new transmission from Carmacks to at least about Pelly Crossing with spurs to connect these two new mines.

Capacity: Under this case, capacity shortfalls of 0.7 MW arise in 2006, growing to 21.5 MW by 2012 (in this case driven by the LOLE criteria instead of the N-1 criteria which drove capacity shortfalls for the Base and Low sensitivity cases)[3]. The capacity shortfall is illustrated in Figure 4.5 below as six new 4 MW diesel units (24 MW) assumed by 2012.

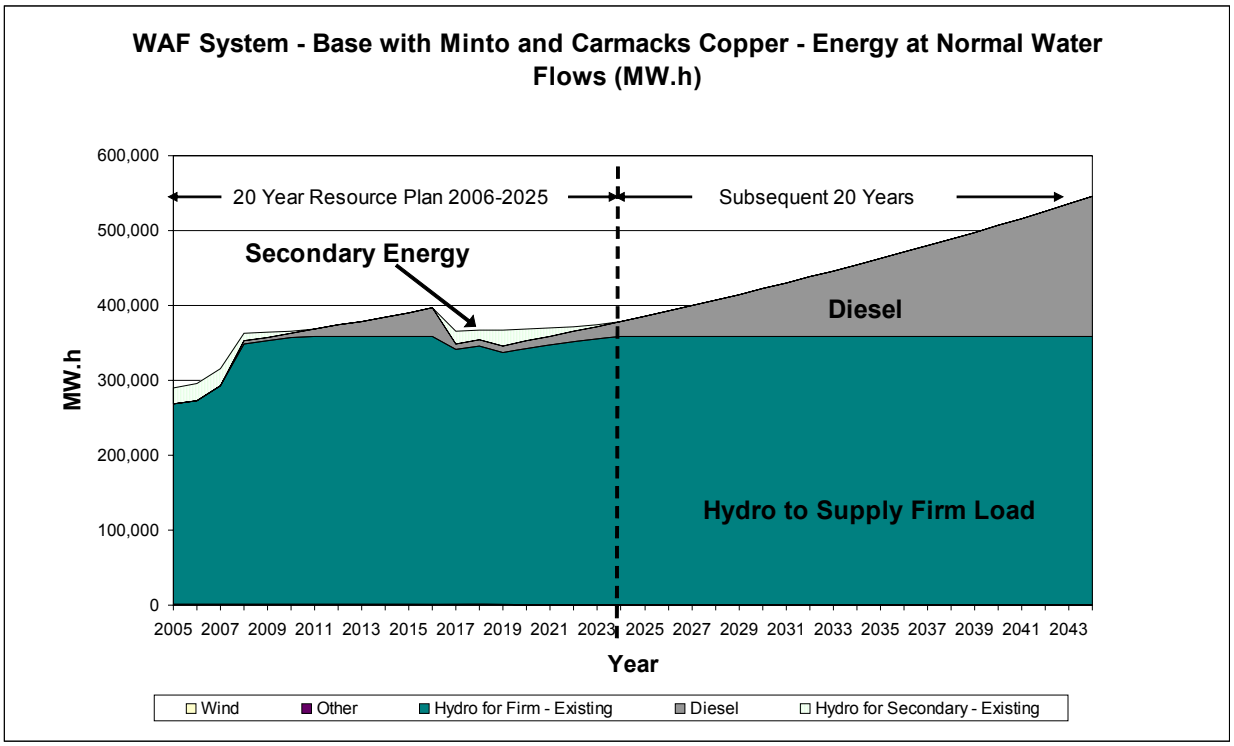
Figure 4.5:
WAF Base Case with Mine Capacity Requirements



[3] The combined mine loads in this scenario total 9 MW. Mine loads do not contribute towards peak loads for N-1 calculations but do contribute for LOLE (see Section 3.3). Under Base Case load scenarios, N-1 is requiring additions of capacity approximately 6.2 MW ahead of LOLE requirements. For this reason, the first 6.2 MW of industrial load do not drive any additional capacity requirements over and above the basic base load requirements. The result in this case with the added 9 MW of industrial load is an increase in capacity required compared to the Base Case (in order to serve the two mines) of only 2.8 MW (9 MW total load less 6.2 MW that can be served without additional capacity).

Energy: Under this scenario, as reviewed in Figure 4.6, the incremental mine load consumes largely hydro energy that would otherwise be surplus under the Base Case. However, with ongoing non-industrial load growth during the life of the mines, the WAF system begins to utilize diesel of up to about 40 GW.h per year for modest base load generation (reflects WAF system hydro capability of about 358 GW.h in a normal water year, with system energy requirements approaching 400 GW.h in about 2016 at the highest levels before mine closure). After the mine closures as assumed in this case, however, there would be a period of about seven years when excess hydro would return to the WAF system (along with the opportunity to make secondary sales) before normal non-industrial load growth would eliminate the hydro surplus (in 2024) and begin to drive new base load diesel requirements (beyond the current 20 year Resource Planning horizon). Although this load pattern may give rise to the opportunity to consider very small hydro or other low variable cost generation within the 20 year horizon (perhaps up to a 2-3 MW), the scale of any such generation would not materially affect the large capacity requirements (21.5 MW) beginning in the very near term.

Figure 4.6:
WAF Base Case with Mine Energy Requirements

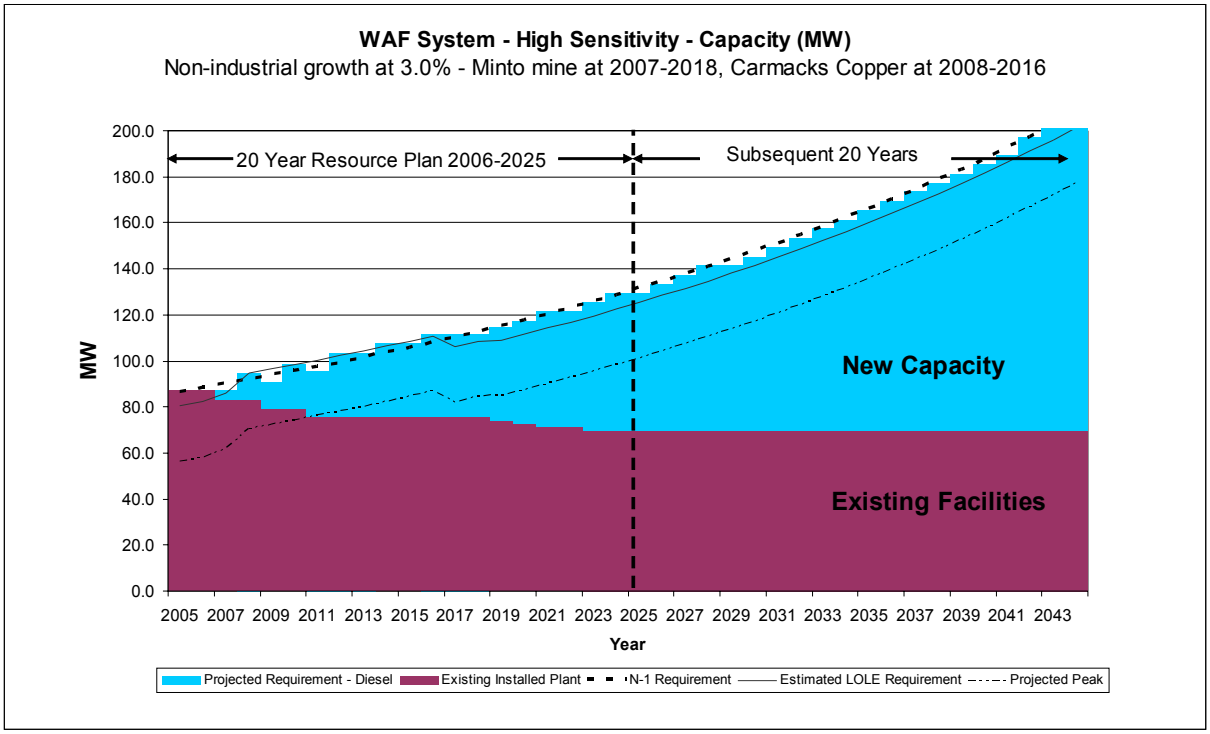


4.2.7 High Sensitivity Case Including Mines

In the High Sensitivity Case, the non-industrial load growth is forecast at 3.0% per year plus near term addition of the Minto and Carmacks Copper mine loads (which presumes near term development of new transmission from Carmacks to at least about Pelly Crossing with spurs to connect these two mines).

Capacity: Under this case, as reviewed in Figure 4.7, there would be material increases in the required installed capacity to meet the loads, assuming that the new capacity criteria are adopted. Capacity shortfalls in 2006 are at 1.4 MW, and by 2012 are at 26.7 MW (indicating the need in Figure 4.7 for an assumed seven new 4 MW diesel units, or 28 MW)[4].

Figure 4.7:
WAF High Sensitivity Case with Mines Capacity Requirements

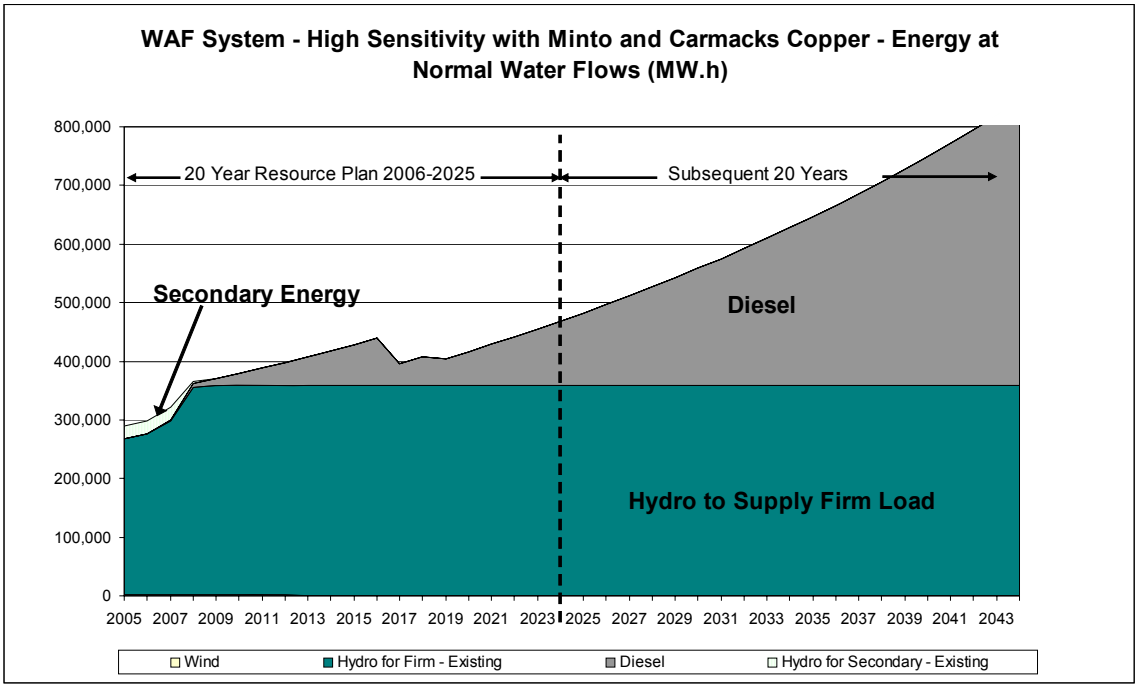


Energy: If the WAF system were to experience material sustained ongoing growth at the 3% level year over year, as well as the near term opening of both the Minto and Carmacks Copper mines as assumed in this high sensitivity case, the system will begin to experience base load diesel generation needs beginning

[4] Without the two mines, the High Sensitivity Case capacity shortfall in 2012 is 24.1 MW.

in 2009[5]. This may present near term opportunities to examine new non-diesel (e.g., hydro) generation. However, on a sustained long-term basis as reviewed in Figure 4.8, the requirement for new generation such as hydro after the mines close as assumed in this case is only in the range of about 50 GW.h per year (due largely to load reductions upon the closure of the mines)[6]. This scale of generation is consistent with hydro sites of about 8 MW. Consequently, even if new baseload energy projects are enabled by this major load growth, they will not be of sufficient size to address the very material (27 MW) new capacity requirements indicated under this scenario by 2012.

Figure 4.8:
WAF High Sensitivity Case with Mines Energy Requirements



Yukon Energy will also not likely be able to provide commitments to develop such capital intensive energy projects within the near term timeframes where capacity shortfalls begin to arise on the WAF system. This is because it would take a number of years to see loads develop at this high annual growth rate, as well as greater certainty with respect to mine loads, before capital intensive projects of this type would be suitable to consider. In addition, following appropriate commitments, hydro projects also typically require several years to plan, licence, design and construct.

[5] Without the two mines, the High Sensitivity Case will begin to experience base load diesel generation only in 2017 (when no surplus hydro for secondary sales).

[6] If 3% per year growth in non-industrial loads is sustained, as assumed in this case, diesel energy requirements grow to 124 GW.h by 2025.

4.3 OPTIONS

Based on the above requirements, three broad categories of project resource options are noted for the period prior to 2012:

1. **Opportunities projects to enhance existing facility energy and/or capacity output** or to allow better use of existing capabilities to ensure Yukon Energy has maximized the potential from past investments in major generating facilities. There are three well-defined near term project options in this regard:
   a) **Aishihik 3rd Turbine project:** Facility enhancements at Aishihik via a third turbine of 7 MW costing over $3 million to allow better ability to use the existing plant to meet peak loads, as well as more efficient use of water when operating at low outputs.
   b) **Marsh Lake Fall/Winter Storage project**: Improved water management at Whitehorse via changes to the water licence for upstream storage not costing over $3 million, in order to allow reduced discharge of water during the fall months to enhance the ability to store water for winter.
   c) **Carmacks to Stewart Transmission project**: The opportunity to use Government of Yukon infrastructure funding to develop new transmission costing over $3 million to interconnect the WAF and MD systems, including opportunities to connect to the WAF two potential new mines north of Carmacks.

2. **Major capacity-related replacement and/or expansion projects** costing $3 million or more to address substantial impending and unavoidable capacity shortfalls on WAF (approaching 15 MW to 27 MW by 2012) requiring new generation and/or transmission to ensure sufficient firm capacity to supply forecast peak loads. As noted in Section 3.3, this shortfall is driven in large part by exposure to Aishihik transmission line outages. Two main concepts are explored in this regard:
   a) **Maintain/Replace/Expand Whitehorse Diesel projects:** One concept seeks to reduce exposure to the transmission line weaknesses through reducing the potential *impact* of transmission line outages, focused on maintaining existing diesel (a major Life Extension project on the Mirrlees units), or installing new diesel generation on the WAF grid not dependent on the Aishihik transmission line (a major Whitehorse Diesel Replacement and Expansion project).
   b) **Aishihik 2nd Transmission Line project**: Alternatively, the Aishihik 2nd Transmission Line Project concept seeks to reduce exposure to weaknesses through reducing the potential *incidence and duration* of transmission line outages through developing redundancy in the Aishihik transmission connection.

3. **Smaller supplemental projects** that may contribute towards meeting WAF supply requirements, but are either not currently defined or not currently expected to cost at least $3 million, and do not independently offer sufficient capacity to play a major role in satisfying the near term capacity shortfall requirements. Yukon Energy continues to evaluate supplemental projects in the near term and on an ongoing basis, but the main near term focus is on system enhancement opportunities and major replacement and/or expansion projects that will be required based on the new capacity planning criteria.

Studies are ongoing with regard to each of the above major near term options. The Submission provides a screening of projects based on current information (as summarized below), setting out the conditions and requirements relevant to proceeding with each specific option as well as initial cost estimates currently available for each option (which, aside from opportunity projects, remain preliminary and subject to ongoing adjustment and refinement). Updates will be provided during the review of the Submission to the extent that relevant new information is forthcoming for the ongoing studies of these projects.

4.3.1 Overview of "Opportunity" Project Options

The implementation of supply side enhancement or Resource Smart projects reflects a sensible and prudent approach to maximizing the value of existing resources. Such projects are routine in other jurisdictions in Canada, and often offer the lowest cost sources of supply available (although the scale can be modest in some cases).

Opportunities to put in place enhanced system assets can also be enabled by new loads or external funding to offset capital costs so as to put no burden on ratepayers.

Yukon Energy has focused on three major opportunity projects in the near term:

- **Aishihik 3rd Turbine Project (7 MW; 5.4 GW.h/year):** Up to 7 MW of capacity could be added to the existing Aishihik hydro plant through addition of a third turbine. This potential project was reviewed in the 1992 Resource Plan hearing as a potential 5 MW unit, and pursuant to YUB recommendations from that proceeding[7], Yukon Energy pursued and received environmental approvals for the unit in the new Aishihik Water Licence of up to 7 MW. The third turbine would yield an increase in long-term average hydro energy supply from Aishihik of up to 5.4 GW.h/yr (if load conditions on the system are sufficiently high) but

[7] The YUB recommended that Yukon Energy pursue a licence for "the maximum capacity that is economically, technically and environmentally feasible".

in certain conditions prior to high WAF load conditions can allow displacement of diesel generation in excess of this level due to the ability to allow added Aishihik generation at the time of system winter peak (see Section 4.3.8). The 3rd turbine by itself is of no reliable peak capacity value whatsoever under the N-1 criteria as it is subject to the same Aishihik transmission line constraints as the existing units (unless an Aishihik 2nd Transmission Line project is in-service) and is similarly of limited reliable peak capacity value (0.6 MW) under LOLE criteria. Current investigations are updating capital costs and planning for this project.

- **Marsh Lake Fall/Winter Storage Project (about 1.6 MW; 7.7 GW.h/year):** There is the potential with a Marsh Lake Fall/Winter Storage project to increase the firm winter capacity of the Whitehorse Rapids hydro facility by about 1.6 MW and to increase its long-term average hydro energy by about 7.7 GW.h/yr (actual enhancement depends on load conditions assumed). The project involves seeking changes to the Whitehorse Rapids water licence to allow Yukon Energy to reduce the amount of water it releases from Marsh Lake in non-flood years from August 15 to the end of September, to allow that water to be used instead during the peak winter generation period (during flood years, no change would be made during August and September, until after flood levels subside). In all cases, the water levels would remain within the lake level limits currently experienced (i.e., the peak controlled level would be below the natural high water levels experienced in the lake). Basically no new physical works are expected to be required for this project[8].

- **Carmacks-Stewart Transmission Line Project (about 6 MW; 15 GW.h/year, decreasing with time as MD load grows, plus opportunity to connect up to 2 new mines):** Yukon Energy is currently using Yukon Government Infrastructure Funding to carry out initial planning and permitting for this project; development of this project at this time is contingent on commitment of the necessary Yukon Government Infrastructure Funding as needed to ensure no adverse impacts on Yukon ratepayers. The development from Carmacks to at least Pelly Crossing would provide the basis to supply potential mine loads at Minto and Carmacks Copper with WAF surplus hydro energy. Development beyond Pelly Crossing to Stewart Crossing would interconnect the WAF and MD grids, thereby accessing surplus MD capacity for WAF in the near term. The full project with interconnection of the two grids would provide about 6 MW and 15 GW.h/yr of hydro energy to WAF, with this contribution decreasing as the MD load grows.

[8] This project concept would increase the licensed full supply level by 0.3 meters. The lake would not experience water levels higher than are currently experienced. No environmental studies on this specific project concept have been completed to date.

4.3.2 Aishihik 3rd Turbine

The Aishihik 3rd turbine project (current capital cost forecast of $7 million for 7 MW[9]) has long been considered as a relatively cost-effective means to add material new capacity to the WAF system, as well as a modest amount of new hydro energy.

Review of the system capacity constraints as part of the Capacity Planning Criteria review indicates that the capacity value of Aishihik 3rd turbine is extremely modest (about 600 kW under an LOLE of 2 hours/year, 0 MW under N-1) in the absence of a second Aishihik transmission line. This is because there is already a disproportionate amount of WAF generation at risk of an Aishihik transmission line outage, and the firm load carrying capability of WAF (under a probability-based assessment approach such as LOLE, or an N-1 approach) is not aided by further capacity development at Aishihik.

However, there remain two other enhancement aspects of the Aishihik 3rd turbine that cannot be ignored:

- First, there are certain circumstances where an Aishihik 3rd turbine could be valuable capacity to WAF (most notably if an Aishihik 2nd transmission line were developed, but also with major future generation development elsewhere on WAF which would reduce the relative weighting of Aishihik in the generation mix).
- Second, and likely of greater near term value, the long-term energy value of the Aishihik 3rd turbine (estimated at 5.4 GW.h per year under high load scenarios and new Water Licence terms) can be of value to WAF and can potentially yield diesel unit cost savings to offset the Aishihik 3rd turbine capital cost[10].

The Aishihik third turbine also provides material added near term enhancement benefits in displacing peaking diesel energy generation on the WAF system (as well as enhancing the ability to maintain maximum secondary sales revenues) while WAF surplus hydro is still available. This is because the presently installed firm winter hydro capability is only 54.4 MW (30 MW at Aishihik and 24 MW at Whitehorse plus 0.4 MW for Fish Lake) with normal winter hydro capacities in the range of 56-58 MW (i.e., in non-drought years). Consequently at the present time the maximum WAF load that can be allowed before diesel units must be started (and secondary sales interrupted) is a maximum of about 54 MW or less. With the addition of 7 MW of new hydro capacity at Aishihik, the operation of peaking diesel

[9] The $7 million cost estimate is currently under active review and refinement to reflect current pricing.

[10] The potential energy of 5.4 GW.h/yr represents an annual capacity factor of only 8.8% for the 7 MW unit; however, offset cost savings of about $1 million or more per year will occur if this displaces diesel fuel generation at 65 cents/litre cost. Base Case loads are not sufficient to yield any material diesel fuel displacement in the near term, but this starts to occur before 2025. Peaking diesel savings, which are discussed separately, are also material during this period under Base Case assumptions.

(and interruption of secondary sales) will not occur until closer to 61 MW. This can lead to material savings in WAF diesel generation starting when the unit comes into service (ranging under Base Case conditions from 0.4 GW.h a year in 2009 to as high as about 6 GW.h per year over the period of the Resource Plan). This effect also is expected to result in an increased number of hours of secondary sales availability and consequently secondary sales revenues[11] (this benefit has not been quantified).

The Aishihik 3rd Turbine is already authorized in the renewed water licence. Approximately 20-24 months are estimated to be needed from commitment until it comes into service (i.e., time needed for remaining pre-decision final design and costing and tendering as well as for subsequent construction). It is assumed that the project, if committed, would at the earliest come into service in 2009.

4.3.3 Marsh Lake Fall/Winter Storage

Although the Whitehorse Rapids hydro generating station is a largely run of river plant, there is some modest storage available at Marsh Lake, controlled via the Lewes Dam (a control structure upstream of Miles Canyon).

Various options have been reviewed over many years to enhance the output of Whitehorse Rapids by increasing the ability to control Marsh Lake.

One option that was previously studied and not adopted in 1992 was a project called the "Marsh Lake Top Storage Project" which YEC investigated in 1991-92 at the request of the YUB, to raise the licenced maximum storage on Marsh Lake by five feet (as well as associated lake level impacts on Tagish and Bennett Lakes). A study produced at that time for YEC estimated a requirement for only $760,000 (1992$) of physical works to the Lewes Dam control structure, but likely well over $25 million (1992$) in mitigation costs related to significant adverse impacts on many properties and developments affected by the higher water levels (YEC noted to the YUB that the company considered the study's estimates to be low). Consequently, YEC recommended in the 1992 Resource Plan that it not proceed with the project, and the YUB agreed with this recommendation in its 1992 Report.

The Marsh Lake Fall/Winter Storage project under consideration today is a fundamentally different project than that considered in 1992. In this case, the project involves seeking changes to the Whitehorse Rapids water licence to allow Yukon Energy to reduce the amount of water it releases from Marsh Lake under

[11] The impact on secondary sales quantities from hydro peaking resources such as the Aishihik Third Turbine has not been assessed. At certain loads, the Third Turbine may also reduce somewhat the availability of surplus power for secondary energy, as the water would be used to avoid baseload diesel and consequently no longer be "surplus hydro". However, this is not expected to occur until the system is near the full utilization of hydro capability and only for a limited number of years.

certain conditions in the fall and early winter, in order to enhance Yukon River flows during the coldest months of winter[12]. The effect of the revised water licence would be as follows:

- **In non-flood years:** The licence revision would allow Yukon Energy to reduce Marsh Lake outflows from August 15 to the end of September, to allow that water to be used instead during the peak winter generation period.
- **During flood years:** In years where Marsh Lake levels are at flood stages, no change would be made during August and September until after flood levels subside. Similar to existing rules, once the floods have subsided, water levels would be controlled to reduce further spillage in fall and early winter months (at a level about one foot higher than presently allowed), to allow the water to be used instead during the peak winter generation period. In all cases, the water levels would remain within the lake level limits currently experienced (i.e., the peak level that YEC is allowed to maintain by use of Lewes Dam would be below the natural high water levels experienced in the lake during uncontrolled summer periods). There would be no effect on the flood levels experienced on Marsh Lake.
- **During drought years:** Yukon Energy is currently permitted to help alleviate summer drought levels on Marsh Lake through "early closures" of the Lewes Dam (as early as July 7 in extreme droughts). These provisions would remain, and would likely be adapted somewhat to further alleviate summer drought conditions to ensure the lake reached the full controlled supply level (as revised) in each year.

Environmental licencing activities for the project have not been initiated. Studies will need to confirm the extent (if at all) to which the project may affect water levels in lakes that extend into BC.

The Marsh Lake Fall/Winter Storage project has the potential to enhance the output of the Whitehorse Rapids hydro facility by about 1.6 MW and 7.7 GW.h/yr long-term average hydro energy (actual enhancement will depend on load conditions assumed and revised maximum licence level allowed, which is assumed here to be one foot). Basically no new physical works are expected to be required for this project.

[12] During uncontrolled periods of summer and fall (when YEC has no control over the lake and it is operating under an entirely natural regime), Marsh Lake has been known to peak at two feet above the Yukon Energy "controlled maximum" level currently provided for in the water licence, and to typically peak at least one foot above the "controlled maximum" level. The specific revision sought to the water licence would be to change the licenced "controlled maximum" level that YEC can maintain at Marsh Lake upwards by likely in the range of one foot, i.e., the proposed licence revision will still be well within the normal natural levels experienced on the lake.

Costs of the project relate almost entirely to environmental licencing and mitigation, which are very difficult to predict. Given the relatively limited potential for physical or environmental effects (but recognizing the potential for notable public interest in ensuring full review of all potential effects) the costs of the project are not expected to exceed $1 million. Licensing and other pre-decision activities are assumed to require a year such that the project could potentially come into service in 2007 (in time to be of value in addressing the 2007/2008 winter peak).

4.3.4 Carmacks to Stewart Transmission Line Project

The proposed 138 kV Carmacks to Stewart Transmission Line would extend the WAF system north from Carmacks generally along the Klondike Highway to at least Pelly Crossing, and potentially as far as Stewart-Crossing in order to provide full interconnection with the MD system. Interconnection of the WAF and MD grids would provide near term capacity and energy benefits to the WAF system.

If the project is developed from Carmacks to at least Pelly Crossing, potential new mine developments in close proximity to the new transmission line could have access to service with WAF surplus hydro energy. In particular, the Minto mine and the Carmacks Copper mine, located between Carmacks and Pelly Crossing, are both located in areas that could be serviced with the proposed line. Development only to Pelly Crossing, however, would not result in interconnection of the MD and WAF grids.

Costs to develop this project from Carmacks for full interconnection to Stewart-Crossing have been estimated at about $35 million (2005$). It is not currently economic for Yukon Energy, as a regulated utility, to develop this project since both the WAF and MD systems today have surplus hydro power and the line would not at this time displace the level of diesel fuel or other high cost generation needed to justify its costs. Accordingly, this project is being examined as a key Yukon territorial infrastructure initiative to meet a specific window of opportunity related to two potential new mines (Minto and Western Silver at Carmacks Copper) and current Yukon Government Infrastructure Funding.

The project is currently being advanced using Yukon Government funding for permitting and approvals activities, including licencing under the new *Yukon Environmental and Socio-Economic Assessment Act (YESAA)*, as well as for finalizing project final design and costing. If critical planning does not proceed in a timely way through 2006 using Yukon Government Infrastructure Funding, permits and other preparatory work will not likely be done in time to enable the project to help in the development of these two mines (based on the current planned development schedules for Minto in particular). Current planning is seeking to protect a potential in-service date for this project between mid-2008 and mid-2009.

The extent to which the ultimate project concept is developed in the near term will be determined based on available Yukon Government Infrastructure Funding as well as the mine development that will actually occur. The project's capital costs will not impact regulated utility rates to the extent that its costs are funded through Yukon Government grant funding or through customer contributions from mines connecting to the WAF grid. Rates charged to such mines for use of WAF power would need to be approved by the YUB in accordance with OIC 1995/90 (which requires that such rates at least cover utility costs of service evaluated on a Yukon wide basis).

Development of this project from Carmacks to Pelly Crossing is estimated to cost in the range of about $20 million (2005$). This extent of development, in combination with the two proposed mines being developed and connected (costs for "radial" lines to service Minto and Carmacks Copper sites will be addressed via normal utility and customer investment policies), would fully utilize WAF surplus hydro in the near term.

Extending the project fully from Carmacks to Stewart Crossing (a further likely capital cost (2005$) of about $15 million over and above the cost for the project from Carmacks to Pelly Crossing) would provide near term capacity and energy benefits for the WAF system related to interconnection of the WAF and MD systems. It is estimated that such interconnection would provide in the near term about 6 MW of net capacity benefit to WAF[13] as well as another 15 GW.h/yr of net long-term average hydro energy; these benefits would decrease in future as MD load grows (or if new industrial developments, such as reopening of the UKHM mine, connect to the MD system). The surplus hydro made available can yield

WAF economic benefits during the planning period through both diesel unit cost savings and extended maintenance of secondary sales revenues[14].

In assessing various alternatives related to the Carmacks to Stewart Transmission Line project, Yukon Energy is examining the net cost that could be funded through rates in order to make interconnection cost competitive with other options. This is based on the assumption that if the project was to be developed in the near term, the project's capital cost will be provided for through Yukon Government Infrastructure Funding as required to ensure no impact on regulated utility rates.

[13] This reflects 12 MW of installed MD firm capacity and MD peak load forecast (2008) of 5.9 MW.

[14] The present value (2005$) of these diesel cost savings and extended secondary sales revenues approximates only $1.2 million over the 20 year planning period under Base Case conditions; under Base Case including Mines conditions (which are likely to be required, at least in part, if the interconnection is to be developed at this time), and excluding consideration of any other opportunity projects, this present value increases to $4.7 million. (These present values assume a discount rate of 7.52%/year, diesel unit efficiency at 3.48 kW.h/litre for peaking and 3.9 kW.h/litre for baseload, diesel fuel prices at $0.65/litres (2005$), diesel O&M at $0.016/kW.h (2005$) and inflation at 2%/yr. No firm capacity benefit is included in these present values.)

Long term benefits from the Carmacks Stewart Transmission project connecting the two grids include: encouraging economic development along the corridor of the new line and its extended environment; enhancing overall power system reliability on these systems; and providing greater flexibility to accommodate future load and generation interchange between the WAF and MD systems as they are currently known. Potential benefits, for example, include the ability under certain load development scenarios to move surplus WAF power to serve major new mine developments in the MD grid region should they arise; or to move surplus MD power to the WAF grid region from potential new hydro developments in the MD grid or Pelly Crossing regions, as well as from potential future Mayo hydro plant enhancements.

The Carmacks to Stewart Transmission Line project (full interconnection) impact on WAF firm winter capacity, plus other new diesels as required to meet capacity requirements, is illustrated in Figure 4.9 (at Base Case loads and excluding consideration of any other non-diesel capacity enhancements).

- The Base Case capacity shortfall in 2012 with interconnection of the MD and WAF grids is approximately 13.1 MW, and is assumed in Figure 4.9 to be met through 16 MW of added diesel units (4 MW in 2009, 4 MW in 2010, and 8 MW in 2012).
- Under other forecast conditions examined, the capacity shortfall in 2012 with the Carmacks to Stewart Transmission Line project (full interconnection) is 8.7 MW (Low Sensitivity case), about 15.8 MW (Base Case including Mines), and about 21.5 MW (High Sensitivity including Mines).

Figure 4.9:
Carmacks to Stewart Transmission Line in 2008

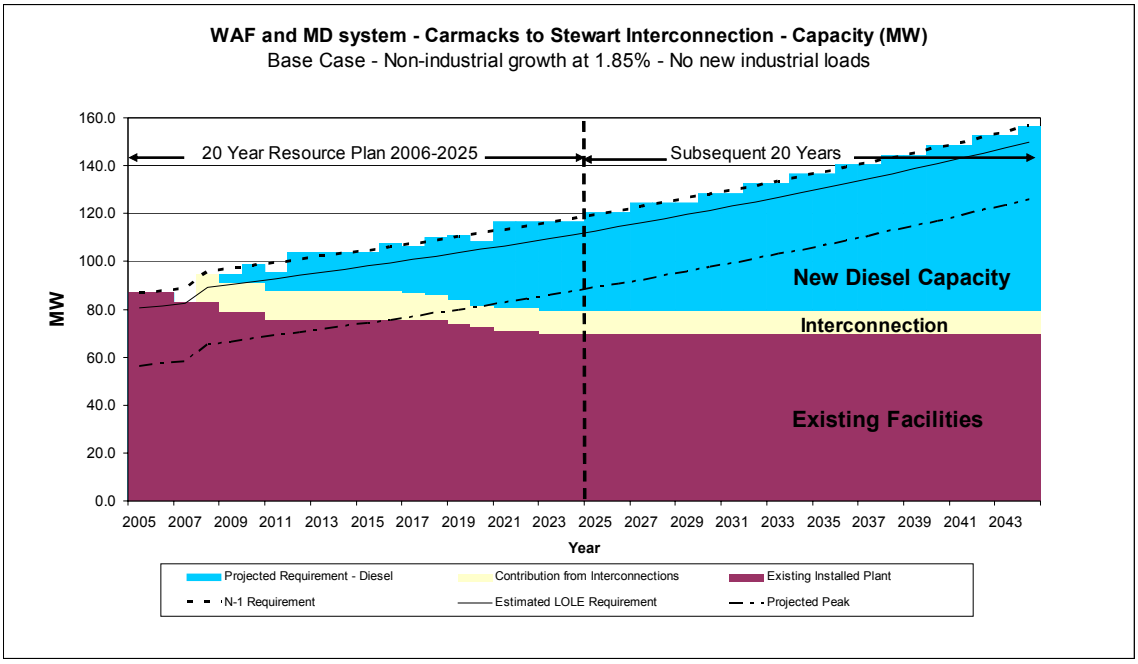


Figure 4.10 reviews the hydro and diesel energy loads under the Base Case forecast with interconnection of the MD and WAF grids, indicating surplus hydro remaining throughout the 20-year planning period.

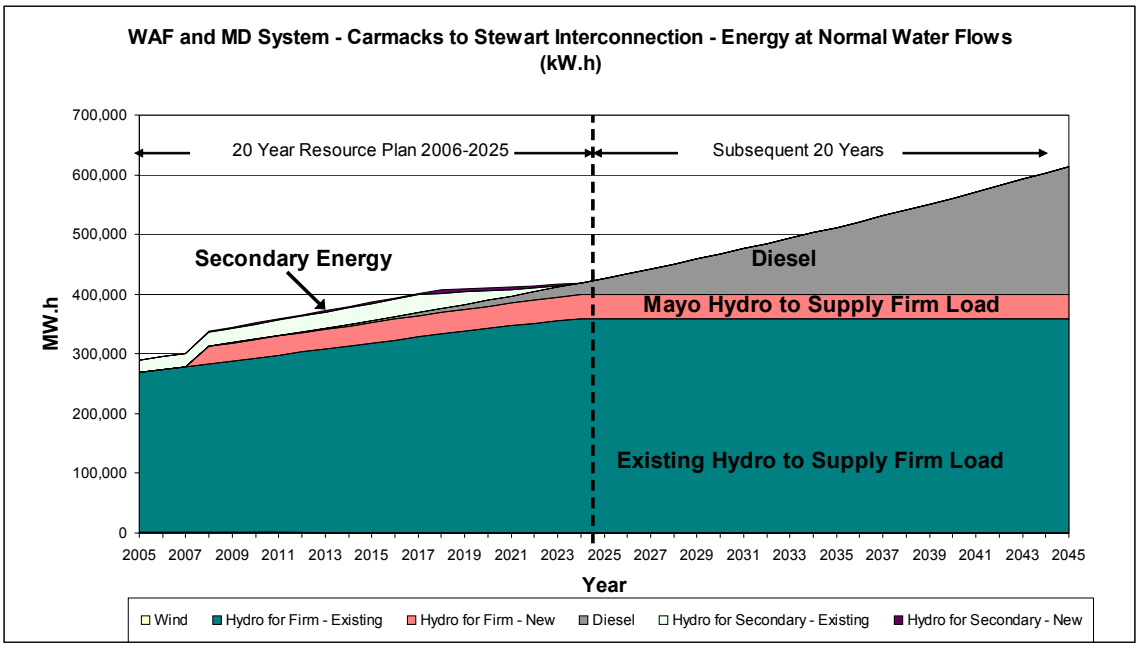
- Under Base Case forecast conditions including the Minto and Carmacks Copper Mines, the full interconnection project has the same surplus hydro after the mines close in 2016 and 2018.
- Under the High Sensitivity case including these mines, the full interconnection project has no surplus hydro available after the mines close.

Figure 4.10:
Carmacks to Stewart Transmission Line in 2008



4.3.5 Overview of Major Capacity-Related Project Options

Under the new capacity planning criteria, the WAF system is facing a capacity shortfall in the very near term. As reviewed in Section 4.2, the magnitude of the capacity shortfall depends in part on the load growth that occurs over the next few years (including the extent to which new mine loads, if developed, are connected to WAF through new transmission facilities). However, even under the lowest load growth scenarios, the shortfall approaches 15 MW by 2012, which is a very material scale for the WAF system (which peaks at about 56 MW today).

Facing this requirement, Yukon Energy has identified three major replacement and expansion project options (beyond the "opportunity" project options already noted) that have the potential to largely or entirely address major capacity shortfalls by 2012 on the WAF system:

- **Mirrlees Life Extension Project (14 MW):** One option that requires consideration is a major refurbishment of the three existing Mirrlees units at Whitehorse to reclaim the full 14 MW nameplate ratings and extend the life of the units for 10 years or more. The project would require a full "tear down" overhaul of the three units as well as upgrading to various shared systems in the Whitehorse diesel plant. As the project would only provide 14 MW of capability, it would need to be combined with other projects to meet the full 2012 shortfall

assumed based on retirement of these Mirrlees units (i.e., to achieve the full 15 MW to 27 MW under the various scenarios in Section 4.2). This option is reviewed in more detail below (see Section 4.3.6).

- **Whitehorse Diesel Replacement/Expansion Project (unlimited MW):** This flexible option is available to meet the full range of possible new capacity requirements in near term (up to the full high load scenario requirements of 27 MW by 2012). New units of any type or combination could be added to the system incrementally as required. In all likelihood the units would be installed as replacements for the retired Mirrlees (in the bays vacated by the retirements) and, if undertaken with large units such as modern 8 MW Wartsila gensets (or larger, such as 11 MW units), could largely or entirely be accomplished within the confines of the existing site. In addition, other major resource options that are not sufficiently large to address the entire 2012 shortfalls may be combined with a smaller scale of new diesel installation. This option is reviewed in more detail below (see Section 4.3.7).

- **Aishihik 2nd Transmission Line Project (15 MW under N-1 criteria, 8.0 MW under LOLE criteria):** As discussed in detail in Section 3.3, the largest single factor influencing the reliability and risk profile of the WAF system today is the non-redundant nature of the Aishihik transmission line. A major rationale for maintaining substantial "stand-by" diesel in Whitehorse is to address the risks of an Aishihik line failure. One project option that consequently merits consideration is a "twinning" of the Aishihik transmission line to provide required redundancy. Were such a facility to be put into service to provide complete redundancy, the N-1 criteria would be revised to indicate 15 MW as the largest single contingency (based on one of the hydro units at Aishihik, which are the largest single units on the system) rather than 30 MW currently arising from a potential loss of the line. Under the N-1 criteria, this would currently be a 15 MW benefit to the load carrying capability of the system. Under the LOLE criteria, also as noted in Section 3.3, the benefit from a redundant Aishihik transmission line would currently be about 8.0 MW. In addition, this option enables the opportunity for additional firm capacity benefits related to other potential enhancements at the Aishihik generating station such as the Aishihik 3rd Turbine, as well as the potential for re-runnering (as discussed below). As the Aishihik 2nd Transmission line project would currently only provide 15 MW of new load carrying capability, it would currently need to be combined with other projects to meet the full 2012 shortfall (to achieve the full 15 MW to 27 MW under the various scenarios in Section 4.2). This option is reviewed in more detail below (see Section 4.3.8).

Aside from relying only on diesel expansion/replacement, none of the above major options on its own is likely to address the full WAF capacity shortfall expected in the near term (to 2012). For initial review below, it is assumed that additional diesel engines are the default option to be used as required with each of the other options in order to meet the full near term capacity shortfall. Later, in section 4.4, optimum combination of these options is examined under a range of planning assumptions.

4.3.6 Mirrlees Life Extension Project

As noted in Section 4.1, the Whitehorse Diesel Units WD1, WD2 and WD3 are the three largest units in the Whitehorse diesel plant. Although planned for retirement at an earlier date, Yukon Energy was able to delay the retirement of the units largely as a result of the closure of the Faro Mine.

BC Hydro's Condition Assessment in 2004 recommended that the retirement of these units be seriously considered if significant further use was anticipated (*Section 3.1: Current Facilities Condition Assessment*). Assumptions regarding retirement of these units have at various times been based to a greater or lesser extent on the following cited issues:

- The units' condition is becoming unacceptably poor, and would require substantial investment to bring them back up to a utility quality condition;
- The units are poorly suited to the current operating regime of stop-and-start operation;
- Parts and technical support are lacking and expensive; and,
- The units are expensive to operate and maintain.

Despite these limitations, the retirement of the Mirrlees engines will necessitate major new capacity-related investment in the near term (particularly under the new capacity criteria, but also to a lesser degree even under the previous criteria). In addition, the YUB recommended in its 1992 Report on the utilities' Resource Plan that before the Companies commit to the construction of a supply option they should critically assess a number of factors including "the necessity for diesel retirements". As a result, Yukon Energy is currently undertaking a critical assessment of the potential for a "Life Extension Project" for the units. Such a project must, at a minimum, ensure the above concerns with respect to condition can be fully addressed (including reclaiming the previous full 14 MW combined nameplate ratings).

If feasible, such an option would materially reduce capacity shortfalls in the next five to six years; it would also materially reduce capital costs relative to those needed for any other available option to meet WAF near term capacity requirements. Such an option, if practical, is expected to involve capital costs (2005$) potentially in the order of $0.5 million to $1.0 million for each unit (with material risks that costs could not be readily estimated with any degree of certainty before the project is undertaken, as the

status of internal parts and mechanisms cannot be readily ascertained until the tear-down is underway). In addition there would be substantial initial work in the order of $1.0 million to $1.5 million related to shared aspects of the Whitehorse diesel facility systems requiring material improvements (such as cooling systems, fuel delivery systems, foundation, etc.).

There remain two key concerns with the Mirrlees: the cost and availability of parts and support from the manufacturer, and the suitability of the units to the current Yukon operating environment.

With respect to the manufacturer, it will not be prudent for Yukon Energy to proceed with any Mirrlees Life Extension project unless Yukon Energy can receive clear and reliable assurances that the manufacturer can provide full competent and cost-effective parts and technical support for these units for the next 10-20 years. Recent Yukon Energy experience indicates this concern to be very material. Yukon Energy is in the process of assessing the manufacturer's claims that they can continue to provide competent support on these units, including discussing Yukon Energy's recent experiences with the manufacturer, and seeking references from other utilities who have pursued a similar course of action.

With respect to the operating environment, despite a full tear-down overhaul, the Mirrlees units will remain low speed base load units which are poorly suited to the current Yukon operating environment (stop-and-go operating, limited running hours). This limitation cannot be fixed. However, it is not sufficiently severe to rule out a Life Extension project option, given competitiveness on other grounds as well as the expected use primarily for reserve rather than planned operation purposes (see Section 4.4 regarding "Assessment" below).

Yukon Energy is aware that Northwest Territories Power Corporation ("NTPC") has plans to retire their two KV16 Mirrlees units in Yellowknife in the next number of years (NTPC has already retired a similar unit in Inuvik; the Yellowknife units are similar in running hours to Yukon Energy's units, but about six to seven years newer). The NTPC retirement plans are due primarily to two concerns: part and technical support availability, and suitability to a stop-and-go unattended operating environment. Further discussions with NTPC are planned to compare experiences on these two matters.

If the Mirrlees Life Extension project is pursued and 14 MW of capacity is restored for these units, by 2012 additional diesel capacity will still be required under the capacity planning criteria (capacity shortfalls of 4.7 MW would exist under the Base Case, 0.7 MW under the Low Sensitivity Case, 7.5 MW under the Base Case with mines, and 12.7 MW under the High Sensitivity Case with mines).

Overall, likely costs (2005$) for the Mirrlees Life Extension project to 2012 can be estimated for screening purposes as follows, assuming that added requirements beyond 14 MW are met though additional diesel capacity[15]:

- **Base Case:** Mirrlees Life Extension at $3.0 million to $4.5 million, plus 4.7 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total ***$6.8 million to $8.7 million***.
- **Low Load Sensitivity:** Mirrlees Life Extension at $3.0 million to $4.5 million plus 0.7 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total of ***$3.6 million to $5.1 million***.
- **Base Case with Mines:** Mirrlees Life Extension at $3.0 million to $4.5 million, plus 7.5 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total ***$9.0 million to $11.3 million***.
- **High Load Sensitivity including Mines:** Mirrlees Life Extension at $3.0 million to $4.5 million, plus 12.7 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total ***$13.2 million to $15.9 million***.

In summary, the capital cost (2005$) of the Mirrlees Life Extension Project plus other diesels as required to meet peak loads to 2012 is expected to cost in the range of $6.8 million to $8.7 million, with potential under various load developments to range from $3.6 million to as high as $15.9 million.

Timing with respect to the Mirrlees Life Extension is expected to be quite flexible. Major tear-down overhauls can likely be scheduled on six months notice, and major upgrades to common facilities can likely be staged so as to meet in-service requirements of the overhauled units (although the lead times will in all likelihood be slightly longer than for overhauls, due to design requirements). The project can also likely be staged over a number of years (summers) if preferable. The project is assumed to be suitably organized in an orderly fashion by sequencing one unit per year from 2007 to 2009 (starting with the largest) with common facilities upgrades occurring in 2007. Work on the existing units and facilities that disrupt current capability must occur during summer months (as the units are needed during winter to provide firm capacity).

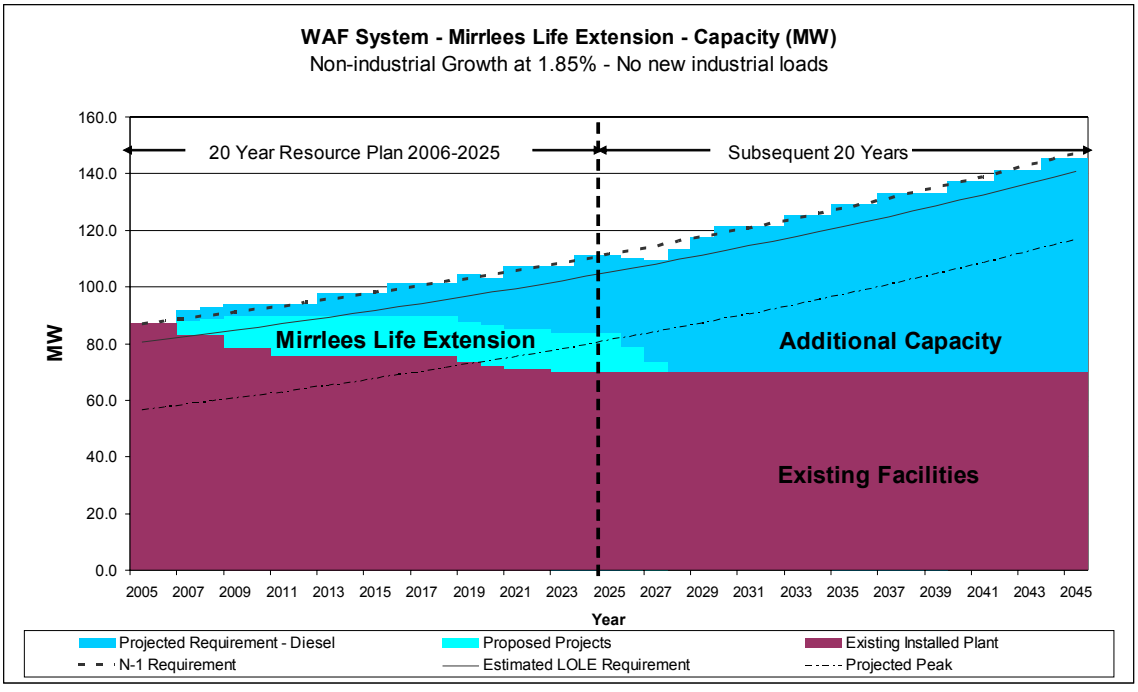
[15] See Section 4.3.7 for a more detailed review of costs for additional diesel units. As a rough measure for screening purposes, diesel units installed for capacity reserve purposes without a need for major "Green Field" support systems (e.g., fuel tanks, substations, control systems) are estimated to cost (2005$) in the range of $800,000 to $900,000 per MW (e.g., $3.2 to $3.6 million for a 4 MW unit). Under the Mirrlees Life Extension option the Whitehorse diesel plant facilities would be utilized for the Mirrlees units, and costs for additional diesels therefore may tend to be higher than otherwise assumed, particularly if a new diesel generation site would need to be developed for these added units.

For the added diesel units that are assumed to be required, issues also arise with respect to locating such diesel units if the entire Mirrlees Life Extension project is pursued. Were the three Mirrlees to be retired, the three "bays" of the existing diesel plant would allow three new units to be installed (units of 8 MW are expected to fit readily into the existing bays, allowing for up to 24 MW of new capacity; units of 11 MW or larger may also fit, but require further consideration). However, if the Life Extension is pursued, these bays will be in use by the Mirrlees and new units will require modifications or expansions to the existing building, or pursuit of other options with respect to unit location.

The Mirrlees Life Extension project impact on WAF capacity, plus other diesels as required to meet capacity requirements, is illustrated in Figure 4.11 (at Base Case loads). This figure focuses on a Life Extension project to add 20 years to the lives of the Mirrlees units. Under this forecast scenario, one new diesel unit (about 4 to 5 MW) would be required in 2007.

One potential variation on implementing the Life Extension project could involve Life Extension of the two largest Mirrlees units (10 MW total) combined with replacement of the smaller third Mirrlees unit (4 MW) with a larger 8 or 11 MW new unit. Under this variation, there would be no need for any other new diesel unit by 2012.

Figure 4.11:
Mirrlees Life Extension



4.3.7 Whitehorse Diesel Replacement/Expansion Project

The Whitehorse Diesel Replacement/Expansion project encompasses various potential concepts of meeting all capacity requirements (including those driven by Mirrlees retirements) using new diesel units at Whitehorse. This could include various combinations of unit sizes (e.g., approximately 4 MW or 8 MW or potentially others such as 11 MW or 15 MW) sequenced as needed to meet load requirements as well as other implementation practicalities. Ongoing investigations are examining issues and costs related to alternative ways to implement this generic option, including common plant upgrade requirements.

Purchase of new diesel units is likely the most flexible approach possible to addressing capacity shortfalls, as units can be sourced that are properly suited to standby use in a wide range of sizes and specifications. However, due to presently high worldwide demand for new diesel units, lead times for new orders from initial commitment through to in-service (including engineering, manufacture, delivery, installation and commissioning) can be on the order of 18 months, which is well above the traditional lead time for new units. As note earlier, work on the existing units and facilities that disrupts current capability must occur during summer months (as the existing units are needed during winter to provide firm capacity).

Diesel units installed at the current Whitehorse plant, without the need for major "Green Field" support systems (e.g., fuel tanks, substations, control systems), are estimated to cost (2005$) in the range of $800,000 to $900,000 per MW[16]. Estimated capital costs (2005$) to 2012 for screening purposes of the Whitehorse Diesel Replacement/Expansion Project are as follows:

- **Base Case:** 18.7 MW requirement for new diesels at $0.8 million to $0.9 million per MW, for a total of ***$15.0 million to $16.8 million***.
- **Low Load Sensitivity:** 14.7 MW requirement for new diesels at $0.8 million to $0.9 million per MW, for a total of ***$11.8 million to $13.2 million***.
- **Base Case with Mines:** 21.5 MW requirement for new diesels at $0.8 million to $0.9 million per MW, for a total of ***$17.2 million to $19.4 million***.
- **High Load Sensitivity including Mines:** 26.7 MW requirement for new diesels at $0.8 million to $0.9 million per MW, for a total of ***$21.4 million to $24.0 million***.

[16] By way of example, based on prices recently quoted to YEC and estimates for costs to install and commission at Whitehorse, a 4.3 MW EMD 16-265H using 6.9 kV generators has been estimated to cost (2005$) about $730,000 per MW ($3.1 million), and a 7.8 MW new 7.8 Wartsila 18V32 using 13.8 kV generators has been estimated to cost (2005$) about $740,000 per MW ($5.8 million). In addition, common plant upgrade costs of $1.0 million have been estimated to apply in each case (assuming installation at the current Whitehorse plant to replace the Mirrlees units, which are assumed to be removed and replaced with from 12 to 24 MW, depending on the unit size selected). Together, these costs average at between $786,000 and $808,000 per MW (depending on the units size selected).

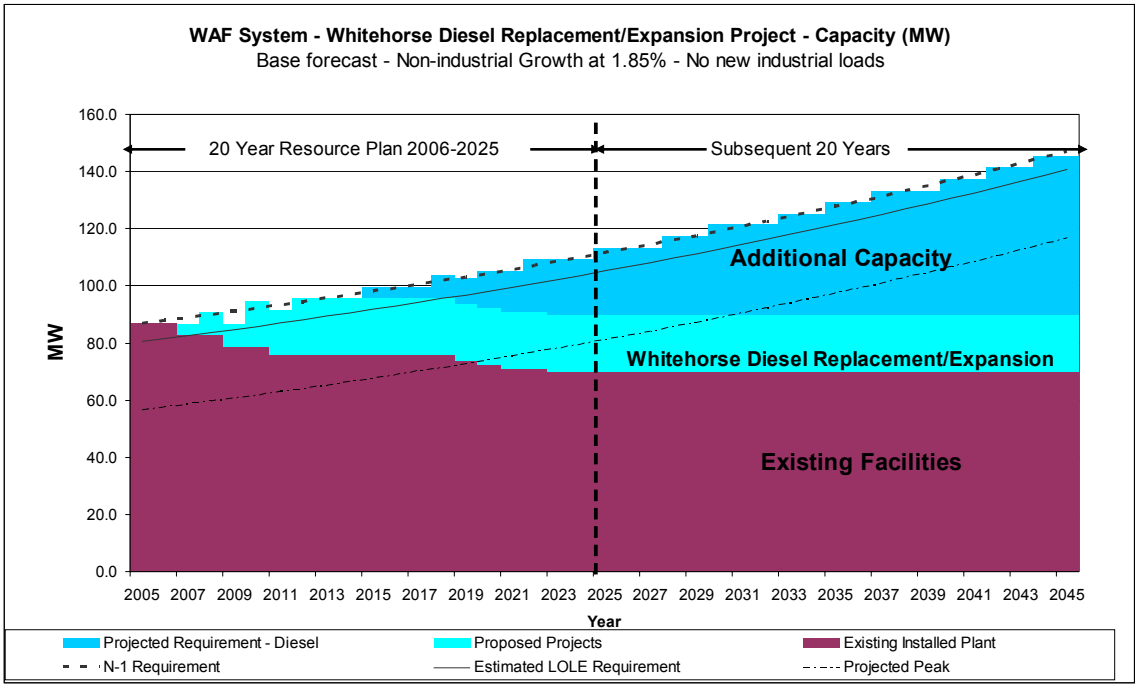
In summary, the capital cost (2005$) of the Whitehorse Diesel Replacement/Expansion Project as required to meet peak loads to 2012 is expected to be in the range of $15.0 to $16.8 million, with potential under various load developments to range from $11.8 million to as high as $24.0 million.

For the first three units installed, there is little issue with space or support systems at the current Whitehorse diesel plant, as the three bays vacated by the retired Mirrlees are of sufficient size to accommodate the noted 4 MW or 8 MW units and perhaps up to 11 MW or larger.

However, issues begin to arise if either a) more than three units are required in the sequence to 2012 (as would occur with new units of 4 MW rather than 8 MW, or would occur under the High Load Sensitivity Scenario with Mines which requires more than three 8 MW units) or b) units are required at a rate faster than the Mirrlees are planned to be retired. If this arises, modifications or expansions will be required to the existing building, or other options required regarding unit location.

The Whitehorse Diesel Replacement/Expansion Project impact on WAF capacity is illustrated in Figure 4.12 (at Base Case loads and assumed increments generally at 4 MW units). Under this forecast scenario, an added diesel unit would be required in 2007, another 4 MW unit would be required in 2008, an 8 MW unit would be required in 2010, and a further 4 MW unit in 2012.

Figure 4.12:
Whitehorse Diesel Replacement and Expansion



4.3.8 Aishihik 2nd Transmission Line Project

The Aishihik Transmission Line is a key component of the WAF 138 kV system. It connects 30 MW of hydro generation from Aishihik to major load and generation centers at Whitehorse and beyond. The Aishihik 2nd Transmission Line Project is a near term option for potential development under the new capacity planning criteria if the existing Mirrlees diesel units at Whitehorse are confirmed to be retired. The project concept is to establish a redundant circuit for Aishihik generation to reach the remainder of the WAF system at Whitehorse.

The net effect of this project under forecast loads would be a reduction in the N-1 capacity planning criteria "reserve" currently of about 15 MW, approximately equal to adding 15 MW of new diesel units. Under the LOLE criteria, the Aishihik 2nd Transmission Line project benefit currently is 8.0 MW. However, under the Base Case forecasts with current facilities, the N-1 criteria is the key factor in requiring new capacity in the near term[17]. Subject to timing issues for its in-service, the project would eliminate the need for any new capacity under Base Case load forecasts until 2012.

Pending results of the current Mirrlees Life Extension investigations, Yukon Energy has not proceeded with material work to date on potential routing options for the Aishihik 2nd Transmission Line project. There exist a number of options to connect to any of 3 substations in the Whitehorse area, or alternatively potentially to the WAF grid line north to Carmacks. Regardless of the routing, the project requires that full redundancy on the delivery of power to the Whitehorse is to be established, including substation components and Whitehorse area transmission connections.

Preliminary costing (2005$) indicates a transmission line development cost (planning, permitting, design and construction) for the simplest project alternative roughly paralleling the existing line on the order of $16 to $19 million. The total costs (2005$) to meet capacity requirements to 2012 with the Aishihik 2nd Transmission Line project are therefore currently estimated for screening purposes as follows:

- **Base Case:** Aishihik 2nd Transmission Line at $16 to $19 million, plus 4.5 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total of ***$19.6 million to $23.1 million***.
- **Low Load Sensitivity:** Aishihik 2nd Transmission Line at ***$16 to $19 million*** fully satisfies the capacity requirements to 2012.

[17] In contrast, if the Aishihik 2nd transmission line was to be built, the LOLE criteria would become the driving factor by 1.1 MW.

- **Base Case with Mines:** Aishihik 2nd Transmission Line at $16 to $19 million, plus 13.5 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total of ***$26.8 million to $31.2 million***. The substantial diesel requirement over and above the Base Case is due to the fact that with 9 MW of mining loads, the LOLE criteria becomes the driving consideration in new capacity, which only credits the Aishihik 2nd transmission line project with 8.0 MW rather than the 15 MW under the N-1 criteria.
- **High Load Sensitivity including Mines:** Aishihik 2nd Transmission Line at $16 to $19 million, plus 18.7 MW requirement for new diesel at $0.8 million to $0.9 million per MW, for a total of ***$31.0 million to $35.8 million***.

In summary, the capital cost (2005$) of the Aishihik 2nd Transmission Line Project plus additional new diesel units as required to meet peak loads to 2012 is expected to be in the range of $19.6 to $23.1 million, with potential under various load developments to range from $16 million to as high as $35.8 million. In particular, costs under this scenario (without examining any other potential benefits noted below) are materially increased by the presence of the potential mining loads.

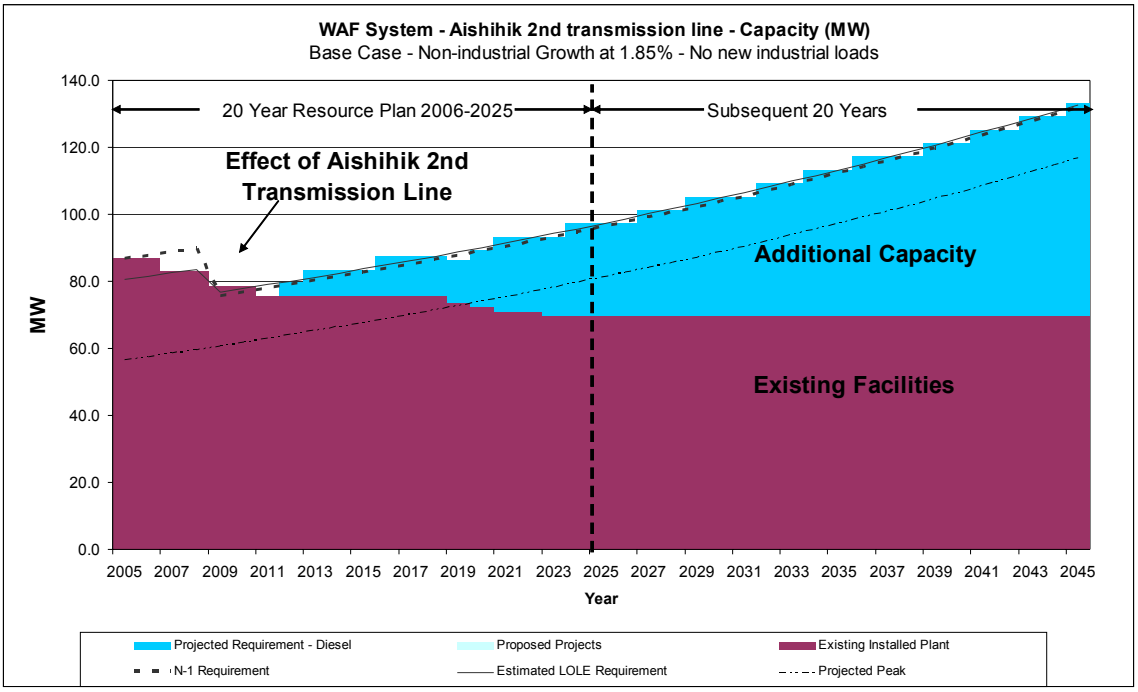
The Aishihik 2nd Transmission Line project would somewhat reduce operating costs compared to diesel in the near term as the project would allow for greater flexibility to keep Aishihik on-line during line maintenance activities which may serve to reduce diesel energy generation that would otherwise be required. In contrast, an equivalent 15 MW of diesel units would require some new spending on diesel fuel in order to maintain and exercise the units regularly.

The development of the new transmission line would involve much longer lead times from commitment to in-service than the other options noted above (potentially three years or more after a commitment to do detailed planning and construction), as well as be less flexible in the near term given the impact of an addition of 15 MW all at one time (compared to diesels which can be added in selected increments as desired). For the purposes of planning, it is not expected that an Aishihik 2nd Transmission Line could be in service any earlier than 2009, which would additionally raise concerns over capacity shortfalls in the 2006-2008 period (under the assumption that under Base Case conditions it may not be sensible to install sufficient new diesel engines (8 MW) to address this two to three year capacity shortfall).

In addition, due to the nature of transmission line contracting, it would not be possible to develop a materially more reliable estimate of the capital costs until such time as permitting and environmental approvals were completed, final tenders were received and contracts concluded (likely requiring a planning cost expenditure of about 10% of the capital cost, or about $1.6 to $1.9 million to get to this stage).

Figure 4.13 below illustrates the capacity criteria benefits of twinning the Aishihik line. Under Base Case assumptions, new diesel (about 4 to 5 MW) would not need to be added to the system until 2012.

Figure 4.13:
Aishihik Second Transmission Line 2009



In addition to ensuring existing Aishihik capacity can remain substantially more reliable to the system, the Aishihik 2nd Transmission Line project also has the benefit of enhancing the opportunity provided by two projects to provide additional capacity at Aishihik:

1. The 7 MW Aishihik 3rd Turbine.
2. A re-runnering of the existing Aishihik turbines for potentially up to 6 MW of added capacity.

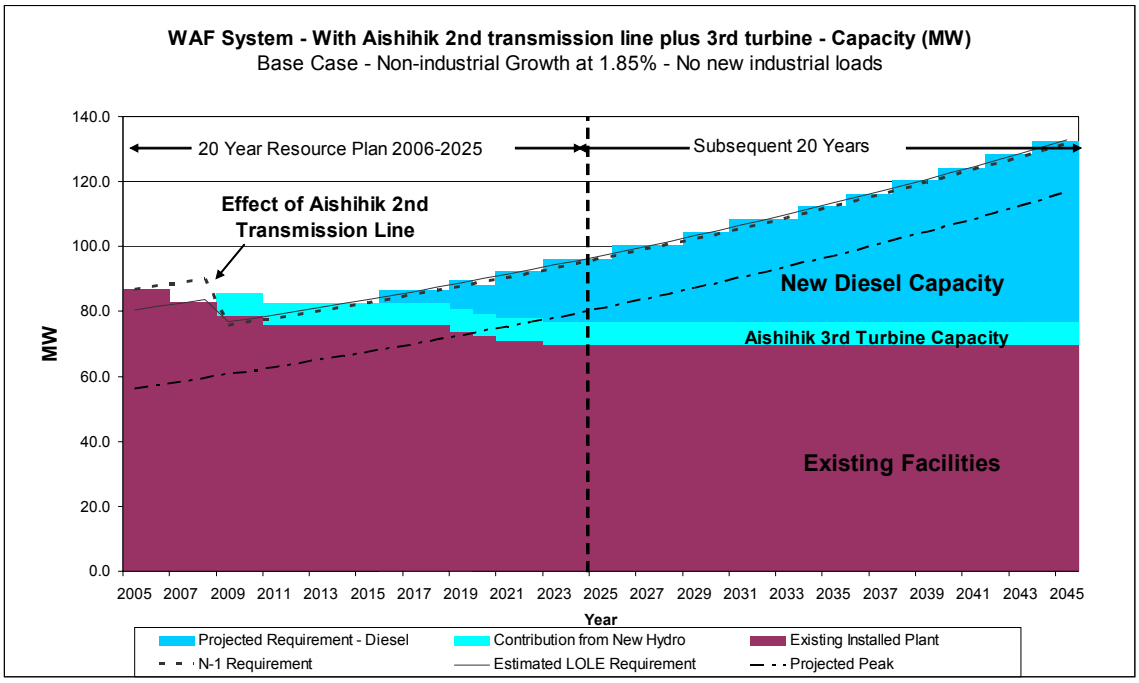
The Aishihik 3rd Turbine is discussed in detail in section 4.3.2. At this time, there is insufficient definition on the potential Aishihik re-runnering project to determine likely costs and practical full capabilities; however, re-runnering projects in other jurisdictions are frequently pursued as cost-effective sources of new capacity and/or energy.

In the event the Aishihik 3rd Turbine project is pursued independently as an “opportunity” project in the near term, development of the Aishihik 2nd Transmission line (under Base Case load conditions) would provide 22 MW of firm capacity, which would allow for a full retirement of the Mirrlees engines and defer

until 2016 the need for any new diesel units on the WAF system. However, without an Aishihik 2nd Transmission line, the Aishihik 3rd Turbine project cannot be considered reliable capacity under the N-1 criteria and only 0.6 MW of the 7 MW can contribute to the Load Carrying Capability under the LOLE criteria. Accordingly, the added capacity value of the Aishihik 2nd Transmission Line become 22 MW under the N-1 criteria and 14.4 MW under the LOLE criteria[18].

Figure 4.14 below notes, under Base Case assumptions, the added benefit of a third turbine separately from new diesel (in this case the 3rd Turbine is assumed to be placed in service in 2009, with new diesel not required until 2016)[19].

Figure 4.14:
Aishihik Second Transmission Line in 2009 (with Aishihik 3rd Turbine in 2009)



[18] Under N-1 criteria with the Aishihik 2nd Transmission Line, a full 37 MW (30 MW existing plus 7 MW for 3rd Turbine) is now recognized at Aishihik (versus no MW recognized without the 2nd Transmission line), less 15 MW for loss of one unit (which once again becomes the largest single contingency event at the time of winter peak), resulting in a net firm capacity gain due to the 2nd line of 22 MW. Under LOLE criteria, the Aishihik 2nd Transmission Line benefit is 8.0 MW regarding the existing Aishihik capacity plus 6.4 MW regarding the Aishihik 3rd Turbine (0.6 MW of the 7 MW would be recognized without the 2nd transmission line), resulting in a net firm capacity gain due to the 2nd line of 14.4 MW.

[19] Approximately 20-24 months are estimated to be required from commitment of the Aishihik 3rd Turbine project until it comes into service. Accordingly, this project could, if so required, be brought into service by as early as during 2008.

4.3.9 Supplemental Project Options

Supplemental project options can serve to complement the major "opportunity options" as well as the major replacement and expansion options noted above. These supplemental project options have the potential to increase capacity, but are not of a sufficient size to materially address the near term capacity shortfall forecast for WAF. These options also remain relatively undefined at this time.

a) **Other facility enhancements that are preliminary and likely far too small to address the entire forecast shortfall:** Supply-side enhancement opportunities are limited by site and/or unit specific opportunities to increase winter peak capacity. Examples under consideration include re-runnering of the two existing Aishihik units (although any new capacity would be subject to the same N-1 constraints as the existing units), and re-runnering of Whitehorse hydro units WH3 and WH4.

b) **Projects without sufficient definition to pursue in the near term:** A range of possible longer-term projects related to the Southern Lakes, as well as Atlin Lake Top Storage have the potential to increase capacity and energy outputs of the Whitehorse Rapids plant (as well as potentially to establish new generation south of Whitehorse). However, these projects are not considered to be potential options to meet near term capacity focused needs, as they are not sufficiently defined or studied at this time. Yukon Energy is currently undertaking a study to update and refine its knowledge of the specific hydrology of the southern lakes area, but until this work is completed, it is difficult to know the potential for cost-effective water management (or hydro generation) structures in the region.

c) **Projects with no reliable capacity contribution:** New wind generation, small scale run-of-river hydro generation, solar, major new DSM initiatives or various other potential new generation technologies are not typically considered by utilities to provide reliable capacity towards meeting near term capacity shortfalls of the type forecast in Yukon.

d) **Projects that require major energy load to be economic:** New storage hydro projects, biomass generation (e.g., wood), and coal generation are not considered to be feasible cost effective options to meet near term capacity focused needs. These projects can only typically be developed when systems require both capacity and sustainable new energy that would otherwise need to be supplied by higher cost options; in Yukon's case past experience has shown that these projects can only be developed on a cost-effective basis when there is sufficient energy being generated with diesel, and substantial certainty that this diesel generation would continue well into the future absent a major capital intensive new generation development of this type (see Chapter 5).

e) **Addition of new diesel generation capacity at Carcross (likely by YECL) of about 1 MW:** Carcross and the connections to Tagish are the only WAF communities of reasonable size (over about 300 people) which do not have local diesel generation installed. In the event that new diesel generation is required on WAF, it may be prudent to locate a small portion of this generation (likely about 1 MW) in the Carcross or Tagish area.

4.4 ASSESSMENT

Assessment of the above near term major project options (i.e., options costing $3 million or more for commitment before 2009) focuses on system optimization and economics for opportunity projects, and on requirement to address the new capacity planning criteria for capacity-related projects.

- **Opportunity Projects:** Assessment of the three identified opportunity projects is set out in Section 4.4.1 below. These three projects reflect both qualitative benefits from maximizing the use of existing investments and infrastructure, as well as quantitative economic benefits from enhanced hydro energy and/or capacity availability to serve loads.
- **Capacity-related projects:** Assessment based on the revised capacity planning criteria, as described in Chapter 3 (Section 3.4), is set out in Section 4.4.2 below. Under these criteria, and assuming retirement of the Mirrlees units, new capacity is needed on WAF under the Base Case in 2006 (0.7 MW), with an 18.7 MW forecast shortfall in 2012[20]. The MD system has no forecast capacity shortfalls by 2012 under the revised capacity planning criteria in the absence of new major industrial loads.

There is no economic opportunity in the near term to develop new capital intensive energy projects such as hydro or coal (without major new industrial loads at the level discussed in Chapter 5) outside of the identified opportunities regarding enhancements to existing facilities.

Resource options are assessed and/or screened over the near term and beyond, based on technical feasibility (including timing), cost efficiency and effectiveness, reliability, and risk (in particular risks related to future load requirements developing differently than indicated by current forecasts). Section

[20] Assessment based on the previous capacity planning criteria is not addressed. Under the previous criteria, and assuming retirement of the Mirrlees units, no new capacity would be needed on WAF under the Base Case until 2010 (0.6 MW), with a 5.6 MW forecast shortfall in 2012. Meeting these requirements would not require cost commitments by Yukon Energy of $3 million or more before 2009. However, even if the previous capacity planning criteria were still in place, it would remain relevant to assess the feasibility of 10 to 20 years Life Extension for the three Mirrlees diesel units at Whitehorse as a cost effective way to retain 14 MW of capacity capability on WAF.

4.4.3 below examines the expected effects of preferred near term projects on overall utility costs and rates.

4.4.1 Assessment of Opportunity Projects

There are three ways that the identified major opportunity projects can provide qualitative and quantitative benefits to Yukon power systems:

- **Peaking diesel fuel use reductions:** Although WAF loads today are at a level where surplus hydro exists on this system, peaking diesel is becoming required on the coldest days of the year and a reasonably high load growth rate is driving the system towards further requirements for peaking diesel each year. Expansion of Aishihik capacity is particularly beneficial in this regard until load growth in effect removes most of the opportunities for secondary sales.
- **Firm winter capacity benefits:** Certain enhancements to existing facilities can provide additional firm capacity to aid in meeting the WAF firm capacity shortfalls noted above. This applies to the Marsh Lake Fall/Winter Storage project and to the Carmacks to Stewart Transmission Line project, but does not apply to the Aishihik 3rd Turbine in any material way unless and until the Aishihik 2nd Transmission Line is developed.
- **Long-term average hydro energy benefits**: Finally, over the long-term, projects that bring new long-term average hydro energy can provide the ability to displace diesel fuel once loads grow to the point of diesel being required for baseload purposes (either through retail customer load growth or the addition of new industrial customers). This benefit applies to all three of the identified “opportunity” projects.

Table 4.2 provides a summary of the near term opportunity projects, including capital costs, in-service timing. Capacity and energy benefits, and present value assessments (for at least two options) of the long-term net diesel costs savings after consideration of project capital and operating costs.

Table 4.2:
Summary of Near Term Opportunity Projects to 2012 (2005$ millions)

PROJECT[21]	BASIS FOR PROJECT	PROJECT CONTRIBUTION[22]
IN PROJECT PLANNING STAGES (PRE-CONSTRUCTION ACTIVITIES, INCLUDING YUB REVIEW)		
Aishihik 3rd Turbine (2009) Capital cost: $7 million	Economic opportunity for "Supply Side Enhancement" to existing facilities.	• Hydro peaking capability (7 MW). • Long-term energy enhancement (5.4 GW.h/year). • no contribution to required firm capacity criteria without 2nd Aishihik Transmission. • Long term net diesel cost savings of $4.1 million (NPV, 2005$) under Base Case load forecasts
COMMITTED PROJECTS PROCEEDING TO PROJECT PLANNING STAGES (INCLUDING YUB REVIEW)		
Marsh Lake Fall/Winter Storage (2007) Capital cost: up to $1 million	Economic opportunity for "Supply Side Enhancement" to existing facilities.	• 1.6 MW of firm capacity toward criteria, plus • Hydro peaking capability, plus • 7.7 GW.h/year long-term energy. • Long term net diesel cost savings of $10.0 million (NPV, 2005$) under Base Case load forecasts.
Carmacks to Stewart Transmission Line Project (2008) Capital cost: $35 million funded by YTG as required to ensure no adverse rate impacts.	Expansion of WAF system to interconnect WAF and MD, and to link two mine projects to WAF hydro surplus. (YTG funding of capital cost to ensure no adverse rate impact).	• Enhance near term link for new mines to WAF hydro surplus. • No new MD supply to WAF unless connect WAF and MD systems. • Once connected, up to 6 MW of enhanced capacity for criteria, and up to 15 GW.h/year added hydro energy (decreasing over time).

[21] Table 4.2 is in 2005$. This table does not indicate the discounted present value of capital costs given in-service dates, the life of each option, or the rate-related impacts of depreciation, interest and return on equity.

[22] NPV long-term net diesel savings reflects ratepayer NPV diesel savings less NPV for capital and operating costs of the project. Present values are assessed over an assumed 65 year life based on the assumed in-service dates, a discount rate of 7.52%/year, diesel unit efficiency at 3.48 kW.h/litre (peaking) and 3.9 kW.h/litre (baseload), diesel fuel prices at $0.65/litres (2005$), diesel O&M at $0.016/kW.h (2005$) and inflation at 2%/yr. No firm capacity or secondary sales benefits are included. See Appendix C for NPV long-term net diesel savings for the Aishihik 3rd Turbine Project (without and with Marsh Lake Fall/Winter Storage).

The costs and time requirements for the identified "opportunity" projects vary significantly, and are material when assessing each option. Based on Table 4.2, the following summary observations are provided:

- **Marsh Lake Fall/Winter Storage**: The least costly option (up to $1 million estimated cost) and potentially fastest to implement option (potential in-service by fall 2007) is the Marsh Lake Fall/Winter Storage project, where the only major work required is to secure the relicencing as needed. Under these circumstances, it is readily apparent that, once developed, the project's economic benefits materially exceed its economic costs during the 20-year planning period as well as during the longer-term. Table 4.2 indicates long term net diesel savings of $10.0 million (NPV, 2005$) under Base Case loads.
- **Aishihik 3rd Turbine**: In contrast, even though the necessary licensing is in place, the Aishihik 3rd Turbine project requires both material costs (estimated currently at about $7 million) as well as material time to implement (earliest likely in-service may be 2008, but more reasonably scheduled for 2009). Under these circumstances, more detailed economic and financial assessments are needed to determine whether the project is likely to yield net economic benefits during the planning period (even though long term net benefits are likely to occur, based on assessments done in the past). Table 4.2 indicates long term net diesel savings of $4.1 million (NPV, 2005$) under Base Case loads.
- **Carmacks to Stewart Transmission Line**: This project will proceed only if Yukon Government funding ensures no adverse impact on ratepayers. Accordingly, costs are not a driver in its assessment in this Resource Plan, i.e., if developed under these terms, its costs will be required to be competitive with the least cost options then available to meet system requirements. The project is in the early project planning stages and at the earliest could be in service between mid-2008 and mid-2009.

More detailed assessment reviews are provided below of each project.

4.4.1.1 Aishihik 3rd Turbine Project

Under Base Case or higher loads without other sources of new hydro energy, the present value savings from displaced diesel for the Aishihik 3rd Turbine option are expected to offset fully its capital costs. Specific economic assessment cases are reviewed below (see Appendix C for more detailed tables setting out the economic and financial present value assessments by year over the 65 year assumed economic life of this project):

- **Base Case with no other projects:** Under Base Case conditions, assuming a 2009 in-service the present value (2005$) over the 20 year planning period of these diesel cost savings is approximately equal to the costs that would be imposed on ratepayers of the third turbine (depreciation, interest, return on equity, O&M) based on diesel prices at $0.65/litre (2005$); this present value is beneficial by $4.1 million over the 65 year life of the project[23].
  - This reflects a NPV of diesel fuel and O&M savings of $11.2 million (2005$, largely increasing throughout the period) and a NPV cost of the project (capital plus O&M) of $7.1 million.
  - It ignores benefits from increased ability to make secondary sales[24].
  - Under this scenario, the project would require 8 years from in-service until it was a net positive impact on annual rates (to 2017)[25].
  - The impact on YEC's revenue requirement in any given year over the 20 year planning period would vary from about negative $0.67 million (first year) to a savings of about $1.44 million (2022) without including any secondary sales benefits in the near term.

- **Base Case with Mines:** If Aishihik 3rd turbine is developed concurrently with about 10 MW of new mining load (the "base case with mines" scenario), the project net benefits over the 20 year planning period total $3.7 million (NPV, 2005$) and $7.9 million over the 65 year life of the 3rd turbine project. In this case, the project is a positive impact on revenue

[23] Assuming a nominal discount rate of 7.52%/year, diesel unit efficiency at 3.48 kW.h/litre for peaking and 3.9 kW.h/litre for baseload, diesel fuel prices at $0.65/litres (2005$), diesel variable O&M at $0.016/kW.h (2005$) and inflation at 2%/yr. Depreciation over 65 years is consistent with the "waterwheels, turbines and generation" category of assets as approved in the 2005 Required Revenues and Related Matters Application.

[24] Yukon Energy does not presently have sufficient load data to analyze the potential revenue benefits related to increased number of hours of secondary sales availability. In rough terms, winter secondary sales average at about 3 MW, or about $198/hour at the current 6.6 cents/kW.h rate effective January 2006 (the rate approved by the YUB in Order 2005-12 was 5.2 cents/kW.h, effective January 2005 with ongoing quarterly adjustment to reflect changes in hearing oil prices). The Aishihik 3rd turbine will reduce the number of hours of diesel generation required on the system by about 127 hours in 2009 (first year of in-service) to about 1004 in 2021. In practice, secondary sales are interrupted for much longer than actual diesel generation time, as these sales can be interrupted for 24-48 hours in advance of expected cold weather. Even at the 127-1004 hour range of actual diesel generation, added secondary revenues would approximate $25,000 to $199,000 per year over the period (prior to WAF requiring base load diesel, which would lead to a total secondary sales interruption year round).

[25] Were Marsh Lake Fall/Winter Storage developed separately in advance of the Aishihik 3rd turbine (in 2007), the NPV of the project under Base Case loads over 20 years would become negative $1.0 million, and positive $3.1 million over the life of the project (ignoring secondary sales benefits), with 9 years required from a 2009 in-service to net annual cost savings to ratepayers (by 2018). Under this scenario, and without further development of mine loads or additional load growth, a delay of 1-2 years may be advisable (decision to proceed in 2009 for in-service in 2011) which would reduce the number of years of adverse rate impact back to 7, with an NPV over the period to 2025 (reflecting only 15 years of project service to that time) of negative $0.3 million (lifetime NPV savings of $3.8 million, compared to $3.1 million if developed at 2009 after Marsh Lake, or $4.1 million if developed at 2009 with no Marsh Lake).

requirement by year 3, with the annual impact varying from negative $0.10 million (first year) to $1.44 million (2022)[26].

In summary, the Aishihik 3rd turbine project is an economically viable upgrade to the existing system that can be economically pursued in the near term. The project economics are enhanced to the degree that mine loads arise in the near term. The Resource Plan reflects commitment to this project for an in-service of 2009 (requiring major design and tendering, as well as a YEC Board of Directors decision to construct, to occur in late 2007/early 2008)[27]. Projects assessed in subsequent sections of this Chapter presume successful implementation of this project by fall 2009.

4.4.1.2 Marsh Lake Fall/Winter Storage Project:

The Marsh Lake Fall/Winter Storage project provides three sources of benefits:

1. **firm capacity** (1.6 MW towards both N-1 and LOLE),
2. **ability to avoid peaking diesel** (via extra 1.6 MW of hydro available at peak times before YEC must run diesels), and
3. **increase to long-term average energy** (7.7 GW.h but varies somewhat based on system loads).

As a source of new capacity alone, the expected costs of the project are not expected to be more than $1 million (primarily related to environmental licencing and mitigation works) and equate to $0.625 million/MW (compared to $0.8 to $0.9 million/MW for new diesel).

However, the capability to enhance the system with added peaking ability as well as added long-term average energy equally justifies the Marsh Lake project (at an expected net present value of $10.0 million in diesel savings to ratepayers (2005$) over the life of the project (at Base Case loads) with $1.9 million (2005$) of these savings occurring during the period of the Resource Plan to 2025).

[26] Were Marsh Lake Fall/Winter Storage developed separately in advance of the Aishihik 3rd turbine (in 2007) under the Base Case with Mines load forecast, the NPV of the Aishihik 3rd Turbine project over 20 years would become positive $2.6 million, and positive $6.7 million over the life of the project, with three years required from a 2009 in-service to net annual cost savings to ratepayers (by 2012). This assessment is not adversely affected if the Carmacks-Stewart Transmission Project is also developed in 2008 (see Appendix C).

[27] In the event that Marsh Lake Fall/Winter Storage is pursued, mine loads are not proceeding towards commitment, and WAF loads are below forecast through 2006 and 2007, it may become necessary to delay the decision to construct by one to two years or more, depending on load conditions and forecasts at that time, in order to minimize potential adverse rate impacts in the early years of the project.

Accordingly, the Resource Plan reflects commitment to proceeding to the licencing and detailed technical stages with this project for in-service by August 2007 or August 2008. Projects assessed in subsequent sections of this Chapter presume successful implementation of the Marsh Lake Fall/Winter storage project by August 2007.

4.4.1.3 Carmacks to Stewart Transmission Project:

This project is being examined using Yukon Government funding, on grounds separate from near term WAF capacity needs.

As Yukon Energy cannot independently justify the interconnection on any reasonable current economic grounds based on specific diesel savings or capacity benefits, the proposal to proceed with the project is solely linked to external factors related to Yukon Government funding and the development of the two mines. Accordingly, assessment of other project options in this Resource Plan does not presume development of this interconnection.

The portion of this project from Carmacks to at least Pelly Crossing is likely to be in place if and when the Minto and/or Carmacks Copper mines are supplied with WAF grid power[28]. Accordingly, if and when it becomes clear that these mine loads will develop for WAF, extension of this transmission project from Pelly Crossing to Stewart Crossing (to provide full interconnection of the MD and WAF grids) is likely in any event to be a technical option to provide WAF access to additional capacity (about 6 MW) and surplus hydro energy (about 15 GW.h).

- The cost effectiveness of this interconnection option will continue to depend on Yukon Government funding to ensure that there is no net cost to Yukon Energy or Yukon ratepayers beyond what would be required for any other option to provide required capacity and energy.
- In this situation, assessments will need to consider the extent to which the surplus hydro made available under this load situation will yield WAF economic benefits during the planning period that serve to offset at least some of the capital costs through both diesel unit cost savings and extended maintenance of secondary sales revenues.
- Full assessment of this option will also need to address risks related to re-opening of the UKHM mine (or other new industrial developments) which would reduce or eliminate the MD surplus hydro, as well as potential new opportunities provided by the interconnection, such

[28] Together, these mines are currently expected to require between 9 and 11 MW of peak power, and up to about 60 GW.h/yr of energy. The added net peak load imposed on WAF by these mines will depend on the extent to which these new mining operations develop their own on-site diesel plants either for backup or other reasons (potentially including interim operation prior to the arrival of utility power, or for benefits associated with waste heat during certain seasonal operations).

as potential additional enhancements for the existing Mayo hydro facility (including enhanced peaking capability) or other new generation opportunities in the MD area.

4.4.2 Assessment of Capacity-Related Projects

With the adoption of new capacity planning criteria, major investments in the near term are required to adequately serve forecast WAF loads. This conclusion is consistent over a wide range of possible load forecast conditions, which indicate WAF capacity shortfalls beginning in 2006 and increasing to between 15 MW and 27 MW by 2012 for the current customer classes plus potential mining operations. In contrast, the MD system has no forecast capacity shortfalls by 2012 under the revised capacity planning criteria in the absence of new major industrial loads.

Based on assessment of the "opportunity" projects reviewed in Section 4.4.1 above, the Resource Plan assumes commitment to the Aishihik 3rd Turbine project for in-service at 2009 and to the Marsh Lake Fall/Winter Storage project for an in-service date of August 2007. Accordingly, these projects are assumed to be in-service at the noted dates for the purposes of assessing the requirement for capacity-related projects. However, because the proposal to proceed with the Carmacks to Stewart Transmission Line project is solely linked to external factors related to Yukon Government funding and the development of the two mines, assessment of capacity-related project options does not presume development of this interconnection. Accordingly, the possibility of the Carmacks to Stewart Transmission Line project (as an option) is included in the assessment of the capacity-related project options.

Table 4.3 summarizes the capital cost (2005$) estimates outlined in Section 4.3 for screening purposes related to the near term major resource options to address capacity shortfall requirements. These initial screening cost estimates assume additional diesel units as the default option to provide any remaining capacity needed beyond that provided by the major project option, as well as the opportunity projects presumed to be in place (Aishihik 3rd turbine at 2009 and Marsh Lake Fall/Winter Storage at 2007)[29].

[29] Capacity required over and above major project options are lower than noted in *Section 4.3 Options* due to the assumed in-service of Marsh Lake Fall/Winter Storage in 2007 and Aishihik 3rd turbine (where relevant) in 2009.

Table 4.3:
Comparison of Near Term Capacity-focused Options to 2012
Assuming Marsh Lake Fall/Winter Storage in 2007 and Aishihik 3rd Turbine in 2009
Without Carmacks to Stewart Transmission Project Interconnection of WAF and MD
(Capital costs (2005$ millions) - No present value assessments)

MAJOR PROJECT OPTIONS	**ADDITIONAL DIESEL REQUIREMENT BY 2012 and costs if met with new diesel capacity**[30]						**TOTAL COSTS TO 2012**
	Base Case Loads		***Low Sensitivity***		***High Sensitivity with Mines***[31]		
	Capacity	Cost	*Capacity*	*Cost*	*Capacity*	*Cost*	
Mirrlees Life Extension (14 MW; $3.0 to $4.5 million)	3.1 MW	$2.5 to $2.8 million	*0 MW (0.9 MW surplus)*	*$0*	*10.5 MW*	*$8.4 to $9.5 million*	**Base Case**: $5.5 - $7.3 million **Range**: $3.0 - $14 million
Whitehorse Diesel Replacement / Expansion (expected maximum of 33 MW[32])	17.1 MW	$13.7 to $15.4 million	*13.1 MW*	*$10.5 to $11.8 million*	*24.5 MW*	*$19.6 to $22.1 million*	**Base Case:** $13.7-$15.4 million **Range**: $10.5 - $22.1 million
Aishihik 2nd Transmission Line in 2009 (22 MW at N-1 and 14.4 MW at LOLE; $16.0 to $19.0 million)[33]	0 MW (4.1 MW surplus)	$0	*0 MW (8.1 MW surplus)*	*$0*	*10.1 MW*	*$8.1 to $9.1 million*	**Base Case**: $16.0 - $19.0 million **Range**: $16.0 - $28.1 million

[30] Costs to meet calculated shortfall in capacity, at $0.8-$0.9 million per MW (2005$) – assessment does not reflect optimization of unit size increments. Estimates assume Carmacks to Stewart Transmission is not developed (with development of this project, capacity shortfalls to be supplied by additional diesel would be reduced by about 5 to 6 MW in 2012).

[31] The Base Case with Mines capacity shortfalls in 2012 are 5.2 MW less than shown here for High Sensitivity with Mines.

[32] Capital costs at $0.8-$0.9 million per MW (2005$); 33 MW is expected to be possible at the existing Whitehorse Rapids diesel plant using 3 - 11 MW units. Beyond 33 MW, consideration is required of site options given limitations of existing building and site.

[33] If an Aishihik 2nd transmission line is constructed, the WAF system capacity requirements become driven by the LOLE criteria not the N-1. Consequently, although the Aishihik 2nd transmission line provides 22 MW load carrying capability under the N-1 criteria, and 14.4 MW under the LOLE criteria, the net effect of constructing the line under the Base Case conditions is 21.2 MW (from a 17.1 MW shortfall to a 4.1 MW surplus at 2012), reflecting that with the 2nd line the LOLE criteria rather than the N-1 criteria creates the ultimate capacity requirement.

Assessment of options to address near term requirements remains dependent upon ongoing investigations to define in more detail each option's conditions and costs. The major Resource Plan near term options to address capacity shortfalls are assessed below in light of current information and the revised capacity planning criteria requirements. The assessment is addressed under two main situations regarding the technical feasibility of the Mirrlees Life extension option, assuming that it will be determined within the next few months to be either feasible or not feasible.

4.4.2.1 Assuming Mirrlees Life Extension Project is Technically Feasible

If the Mirrlees Life Extension project is technically feasible, this is the clear least cost option to provide 14 MW of reliable near term capacity. At $3.5 to $4.5 million for all three units, this option costs from $250,000 to $321,000 per MW. These costs are well below those needed for diesel replacement/expansion (at $800,000 to $900,000 per MW), or the costs for an Aishihik 2nd transmission line. Mirrlees Life Extension can also be developed incrementally as needed.

Notwithstanding these obvious advantages, serious technical issues are still being addressed to determine if this option is feasible and capable of providing full life extension of 10-20 years (including all required parts and technical support from the manufacturer). It is expected that an initial decision will be made in first quarter of 2006 based on an assessment of the capability of the manufacturer to provide technical resources and support, references of other utilities who have pursued life extension options with similar Mirrlees units, and refined expected costs of the option based on further assessment of both overhaul requirements and shared facility requirements (which are ongoing).

If the Mirrlees Life Extension option is determined to be feasible and acceptable on technical grounds, a series of steps and assessments will remain to address the expected near term capacity shortfalls and other near term resource development opportunities. These assessments are set out below:

1. **Proceed with initial Mirrlees 5 MW Unit Life Extension project in 2007**: The first step will involve Yukon Energy contracting out a first "teardown" level of overhaul on one of the units to occur during the summer of 2007 (focusing likely on the 5 MW unit to be retired currently in 2007). The common diesel plant upgrade work would also be undertaken at the same time (at an estimate cost of $1.0 to $1.5 million). Yukon Energy is proposing this schedule in light of the current expectation that the maximum cost commitment for this first unit would not exceed $2.5 million (2005$). Under this scenario, the WAF system would experience an expected capacity shortfall during the winter of 2006/07 of about 0.7 MW prior to the planned capacity work in 2007.

2. **Proceed with the other two Mirrlees unit Life Extensions in 2008 and 2009**: The other two unit Life Extension projects would be proceeded with on a timely basis. Prior to proceeding with each of these projects, which are currently expected to cost up to $1.0 million (2005$) per unit, Yukon Energy would review the experience gained from Life Extensions carried out to date.

3. **Preferred Options to meet the Remaining Capacity Shortfall on WAF (3.1 to 10.5 MW)**: Even with provision of 14 MW from the Mirrlees Life Extension project, Yukon Energy will still need under the Base Case load conditions to develop at least an additional 3.1 MW new capacity by 2012 (and this added requirement could range up to 10.5 MW under the high load cases examined). Adoption of the Life Extension option will affect the assessment of the other remaining options to provide the balance of the capacity requirement (based on the assessments below, the Carmacks to Stewart Transmission Line Project, if developed with Yukon Government funding, could provide a preferred way to provide up to about 6 MW of added firm capacity):

   a) **Whitehorse Diesel Expansion options would be limited - may need to assess other locations for additional diesel unit units as a default option:** The option of developing Whitehorse Diesel Expansion might not be feasible within the current building or even potentially at the current plant site under these conditions, and it may be necessary to assess other locations for any additional diesel unit options. Costs for diesel expansion at a new location as a default planning option involving 4 MW or larger units are likely to approximate $1 million per MW. A variation that may merit consideration is Life Extension on the two larger (5 MW nameplate) Mirrlees units, plus replacement of the smaller Mirrlees unit (4 MW nameplate) with an 8 or 11 MW new unit to secure the needed capacity.

   b) **2nd Aishihik Transmission Line not likely to be cost effective option:** The Aishihik 2nd Transmission Line project by itself is not likely to be cost effective in the near term under these conditions, given its cost (currently estimated at $16 to $19 million) and its “lumpy” delivery of 22 MW of effective capacity all at one time.

   c) **Carmacks to Stewart Transmission Line can be attractive with Minto and Carmacks Copper Mine Loads:** The portion of this project from Carmacks to at least Pelly Crossing is likely to be in place if and when these mines are connected to the WAF grid. Accordingly, if and when it becomes clear that these mine loads will develop for WAF, extension of this transmission project from Pelly Crossing to Stewart Crossing (to provide full interconnection of the MD and WAF grids) is likely in any event to be a

technical option to provide WAF access to additional capacity (about 6 MW) and surplus hydro energy (about 15 GW.h); the cost effectiveness of this option may also be resolved based on Yukon Government funding to ensure no adverse effect on ratepayers relative to any other option. (See Section 4.4.1.3 for further review of this option. [34])

4.4.2.2 Assuming Mirrlees Life Extension is Not Technically Feasible

If the Mirrlees Life Extension project is not technically feasible and the Mirrlees units must be retired, the key initial decision becomes whether or not to develop the Aishihik 2nd Transmission Line Project. As noted in Table 4.3, the Aishihik 2nd Transmission Line fully addresses the capacity requirements of the Base Case loads.

In summary the near term choice under these conditions is between the Aishihik 2nd Transmission Line Project (22 MW of near term capacity benefits under N-1, 14.4 MW under LOLE)[35], versus reliance on major Whitehorse Diesel Replacement/ Expansion for at least the same amount of new near term capacity (17.1 MW, with potential to range from 13.1 MW to 24.5 MW). As reviewed below, current information does not necessarily indicate a clear preferred approach under these conditions. Ongoing investigations will continue to assess these options if it becomes clear that the Mirrlees Life Extension option is not technically feasible.

Technical, cost and risk issues assessed with regard to this choice (see below) underline the nature of the problems and opportunities associated with selecting the Aishihik 2nd Transmission Line option at this time rather than pursuing Whitehorse Diesel Replacement/Expansion on an incremental basis in the event that the Mirrlees Life Extension is not feasible:

1. **Cost effectiveness of capacity benefits for Aishihik 2nd Transmission Line option is affected by several factors**: Initial review of capital costs per MW indicates that the Aishihik Transmission Line option is likely to cost from $0.73 to $0.86 million per MW (2005$) under the N-1 condition (from $16 to $19 million, to provide 22 MW) or from $1.11 to $1.32 million per MW (2005$) under the LOLE condition (for 14.4 MW firm load carrying capability).

[34] Assuming Mirrlees Life Extension is implemented, the Carmacks to Stewart Transmission Line would displace up to about 6 MW (depending on the load case assumed) of new diesel expansion capacity costing about $1 million per MW (2005$).

[35] Given that the Aishihik 3rd Turbine is economic on its own for energy-related reasons in the near-term, the benefits of the Aishihik 2nd Transmission line are 22 MW under N-1 (i.e., if Aishihik 3rd Turbine is already built prior to the line, the line would serve to reduce the "N-1" factor from 37 MW (the total capacity output of Aishihik) to 15 MW (the largest single wheel at Aishihik).

2. The cost effectiveness of this option is affected by several factors:
   - Transmission Line Capital Cost is lower than comparable Diesel Replacement/Expansion Capital Cost under non-industrial scenarios: This transmission project capital cost under N-1 is estimated to be slightly lower than the capital cost (2005$) expected for Whitehorse Diesel Replacement/Expansion ($0.8 to $0.9 million per MW). This however ignores the addition risks related to transmission line cost estimating compared to new diesels, as set out below.
   - Transmission Line Capital Cost is higher than diesel if LOLE criteria applies with sufficient mine development: The cost competitiveness of the Aishihik 2nd Transmission Line option is eroded in the event that mine development is sufficient to reduce its effective capacity contribution to only 14.4 MW (in the event that the LOLE criteria becomes dominant over the N-1 criteria).
   - Added Offset benefits possible from Aishihik 2nd Transmission Line if develop future Aishihik capacity via re-runnering: The Aishihik 2nd transmission line enables the opportunity for other potential capacity-related projects at Aishihik (as yet relatively undefined) focused principally on re-runnering the existing units for added capacity output of potentially up to 6 MW. Although this potential future project has not been costed or had sufficient technical or environmental analysis (such as flow velocities), re-runnering is often viewed in other jurisdictions as a cost-effective way to enhance the existing system for added capacity (and/or energy). Without the Aishihik 2nd Transmission Line project, it is unlikely that rerunnering at Aishihik would be economic (sicne it would not provide any effective ability to contribute to firm WAF capacity during the winter peak).

3. **Timing and Cost Risk Concerns with Aishihik 2nd Transmission Line options:** Key concerns with regard to the Aishihik 2nd Transmission Line Project include the timing and substantial costs needed to deal with planning, permitting, and approvals prior to receiving solid capital cost estimates via the tendering process. If a preliminary commitment to the project was in place in 2006, planning and firm cost estimates would not likely be completed until well into 2007 at the earliest and the transmission line's in-service would in all likelihood be no earlier than 2009. During the period to 2009, capacity shortfalls on the WAF system would grow to 7.1 MW (related to both load growth and retirement of the first Mirrlees WD3). On these matters (timing, and the delayed certainty with respect to cost estimates, and the risks of capacity shortfalls in the interim) the Whitehorse Diesel Replacement/Expansion option is expected to have a clear advantage.

4. **Load Risk Concerns with Aishihik 2nd Transmission Line options:** The potential cost effectiveness of the Aishihik 2nd Transmission Line combined with the Aishihik 3rd Turbine project is dependent on load conditions. This is because the project provides more capacity than is required at 2012 under the Base Case and Low Sensitivity scenarios, but is of lesser capacity value under the very high sensitivity case scenarios with mines (14.4 MW, compared to 22 MW under N-1) which clearly exceed Base Case forecasts[36] while also not becoming so high due to new industrial mine loads as to cut back the effective capacity benefits[37].

5. **Issues regarding 2nd Transmission Line Overlap with Carmacks to Stewart Project:** Concurrent development of the Carmacks to Stewart Transmission Line project with the Aishihik 2nd Transmission Line Project could create adverse overlap issues for Yukon Energy with regard to planning, permitting, design and construction if the Carmacks to Stewart project is proceeding as reviewed in 4.4.1. Conversely, in the even of the Base Case with Mines loads, the two project could together meet the overall capacity shortfall by 2012[38].

6. **Carmacks to Stewart Transmission Line can be attractive with Minto and Carmacks Copper Mine Loads:** The portion of this project from Carmacks to at least Pelly Crossing is likely to be in place if and when these mines are connected to the WAF grid. Accordingly, if and when it becomes clear that these mine loads will develop for WAF, extension of this transmission project from Pelly Crossing to Stewart Crossing (to provide full interconnection of the MD and WAF grids) is likely in any event to be a technical option to provide WAF access to additional capacity (about 6 MW) and surplus hydro energy (about 15 GW.h); the cost effectiveness of this option may also be resolved based on Yukon Government funding to ensure no adverse effect on ratepayers relative to any other option. (See Section 4.4.1.3 for further review of this option.)[39].

[36] This option is clearly not cost effective even when assessed over 40 years to 2045 under the Low Sensitivity case. Even under Base Case loads, securing 40-year net present value benefits can be very sensitive to assumed costs and diesel saving magnitudes.
[37] Net benefits over 40 years, for example, will be minimal under some cost and diesel saving assumptions at 25 MW mine loads.
[38] Under such joint development without Mirrlees Life Extension, the Carmacks to Stewart Transmission would displace about 5 MW of new diesel costing about $0.8 to $0.9 million per MW (2005$).
[39] Regardless of the selection of Aishihik 2nd Transmission project or Diesel Replacement/Expansion (assuming Mirrlees Life Extension is not implemented), in the event that the Minto and Carmacks Copper mines are developed the Carmacks to Stewart Transmission Project would appear likely to displace by 2012 up to about 6 MW of new diesel costing $0.8 to $0.9 million per MW.

4.4.3 Schedule and Sequencing of Alternatives

Based on the review of opportunity and capacity-related projects above, the potential scheduling and sequencing of these near term projects is illustrated in Figure 4.15.

As indicated in Figure 4.15, both opportunity projects and capacity-related projects are required to be initiated and pursued in the near term to address constraints (Marsh Lake Fall/Winter Storage and Capacity-Related projects to address capacity shortfalls; Carmacks-Stewart Transmission Line to address opportunity to service mines in the region, as well as access YTG infrastructure funding).

The exception to current timing constraints is the Aishihik 3rd turbine. This project has some flexibility regarding the scheduling and in-service date (as it does not contribute to firm capacity shortfalls). As indicated in Appendix C, the economics of the project are considerably improved if it is in service as of the start of any new mining loads. However, without new industrial loads and with Marsh Lake Fall/Winter Storage proceeding, it may be advantageous to delay Aishihik 3rd turbine by about two years compared to the timing in Figure 4.15; this decision can be part of the late 2007 assessment by YEC as to whether to proceed with the project at that time.

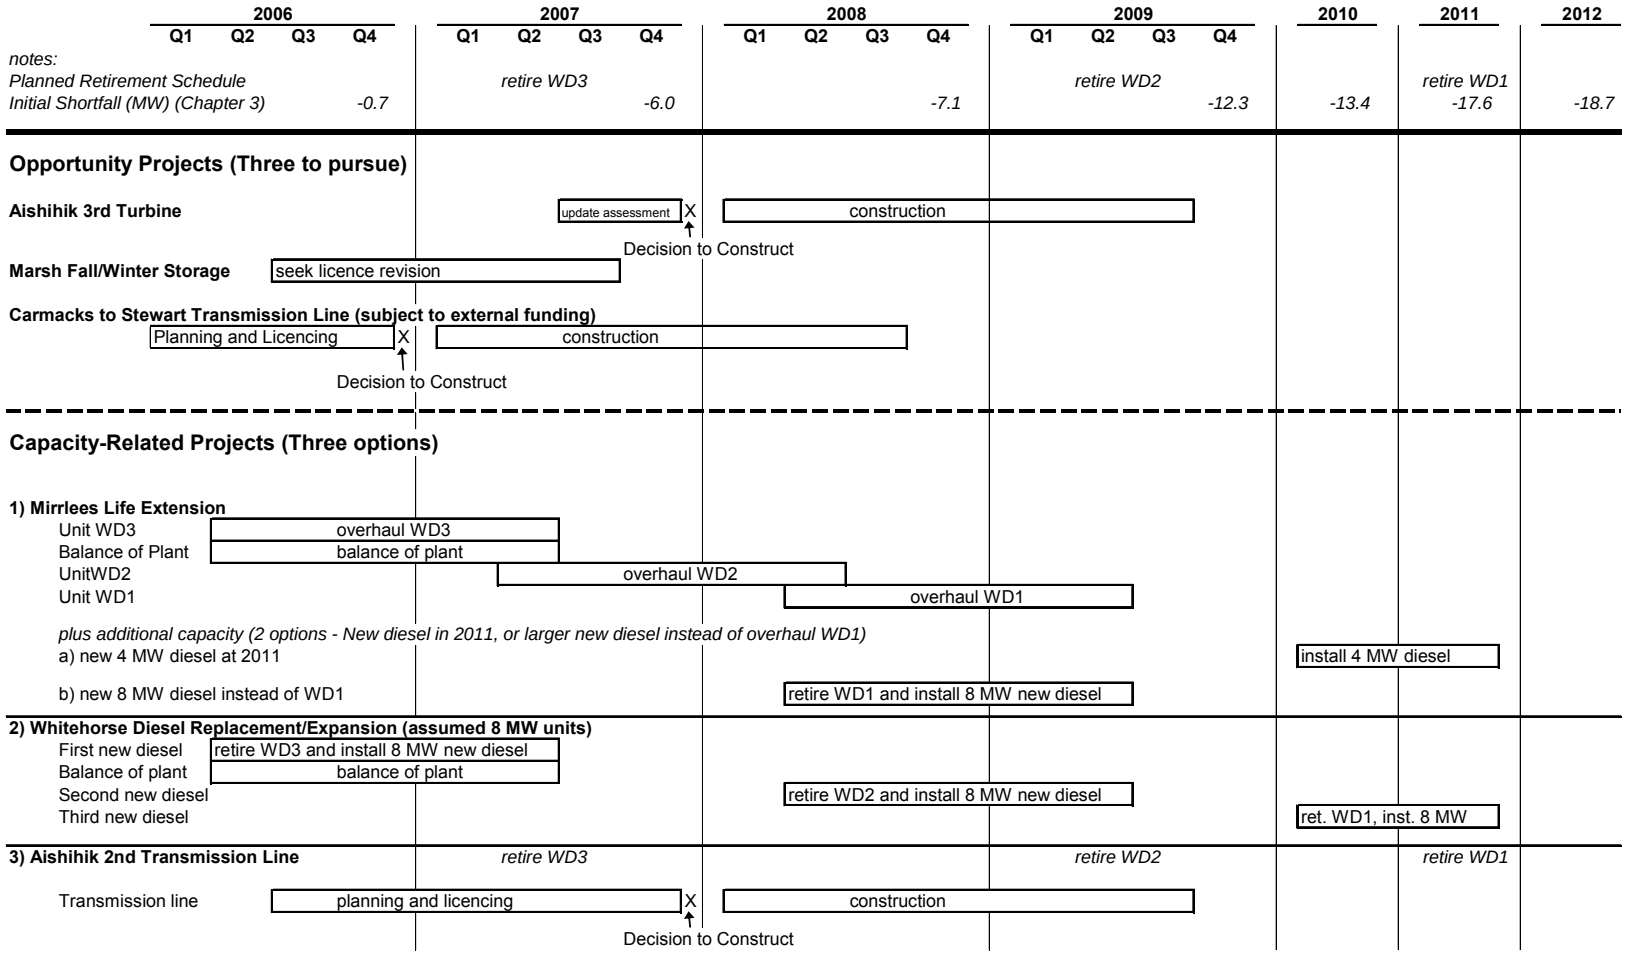
4.4.4 Rate related Impacts of Near Term Options

This section provides a brief examination of the expected effects of preferred near term projects on overall utility costs and rates.

Separate financial assessment is required of the effect of any project on rates, as rates for any given year are set based on annual costs (including depreciation, interest and return on equity) rather than the lifetime long-term costs of projects in service. For capital intensive projects such as hydro or transmission, these annual costs tend to be at a maximum in the first few years of the project (when rate base balances are highest) while benefits can in many cases extend and grow many years into the future (50-100 years in some cases).

Under current rates and OIC 1995/90, Yukon-wide rate impacts are likely to arise of about 1% if utility costs (revenue requirements) are increased in any one year by $360,000 compared to alternatives.

Figure 4.15:
Timing and Sequencing of Opportunity and Capacity-Related Projects



Two key aspects of rate impacts arise with respect to the near term projects:

1. **Opportunity Projects seek to put in place economic assets that provide long-term benefits:** The relative rate impacts of the three opportunity projects vary depending on the particulars of the project:
   a) **Aishihik 3rd turbine:** As reviewed in *section 4.4.1*, the Aishihik 3rd turbine project provides long-term rate benefits. In the first years of the project, however, there is the potential for adverse rate impacts (see Appendix C for more detailed tables):
      i. **Base Case Assumptions:**, Under Base Case assumptions, much like other capital intensive hydro projects, the annual costs of the project will outweigh the annual benefits for a number of years (until offset by inflation and load growth). At a maximum (year 1 if developed in 2009) this impact will be less than 2%, which declines through 2017 (2018 if develop Marsh Lake Fall/Winter Storage first) after which it becomes a positive and growing rate benefit.
      ii. **Base Case with Mines:** If about 10 MW of new industrial loads are connected to the system in the near term (consistent with the two mines now proposed north of Carmacks), the maximum adverse rate impact (year 1 if developed in 2009) will be 0.3% (0.9% if Marsh Lake Fall/Winter Storage previously developed), and by year 3 will be a positive and growing rate benefit compared to the situation without the project (year 4 if Marsh Lake Fall/Winter Storage previously developed).

      In this case, some benefits of the capital intensive Aishihik 3rd turbine increase each year as the value of diesel displaced increases with inflation or other upward fuel price drivers. However, the Aishihik 3rd turbine project imposes the highest costs on ratepayers in the early years.

      In summary, although very attractive economically over the long-term, the Aishihik 3rd turbine project will result in adverse rate impacts in the first year of the project under all near term cases assessed (0.3% to almost 2%), with this impact lasting 2-8 years (this is similar to the MD Transmission Project, which was forecast to be a beneficial project for ratepayers over its life, but did result in the need to address what would otherwise have been adverse rate impacts in the first two years via flexible debt financing from YDC).
   b) **Marsh Lake Fall/Winter Storage:** This project brings firm capacity, peaking capacity and long-term energy benefits. The costs of the project (estimated at no more than $1 million) reflect a maximum cost for the firm capacity of $0.625 million/MW, which is

cheaper than new diesel (assuming all capital costs of the Marsh Lake project are calculated in the cost/MW, ignoring energy benefits). Ignoring energy benefits, the capital-related costs of Marsh Lake at the maximum $1 million level would drive annual depreciation costs of $0.016 million plus interest and return on equity costs in the first year of about $0.078 million plus O&M costs of about $0.005 million. At a maximum, the project will be an upward rate driver of about 0.28%, offset by the savings in peaking diesel (which exceed this level by 2013).

c) **Carmacks-Stewart interconnection:** This project will only be developed if funded via no-cost capital (e.g., Yukon government funding) to a level that ensures no adverse rate impacts on ratepayers. The value of a potential Carmacks-Stewart interconnection will erode over time if the surplus hydro energy and installed capacity available for exchange between the two grids from this project reduce over time with load growth (or new industrial loads) on either system (as will occur at some point if load growth continues without development of new lower cost capital intensive energy resources). However, this limit only occurs to the extent that the flexibility provided by the interconnection does not enable development of attractive new generation projects (such as facility enhancements at the existing Mayo plant or other hydro opportunities in the MD area).

2. **Cannot avoid investment in new capacity, which will tend to be upward rate driver:** The adoption of the revised capacity planning criteria requires that under Base Case load assumptions a material investment in new capital spending will be required by 2012 assuming Mirrlees life extension is implemented, and higher investment if other alternatives are pursued. This amount is over and above normal utility capital amounts for re-investment and facility renewal (which tend to have a relatively stable impact on rates). The major new capacity-driven capital spending to 2012 results in relatively little change to other utility costs. The resulting rough estimations of gross impacts on rates at 2012 are as follows for the screening options noted in Table 4.3[40]:

a) **Mirrlees Life Extension:** With a $5.5 million to $7.3 million capital investment by 2012 (2005$), resulting revenue requirements are likely to be increased by about $0.6 million to $0.8 million (at about 30 years depreciation on diesel assets and 7.52% average cost of capital) or in the range of 1.7% to 2.2% impact on rates.

[40] The calculations do not reflect estimated rate base values at 2012, which would be higher than simple capital cost estimates due to inflation between 2005$ and the actual date of in-service, and be reduced by depreciation from the date of in-service to 2012.

b) **Whitehorse Diesel Replacement/Expansion:** At an estimated Base Case requirement for $13.7 million to $15.4 million capital investment by 2012 (2005$), resulting revenue requirements are likely to be increased by about $1.5 million to $1.7 million (at 30 years depreciation on diesel assets and 7.52% average cost of capital) or in the range of 4.1% to 4.6% impact on rates.

c) **Aishihik 2nd transmission line:** Base Case costs of $16.0 million to $19.0 million (2005$) by 2012 (at 50 years depreciation for transmission line, 7.52% average cost of capital) with resulting annual costs of $1.5 million to $1.8 million, or rate impacts in the range of 4.2% to 5.0%.

The gross impacts noted above are full impacts to address capacity shortfalls to 2012 under the revised criteria. These gross impacts do not address the fact that major capital spending is required by 2012 even under the previous capacity planning criteria to address a shortfall of 5.6 MW under Base Case loads[41].

4.5 PROPOSED ACTIONS

Four separate major investments are proposed for Yukon Energy generation and transmission commitment before 2009, three with anticipated costs of $3 million or more. These proposed major projects will address near term requirements and opportunities to 2012 and together will provide over 21 MW of new WAF firm winter capacity by 2012 (i.e., enough new firm capacity to meet WAF capacity shortfalls that would otherwise be expected by 2012 of 18.7 MW under the Base Case forecast and 21.5 MW under the Base Case forecasts plus the Minto and Carmacks Copper mine loads). The four major proposed projects are reviewed below, along with contingency provisions and other proposed actions before 2012:

1. **Aishihik 3rd Turbine Project:** This project, which was initially reviewed in the 1992 YUB Resource Plan hearing, will provide 7 MW of added peaking capability[42] and about 5.4 GW.h/yr of long-term average hydro energy supply at the existing Aishihik generation station at a capital cost of about $7 million (2005$). Under Base Case loads without any new industrial developments, this project is expected to be economic within the planning period to

[41] If full Mirrlees Life Extension is pursued under Base Case loads under the previous criteria (to secure 14 MW of capacity by 2012, but worth 12.6 MW under the existing capacity planning criteria due to 10% diesel reserve factor, securing a 7.0 MW surplus and ensuring the units are not lost to disrepair and neglect), an estimated $3.0 to $4.5 million in capital costs would be expected to be incurred, for an annual rate impact cost of about $0.3 to $0.5 million or 0.9% to 1.4%.

[42] Without twinning of the Aishihik Transmission Line, none of this added Aishihik capacity is recognized under the N-1 WAF capacity planning criteria, and only 0.6 MW is recognized under the LOLE WAF capacity planning criteria.

2025 based solely on its diesel operating cost saving benefits for the WAF grid, including displacement of peaking and then baseload diesel as WAF loads increase. Yukon Territorial and environmental approvals for the project were received in the new Aishihik Water Licence.

a) Accordingly, this project will proceed with final planning activities to enable a final decision during 2007 to start construction for in-service by October 2009.

b) If Marsh Lake Fall/Winter Storage is developed without any additional non-industrial load growth or new industrial loads emerging, the final decision to start construction is proposed to be deferred until late 2009 for in-service in 2011 or 2012.

2. Marsh Lake Fall/Winter Storage licence revision: This project, which was not reviewed in the 1992 Resource Plan hearing, will increase the firm winter capacity of the Whitehorse Rapids hydro facility by about 1.6 MW and increase long-term average hydro energy from this facility by about 7.7 GW.h/year at a capital cost of no more than $1 million.[43] Yukon Energy will undertake the project planning activities, including consultation and environmental licensing, as required to seek amendment of the Whitehorse Rapids water licence to enable modified operation of Marsh Lake within its current lake levels to enhance fall/winter storage. Basically no new physical works are expected to be required for this project. Project approval is forecast by August 2007 (although provision is made in the event that the new Yukon environmental licencing regime requirements delays completion of the licence amendment to 2008). The effects of the proposed licence amendment are summarized as follows:

a) **Remain within current lake level limits:** In all cases, the water levels with the amended licence will remain within the lake level limits currently experienced (i.e., the peak controlled level would be below the natural high water levels experienced in the lake).

b) **Licence amendment changes the "controlled maximum" level:** The proposed amendment would change the licenced "controlled maximum" level that YEC can maintain upwards by about one foot; however, during uncontrolled periods of summer and fall (when YEC currently has no control over the lake and it is operating under an entirely natural regime), Marsh Lake has been known to peak at two feet above the YEC "controlled maximum" level. The effects of the proposed change are as follows depending on water conditions:

[43] This estimated capital cost is made up of the costs for licencing, any required mitigation works and any potential facility modifications

i. **Non flood year operation other than a drought:** This project would allow Yukon Energy to reduce the amount of water it releases in non-flood years from August 15 to the end of September, to allow that water to be used instead during the peak winter generation period. No effect is to occur under these conditions in any year prior to August 15, other than under drought conditions (see below).

ii. **Flood year operation:** During flood years, there would be no change in the flood levels experienced on Marsh Lake, and no change to operations would be made during August and September until after flood levels subside.

iii. **During drought years:** Current licence provisions to help alleviate summer drought levels on Marsh Lake through "early closures" of the Lewes Dam would remain, and would likely be adapted to alleviate further summer drought conditions to ensure the lake reached the full supply capacity level in each year.

3. **Carmacks-Stewart Transmission Line Project:** This project will fully interconnect the MD and WAF grids as well as facilitate WAF transmission access to potential new mine loads at Minto and Carmacks Copper, providing 5.6 MW of additional firm near term capacity and 15 GW.h/year of additional near term energy for WAF[44]. Development of this project, which is estimated to cost about $35 million (2005$), is subject to provision of Yukon Government funding to ensure that there is no net cost to Yukon Energy or Yukon ratepayers beyond what would be required for any other option to provide required capacity and energy. Based on external funding to assure no adverse impact on ratepayers from project development, planning activities will proceed with the Carmacks-Stewart project to enable a decision to proceed with construction early in 2007 for an in-service date in approximately late 2008.

4. **Mirrlees Life Extension Project:** Subject to confirmation of technical feasibility that is expected to be determined within the first quarter of 2006, the Mirrlees Life Extension Project will conclude final planning activities in 2006 in order to provide in-service during 2007 through to 2009 to provide an additional 14 MW of firm WAF capacity at a cost of up to $4.5 million (2005$).

[44] Added capacity and energy supplied to WAF by this interconnection are subject to MD loads, and will decline as MD loads increase. Reopening of the UKHM mine or other new industrial developments on MD, for example, would reduce MD surplus capacity and hydro energy available to WAF. In contrast, potential additional enhancements at the existing Mayo hydro facility or other new generation opportunities in the MD area could enhance overall WAF/MD power supply in the event of Carmacks-Stewart Transmission line development.

a) **First Mirrlees unit in service by October 2007:** By the summer of 2006 planning work and commitments for construction/implementation will begin on the first Mirrlees unit (5MW) at a cost of up to $2.5 million (2005$)[45] in order that in-service will occur before October 2007.

b) **Other two Mirrlees units by October 2008 and 2009**: Life Extension for the other two Mirrlees units will proceed thereafter for expected in-service in 2008 and 2009, subject to review of the experience gained from Life Extension of the first unit and the possible Yukon Energy consideration of replacing the third Mirrlees unit (4 MW) with a larger capacity new diesel unit (e.g., 8 MW or 11 MW unit).[46]

5. **If Mirrlees Life Extension is not technically feasible, implement diesel replacement/expansion and/or other project options as appropriate:** Without the Mirrlees Life Extension option providing 14 MW of firm capacity, the key near term choice is between the option involving Whitehorse Diesel Replacement/Expansion (capability for three units with combined capacity of up to at least 33 MW) versus the Aishihik 2nd Transmission Line (providing 22 MW under N-1 criteria and about 14.4 MW with LOLE criteria)[47].

Although the expected capacity shortfall can technically be met with the Aishihik-related option, this is not expected to be the lowest cost option to 2012 under Base Case loads and also this is not the lowest cost long-term option under higher loads including mines. The Aishihik-related option also exposes the WAF grid to near term and growing capacity shortfalls until it is completed.

Accordingly, the Diesel Replacement/Expansion option will be implemented as follows in the

[45] This cost includes a "teardown" level of overhaul and the common diesel plant upgrade work necessary to undertake the Mirrrlees Life Extension Project.

[46] In the event that Mirrlees Life Extension proceeds but the Carmacks-Stewart Transmission Line is not developed in the near term, replacing the third Mirrlees unit with an 11 MW new diesel would more than replace the capacity that otherwise would have been provided by the Carmacks-Stewart Transmission Project.

[47] In this context, the Aishihik-related option has been examined for possible implementation assuming that it is feasible to commit development of the Aishihik 2nd Transmission Line by 2009 at the latest; under this option, material near term capacity shortfalls would still occur until the Aishihik 2nd Transmission Line was in service.

event that Mirrlees Life Extension is not technically feasible[48]:

a) **First Diesel Unit (8 to 11 MW) needs to be installed by October 2007** Yukon Energy will need under these circumstances to proceed with final planning work on this project by summer 2006, including orders for the necessary engine unit (with cancellation provisions) in order that the unit can be installed by October 2007 at a capital cost (2005$) of up to about $7.2 million (8 MW) or $8.8 million (11 MW). This will include updating any common diesel plant systems necessary for connection of a new unit.

b) **Other Diesel Units**: Once the first unit is committed, it is expected that up to two additional diesel units (depending on the unit size selected) will be implemented thereafter as required for in-service before 2012.

6. **Ongoing monitoring of existing customer load forecasts and new industrial development opportunities:** In order to facilitate ongoing assessment of generation and transmission options and requirements, Yukon Energy monitoring of annual customer class load trends (peak capacity and seasonal energy) on each grid is required. In addition, Yukon Energy will continue to monitor directly with developers and government specific new industrial development opportunities for grid power service, including assessment of any mine site power contribution to the supply of reliable grid peak capacity.

7. **Other Small Enhancement Projects:** Continued routine utility investment is recommended in assessing and proceeding with projects to enhance existing facilities at a cost less than $3 million. This includes:
   - study of the hydrology of the Southern Lakes, and potentially pursuing small water control structures in this region (new generating stations to manage water plus generate hydro power would, if proposed in the future, exceed $3 million);
   - continued pursuit of opportunities to cost-effectively rewind or re-runner existing hydro generating units at Whitehorse and Aishihik; and,
   - assessing need and timing for a potential 1 MW diesel unit installation at Carcross/Tagish (likely by YECL).

[48] Diesel Replacement/Enhancement will also be the option pursued as required in the event that other major projects do not proceed as proposed, e.g., the Carmacks-Stewart Transmission Line Project (which is assumed to provide 5.6 MW by late 2008) and/or the Marsh Lake Fall/Winter Storage (which is assumed to provide 1.6 MW by fall 2007 or 2008). In the event that mine loads are connected to WAF without completion of the Carmacks-Stewart Transmission, Yukon Energy will review the feasibility of the Aishihik 2nd Transmission Line project.

5.0 INDUSTRIAL DEVELOPMENT SCENARIOS AND OPPORTUNITIES

This chapter addresses planning activities that Yukon Energy may be required to carry out in order to be able to start construction on generation and transmission projects before 2016 (beyond those projects noted in Chapter 4 for commitment in the near term before 2009), largely to meet the needs of potential major industrial customers.

Industrial development scenarios and opportunities include possible new mines, or other major potential developments in Yukon including the Alaska Highway Natural Gas Pipeline project. This chapter focuses on project resource options that have the potential to meet the new capacity and energy needs associated with four potential industrial development scenarios (10 MW, 25 MW and 40 MW industrial development scenarios, and the Alaska Highway Pipeline).

The sections for this chapter are as follows:

- Section 5.1: Planning Approach and Timeline
- Section 5.2: Requirements
- Section 5.3: Options
- Section 5.4: Pre-Assessment and Screening
- Section 5.5: Proposed Actions

5.1 PLANNING APPROACH AND TIMELINE

Planning activities to proceed with other generation or transmission projects beyond 2009 and before 2016 are being driven by the potential needs of a diverse range of possible major industrial developments and the possible energy requirements and/or opportunities related to such developments[1].

Chapter 4 has shown that new near term industrial loads of up to 10 MW within the 20 year planning period typically give rise to capacity-focused resource options[2]. In contrast, new industrial loads above 10 MW within the 20 year planning period may create opportunities for energy-focused resource projects.

[1] Section 4.2.4 shows, under Base Case loads (without new industrial loads), WAF diesel generation remains below 10 GW/h/year until after 2020, and increases only to 28 GW.h/year in 2025. Near term development of the Aishihik 3rd Turbine and Marsh Lake Storage as proposed in Chapter 4 would reduce this Base Case WAF diesel generation, e.g., to about 15 GW.h/year in 2025.

[2] Near term WAF industrial loads of up to about 10 MW could increase this Base Case WAF diesel generation to about 40 GW.h by about 2016 (with development of Aishihik 3rd Turbine and Marsh Lake Storage as proposed in Chapter 4, this WAF diesel generation would be about 25 GW.h/year in 2016); however, in Section 4.2.6 such new near term mine loads are not expected to be sustained beyond about 10 years (i.e., beyond about 2017 if mine developments occur in 2007/2008).

Chapter 5 examines these energy opportunities in the context of the different possible load situations outlined in Chapter 1 (Figure 1.2), the significant uncertainties associated with such load possibilities, and the lead times and other needs associated with Yukon Energy protecting appropriate resource options related to these different possible loads.

The planning approach in this Chapter parallels that used in Chapter 4; namely:

1. **System capability** (part of *Section 5.2: Requirements*) over the intended 20-year horizon as well as to 2045 is reviewed.
2. **System requirements** (part of *Section 5.2: Requirements*) are reviewed over the 20-year plan horizon and to 2045, focusing on key characteristics for each of the four representative industrial load scenarios.
3. **Forecast New Facilities Requirements** (part of *Section 5.2: Requirements*) are reviewed over the 20 year planning term and implications to 2045, focusing on opportunities to develop new capital intensive energy projects with potential to displace future diesel-fuel generation required under each industrial load scenario.
4. **Resource Options** (*Section 5.3: Options*) to meet energy requirements under each industrial load scenario are identified and summarized to the extent that representative non-diesel generation resource projects can be defined today.
5. **Assessment of Options** (*Section 5.4: Pre-Assessment and Screening*): given the limited degree of information available today on most resource options, preliminary pre-assessment and screening of the identified options focuses primarily on “technical” considerations (how well various project sizes and location fit each scenario’s potential load requirements). Where available, screening also considers to a limited degree “economic pre-assessment” of these options based on available information about the likely Levelized Cost of Energy or “LCOE” of each generation component.

This chapter sets out the actions that Yukon Energy proposes to take during the planning period to prepare for potential industrial development scenarios and opportunities beyond the near term, and to protect future opportunities to develop generation and transmission in a timely but cost-effective way. The planning activities proposed in this chapter are intended to strike a balance between the opportunities and risks associated with bulk power resource options selected to supply future Yukon industrial development.

5.1.1 Need to Consider and Balance Several Key Factors

Yukon and other experience in Northern Canada dramatically demonstrate how past industrial developments provided the opportunity to develop new generation and transmission infrastructure in a cost effective way, and how that infrastructure continues to yield sustained lower cost energy benefits to local residential and commercial power users long after the initiating industry has been closed[3].

The existing hydro at Aishihik and Mayo and the 4th wheel at Whitehorse were all linked directly with industrial developments which are now closed, as were the major hydro developments at Snare, Bluefish and Taltson in NWT (developed to service either mines that are now closed, or in the process of closing). Only areas in Northern Canada that have had industrial customer mining load have the benefits today of access to significant low-cost hydro.

Yukon and other Northern Canada experience also demonstrates that power resource planning regarding specific industrial developments can involve long pre-development timelines as well as considerable uncertainty and risk.

Accordingly, Yukon Energy needs to maintain a balanced approach to planning for grid power service to major new industrial loads. In particular, the approach must ensure that Yukon Energy is sufficiently prepared so as to "protect" feasible options to proceed with its own desirable resource projects quickly as needed should new industrial loads develop, while at the same time not spending more than is prudent to protect and advance such resource projects by, for example, proceeding to detailed feasibility stages based on mere load speculation or industrial development scenarios that are highly uncertain. Overall, this balance must be struck between two basic considerations:

a) **Readiness and Timing in relation to supplying new loads:** Due to industrial development planning and construction constraints, there may be limited time after a development's load uncertainties are resolved for Yukon Energy to proceed with the new generation and transmission needed to supply a new industrial load development with grid-based power. In particular, planning, designing, licencing and constructing new generation or transmission can, in many cases, take at least as long if not longer than similar planning, commitment and construction for a new industrial development such as a mine. If not

[3] Section 2.1.1 in Chapter 2 reviews how today's hydro generation and transmission facilities, developed in the past often in response to specific industrial mine-related load opportunities, are the key factor causing Yukon power costs today to typically be lower than those found in Alaska or the NWT.

sufficiently prepared and ready, new grid-based power service opportunities will be missed, likely in favour of on-site generation by the industrial customer. The potential significance of each such opportunity to Yukon's power system in the near and long-term merits careful consideration, along with assessment of the requirements to be sufficiently prepared and ready.

b) Costs, timelines and Risks for resource project planning: The planning phases for new generation or transmission can be costly and require many years of work prior to Yukon Energy being in any position to undertake final commitments to proceed with construction (with corresponding risks that potentially substantial spending on planning studies will indicate a project is not feasible). Understanding the likely costs, timelines, and risks associated with planning specific power resource options is an important precondition to assessing the likely requirements to be sufficiently prepared and ready.

As noted, when considering grid-based power supply options to new industrial loads, the key factors to be balanced in this regard relate both to the industrial development under consideration and to Yukon Energy:

- **Industrial Development factors**: Considerable uncertainty often persists as to timing and prospects to start and complete construction for a major new industrial development; even after successfully developed, material risks and uncertainties can remain as to the length of time for ongoing operation as well as the ability to meet ongoing financial obligations. Key factors in this regard include:
  - **Non-power uncertainty and risk factors:** In general, the key planning considerations and uncertainties for specific industrial developments derive from market, resource or other factors not related to power supply. Although power can be a cost factor that needs to be considered by potential industrial operations, such as mines or pipelines, it is often just one factor among many key considerations (such as financing, markets, licencing, or facility design).
  - **On-site power considerations:** Many major industrial developments if needed can rely upon on-site diesel generation or even (in some instances) their own fuel resource supply (e.g., coal for a coal mine, wood waste for a pulp mill, or natural gas for a natural gas pipeline) and will if required proceed without waiting upon development of access to utility grid-based power supply. In some instances, on-site generation may even provide opportunities to utilize waste heat or waste resources that can be used to supply energy; on-site generation capability may also provide critical requirements during construction or be needed as reliable backup to grid power during operation.

on-site generation capability may also provide critical requirements during construction or be needed as reliable backup to grid power during operation.

- **Short operating life and/or small scale power need:** In instances where a short operating life of (say) five to ten years is expected or at risk, or where the scale of the development involves relatively small power requirements, the incentive to incur material up front capital costs for connection to grid-based power may be severely reduced.
- **Cases where access to grid power is critical:** In some special cases, the feasibility of a specific industrial development may also be critically dependent upon access to grid-based power that is supplied at costs materially less than diesel fuel generation. In such instances, joint planning with the utility will be a key consideration to the industrial development's ability to proceed.

- **Yukon Energy factors**: Yukon Energy can also face a range of its own specific uncertainties and risks related to supplying grid power to major industrial developments. Key factors in this regard include;
  - **Inability to select or "forecast" in advance which industrial development scenario will unfold**: Based on current information, Yukon Energy cannot select or "forecast" in advance on any reliable basis (sufficient, for example, to commit material planning resources on any prudent basis) what level or scope or type of major industrial development is likely to occur by any specific time period under review in this Resource Plan.
  - **Limited value to current information**: Until uncertainties are resolved for a specific industrial development, it is typically also not practical or cost effective based on currently available information (regarding both the industrial development and the power resource options to supply its needs) to plan and assess in any detail how Yukon Energy may serve that development. If and when a development proceeds, its specific energy, power capacity and timing requirements (and the costs and needs for resource options to supply such requirements) in many cases are likely to vary significantly from current estimates.
  - **Limited time to respond to a new development once its major uncertainties are resolved:** As noted above, Yukon Energy will typically have only a very limited time to respond after uncertainties are resolved for a new industrial development before it becomes necessary to undertake power supply commitments; in many instances, as noted above, an industrial development will also simply proceed to use on-site diesel generation if Yukon Energy cannot commit on a timely basis to supply grid-based power.

- **Costs and time to develop new bulk power supply resources:** Yukon Energy may need to develop at least some new bulk power resources to supply grid power in response to a new industrial development. Opportunities to supply grid power that are contingent on planning, permitting and developing material new transmission and/or capital intensive non-diesel fuel generation resources are likely to require many years of work involving major capital costs prior to Yukon Energy even being in a position to make final commitments to proceed with construction of the needed resource projects – and capital intensive construction projects may then require several additional years (and cost risks) before coming into service.
- **Need to assess, and secure YUB approval of, ongoing rates:** Yukon Energy needs also to examine in advance the likely ongoing rate implications and risks, both for the potential industrial customer and for other Yukon ratepayers, and to secure YUB approval of any rate to be charged with regard to commitments to supply any new "major industrial customer" (as defined in OIC 1995/90).
- **No market value to power if developed but not needed in Yukon:** Unlike many southern jurisdictions with export connections, Yukon Energy cannot secure any economic value from projects except from sales to customers in Yukon, due to the lack of grid interconnections with external markets. In this regard, there is considerably more risk today to developing capital intensive bulk power projects in Yukon than in, say, Manitoba or British Columbia. This is because failure of local loads to develop as planned in Manitoba or BC can be offset by the opportunity to sell more power on export markets than otherwise would be the case. In contrast, once Yukon commits to a major capital intensive resource supply project, if the load does not develop or remain as planned the resource project has the potential to have zero or very limited value[4].
- **Resource Projects of a scale at or beyond Yukon Energy's current capability:** In some industrial development scenarios examined in this Resource Plan, the magnitude of required new generation and transmission opportunities may be at or beyond the current capability of Yukon Energy, or other Yukon entities, to finance and construct. For example, Yukon Energy presently has about $57 million in equity, while some of the

[4] This exact situation occurred with the construction of Whitehorse unit #4 in the 1980s. This unit basically provides almost exclusively summer energy, which was only of value at that time if the Faro mine was operating. However during construction of unit #4 the Faro mine closed, such that at the time of commissioning, the unit provided no economic value to the system. Since that time, substantial periods of operation of the Faro mine have provided opportunities to capture good economic value from unit #4. However, had the mine shut for good in the 1980s, unit #4 may have not been of any material value to the WAF system for decades after it was commissioned. Today, limited quantities of surplus hydro can be sold at lower secondary rates, however the potential is somewhat limited and is of lower value that full firm energy sales.

resource options considered in this Chapter approach $500 million to $600 million capital costs for generation alone (plus amounts for substantial transmission upgrades), and would involve the need to assess financial approaches and partnerships, potentially including participation by the Governments of Yukon and Canada. Such additional complications would likely increase planning timeframes and would also likely involve assessing options regarding sharing of risks associated with the projects.

5.1.2 Regulatory and Policy Framework

As a regulated utility, Yukon Energy's planning and developments occur within a regulatory and policy framework relating to its power supply developments and regulated rates charged to recover utility costs of service.

Where new industrial customers are located within areas presently served by Yukon Energy grid power, Yukon Energy must take into consideration its typical utility "obligation to serve" new loads that request electrical service. In contrast, Yukon Energy is not automatically required to serve new industrial loads that are located far away from the current Yukon grids unless the customer (or government) is prepared to fund directly the transmission costs and risks required for Yukon Energy to connect the new load to the grid[5]. In this regard, it is broadly assumed that major new industrial customers located materially away from the current grids would not be added to the Yukon grid systems due primarily to the constraints of incremental transmission connection costs. Without such connections, it is also assumed that a new major industrial load would typically be supplied by isolated on-site diesel generation with all costs being excluded from YUB consideration for the purpose of Yukon wide regulated rate setting (in accordance with OIC 1995/90).

The existing WAF system today can provide substantial (approximately 90 GW.h/year under normal water flows) attractive low-cost surplus hydro power to new industrial customers. The clear implication is that new industrial customers in reasonable proximity to WAF currently have major opportunities to secure material cost savings by purchasing WAF power supplies rather than using on-site diesel generation. Securing new industrial customers on WAF to allow sale of this surplus power at firm rates will also be a beneficial rate driver for all existing Yukon Energy and YECL firm customers, not only on WAF but throughout Yukon (due to the rate directive provisions of OIC 1995/90 which in effect integrate all utility

[5] As with new connection to WAF or MD by new non-industrial customers, transmission or distribution costs driven by new industrial customers are assumed to be funded by the industrial customer themselves (or by government), except to the extent that there is a cost effective case for Yukon Energy to invest in hooking up new industrial customers at a benefit to current ratepayers (pursuant to principles established in the Electric Service Regulations).

costs to equalize retail customer class rates through Yukon)[6].

However, the current WAF hydro power surplus is being reduced by ongoing normal growth in non-industrial customer firm loads, such that Secondary Energy sales on WAF that rely on surplus hydro power are expected to be fully curtailed by 2023 under the Base Case load forecast reviewed in Chapter 4 (see Figure 4.2).

Larger or longer-term new industrial power loads connected to WAF or MD that require energy materially beyond available surplus hydro power would, absent the development of new power resource options, drive major new diesel generation on these grids. Accordingly, Yukon Energy needs to identify and consider carefully the options and impacts to service such new industrial developments. For example, it may not be sensible to develop new transmission to service a mine (with associated transmission line losses) if the power is being largely generated via diesel at Whitehorse, when the same power could likely be generated at the mine site using diesel without the associated transmission losses. New grid extensions will similarly have limited long term value to the extent that they end up being used to transmit diesel generated power rather than hydro or other lower cost based power. Overall, looking at longer-term implications, such new industrial loads are likely to be attractive economically to the existing grid system only if they allow development of new capital intensive low-cost generation, such as occurred with the original opportunities to develop Mayo or Aishihik.

Accordingly, for new bulk power projects that may be developed in response to industrial development opportunities, Yukon Energy needs to assess the economics of the project (including attendant risks), the potential rate impacts on other utility customers as well as for the new industrial customer, and overall Yukon policy objectives.

On the matter of overall policy objectives, in other jurisdictions various broad policy objectives regarding resource development guide electrical system expansions[7]. In Yukon, the traditional energy policy

[6] Up to 30 GW.h of this surplus hydro may currently be sold to secondary energy customers; however, interruption of such secondary sales (as well as use of the balance of the current hydro surplus) to service firm industrial loads will secure much higher revenues for Yukon Energy without incurring material increases in its costs. Under regulated rates, the net benefits of such rate revenue improvements will therefore flow through to reduce overall regulated rates below levels that would otherwise apply. Yukon Energy and YECL customers will accordingly benefit to the extent that rate reduction savings do not simply serve to reduce Rate Stabilization Fund subsidies funded by the Yukon Government.

[7] An example is the BC government directive that BC Hydro not develop nuclear power. In contrast, at times Newfoundland has had a moratorium on developing new small hydro.

objectives have been focused on development, where economically feasible, of local resources compared to imported diesel fuel. Consequently, at times since it was established, Yukon Energy (along with Yukon Development) has assessed, requested proposals, and in some cases conducted research and development projects on the following: Eagle Plains crude oil, wind generation, diesel/coal combined cycle generation (based on coal from Division Mountain), new hydro (including small Independent Power Producer (IPP) hydro projects), diesel/solar hybrid, biomass generation and geothermal resources (many of these at scales well below that needed to supply industrial customers). Planning for major new supply continues to reflect largely the broad "development of local resources" objective where economically feasible.

5.1.3 Planning Framework

The planning framework in this chapter focuses on information that is currently available and on activities Yukon Energy (and the YUB) can control – monitoring potential loads as they develop, conducting appropriate screening and pre-feasibility work on potentially attractive generating and transmission options, and conducting phased and managed feasibility work where appropriate in advance of industrial developments becoming firmly committed to ensure Yukon Energy "protects" the ability to respond when necessary within the timelines required.

To ensure that relevant longer-term service implications are considered, Yukon Energy examines load scenario requirements in this chapter out to the year 2045; however, the analysis addresses only those generation or transmission supply options that may be required to commence development before 2016.

The analysis and project options identified in this chapter build on the Chapter 4, assuming commitment prior to 2009 for resource projects proposed in Chapter 4. In particular, capacity requirements noted in this Chapter reflect adoption of the revised capacity planning criteria (as set out in Section 3.4) as well as prior commitment to and completion of a Mirrlees Life Extension Project (at 14 MW) plus about 4 MW new diesel capacity by 2012 pursuant to the primary contingent recommendations of Chapter 4 to address "Base Case" loads. This chapter also presumes near term development of Marsh Lake Fall/Winter Storage (1.6 MW of added firm capacity) as well as the Aishihik 3rd Turbine project as proposed in Chapter 4[8], without the Aishihik 2nd Transmission Line project (such that the Aishihik 3rd Turbine has no effect on meeting the N-1 capacity planning criteria and only 0.6 MW towards the LOLE criteria), and

[8] In addition to any capacity-related impacts, Marsh Lake Storage and the Aishihik 3rd Turbine as proposed in Chapter 4 together add about 13 GW.h/year to long-term average WAF hydro energy supply (assuming sufficient WAF loads).

takes into consideration the possible near term development of the Carmacks to Stewart Crossing Transmission as reviewed in Chapter 4.

As noted, Chapter 5 identifies four representative industrial development "scenarios" (rather than "forecasts") in order to identify basic planning options for the Resource Plan to consider with regard to different ranges of potential industrial load sizes (as well as load timing, expected life and general location). Individual industrial development opportunities and/or resource supply projects, however, are not the focus of the Chapter 5 analysis.

Four key factors are simultaneously considered in the Chapter 5 screening of potential new resource supply options for each WAF industrial load scenario:

1. **Generation cost of energy supplied by new resource (LCOE):** A primary consideration is the basic generation cost of energy supplied by output from any new resource (with typical focus on overall unit cost per kW.h as opposed to cost per MW of capacity). For the purposes of initial screening, "levelized costs of energy" or LCOE can be used to determine the unit costs/kW.h at the project site of energy produced. Levelized costs reflect the costs of the plant amortized over its life (all kW.h units available to be produced by the plant) assessed on real dollar (2005$) economic terms (i.e., assuming the levelized unit cost after 2005 increases with inflation each year).
    - LCOE focuses only on key generation cost components for a resource option as needed to screen or compare alternative resource options.
    - LCOE for hydro supply projects accordingly focuses in most instances only on capital costs, as these tend to establish the primary overall generation cost for this option. Operating and maintenance costs for large projects can be quite modest (0.5% of capital cost based on BC Hydro estimates) which would tend to increase the LCOE by about 9.4%. Smaller hydro project operating and maintenance costs may vary up to 1.0% to 1.5% of capital cost, which can increase LCOE by 18.8% to 28.3% over the levels estimated in this chapter.
    - In the case of other resource options which involve material fuel operating costs (e.g., diesel generation, or thermal generation using coal, wood biomass or natural gas) it is also necessary that the LCOE reflect fuel as well as capital costs (if the capital costs are also likely to be a key part of the option's overall costs).
    - LCOE automatically takes into consideration variations in the economic lives of alternative resource options.
    - LCOE implicitly assumes that all energy generated over the economic life of a resource option is sold at rates that fully recover the LCOE costs, i.e., this screening tool does not

address the extent to which a resource option may be oversized to meet forecast loads, or otherwise mismatched with forecast loads (in terms of, say, seasonal consideration).

2. **Location of supply and cost of transmission to loads:** If attractive supply options (such as hydro) can be identified that offer lower levelized generation costs of energy (LCOE) than diesel power generation, it is necessary also to screen separately based on location, as low-cost supply options that are materially away from existing transmission systems may not be able to support the costs of major new transmission to connect to the system (particularly for small plants). Similarly, in some cases supply options that are too remote will result in transmission losses that undermine otherwise attractive LCOEs.

3. **Load fit with resource option supply:** Despite a new low cost source of supply being available to Yukon Energy (as assessed based on LCOE per kW.h as well as on location relative to the forecast loads), the overall economics of a resource option also depend ultimately on the supply having actual economic value to the system (such as by displacing energy that otherwise would have needed to be generated using diesel fuel). If some or all of the power provided by a new supply source is surplus to system firm load requirements (e.g., becomes spilled hydro) even very low cost resource options can be uneconomic to the overall power system. Key considerations for section 5.4 on "pre-assessment and screening" therefore focus on "load fit", or how well any given resource project might fit the load requirements (energy in particular) over the next 40 years, how many years of surplus energy may arise if a resource project were to be constructed, and the market risks associated with potential pre-mature closure of industrial customers.

4. **Other associated charges, such as "water rentals" and taxes:** For hydro resource projects that are developed in BC, additional annual charges will be levied on the project that would not be in place if the project was located in Yukon. It is therefore relevant to consider these additional charges when screening such projects in the Resource Plan.

Other major screening factors must separately be considered within the process for evaluating, developing and constructing new power generation facilities, such as environmental factors which may preclude certain developments, or drive material added capital or operating costs (such as for environmental mitigation activities).

The organization and approach adopted in Chapter 5, with its focus on four different industrial load scenarios, reflect the overall importance of "load fit" within the resource option screening process. As reviewed in Sections 5.3 and 5.4, the scale of the industrial loads associated with each scenario drives the identification of relevant resource option technologies. Based on initial screening for this basic "load fit", further screening can then be carried out in accordance with the four key factors noted above.

5.2 REQUIREMENTS

There is a diverse range of industrial development opportunities that could develop in the Yukon during the 20 year planning period, providing an equally diverse range of potential opportunities to develop new energy resources.

At present, base metal prices in particular are at high levels and mining exploration in Yukon has expanded. Yukon Energy has worked with the Government of Yukon Mineral Development Branch to identify potential future mining industrial customers based on specific prospects and proponents, as well as based on the nature of the development, its expected life, and its location in relation to developed grid power.

Larger opportunities may be presented by an Alaska Highway Pipeline, and information on the potential loads for pipeline pumping (which could be served by electricity under certain circumstances) has been included in the planning exercise.

Potential industrial developments considered in this chapter are detailed in *Table 5.1 Industrial Development Opportunities*. Locations of these potential developments are indicated in *Figure 5.1: Map of Industrial Development Opportunities and Power Infrastructure*.

Figure 5.1:
Map of Industrial Development Opportunities and Power Infrastructure

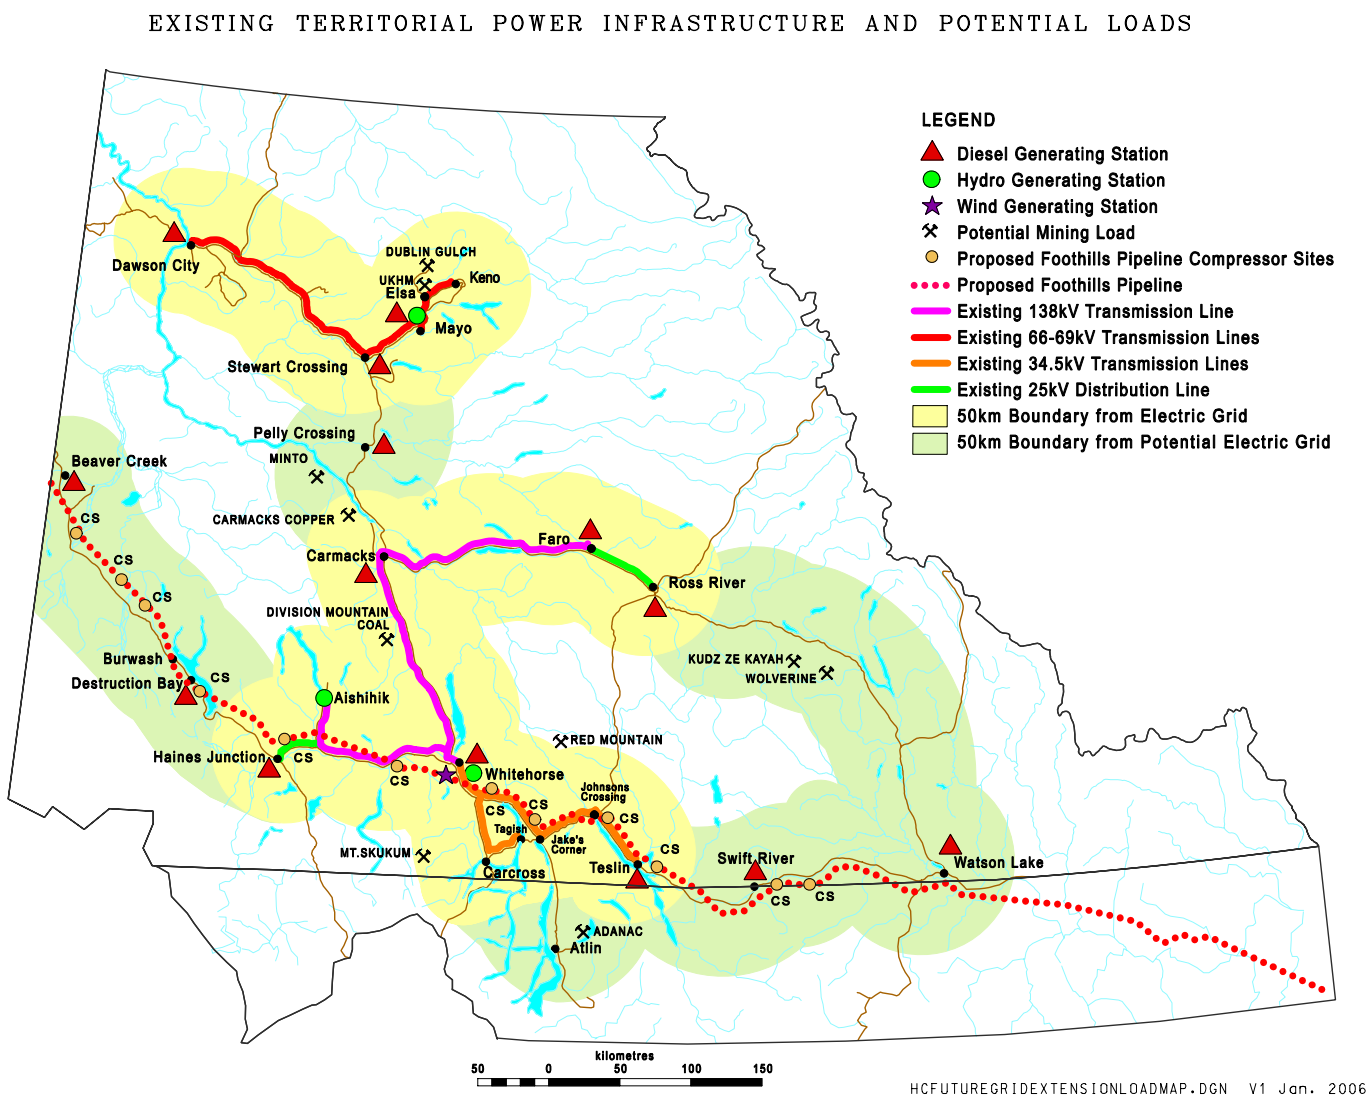


Table 5.1:
Industrial Development Opportunities

Project	Proponent	Location	Grid	Commodity	Road Access	Distance To Grid (km)	Peak Demand (MW)	Annual Energy (GW.h)	Project Life	Assumed In-Service Date
Alaska Highway Pipeline, WAF

1-The initial four compressor stations are shown here. Up to eight additional compressor stations (each with similar 30 MW potential load) could be added within the following four to five years. The pipeline electrical loads in this table assume use of electric power rather than natural gas from the pipeline to run these compressor stations. There will also be some ancillary pipeline power loads in any event (not shown here) even if the compressor stations use natural gas.

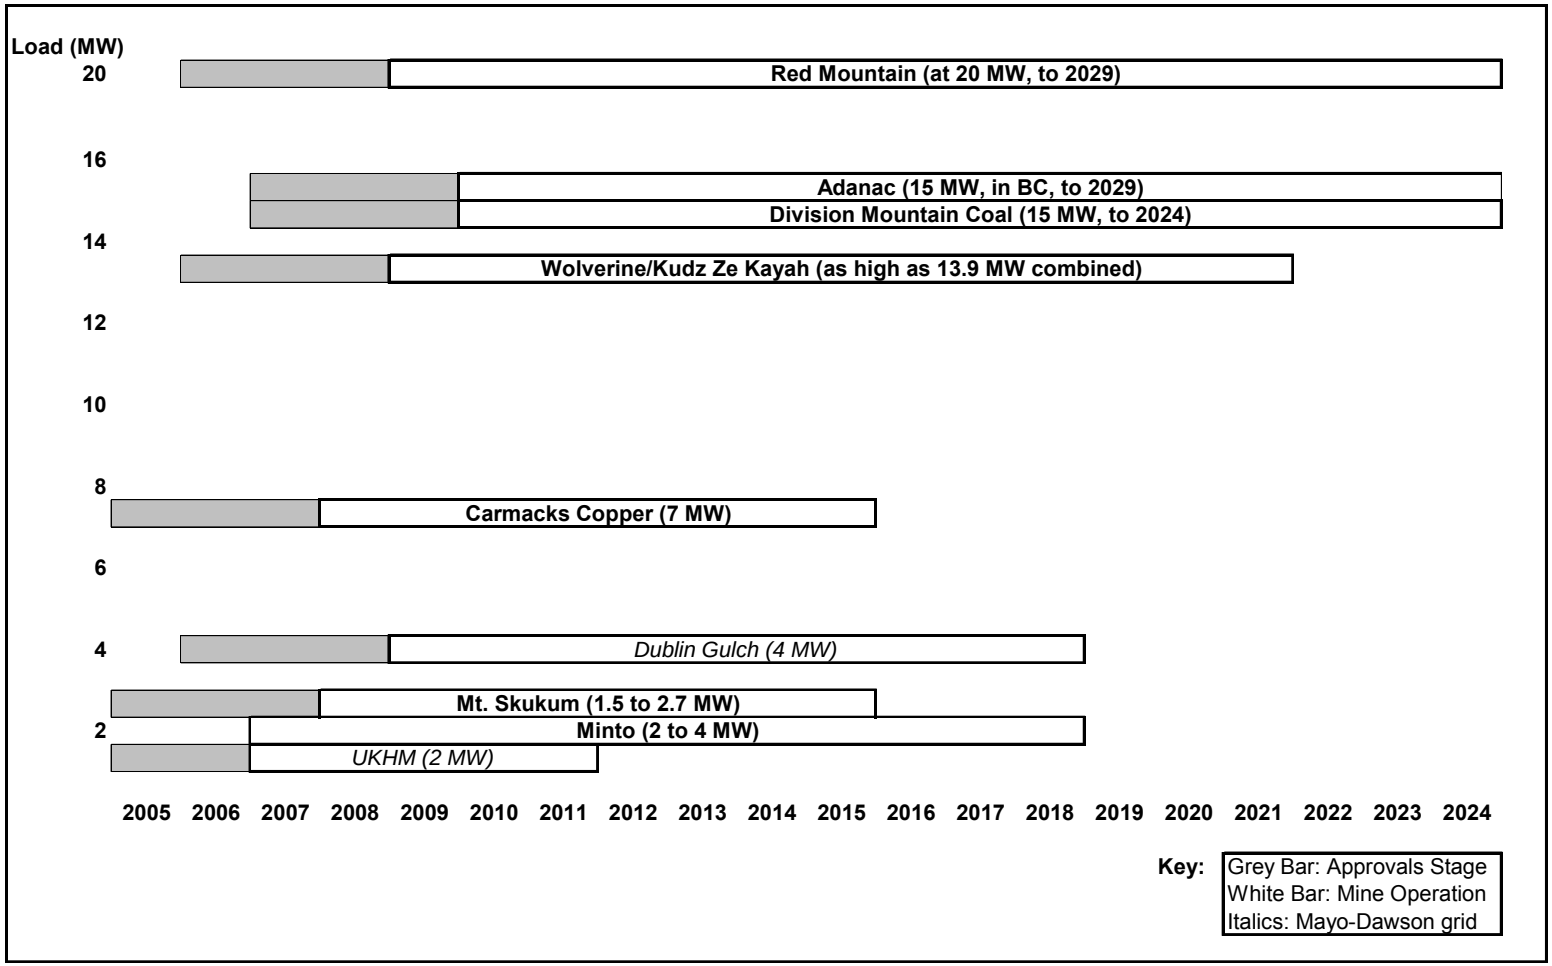
Figure 5.2 Earliest In-Service Dates and Power Loads for Potential Mine Developments illustrates the currently estimated potential timelines associated with mining load opportunities being considered.

Individual industrial developments noted in Table 5.1 and Figure 5.2 could result in possible new generation projects starting construction before 2016, based on industrial load requirements ranging from 2 MW to 360 MW and energy requirements ranging from 11 GW.h to 2,680 GW.h per year, and with service lives ranging from 5 to 30 years or more.

Many of the potential industrial mine loads considered in this chapter are well beyond the bounds of existing transmission, which may limit opportunities for grid service unless other outside funding (such as YTG) is available to enable the connection and eliminate potential adverse rate impacts. The mine developments noted in this chapter are within 273 km of either the WAF or MD grids (see Table 5.1).

When considering the potential "start dates" and development uncertainties for any of the mine projects considered in this chapter it is relevant to note that many of the industrial developments being considered today have been under active consideration as "near term development" prospects for some time. Yukon Energy's internal Resource Plan update process in 1996/97, for example included many of these projects as "advanced mineral projects" relevant at that time for possible power requirements, including Minto, Kutz Ze Kayah, Dublin Gulch, UKHM and Carmacks Copper as projects then engaged in environmental permitting (with all of these developments then expected to use on-site diesel, except for Carmacks Copper and UKHM which were then expected to secure grid power), and including Division Mountain Coal (grid power) and Mt. Skukum (on-site diesel) as projects with anticipated environmental review. Rates approved by the YUB from the 1996/97 GRA included a "New Mine Rider" (Rider K) to address adjustment of retail rates throughout Yukon in the event either Carmacks Copper (WAF) and/or UKHM (Mayo system) was connected to a system in 1996 or 1997.

Figure 5.2:
Earliest In-Service Dates and Power Loads for Potential Mine Developments



To address forecasting uncertainty regarding these industrial development opportunities, four "scenarios" have been selected related to industrial development. Given the range of potential development options, the four scenarios allow Yukon Energy to identify basic planning options relevant to consider in the Resource Plan. If and when specific loads of a certain magnitude develop, Yukon Energy can at that time refine and develop specific plans for serving the load.

Industrial Development Scenarios and Opportunities identified for this Resource Plan focus on the WAF grid (includes possible MD supply options if the Carmacks-Stewart Transmission project is developed) and include:

- **Scenario 1: A 10 MW WAF Industrial Scenario:** This scenario includes one to two smaller mines, which are represented in the analysis by the addition of the Minto (2 MW to 4 MW) and Carmacks Copper (7 MW) mines.
- **Scenario 2: A 25 MW WAF Industrial Scenario:** This scenario includes multiple major developments comparable overall to the traditional load impact of the Faro Mine when it was operating. This scenario is roughly based on the development of three mines, focused on: Minto (2 MW to 4 MW), plus Carmacks Copper (7 MW) and either Red Mountain (11 MW to 20 MW) or Division Mountain coal for export markets (15 MW).
- **Scenario 3: A 40 MW WAF Industrial Scenario:** A larger 40 MW scenario is considered to focus on a potential major mining industry development scenario in Yukon. This scale of mining power load would be in excess of the loads experienced when the Faro mine was operating. As an example, such a scenario could be enabled by the development of Minto (2 MW to 4 MW), plus Carmacks Copper (7 MW) plus Red Mountain at the largest load level assumed to date Mountain (11.3 MW to 20 MW, likely at larger end of scale) plus Division Mountain coal for export markets (15 MW).
- **Scenario 4: A 120 to 360 MW WAF Alaska Highway Natural Gas Pipeline Scenario:** This largest scenario is based on the development of an Alaska Highway Natural Gas Pipeline in the 2012-2015 period and assumes that this development elects to use electricity for pipeline compression. The magnitude of power use is based on an initial four compressor stations at 30 MW each, ultimately being expanded over time to 12 compressor stations at 30 MW each, each with a life of 30 years.

All scenarios forecast non-industrial loads at the Base Case level from Chapter 4 and reflect schedule in-service of projects recommended in Chapter 4 including Aishihik 3rd Turbine, Marsh Lake Fall/Winter Storage and Mirrlees Life Extension. For simplicity, it is also assumed that additional diesel capacity (about 3-4 MW) is developed to meet the balance of the Base Case capacity required by 2012; as noted

in Chapter 4, Base Case options in this regard include replacing the smaller third Mirrlees unit (4 MW) with a larger new diesel unit (8-11 MW).

The following Chapter 5 requirements analysis also initially assumes reliance on new diesel generation to supply additional new capacity required to meet new industrial loads.

5.2.1 Scenario 1: A 10 MW WAF Industrial Scenario

Within the next number of years, there is a credible scenario of Yukon Energy potentially connecting service to two mining loads at Minto (Sherwood Mining Corporation) and Carmacks Copper (Western Silver Corporation). Analysis of a 10 MW load scenario, however, is applicable for other potential load developments of a similar scale (including potentially Mt. Skukum gold at 2 MW, Red Mountain in its smallest form at 11 MW, or major expansion of transmission along the Robert Campbell highway to connect Kudz ze Kayah at 8.8 MW or Wolverine at 5.1 MW should other non-utility funding be available to develop transmission along this route).

Focusing on the development of Minto and Carmacks Copper, the projects together would likely have a capacity requirement of 9 MW to 11 MW, and up to 64 GW.h of annual energy sales (about 70 GW.h of annual generation). The projects are not expected to be long-lived. Minto is expected to start in 2007 and run for 12 years. Carmacks Copper is expected to start in 2008 and run for 8.5 years. These starting dates may be delayed by other processes and development timelines.

The Scenario 1 loads are equivalent to the "Base Case with Mine Loads" discussed in detail in section 4.2.6 of Chapter 4, except that the Chapter 5 approach to determining requirements presumes previous near term completion (before 2012) of the Mirrlees Life Extension and installation of 3-4 MW of additional diesel generation, as well as near term development of Marsh Lake Fall/Winter Storage (by 2008) and the Aishihik 3rd Turbine (2009).

Capacity: Based on the revised capacity planning criteria (see Chapter 3), up to 6-7 MW of mining load can be added to the WAF system without driving a need for any new capacity. Even the addition of 10 MW of mining load may not drive any need for new capacity if this new load is either matched with some degree of on-site diesel capability at the mines, or peaks at times other than the current coincident peaks of residential and commercial customers on the coldest days of the year[9]. However, absent any on-site

[9] Assuming only modest on-site diesel in each case (about 20-40% of the peak load), there would be no incremental requirement for capacity on the YEC system in order to serve this scale of mining load.

diesel at the mines, development of this scale will drive an added capacity requirement of up to about 2-3 MW by 2012 compared to the Base Case[10].

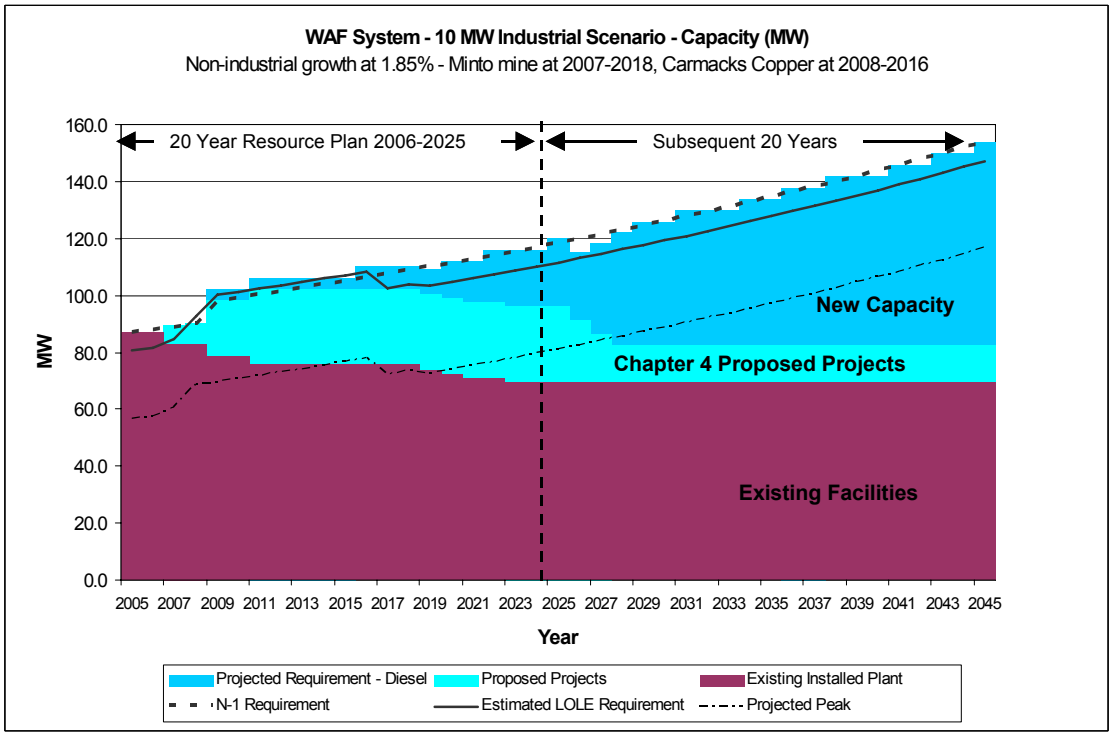
The WAF integrated system peak loads once the two mines are connected would approach the 65-70 MW level, growing to about 78 MW by the end of the mine life[11],

With the current installed plant (and including the proposed 7 MW of hydro from the Aishihik 3rd Turbine and 1.6 MW of new capacity with the Marsh Lake Fall/Winter Storage), YEC can reliably supply about 62 to 63 MW of peak load with hydro (higher in some winters depending on Yukon River flows). Consequently, Yukon Energy would need to rely at times on dispatching up to 15 to 16 MW of diesel capacity during a relatively limited number of hours at the coldest times of the winter to meet peak loads. This is well within the system capability from a reliability/capacity perspective.

[10] Based on the earlier more detailed review in Section 4.2.6, prior to addition of the Aishihik 3rd turbine and Marsh Lake Fall/Winter Storage, the two mines add 2.8 MW to the firm WAF capacity needed (assuming no on-site mine diesel capacity). This is because the mines are assumed at 9 MW (2 MW for Minto plus 7 MW for Carmacks Copper) but 6.2 MW of this load can be carried under the LOLE criteria without driving a need for new capacity (once the mines are connected, the LOLE criteria drives new capacity additions, not N-1). However, later in Chapter 4, the Aishihik 3rd turbine project is proposed to proceed, which adds 0.6 MW to LOLE load carrying capability, so the incremental effect of the mine loads drops to 2.2 MW. Accordingly, the incremental impact on capacity requirements in 2012 due to these two mines would be about 2.2 MW. However, it is noted that a portion of the 2.2 MW requirement may be met by either on-site diesel, or by Chapter 4 projects that add capacity beyond the strict amounts required through 2012. (Chapter 4 assumed, to meet Base Case loads, 18.7 MW is installed separately through implementation of the Chapter 4 proposed actions regarding Marsh Lake Fall/Winter Storage at 1.6 MW, Mirrlees Life Extension at 14 MW plus at least 3.1 MW of new diesel at Whitehorse to address the remaining shortfall. As noted in Chapter 4, a 4 MW new diesel unit may be installed (resulting in a surplus of 0.9 Mw at 2012 under Base Case conditions), the third (4 MW) Mirrlees unit might be replaced by new diesel at from 8 to 11 MW (resulting in surplus capacity under Base Case of between 0.9 and 3.9 MW), or the Carmacks to Stewart Transmission might be developed (providing surplus capacity under Base Case conditions of 1.9 to 2.9 MW of added capacity).)

[11] Chapter 5 assumes that new mine loads are consistent throughout the winter, even at very low temperatures – this may not be correct as some mining operations are limited in terms of the activities they can pursue once temperatures drop to very cold levels.

Figure 5.3:
Scenario 1: WAF Capacity Requirements



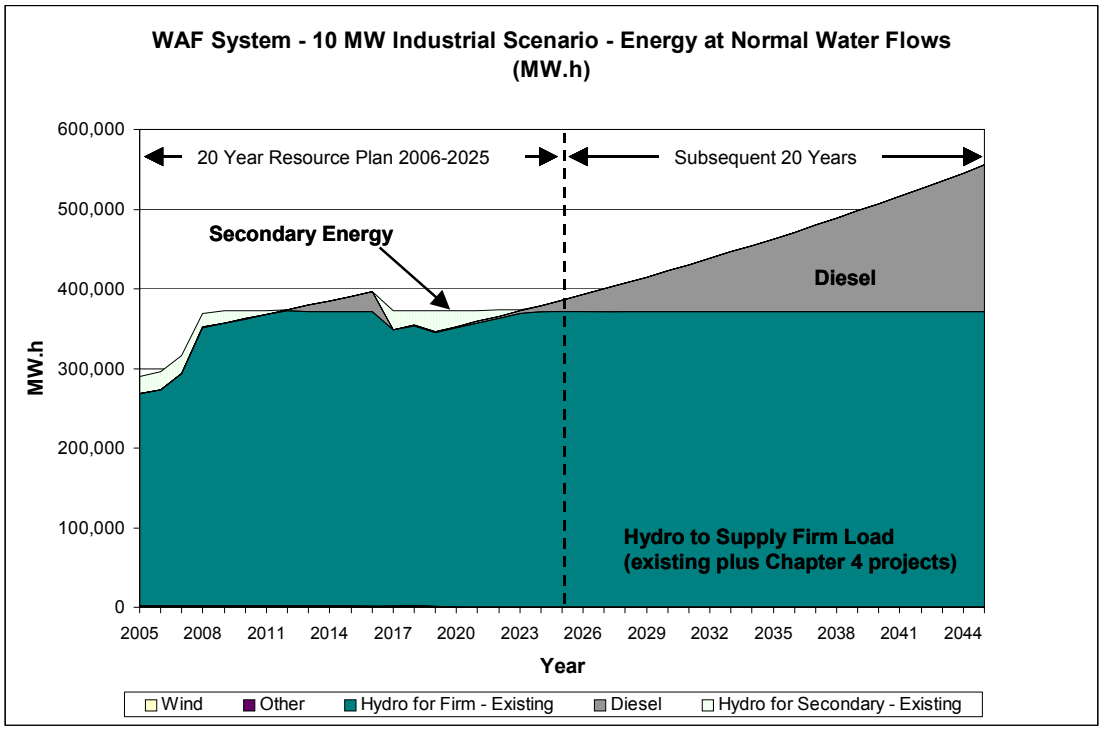
Energy: Under this scenario, surplus WAF hydro would provide most of the incremental energy needs if the mines are connected to WAF. From an energy perspective, the development of Minto and Carmacks Copper are well suited to the current scale of system surplus hydro. At the assumed time of their expected connection (2007-2008), basically the entire loads of these two customers can likely be served with surplus hydro for most of the year (with the relatively minor exception of winter peaking as noted above, subject to receiving further confirmation regarding the seasonality of the loads).

However, diesel generation use would increase throughout the period while the mines are connected. Assuming development of Marsh Lake Storage and the Aishihik 3rd Turbine (as proposed in Chapter 4 to capture energy benefits as noted), diesel generation of 2 GW.h to 25 GW.h per year would arise in the period 2012-2016 (prior to the expected closure of Carmacks Copper in 2017)[12]. After 2017, surplus

[12] Over the life of the two mines as assumed in Scenario 1, about 10% of the incremental energy requirement is supplied by diesel generation in Figure 5.3.

hydro would return to the system for about 7 years to 2023, when base load diesel would again be required, in this case due to non-industrial load growth.[13]

Figure 5.4:
Scenario 1: WAF Energy Requirements



The load balance information above notes a small incremental requirement for diesel generation under this scenario. However, over the next 20 years (the period of the current Resource Plan) the maximum diesel requirements at normal water flows in any year is about 25 GW.h/year, with only 4 of the 20 years above 10 GW.h/year. Diesel requirements for the remaining 16 years vary from about 0.1 GW.h/year to 8 GW.h/year and average about 2 GW.h/year. Under this load scenario, it would be difficult to justify even considering new energy projects for commitment before 2016 based on mine loads of up to 10 MW that are not sustained well beyond 2016[14].

[13] See Appendix C, Table C.5 for a review of diesel requirements by year assuming these two mine loads as well as development of Marsh Lake Fall/Winter Storage and the Aishihik 3rd Turbine.

[14] Variations on Scenario 1 might change this conclusion, i.e., if the same mine development was delayed until about 2016, sustained levels of diesel generation into the future 20 years and beyond would be much higher. However, this type of variation provides minimal guidance to Yukon Energy Resource Plan activities during the next several years.

5.2.2 Scenario 2: A 25 MW WAF Industrial Scenario

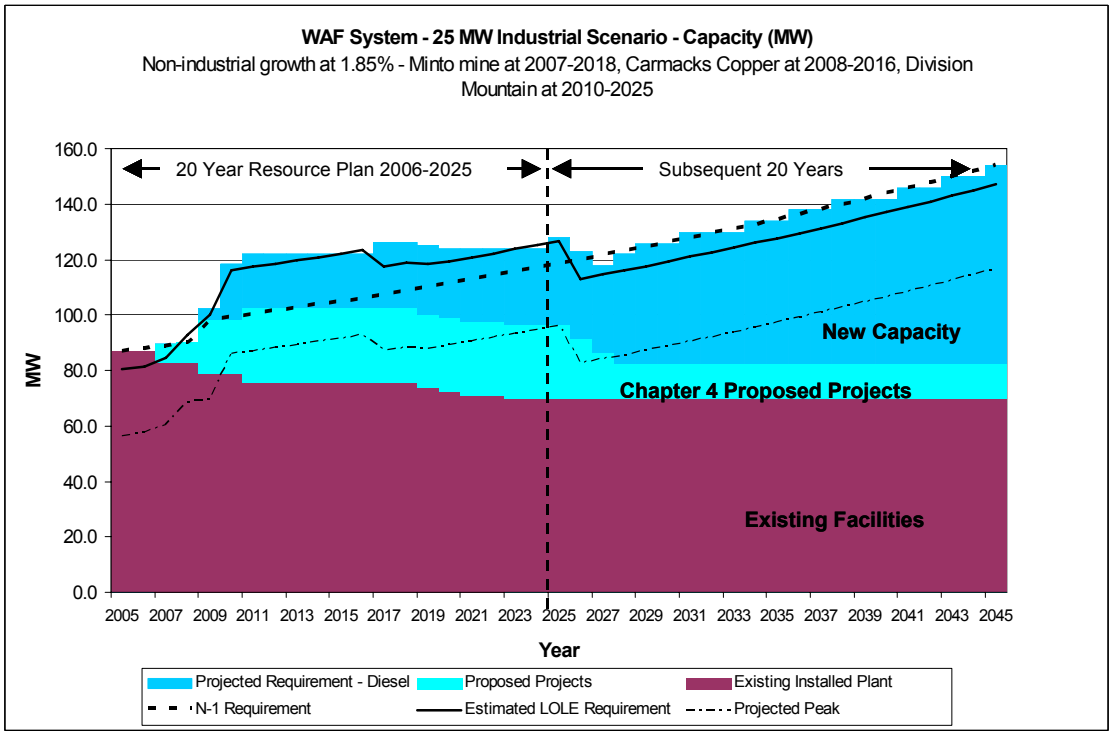
The 25 MW industrial scenario focuses on a larger load development, based on service to Minto and Carmacks Copper via new transmission north from Carmacks, plus additional major industrial load in the 10-20 MW range, with serious potential candidates being Division Mountain coal (15 MW, at Braeburn on existing WAF transmission) or Red Mountain (11.3 MW - 20 MW, north of Johnson's Crossing, requiring 70-100 km or more of new major transmission).

The scenario is examined assuming development of Minto, Carmacks Copper per the loads in Scenario 1, plus Division Mountain coal (15 MW load assumed at 105 GW.h/year from 2010 for 15 years). Overall supply requirements are similar to what existed to supply the Faro mine loads when it was last operating, and approximate 180 GW.h/year of incremental generation when all three mines are operating.

Capacity: If this scenario were to arise, Yukon Energy would face substantial requirements for new capacity in excess of that indicated in Chapter 4. This added capacity required for these industrial loads would potentially be up to an additional 17.2 MW of new diesel units or equivalent capacity, assuming minimal on-site diesel installations at the three mines[15].

[15] As noted in the summary of requirements, the scenario case is modeled using a maximum 24 MW of industrial load. Of this amount, and assuming development of the Aishihik 3rd Turbine, 6.8 MW of industrial load may be carried under the LOLE criteria without a need for new capacity (over Base Load N-1 requirements), and 17.2 MW of new capacity is therefore required.

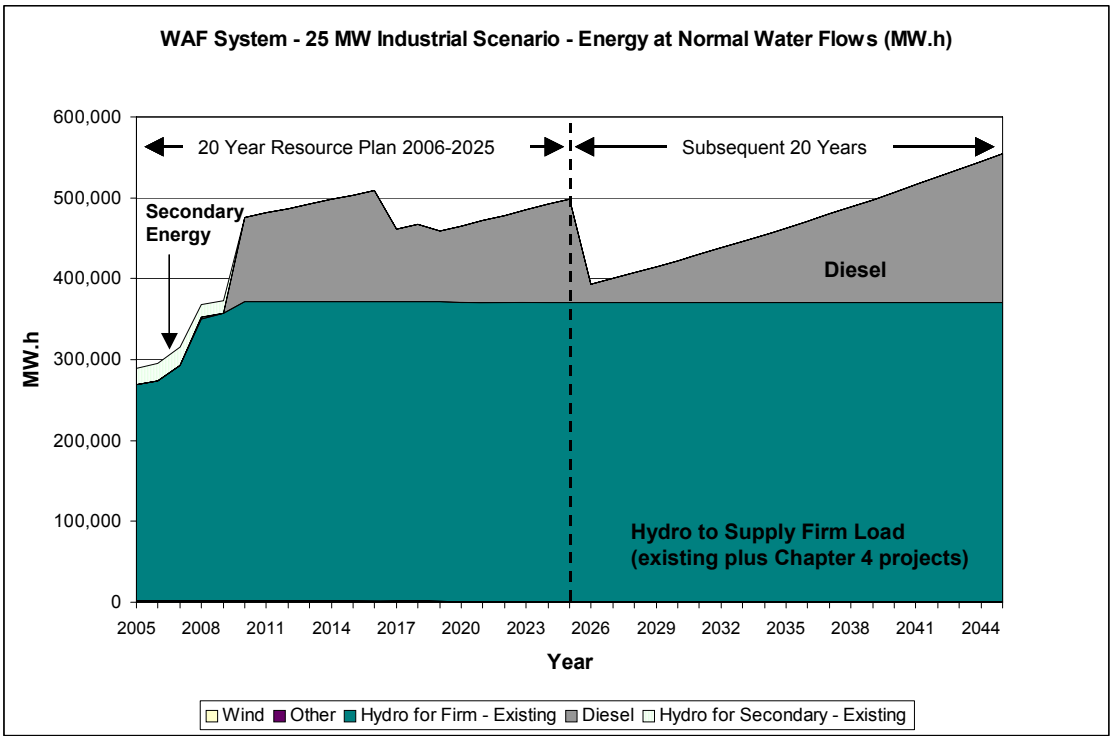
Figure 5.5:
Scenario 2: WAF Capacity Requirements



The WAF integrated system peak loads once the two mines are connected would approach the 85-95 MW level during the mine lives under the assumptions adopted. However, given the scale of the mine loads in this case and without development of new non-diesel generation, the WAF diesel units would be operating for basically the entire year (similar to when Faro was in operation) so “peaking diesel” would no longer be a relevant concept for the YEC WAF system.

Energy: This scenario gives rise to major new requirements for diesel baseload generation, which over the life of the mines would supply about 70% of the mine load incremental generation. Without new development of hydro or other capital intensive generation, WAF diesel fuel generation required would range from about 90 to 140 GW.h/year for a period of 16 years (from 2010 to 2025); thereafter, as the new industrial loads close, diesel generation would approximate 21 GW.h/year (growing each year by 7 to 8 GW.h as WAF non-industrial load grows) and not reaching the 100 GW.h per year level again for 10 years (until 2036), well outside the horizon of the current Resource Plan.

Figure 5.6:
Scenario 2: WAF Energy Requirements



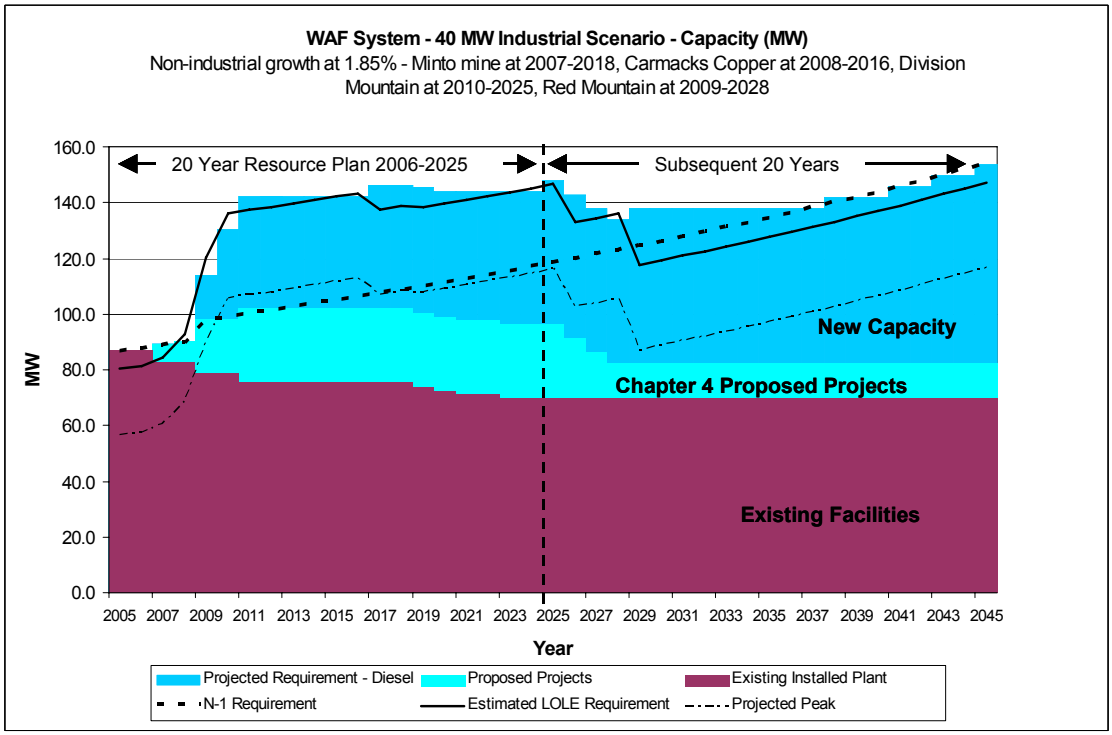
5.2.3 Scenario 3: A 40 MW WAF Industrial Scenario

This scenario is based on an assumption that Yukon Energy is able to connect service to numerous new mining developments and that these developments coincide in the next 10 years. A larger scenario in excess of the Faro mine, this scenario could potentially include the same mines identified in the 25 MW industrial scenario, with the development of the Red Mountain mine. Other possible development combinations in this scenario (but more distant from current grids) including Adanac (15 MW) and Kutz Ze Kayah and Wolverine (8.8 and 5.1 MW) should other non-utility funding enable transmission development along this route.

The specific scenario developed for analysis assumes four new mines all coming into service no later than 2010. These mines include Minto, Carmacks Copper, and Division Mountain per Scenario 2 (the 25 MW scenario), plus Red Mountain assumed to be developed at 20 MW and 126 GW.h/year from 2009 for 20 years (also requiring 70-100 km or more of new major transmission). Without new development of hydro or other capital intensive generation, overall generation supply requirements would approximate 315 GW.h/year when all four of these mines are operating.

Capacity: The scale and duration of development of this major combination of mining loads is such that material increases in system installed capacity are required to service the loads. Yukon Energy would face substantial requirements for new capacity in excess of that indicated in Chapter 4. This added capacity required with these industrial loads would be more than 35 MW of new diesel units or equivalent capacity, assuming minimal on-site diesel installations at the four mines[16].

Figure 5.7:
Scenario 3: WAF Capacity Requirements

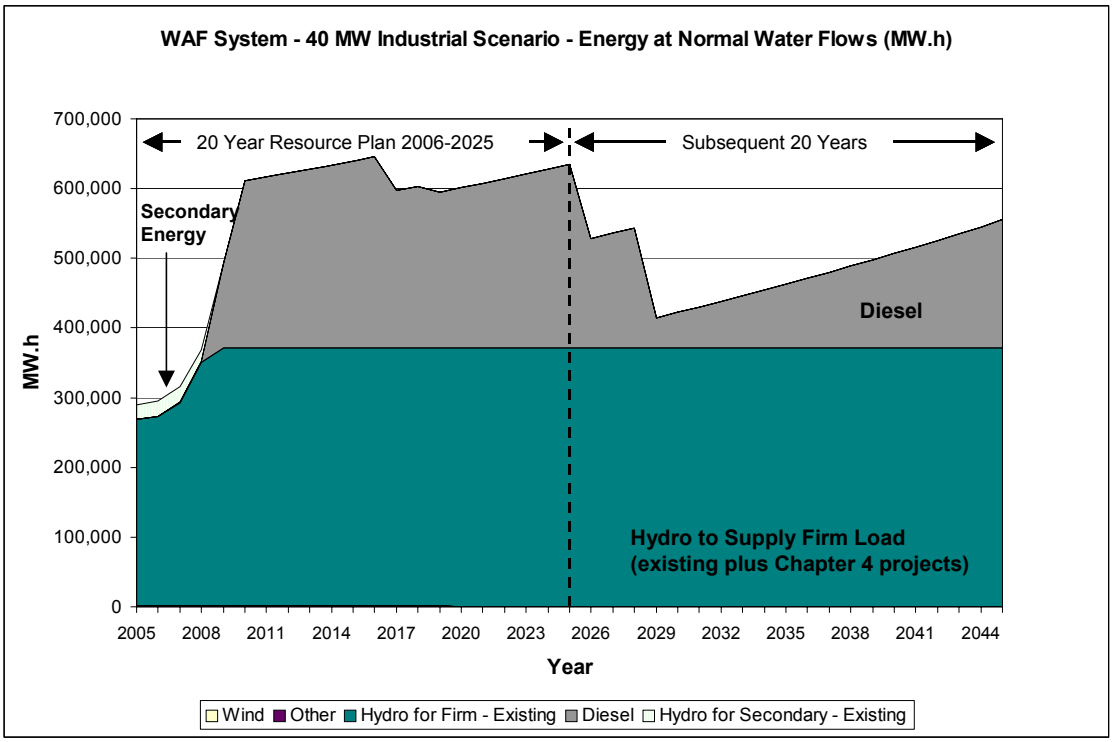


Energy: From an energy perspective, the development of 40 MW of industrial load well exceeds the current scale of system surplus hydro. For a period of 16 years, the magnitude of diesel generation under this scenario (if all new energy was supplied by diesel fuel generation) would range from 220 to 275 GW.h at normal water flows, with four additional "shoulder" years before and after the peak averaging 120 to 170 GW.h. Without new development of hydro or other capital intensive generation, over the life of the mines diesel generation would supply about 85% of the mine load incremental generation.

[16] As noted in the summary of requirements, the scenario case is modeled using a maximum 44 MW of industrial load. Of this amount, and assuming development of the Aishihik 3rd Turbine, 6.8 MW of industrial load may be carried under the LOLE criteria without a need for new capacity (over Base Load N-1 requirements), and 37.2 MW of new capacity is therefore required.

After the period of mine closures (assumed here at 2029), the WAF system under this scenario would be back down to a non-industrial load level that requires all the existing hydro output plus about 44 GW.h of diesel generation, and it will take approximately 13 years (assuming no additional new industrial developments) before it increases back to the 150 GW.h of diesel generation level (to 2042). This period is well beyond the current 20 year Resource Plan framework.

Figure 5.8:
Scenario 3: WAF Energy Requirements



5.2.4 Scenario 4: A 120 to 360 MW WAF Alaska Highway Natural Gas Pipeline

The largest potential industrial power load in the near-term in Yukon is the Alaska Highway Pipeline. For the purposes of current planning, Yukon Energy is working with initial plans that four compressor stations each potentially requiring 30 MW and 223 GW.h/year for 30 years may require service (totalling up to 120 MW and 894 GW.h/year). The earliest in-service date for the first four compressors is assumed to be in the 2012-2015 period, assuming development of the pipeline by this time as well as use of electric power rather than natural gas from the pipeline to run these compressor stations. Up to eight additional

30 MW compressors could be added within the following four to five years (potential total 360 MW and 2,680 GW.h/year for this scenario).

Under normal circumstances, a natural gas pipeline operating in remote areas will power compressor stations with direct drive natural gas compressors without the use of electricity. In areas where there is access to low cost electrical power, pipelines have been converting to electrically powered compressors. In Yukon, the terms of the current agreement relating to this pipeline state that the proponent will be required to use electric compression if it can be provided on a "reasonably economic" basis. Accordingly, the Scenario 4 potential power load is contingent not only on the pipeline being developed as assumed, but also on Yukon Energy being able to establish that it can provide a "reasonably economic" electricity option for the pipeline to use electric compression.

Capacity and energy graphs indicating existing supply versus new 120-360 MW loads for Scenario 4 are not meaningful, given the current installed winter capacity for the entire WAF grid at only 87 MW.

5.3 OPTIONS

New generation options to supply future industrial developments focus on energy rather than capacity requirements.

New industrial WAF power loads beyond Scenario 1 levels would lead to increased reliance on available diesel generation to meet incremental baseload energy requirements[17], and high costs associated with non-peaking diesel energy generation would thereby create opportunities to develop new supply resources to displace the need for incremental diesel energy generation. In each scenario, non-diesel energy resource development opportunities are shaped by the magnitude and duration (seasonal and multi-year) of the incremental baseload energy that would otherwise need to be supplied by available diesel generation.

Yukon Energy has identified on technical grounds an initial list of potential generation options to examine

[17] "Baseload" here means annual energy generation other than "peaking" energy generation. "Peaking" energy generation is generation that occurs in any year only over short-term periods (hours or days) to aid in meeting the peak demand (MW) for electricity, typically during business day hours in winter; peaking generation units accordingly will typically operate only a small percent of the time in any year (e.g., say up to 10% to 15% of total annual hours). In contrast, typical baseload generation units will typically operate for most of the time in any year, e.g., Whitehorse Rapids hydro units (40 MW capacity) on a long-term basis will generate about 246 GW.h/year, implying average annual operation at about 70% of annual capacity. Due to seasonal as well as peaking operation, long-term average annual energy generation at Aishihik approximates only about 40% of the plant's 30 MW capacity.

for each of the four WAF industrial development scenarios (in addition to diesel generation as a standard default option, and transmission required to connect new industrial loads and/or new generation under each scenario).

At this stage, further to discussions related to the 1992 YUB hearing, the Resource Plan also considers briefly potential development of resource options by IPPs.

5.3.1 Overview of Resource Supply Options

Major power resource supply technology options considered in this chapter for possible commitment before 2016 fall into one of three categories: hydro, thermal (coal, or potentially biomass), or natural gas. Potential interconnection to the BC grid is also considered with the pipeline scenario.

For the major supply options considered, the relevant technology characteristics of each type are critical to considering its suitability to the loads to be served during the planning period. Beyond the major supply technology options considered in this chapter, a number of other technology options have been reviewed and determined to not provide the necessary characteristics for major development options in Yukon at this time. Details on the following additional technology options are set out in *Appendix A: Generation Technologies*), along with review of the major technologies addressed below in this chapter:

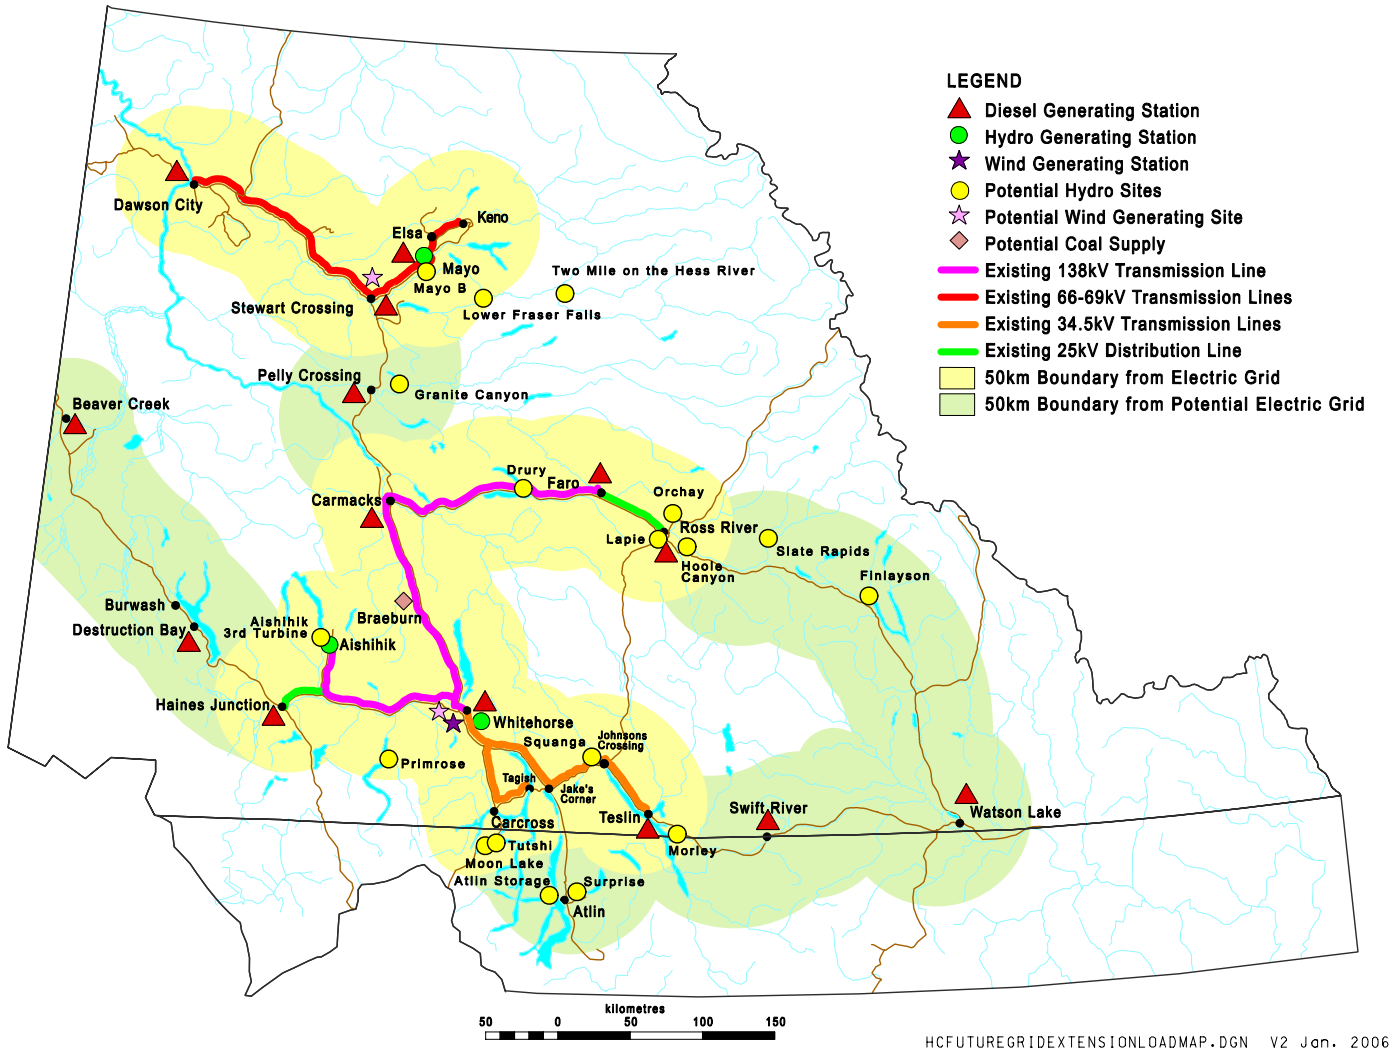
- Wind
- Coal-bed methane
- Hydrogen
- Nuclear
- Biomass
- Geothermal
- Solar
- DSM

Before reviewing supply options specific to each of the four WAF industrial development scenarios, the technology characteristics for each of the major supply technology options considered in this chapter are highlighted separately below. In addition, potential consideration of IPPs to develop these major resource options is also reviewed.

Figure 5.9: Map of Potential Supply Option Sites provides an overview of hydro and coal site option locations examined in this chapter in the context of the current WAF and MD power supply infrastructure, identifying as well areas within a 50 km boundary from current and potential electric grids.

Figure 5.9:

Map of Potential Supply Option Sites



5.3.1.1 Hydro Technology Characteristics

The potential hydro supply options identified in the Resource Plan for the Yukon are detailed in *Table 5.2: Potential Hydro Resource Options* as well as in *Appendix B: Hydro Project Options*.

Table 5.2:
Potential Hydro Resource Options[1]

	Grid	Installed MW	GWh	Capital Cost (2005$millions) (excl. trans.)	Trans. Distance (km)	Protected under Yukon land claims	In BC	Capital Cost LCOE (cents/KWh) excl. trans (2005$ real)
Existing Hydro Enhancements								
Aishihik Diversions	WAF	0	total of 24	n/a	0	X		n/a
Atlin Storage	WAF	2	9	n/a	0		X	n/a
Very Small Hydro Projects (1-4 MW)								
Drury	WAF	2.6	23	31	0	X		7.2
Squanga	WAF	1.75	8.3	12	5			7.7
Orchay	WAF	4.2	27	47	15			9.2
Morley	WAF	4	22	31	30	X		7.5
Lapie	WAF	2	10	14	8			7.4
Small Hydro Projects (5-10 MW)								
Moon	WAF	8.5	50	51	66		X	5.4
Surprise	WAF	8.5	50	50	100		X	5.3
Tutshi	WAF	7.5	50	79	25		X	8.4

Very Large Hydro Sites (60+ MW)								
Granite	WAF	80 (up to 250)	660	706	125	X		5.7
Fraser Falls	MD	100 (up to 450)	613	555	n/a			4.8
Yukon River *(such as Rink Rapid, Eagles Nest, Five Fingers)*	WAF	various 75-240	n/a	n/a	n/a			n/a

[1] See Appendix B for more information on specific hydro options and for review of Capital Cost LCOE (2005$).

Hydro resource options exist under each of the four industrial development scenarios, addressing new energy requirements that emerge when loads develop sufficiently to fully utilize the current hydro generation surplus on each grid. Hydro is a proven technology in Yukon and considerable effort has been spent over the years to assess and catalogue potential for hydro throughout the territory. Key characteristic of hydro generation include the following:

- **High initial cost of plant, with very low to zero variable costs:** This key characteristic of hydro derives from the nature of the "fuel" – running water. Consequently, once hydro

plants are constructed, they need for economic reasons to be used on a sustained ongoing basis (unless intermittent use is done simply to store water for more cost effective future peaking, seasonal or other use) as there are very little cost savings if the plant is not in use. This leads to situations such as now exist on WAF, where hydro fixed costs are shared across less energy sales than would be the case if the existing hydro assets could be fully utilized by higher firm loads. This is also the economic basis for current WAF and MD secondary sales, essentially to help spread the fixed costs of the hydro plant across more kW.h output units. Consequently, it is difficult to justify hydro projects unless maximum use can be made of the entire output in as many years as possible. The convenient corollary is that hydro project costs are largely incurred up front as capital outlays, so over time the annual expenses accounted for hydro facilities tend to be very stable (with real or constant dollar costs tending to decline[18]) compared with diesel or coal, where nominal fuel costs do tend to increase over time with inflation (among other factors).

- **Very long project lives:** In conjunction with very low variable costs, hydro projects tend to have a very long economic life (in some cases 100 years or more) and accordingly economic justifications for such projects typically also assume sustained and effective use throughout a correspondingly long economic life. As a result the exposure risks related to market requirements or other factors for new hydro projects extend farther into the future than facilities that are expected to provide similar benefits over shorter economic lives.
- **Long lead times for permitting, approvals and construction, with substantial investment in planning studies required in advance of determining full project feasibility and making commitments:** The time required to assess, licence and construct a hydro project is much lengthier than for most other generation technologies. The 1992 Resource Plan reviewed in detail the planning stages for a typical hydro project that might have been considered at that time.

Hydro generation project feasibility in each instance is sensitive to certain key factors:

- **Water availability:** Knowledge of dependable flows; head under natural (run of river) water conditions; potential options for reservoir storage and/or diversions; availability of water throughout the year, particularly during winter peak periods; and opportunities for seasonal or multi-year reservoir storage.

[18] By way of example, consider that the bulk of the initial Whitehorse Rapids hydro plant was built in the 1950s for $7.2 million. Today's costs for this plant include depreciation on the $7.2 million as well as interest on the undepreciated component of this original capital cost.

- **Generation site:** Foundation conditions; general terrain; and access during construction and operation.
- **Project location:** Distance from existing and expected future loads; and transmission requirements.
- **Regulatory approvals:** Environmental and socio-economic impacts; and mitigation requirements.

When undertaking hydro project planning, there is a need for sequential planning stages given the relatively high potential planning costs for each potential site. Experience establishes that project selection should be in clearly defined stages in order to control time and cost commitments, to account for environmental regulatory requirements as well as technical, economic and financial issues, and to allow for an orderly project screening and assessment before commitment and construction of any project without unnecessarily committing excessive capital for assessing multiple sites to the same level of detail.

The 1992 Resource Plan set out three levels or stages for hydro project planning and selection in Yukon, with the need for any site to proceed successfully through all three stages before any commitments may be considered.

- **Level 1/Stage 1 – River Reconnaissance/Inventory (all sites):** Air reconnaissance to locate/evaluate potential sites; existing water flow data. In the 1992 Resource Plan, Level 1 was estimated to cost $20,000 per site (resulting cost estimates considered to be within +/- 50%). Yukon Energy has developed an inventory of many sites in Yukon and in northern BC that have been studied in the past (primarily by NCPC or Government of Canada, and reviewed from time to time by Yukon Energy). Based on inventory of sites studied in the past, Yukon Energy has identified certain sites in this Resource Plan with the potential to meet the forecast electricity needs of Yukon under each of the four industrial development scenarios.
- **Level 2/Stage 2 – Site Reconnaissance/Pre-Feasibility:** Field investigations to evaluate foundation conditions, preliminary hydrological studies, preliminary office studies (power availability, structural lay-outs and capital costs at +/- 25% accuracy), confirm or reject some of the key initial assumptions in an inventory study and provide some data needed for further studies if justified. In the 1992 Resource Plan, Level 2 was estimated to cost $80,000 per site. Level 2 was achieved at a minimum for all sites reviewed in the 1992 Resource Plan report.

- **Level 3/Stage 3 – Feasibility Studies**: Further field investigations (geological reports, foundation investigations through test pitting and drilling, construction material investigations to finalize sources), site topography (scale 1:20,000 or 2 m contours), updated hydrology, environmental and socio-economic studies, consultations with First Nations and others, detailed office studies (to determine structure sizing and location, final concept, power availability, and project capital cost at +/-20% accuracy). In the 1992 Resource Plan, Level 3 was estimated to cost $400,000 per site. Level 3 should be substantially completed prior to any decision to proceed to licensing; required for regulatory submissions, construction contract packages, financing arrangements. Level 3 review was started on only some of the projects examined in the 1992 Resource Plan report (only some of the small scale projects).

The cost today to carry out each Stage/Level of site specific planning would be higher than indicated in the 1992 Resource Plan, both to reflect current day dollars and to reflect any current projects that are larger or more complex than those considered in 1992. Costs to proceed through full scale feasibility studies, licencing/permitting and final design/costing prior to any final commitments for even a "small" hydro project (5-10 MW) might, for example, range from $5 to $10 million[19].

Yukon Energy will only proceed with the final design and construction of sites (effectively Level 4 or Stage 4) that are required (based on load growth, or commitments by industrial customers), that can be successfully licensed in a timely manner, and that are not expected to have a long-term adverse impact on ratepayers relative to other available options.

5.3.1.2 Coal and other Thermal Technology Characteristics

Environmentally sound coal generation is considered in this chapter consistent with past reviews in Yukon based on a presumed pre-development of local supplies (Division Mountain). Coal development solely for power generation, and associated costs of mine development, is not considered.

Coal generation has been reviewed a number of times for application in Yukon. Coal in particular as a fuel source has also been examined in many other jurisdictions beyond Yukon, and is a major generation option that is subject to extensive ongoing technology development to address emissions controls as well as other features (see also Appendix A). Key characteristics of coal relevant to the WAF system are as follows:

- **Economics very sensitive to size of plant:** Repeated assessment of coal potential in Yukon has focused on 20 MW size, as that is the largest single unit that WAF could handle

[19] Estimate based on 10% of estimated capital costs from Table 5.2.

within operating reliability considerations. Economic preference exists for larger plants up to 50 MW or more to secure lower costs per kW.h of output. This size sensitivity extends to capital costs and operating costs (i.e., largely need same material staff complement for 20 MW plant as for 50 MW[20]). However, energy output from larger potential sizes of plant at perhaps 360 GW.h per year (50 MW) are well in excess of most WAF scenario requirements other than the Pipeline.

- **Technologies for use of coal have been advancing at a rapid pace**, particularly with regard to reducing emissions. Any coal generation plant would have to be environmentally sound in order to be considered by Yukon Energy.
- **Facility life of 20-30 years can be well suited to Yukon loads:** The industrial loads in Yukon can allow for large loads of limited life, with risks of major reductions at the end of the life of the mine(s). With a hydro development, the long life of the facility can increase the exposure to this market risk, while the 20-30 year life of coal or other thermal plants is better suited to the timelines of mine life for many developments and to the mitigating of risks of load decreases when the mine closes.

Similar to coal, biomass generation (i.e., wood waste) is subject to the same economic constraints. Specifically, the fixed costs (including fixed operating and maintenance costs) do not vary dramatically with the size of the operation or the load. In these circumstances, economic viability hinges on relatively large and virtually constantly run facilities. As a general principle, however, biomass generation in Yukon would not typically become economic unless three key conditions are met (these same conclusions have also recently been cited as preconditions for biomass electricity generation in Alaska - see Appendix A):

1. The fuel (typically wood) must be available from a source that would otherwise have to pay to dispose of it. Economic biomass generation is not typically possible even outside Yukon with a wood product that has a cost to harvest. Biomass generating facilities at a minimum typically need a secure source of forestry waste biomass such as sawdust or bark waste from a pulp mill that is in close proximity to the biomass generating plant or even (in at least some cases) that can be delivered to the plant for free; for this precondition to apply, there often has to be savings achieved from avoided disposal costs.
2. The wood-fired power displaces diesel power.
3. The waste heat from the biomass generation also must be of economic value on-site, or be able to be sold.

[20] An earlier study for YDC indicated that 13 staff FTE would be required to operate a 20 MW plant. This number was not sensitive to size (in the extreme, a 1 MW plant was considered and determined to still require 12 staff FTE).

To date, proposals discussed in Yukon do not meet any of these three key criteria, and accordingly the thermal biomass option is not considered likely to be economically feasible for commitment prior to 2016 for any of the industrial development scenarios being considered.

5.3.1.3 Natural Gas Technology Characteristics

Natural gas generation is a major supply option to southern utilities (as well as NWT in Inuvik) that may become an option in Yukon if the Alaska Highway Pipeline project proceeds. The current expectation is that any pipeline developed along the Alaska Highway will allow access for at least the major centers to natural gas for local distribution. However, there appears to be uncertainty as to pricing regimes for bulk gas delivered to Yukon.

In terms of the Resource Plan, potential for Natural Gas availability focuses on three major areas:

- **Natural Gas used by the pipeline for compression:** As reviewed earlier in Section 5.2.4, under normal circumstances a natural gas pipeline operating in remote areas will power compressor stations with direct drive natural gas compressors without the use of electricity. In areas where there is access to low cost electrical power, pipelines have been converting to electrically powered compressors. In Yukon, the terms of the current agreement relating to this pipeline state that the proponent will be required to use electric compression if it can be provided on a "reasonably economic" basis. Outside of compressors, pipelines have reasonably material other electrical loads (including potentially cooling loads) that may be ideal candidates for grid power service even if compressor loads are determined to be better served directly by natural gas.
- **Natural Gas for Yukon power generation:** Regardless of whether the pipeline operator uses natural gas or electrically powered compression, the pipeline will likely create opportunities for natural gas based power generation in Yukon. Evidence from southern jurisdictions and NWT indicates that natural gas generation is a major technology option for new power generation and can be well ahead of diesel in terms of costs, reliability and impact on the environment. In addition, unlike coal, natural gas generation is more readily "scalable" to sizes suitably for Yukon as well as more suited to timely regulatory review and approvals and flexibility to operate in response to load variations.
- **Natural gas availability to Yukoners for heating supply:** Natural gas will become a heating supply option for residential and commercial customers under the pipeline scenario. In 1977 Foothills did include a proposal to provide natural gas to communities along the pipeline route including Beaver Creek, Burwash Landing, Destruction Bay, Haines Junction, Whitehorse, Teslin, Upper Liard, and Watson Lake. Although electrical heating is no longer

considered to be a major component of Yukon Energy's loads, there is likely to be some reduction in load (including winter peak loads) from electrical heating customers converting to natural gas.

5.3.1.4 Independent Power Producers

Power delivered to a grid (e.g. through purchases by Yukon Energy) from IPPs rather than generated from assets owned and operated by regulated utilities typically follows the underlying technology characteristics for the generation source used, e.g., IPPs developing hydro sites have some of the same characteristics as utility-developed hydro site projects noted above.

IPPs in certain instances can offer specialized skill, experience, or knowledge that may allow a specific supply option to be cost effectively developed by the IPP to meet utility requirements as stipulated in its contract with the IPP; such contracts are also intended to provide the IPP with unregulated profit incentives to be efficient and effective in supplying such generation outputs. However, there are some unique non-technology characteristics of IPPs that were reviewed in some detail at the 1992 Resource Plan hearings, and that merit specific attention as they may potentially drive material additional risks to a utility and its ratepayers compared to regulated utility power supply projects:

- **Unit pricing, including issues of levelized costs and sharing of benefits from diesel displacement:** As of 1992, the last major YUB review of IPP matters, there remained significant issues outstanding in regards to approaches to pricing for potential IPPs in Yukon. Major issues relate to how to determine the "value" of the IPP to the system (typically based on avoided costs for the system, which can be difficult to calculate for various supply types), how to share between the IPP developer and the utility ratepayers the "benefits" associated with developing lower cost generation, and the potential use of "levelized" nominal prices for IPPs (which tend to provide higher real prices in the near-term and lower real prices over the long-term, and are typically preferred by IPP developers). At a basic level, it is likely that hydro supply projects that can effectively displace regulated utility diesel generation will yield material avoided cost savings within Yukon; however, while almost all such savings will typically go to the benefit of ratepayers when such hydro projects are developed by a regulated utility, the IPP development option introduces a separate step whereby some (or perhaps even all) of the avoided costs savings can be captured by the IPP developer.
- **Take-or-pay contracts:** Similar to other Yukon generators, IPP developers would likely have no market for their power other than the utility. Financing for such IPP projects is expected to require the utility to commit to a "take-or-pay" contract that means the utility will be committed to buy most or all of the project's output at full prices, whether the utility

requires the power or not and perhaps even whether the IPP is able to sustain production of the power. As a result, market and likely other risks of the development can in effect be fully borne by the utility rather than by the IPP developer, even though the IPP may capture most or all of any avoided cost benefits when the facility is able to displace diesel generation. Under some potential IPP arrangements, avoided costs benefits may be locked in for the IPP developer (and paid for by ratepayers as though the diesel savings were in fact occurring) regardless as to whether in fact any such diesel cost savings are being realized by the utility.

- **Delivery of power/reliability:** If an IPP project on a system in Yukon is not functioning at any point in time, regardless as to whether or not the utility must still make payments to the IPP, there is the separate risk that the utility (due to default by the IPP) may not be able to meet its committed supply of power to its ratepayers. However, the utility itself typically has little or no control over the IPP facility, its maintenance activities, emergency procedures, or scheduling and thus can run into problems with the continuity of supply to its customers. For this reason, it is difficult for a regulated utility to treat IPP or other generation not under utility control as "firm" supply for a regulated utility system[21]. A utility also has no control (beyond penalties) over the construction of IPP projects and whether the IPPs can in fact meet key contracted commitments such as in-service date.
- **Financial guarantees:** IPP producers typically seek external bank financing for portions of the capital cost of their facilities. For this reason, these producers typically require power purchase contracts from the regulated utility with strong terms in favour of the IPP and may also include various guarantees from the utility, ultimately focusing the lender's assessment of their risks onto the financial strength of the utility. The end result can be effective requirements for the utility to backstop or guarantee the risks of the private investor to further disproportionately focus the risks of any development on the utility itself and its ratepayers.

Consequently, as discussed in the 1992 hearing, it is difficult to establish an IPP arrangement in Yukon that would reflect a fair sharing of the risks between the utility (and its ratepayers) and the private IPP developer. Yukon Energy in 1996 did complete a major call for "Expressions of Interest" including for IPP supply,. This call yielded some potential focused opportunities for future investigation of small IPPs should material loads develop and base load diesel become an ongoing requirement. However, as noted

[21] As an example, the Snare-Yellowknife system in NWT has a hydro facility that was previously owned and operated by one of the mines. NTPC had a supply agreement with the mine to meet their peak loads in the event the hydro site was not producing. Consequently, when the capacity criteria was assessed for the entire grid, this hydro station was not considered firm capacity for the purposes of planning the system. In 2003 NTPC purchased this station and, now that it no longer is owned and operated as an IPP, it is now included in the new firm capacity planning approach for the system.

in the 1992 hearing, IPP focus in Yukon to date has been on small projects - other than small hydro projects, it remains unclear how difficult it will be in Yukon to develop or negotiate an IPP arrangement to suitably share risks on resource projects of any material size.

5.3.2 Options for Scenario 1: A 10 MW WAF Industrial Scenario

A 10 MW industrial scenario would not likely require the addition of capacity or energy projects. Up to 6-7 MW of industrial load can be added to the system without driving a need for new capacity. Depending on the seasonality of the load and quantity of on-site diesel generation installed by the mines, it is possible that all of the 10 MW in new load could be served without driving a need for new capacity.

There is also a current ability to serve about 90 GW.h per year of energy from existing surplus hydro, decreasing as non-industrial load grows over the life of the mines. Under this scenario, there remains some diesel generation required for peaking and, as the non-industrial load grows, some requirements for baseload diesel. However there is limited value to any new hydro or thermal generation to displace diesel fuel, as the number of hours per year of diesel requirements remains quite limited.[22] In addition, the specific early mine developments considered in Scenario 1 are of relatively short duration (i.e., mine shutdowns are assumed to occur in 2016 and 2017), with the result that surplus hydro is expected to remain under this scenario for half of the 20 year planning period (from 2006 to 2009, and from 2017 to 2022).

As a result, any opportunities for new generation developments are likely limited to existing hydro enhancements (including those identified in Chapter 4, Section 4.3.6) and/or possibly the smallest of the hydro sites identified in Yukon, at most, and likely only those that can provide both capacity and energy benefits. A list of "very small hydro projects" (1-4 MW) is provided in Table 5.2 and in *Appendix B: Hydro Project Options*. Among these options, only Drury is considered to be reasonably well defined at this time.

5.3.3 Options for Scenario 2: A 25 MW WAF Industrial Scenario

A 25 MW industrial scenario, which would be similar to WAF loads experienced when the Faro mine was operating, would provide opportunities for the addition of both capacity and energy. Without new development of hydro or other capital intensive generation, incremental WAF diesel generation required under the Scenario 2 case examined in Section 5.2.2 would range from about 90 to 140 GW.h/year for a

[22] Over the life of these two mines with the timing assumed in Scenario 1, only about 10% of the incremental energy requirement would need to be met by generation beyond that available from current hydro surplus resources (assuming average long-term flows).

period of 16 years (from 2010 to 2025) out of the 180 GW.h/year of overall increased energy required due to the new industrial developments.

Under the Scenario 2 case examined in Section 5.2.2, if no new capital intensive generation was developed and the WAF system had to be served solely with incremental diesel, the assumed industrial loads would only be supplied about 30% with surplus hydro and about 70% with incremental diesel generation over their life. Under these conditions, (i.e., if diesel generation is to be relied upon to supply the incremental energy requirement), there is no apparent basis for Yukon Energy developing any new transmission interconnections to the bulk of this mine load (with the associated risks and transmission losses) rather than the mines simply using isolated diesel plants at their mine site.

However, this scale of industrial load on the WAF system would provide material potential opportunities to develop new capital intensive generation on WAF. If the assumed industrial loads arise, diesel requirements over the life of the industrial loads (absent new capital intensive generation) would approximate 90-140 GW.h/year; however, after the mines close, diesel generation on WAF would fall back to about 21 GW.h/year, growing at about 7 to 8 GW.h/year as non-industrial load grows. Accordingly, the size range of new capital intensive generation suitable for this magnitude of load is likely to be about 50 GW.h per year, or about 7-10 MW of reasonably high capacity factor generation (such as those reviewed in 1992 when the Faro mine was operating)[23]. If such development could be pursued, there would remain 7-10 MW of other new “reserve” capacity required (for largely peaking or standby) where low capital costs are the driving economic factor (i.e., likely new diesel units) over and above the commitments recommended in Chapter 4.

Hydro projects in excess of about 7-10 MW size would impose risks of substantial periods of surplus hydro after the planned closure of the mines (with 10 years required for diesel consumption to move back up to 100 GW.h/year from 2026 to 2036) outside of risks related to premature closure of one or more mines under this scenario.

In contrast, as reviewed below, the scale of diesel generation displacement offered by Scenario 2 appears to be too small to support any feasible thermal coal supply options, even though the overall mine life assumed better fits thermal than hydro supply alternatives.

[23] At that time, projects up to about 8 MW per year and 50 GW.h/year were considered (implied annual capacity factor of 70%).

Hydro: Options can include those identified for the 10 MW scenario (very small hydro projects), as well "small hydro projects" (5-10 MW) and Existing Hydro Enhancements noted in Table 5.2 and *Appendix B: Hydro Project Options*. Aside from Drury, each of these options is considered to be relatively undefined at this time.

The projects identified reflect a lack of suitable hydro sites identified to date in this size range in Yukon. The primary supply options considered in 1992 in this size range (such as Moon Lake as well as Surprise Lake) are in BC and consequently attract significant additional charges for water rental fees and taxes.

Thermal – Coal: There are no credible opportunities to develop coal generation at this scale. As reviewed earlier, the practical minimum size coal development considered for Yukon has been 20 MW, which roughly equates to 144 GW.h/year or well in excess of the requirements under this scenario (other proposals have focused on coal generation in excess of this range up to 50 MW).

5.3.4 Options for Scenario 3: A 40 MW WAF Industrial Scenario

Under the 40 MW scenario, as under the 25 MW scenario, any loads connected to the WAF clearly push the system well onto diesel. Without new development of hydro or other capital intensive generation, incremental WAF diesel generation required under the Scenario 3 case examined in Section 5.2.3 would range from 220 to 275 GW.h/year for a period of 16 years, with four additional "shoulder" years averaging about 120 to 170 GW.h/year. After these mines close (assumed to be 2029), diesel generation on WAF for non-industrial loads would fall back to about 44 GW.h/year, growing at about 7 to 8 GW.h/year as non-industrial load grows.

If diesel was relied upon to supply loads of this magnitude, the industrial loads in effect would only be supplied about 15% with existing surplus hydro and 85% with incremental diesel generation over their life. As noted above for the Scenario 2 case, if WAF diesel generation is to be relied upon there is no apparent basis for Yukon Energy developing any new transmission interconnections to the bulk of this mine load (with the associated risks and transmission losses) rather than the mines simply using isolated diesel plants at their mine site. Consequently, if such loads are to be considered for connection to WAF, a major focus is required on developing new capital intensive generation larger than the 50 GW.h/year (7-10 MW) examined under Scenario 2 options.

New capital intensive energy projects in the range of 50 GW.h/year (about 7-10 MW) would be expected to be fully utilized in each year of this scenario. In contrast, long-term capital intensive energy projects in the range of 150 GW.h/year (in the range of 20-30 MW if baseload) would experience about 13 years or

more of surplus energy after the closure of the mines until non-industrial load growth consumed the excess output. Projects in excess of this level would see about 20 years of sustained use, then significant periods where they far exceed system requirements.

Overall, hydro project options above about 100 GW.h per year may be difficult to justify unless there is substantial expectation of subsequent industrial loads after 2024, and solid measures to address downside risks of premature mine closings. Thermal coal project options, however, with levels of energy generation of about 150 GW.h/year that are focused on a 20-year life may become feasible at this scale of mine loads. Each of these options is reviewed below, and is considered to be relatively undefined at this time.

Hydro: Hydro projects to supply the 40 MW scenario result in significant issues with respect to load stability and economic value of power over their life after the planned closure of the mines (outside of risks related to premature closure). This is because hydro projects are very long-term investments that can produce power well beyond the expected life of the mine being considered.

At this size range, options can include those identified for the 5-10 MW scenario (small hydro projects), as well "medium hydro projects" (10-30 MW) noted in Table 5.2 and *Appendix B: Hydro Project Options*.

At this size range, projects can support some costs for new transmission, so generation sites within about 50-100 km or more of the established 138 kV grid become worthy of investigation.

Thermal – Coal: Under the 40 MW scenario, the scale of new requirements increase to a point where opportunities may arise to develop coal or other thermal generation. The practical minimum size coal development considered earlier (1992) for Yukon has been 20 MW which roughly equates to 144 GW.h/year or in the range of the new energy requirements under this scenario. As coal plants have a life more consistent with the mine lives being considered (often assessed for project planning and feasibility at 25 years, although many plants outlive this), the technical fit of a coal plant to the loads under this scenario is better than hydro in this size range.

The economics of coal generation are very sensitive to the price of the coal, as well as to the quality of the coal and emissions standards, which can materially impact the capital costs required for the plant (for example, ash handling and dealing with sulphur in the coal). A 1995 assessment of coal power generation prepared for YDC by H. A. Simons Ltd. using Division Mountain coal determined a $50 million capital cost (1995$) excluding mine development costs, as well as about $2 million (1995$) for non-fuel annual

operating and maintenance costs (including 13 staff positions). Further assessment in 1996 focused on the potential for coal at $30/tonne to allow for power generation (using a 20 MW plant) at 8 cents/kW.h (1996$).

Based on these earlier 1995/96 estimates, a coal plant could be constructed and operated on the following basis:

- 25 year life at 20 MW, 144 GW.h (a 20 year life is also assessed below).
- $61 million capital cost (2005$), $2.5 million per year non-fuel operating cost (2005$) excluding taxes.
- Coal requirements of 102,000 T per year at $37/T (1995 estimate of $30/T inflated to 2005$).
- Oil requirement of 2.3 million litres at $0.65/litre (2005$) – based on 1995 estimate of 2,220 T/year[24].

The result is an 8.3 cents/kW.h LCOE (2005$, real), excluding transmission and taxes (but in this case including operating and maintenance costs, unlike hydro LCOE costs quoted above, given substantial O&M costs for coal generation) [25].

5.3.5 Options for Scenario 4: A 120 to 360 MW WAF Alaska Highway Natural Gas Pipeline Scenario

Compared to the existing Yukon WAF system (firm non-industrial load of about 270 GW.h per year, installed winter capacity of about 90 MW), the pipeline loads for the first four stations at 120 MW and 894 GW.h/year, are massively in excess of system capability or conditions experienced to date.

Little work has been done since the 1950s and 1960s on hydro sites of the size relevant to this scenario. Any such hydro generation development would involve concurrent major transmission development needs which have not been assessed or costed to date in any detail, although some preliminary transmission concepts have been reviewed.

Timing needed for planning and licensing major generation and transmission projects is likely in excess of ten years, given the need at the outset for extensive and costly pre-feasibility and feasibility studies. This suggests that the pipeline would be operating for many years before the new hydro generation would be

[24] Based on the 1996 study, oil is required to supply the facility during start-up and back up duty. Given increases in the cost of oil since this study was completed, a newer coal plant may have a revised optimal balance between oil and coal, but this has not been assessed.

[25] Coal generation developed to supply a 20 year project life would result in the LCOE being increased to 8.7 cents/kW.h compared to 8.3 cents/kW.h for a 25 year project life (2005$, real)

available. The need for the pipeline operator to install gas compressors at the outset will further reduce the cost effectiveness of the new hydro options. However, previous reviews in Yukon (including the Lysyk inquiry) noted the key importance of the pipeline operator installing stations that can be readily converted to electrical service at a later date if power cannot be coordinated for delivery from the outset of pipeline operation.

The range of potential options for Scenario 4 is reviewed below.

Hydro: Hydro projects to supply the Pipeline scenario are of a magnitude not well understood or recently studied in Yukon. At this size range, options can include more modest "large hydro projects" (30-60 MW) noted in Table 5.2 and *Appendix B: Hydro Project Options* for supply to one or more individual stations, or "very large hydro projects" (60+ MW) for major integrated supply to multiple compressor stations.

At this size range, major redevelopment of Yukon transmission would be required, so transmission is an unresolved issue for all potential generation sites.

Thermal – coal: Power generation from coal can reasonably provide the magnitude of power required to service the pipeline. However, no serious work has been completed in Yukon regarding potential coal developments of this scale. In addition, at least initially coal is not likely to be considered economically viable as supply to electrical compression for the pipeline, as electrical compression is typically attractive to pipeline operators only in low cost hydro-based jurisdictions where rates can be below 6 cents/kW.h to as low as almost 3 cents/kW.h or lower depending on interruptibility (but not typically resorting to electrical compression in higher priced non-hydro jurisdictions dominated by coal).

Interconnection with the BC Grid: There are limited attractive projects in Yukon that have the capability to serve the full power needs of the pipeline. It is possible that such potential new loads would form the basis for BC to extend transmission from BC that would connect Yukon (near Watson Lake) with generation assets located in BC. This option could radically change power supply costs and options in Yukon to the extent that major load centres (e.g., WAF and MD as well as Watson Lake) were linked to this new grid connection.

5.4 PRE-ASSESSMENT AND SCREENING

The options identified under the various scenarios above reflect potential opportunities to put in place capital intensive but overall lower cost sources of supply than alternatives of grid-based diesel supply or isolated diesel supply to the mines.

In assessing grid-based diesel supply, current diesel price forecasts indicate about $0.70/litre to $0.75/litre for Whitehorse for 2010 (based on $50 to $55 US per barrel, 2010$ for NYMEX light sweet crude, reflecting current oil futures markets), equating to about $0.21/kW.h to $0.22/kW.h (2010$, or $0.20/kW.h in 2005$)[26] including modest variable operating and maintenance costs (such as lube), assumed at 0.016/kW.h in 2005$. These costs provide a benchmark for assessing the potential cost competitiveness of any other resource option. These costs also provide an indication of potential ratepayer impacts relating to connection of major new industrial loads if in the end these loads must be supplied through incremental diesel generation.

Based on the information now known to YEC, all potentially feasible generation options noted in the previous sections including their associated transmission, can potentially be economically developed as an alternative to diesel, so long as system loads allow full to near-full use of their output over the life of the project.

There are two major areas of uncertainty, however, that limit ability to develop full detailed assessment of options and conclusions regarding economic and technical feasibility at this time for any specific industrial development scenario:

- There is not sufficient definition of the loads and timing of industrial customers (outside of perhaps Minto at 2-4 MW).
- All project supply options identified above to address these scenarios are at best moderately defined, and most remain relatively undefined. In terms of the hydro project staging, few projects are at Level 2 (Site Reconnaissance/Pre-Feasibility) while most are at Level 1 (River Reconnaissance/Inventory) and in many cases (especially for medium to large projects) even the Level 1 work was completed many decades ago under different expected generation concepts and constraints so is of limited value. Thermal projects are at a similarly early stage in conceptual planning.

The focus of the following pre-assessment and screening is initially on technical pre-assessment and load fit (i.e. how well does the project fit the load requirements under any specific load scenario). As noted, cost effective opportunities to displace diesel generation require full to near-full effective energy use of a resource option's output over its life.

[26] For modeling purposes, fuel costs have been assumed at 65 cents/litre for 2005, inflating at 2% per year, to total 71.77 cents/litre in 2010.

Subsequently, economic pre-assessment is also considered to look at the screening options with respect to economic factors. Within the economic pre-assessment, diesel generation is assumed to be the default source for all energy not supplied by hydro or other resource options under the 10 MW, 25 MW and 40 MW scenarios, as diesel generation provides supply with relatively limited risk related to timing and/or capital costs. Diesel generation is not a reasonable supply option under the pipeline scenario, where the alternative to electrical compression is natural gas driven compression.

5.4.1 Technical Pre-Assessment and Load Fit

The assessment of how well various supply options fit the load requirements focuses around options of various types and size ranges. The analysis focuses on scale of loads relative to scale of various resource project options; however, as noted in Section 5.3, the assumed timing of loads as well as their duration can also be of critical importance in assessing resource options[27].

The load fit assessment is provided separately below for each different supply option technology and scale grouping:

Hydro – Enhancements (Aishihik diversions at no capacity, 1.8-17.7 GW.h/year; Atlin Storage at 2.0 MW, 9.0 GW.h/year; also other potential options being assessed in Southern Lakes; potential planning costs for these projects are estimated to be about $100,000 to $200,000 per project): These projects involve maximizing the value from the existing investments. Under the industrial development scenarios, each focuses on the potential to provide energy as well as in some cases capacity. The projects are all likely to be of relatively modest size that could be relevant under basically all potential industrial scenarios. The planning costs for these projects are estimated to be between $300,000 and $600,000.

Hydro – Very Small (1-4 MW, 5-30 GW.h/year, $12-$47 million; potential planning costs of $1.2 to $4.7 million prior to decision to proceed with project): The projects in this size range

[27] By way of example, a ten year delay in the Scenario 1 mine loads would enhance opportunities to develop at least very small hydro projects (to the extent that non-industrial loads would then have grown sufficiently to sustain long term use of the new energy supply). Similarly, the duration assumed for each mine development load examined is of critical importance in the assessment of resource supply options, e.g., capital intensive supply options can much more easily accommodate loads of 40 years duration than loads of only 10 years duration. In this regard, Scenario 2 and 3 load opportunities relate as much to assumed mine duration (at 15 to 20 years) as to the assumed level or scale of these loads; Scenario 4 load opportunities, with 30 year durations, also elate to more than only scale.

(Drury at 2.6 MW or larger, Squanga at 1.75 MW, also Morley (4 MW), Lapie (2 MW) and Orchay (4.2 MW)) are likely beyond the limits of what can be enabled by the 10 MW industrial development assumed in Scenario 1. The technical assessment of these projects relies on serving a role to supply energy in excess of existing system hydro capability, in order to displace diesel related to serving incremental mine loads while they are in operation, and to displace diesel serving non-industrial loads once the mines close at about 2016-2018. However, absent mine development at or above 10 MW extending through to at least 2020, it is not apparent that the load fit is sufficiently consistent to enable projects of even this very small size range to be feasible. Should they be developed, these projects are well within the financial capability of Yukon Energy/YDC to pursue, including measures to protect against downside market or load related risks.

Hydro – Small (5 -10 MW, 30-70 GW.h/year, $50-$101 million; potential planning costs of $5.0 to $10.1 million prior to decision to proceed with project): Projects in this size range (Moon at 8.5 MW, Tutshi at 7.5 MW, Mayo B at 10 MW) can be enabled by industrial developments in the 25 MW range with relatively limited downside risk outside of premature mine closures over a life of at least 15 to 20 years[28]. These projects are in a size range that can be financed under traditional structures by YEC and YDC, and that YDC likely has the financial capability to "backstop" with respect to various market-related risks. Ongoing current efforts in the southern lakes area may yet identify further potential in this size range for other projects or comparable sized enhancements to the Whitehorse Rapids facility by way of water management projects.

Hydro – Medium (10-30 MW, 70-150 GW.h/year, $179-$191 million; potential planning costs of $17.9 to $19.1 million prior to decision to proceed with project): Sites in this size range (including Primrose at 19-30 MW and Finlayson at 17 MW) only fit the WAF load profile under the largest 40 MW mining scenarios discussed (Scenario 3), which focused on the opening of four mines simultaneously (Minto, Carmacks Copper, Division Mountain and Red Mountain) with lives of 15 to 20 years for most of the load. However, even under these conditions the hydro projects are likely much too large for the system after the closure of the mines (assuming mine closure prior to about 2035), and as such would rely on either new mining loads at that time to sustain the level of WAF energy 20-25 years from now, or would have substantial surplus for likely far many years. In this regard, projects in this size range may also have a difficult time competing with coal with respect to load fit compared to the life of the generating station[29].

[28] Appendix B, Figure B-2 provides a review example of load fit for Moon Lake hydro and the 25 MW Industrial Scenario 2.

[29] Appendix B, Figure B-3 and Figure B-4 provide a review example of load fit for Primrose hydro and the 25 MW Industrial Scenario 2 and 40 MW Industrial Scenario 3.

Serious issues also arise with respect to "market"-related risks in this case such as premature mine closings and even delays in initial development. In addition, these projects are likely at the limits of what YEC/YDC can finance within the existing financial structure. At these limits of the financial capability of YDC and YTG, it would become necessary to identify and/or develop suitable mechanisms within Yukon to "backstop" the downside market risks associated with projects of this size.

Hydro – Large (30-60 MW, about 150-300 GW.h/year, $380-$422 million; potential planning costs of $38.0 to $42.2 million prior to decision to proceed with project): These projects exceed the size required for any credible mining load or combination of loads examined in this Resource Plan and would require well in excess of 40 MW of new mining loads – no such loads or load combinations have been identified to date. Project options in this range focused on Hoole at 40 MW, Slate at 41.6 MW, and Two Mile Canyon on the Hess at 53 MW. There may be options to develop these sites for portions of a pipeline load (1-2 compressors of the planned 4-12 compressor pipeline development), but in all likelihood the economics of a pipeline case will more readily facilitate projects in the 60+ MW range and not multiple projects in the 30-60 MW range. In addition, these projects appear to be at or beyond the absolute limits that Yukon Energy and Yukon Development could potentially finance under any conditions without potential external support or guarantees, such as from Canada.

Hydro – Very Large (60 MW+, over 500 GW.h/year, $555 million+; potential planning costs in excess of $50 million prior to decision to proceed with project): These projects cannot be considered for any practical development without a committed pipeline load (or equivalent) using electricity for compression, and without major transmission system development or redevelopment to handle this scale of generation. The projects identified to date include Granite at 80-250 MW, Fraser Falls at 100-450 MW, and various Yukon River sites at 100-500 MW. Yukon Energy would also need to address financial capability to even plan and carry out pre-construction activities on these projects, as costs for even these pre-development stages would likely exceed Yukon Energy's ready financial capability. Costs for development would require either major financial partners or government debt guarantees from Canada as commitments are likely beyond the capability of Yukon to guarantee.

Thermal – Coal: Development of environmentally sound coal in a size range of 20 MW or more cannot be seriously considered on the WAF system, given current technology, outside of major industrial developments in the range of 40 MW or higher (i.e., well in excess of the Faro Mine when it was operating). In the event very large industrial mine developments do arise in the 40 MW range, however, coal may be a better fit to the life of the load than hydro, and would therefore merit further consideration at that time.

Coal may provide opportunities within the 25 MW scale of industrial load development (similar to Faro-sized load) if constraints on technical feasibility and cost for coal generation projects smaller than 20 MW can be in some way be addressed. Earlier proposals that considered a technology for 15 MW combined coal/oil system have since been abandoned. However, it will remain relevant to monitor technology developments in this area. The capital costs of a coal facility are in a size range that can be financed under traditional structures by YEC and YDC, and YDC likely has the financial capability to "backstop" with respect to various market-related risks.

Coal options must be environmentally sound to be considered. The feasibility of coal generation will depend to some extent on the cost of employing state of the art technologies to reduce emissions.

Coal options also need to address directly who would be responsible for providing this resource, and under what terms and conditions would Yukon Energy secure such supplies. In the event that a coal mining project is developed for export markets, the coal for local thermal markets may become readily available. It is not clear how such supplies could be economically secured, however before such time as a coal mining project is developed for export markets. Other relevant aspects also require further considerations, including ash disposal.

Thermal – Biomass: In the event that Yukon develops a source for waste wood, of sufficient scale and duration, that would otherwise have a cost associated with disposal (e.g., someone willing to pay Yukon Energy or an IPP to dispose of it) there may develop an option for biomass generation. Currently, no such source of biomass supply is apparent in the time period for this Resource Plan. However, given similar fixed cost constraints as for coal, even if such a source was secured it is not likely that this type of generation would fit the load profiles under any but the largest industrial development scenario (e.g., a 20 MW plant enabled by 40 MW of industrial load).

Natural Gas: The pipeline scenario (Scenario 4) will likely create opportunities for natural gas based power generation in Yukon.

Evidence from southern jurisdictions and NWT indicates that natural gas generation is a major technology option for new power generation and can be well ahead of diesel in terms of costs, reliability and impact on the environment.

In addition, unlike coal, natural gas generation is more readily "scalable" to sizes suitable for Yukon as well as more suited to timely regulatory review and approvals and flexibility to operate in response to

load variations. Natural gas generation is also likely to be located near to the main load centres, and thus not subject to the same transmission costs and risks as noted for many other supply options.

It is premature at this time, however, to assess likely charges that will apply for natural gas supplies when they become available[30].

5.4.2 Economic Pre-Assessment

Given a solid load fit in technical pre-assessment, Yukon Energy has an ability to consider in a preliminary way the likely economics of projects to assist in any screening effort. Four key factors come into consideration in this pre-assessment:

1. **Preliminary Generation Capital and fuel-related Levelized Cost/kW.h (LCOE):** At a simple preliminary level, the LCOE noted above can provide a useful screening tool for the various options under consideration.

   Compared to assumed prices for solely the variable cost of diesel at 20 cents/kW.h in 2005$, all supply projects reviewed above have substantial opportunities to produce power over the long-term at a cost lower than diesel.

2. **Transmission Required to access main WAF Grid:** For hydro projects in particular, investment in transmission to connect remote sites with the established transmission system, and associated losses, can be a material factor in project economics. Transmission costs that begin to exceed about 10%-15% of the project costs can be difficult to overcome.

   Rough assumptions to date are that projects in the 1-4 MW range cannot support any material transmission costs beyond simple connection (i.e., must be basically on the established transmission, preferably 138 kV) while 5-10 MW projects may be able to support transmission of 50 km (to perhaps as high as 100 km at a maximum). Projects in the 10-30 MW range may be able to allow for transmission somewhat over 100 km.

   For the large to very large projects (30-60 MW and 60+ MW) there has not been any serious effort to screen based on incremental transmission costs, as this can only likely be usefully considered once loads have been identified and required upgrades or additional circuits to

[30] The Mackenzie Valley Pipeline proponents currently have a proposal before the National Energy Board that includes plans to provide access to gas from the pipeline for use by communities in the NWT along the pipeline route. This proposal, and the current NEB review, may provide guidance as to possible future charges applicable in Yukon after pipeline development in this area.

existing transmission can be incorporated into the assessment – such planning is not possible in the absence of further information about potential loads.

3. **Extra Fees, Charges or Process costs related to hydro developments in BC:** For hydro projects in BC, there is a material additional cost and risk associated with both licencing due to interprovincial processes, as well as water rentals and taxes.

   In Yukon, Yukon Energy does not pay and has complete future protection against any water rentals that may be levied by the federal government for use of waters for power generation. However, such fees are commonplace in other jurisdictions and can result in material costs for the utility (in Manitoba, water rental rates are 0.3 cents/kW.h for generation; rates in BC have been as much as 0.5 cents/kW.h but have recently been under review – the BC charges also include additional amounts for storage of water, as well as taxes). The economics of projects located in BC will require close monitoring of these rates to ensure that these costs are fully included in planning assessments of BC project economics.

4. **Impacts on rates:** Separate economic assessment is required of the effect of any projects on rates, as rates for any given year are set based on annual costs (including depreciation, interest and return on equity) rather than the lifetime long-term costs of projects. Past Yukon experience with the Faro mine well indicates that even long-term economic investments (such as Whitehorse turbine #4) can result in substantial rate impacts in some years when loads drop below the point where the assets are providing economic value[31]. Based on examples in Appendix B, major new hydro projects that have otherwise attractive lifetime LCOE costs can give rise to the potential for serious rate impact risks in some years if loads decline.

   A separate issue with respect to capital intensive projects such as hydro is that annual costs which drive rates are at a maximum in the first few years of the project (when rate base balances are highest). However, the benefits of capital intensive projects tend to increase over time as the value of any diesel displaced increases with inflation or other upward fuel

[31] Past experience with the Faro mine and Whitehorse #4 indicate rate impacts of 20-40% are possible when the Faro mine experienced shut downs in 1993 and 1997/98. This level of rate impact, however, likely understates the true full potential rate impact from major mine closures (i.e., closures for mines that account for a dominant share of WAF loads as was the case with the Faro mine when operating), as in the case of Whitehorse #4 the Government of Canada (via the Canada Flexible Term Note) retained most of the risks with respect to such loads. Absent this mechanism, the rate impact of the 1998 Faro closure would have been about $1 million higher than ultimately experienced (almost 3% higher than the 18.74% increase that ratepayers experienced).

price drivers (this is similar to the Mayo-Dawson Transmission project which will achieve material savings for ratepayers over its life, but did result in the need to address what would otherwise have been adverse rate impacts in the first two years via flexible debt financing[32]). Projects reviewed in the 1992 Resource Plan indicated potential for one to three year adverse impact on rates before savings compared to diesel begin to arise for ratepayers (using a diesel price of $0.26/litre), while Mayo-Dawson Transmission project initial reviews had at times determined the potential for five to ten year adverse impact on rates absent YDC flexible financing (ultimately the flexible financing was only required for 2003 and 2004).

However, due to the higher price of diesel fuel today, rate impacts from each of the resource supply option projects identified above are expected to be positive in year 1 assuming the full output is available to offset diesel generation. For example, Drury at a capital cost of $31 million (2005$) has the potential to offset 23 GW.h of diesel ($4.6 million per year, based diesel on $0.20/kW.h in 2005$). The year 1 costs of Drury (2005$) will total approximately $2.3 million for interest and return on equity (7.52% cost of capital times $31 million[33]) plus about $0.6 million for depreciation (using an aggregate life of hydro-related assets for depreciation of 50 years, and no reserve for salvage). In short, the capital costs of Drury would drive a $1.7 million lower overall system costs in year 1 than supplying this same 23 GW.h with diesel (this ignores what would likely be a relatively small operating and maintenance cost for Drury, but also ignores capital cost benefits from the 2.6 MW of capacity Drury brings to the system avoiding some investment at times in diesel engines).

For Level 2 projects (at this time only includes Drury), full economic assessment can be undertaken once certainty is developed with respect to sustained industrial loads beyond Minto (i.e., Minto is not sufficient to justify any scale of new capital intensive generation).

5.5 PROPOSED ACTIONS

Yukon Energy proposes planning activities as set out below to address a wide range of potential industrial development scenarios beyond the near term, and to protect future opportunities to commit development of additional generation and transmission projects before 2016 in a timely and cost-effective way in the

[32] At this point in time, overall average retail rate increase impacts are likely to be about 1% if utility regulated costs are increased in any one year by $360,000. Rate impacts need to be assessed in this regard by comparing a specific resource option to the available alternative resource options. It is relevant to note that this assessment may prove a resource option to save money relative to diesel, thereby allowing lower rates than would be required with diesel generation, while in reality (due to the need to develop new generation in any event to serve major new loads) overall rates are still being increased.

[33] Note also that Drury has very limited transmission costs required for the facility.

event that one or more of these industrial development scenarios materialize. Planning activities are organized by industrial development load scenario, identifying proposals as to how to approach each load scenario should it arise. "Pre-commitment" activities are also addressed which encompass planning activities Yukon Energy proposes to carry out prior to any certainty or commitment on the part of potential new industrial loads.

5.5.1 Proposed Activities Regarding Scenario 1: A 10 MW WAF Industrial Scenario

This industrial development scenario (which provides for near term development and operation between 2007 and 2018 of the Minto and Carmacks Copper mines) supports commitment of modest existing hydro enhancements, but does not support commitment of any new hydro site development before 2016 unless mine loads of at least 10 MW are sustained well beyond 2016. Consideration of the smallest hydro site options (1-4 MW) could potentially be supported in the event that 10 MW mine load development extends through to at least 2020. In this context, the following planning activities are recommended in the event these mine loads are seriously being considered for development prior to 2016:

- **WAF hydro system enhancements:** If not already committed pursuant to Chapter 4 near-term recommendations, planning should then proceed to commit the Aishihik 3rd Turbine, the Marsh Lake Fall/Winter Storage and any other feasible existing hydro enhancements indicated to date by the Aishihik Diversion assessments, the Southern Lakes hydrology work, and existing WAF hydro plant upgrade assessments.
  - If not already committed, Aishihik Diversions and Atlin Storage should then be advanced to Level 2 studies, including system-wide water and load dispatch modeling, to quantify the energy benefits under this scenario.
  - Ongoing assessment of the Southern Lakes should be completed to identify additional water control or small hydro opportunities to enhance Whitehorse Rapids output.
- **Mayo hydro system enhancements:** If the Carmacks to Stewart transmission line is developed to interconnect the WAF and MD grids, assess and develop as appropriate feasible enhancements at the existing Mayo hydro facility, including enhanced peaking capability.
- **New WAF hydro site development:** If industrial and overall load development commitment is such that both new capacity and baseload diesel generation energy are required through to at least 2020 (and there is no clear indication of more major industrial development scenarios emerging during the 20 year planning period), planning activities should be carried out to enable commitment of a very small hydro site development (1-4 MW, 5-30 GW.h/year)[34] able to provide new capacity and displace diesel energy.

[34] Present estimates of the costs are $12-$47 million generation capital cost (2005$) with potential generation planning costs of $1.2-$4.7 million prior to a decision to proceed with construction.

- Based on current information, this would indicate that the hydro site at Drury should at that time be advanced to full Level 3 studies that include consideration of variations that maximize capacity.
- Possible consideration might also be given to Level 2 studies for Squanga as a utility project or IPP, and/or for Morley, as potential alternatives for comparison to Drury.
- Consideration must include means to mitigate downside risks should industrial loads close prematurely.
- Actual development in each or these cases will involve investments greater than $3 million, or long-term contract commitments in excess of $3 million present value to IPPs, and therefore YUB review will be sought prior to project commitment.

- **Other activities regarding DSM:** If loads of this scale and duration develop, further consideration will be given to DSM programming focused primarily on reduction of system peak demand.

5.5.2 Proposed Activities Regarding Scenario 2: A 25 MW WAF Industrial Scenario

If industrial loads are committed on WAF before 2016 for development of more than 10 MW (70 GW.h/year) but less than about 20-25 MW (comparable to the Faro mine) for a period through to at least 2025, planning activities should be carried out to enable commitment to develop new hydro site resources to provide approximately 50 GW.h per year to WAF.

For potential hydro projects, key options to be considered at such time as greater load certainty develops regarding this level and duration of industrial load are as follows:

- **WAF hydro system enhancements:** If not already committed pursuant to Chapter 4 near-term recommendations, planning should proceed to commit the Aishihik 3rd Turbine, the Marsh Lake Fall/Winter Storage and any other feasible existing hydro enhancements indicated to date by the Aishihik Diversion assessments, the Southern Lakes hydrology work, and existing WAF hydro plant upgrade assessments (see proposals for Scenario 1).
- **Mayo hydro system enhancements:** If the Carmacks to Stewart transmission is developed to interconnect the WAF and MD grids, assess and develop as appropriate feasible enhancements at the existing Mayo hydro facility (including any feasible enhanced peaking capability).
- **New hydro site development:** If industrial and overall load development commitment on WAF before 2016 is such that WAF baseload diesel generation energy of more than 10 MW (70 GW.h/year) is then required through to at least 2025 (and there is no clear indication of more major industrial development scenarios establishing new WAF industrial loads in excess

of about 20 MW (about 125 GW.h/year) emerging during the 20 year planning period and extending beyond 2025, planning activities should then be carried out to enable commitment of a small hydro site development (7-10 MW, about 50 GW.h/year[35]) able to provide diesel displacing energy to WAF.

- New hydro options focused on Yukon-based projects, if available, would be the preference.
- However, given limited attractive projects in this size range identified in Yukon to date, further Level 1 and 2 activity should be undertaken if timing permits in areas within 50 km of existing 138 kV WAF transmission focused initially on scans of the various inventory studies completed by NCPC or others.
- Sites in BC, including Moon Lake and Tutshi[36], should have Level 2 studies updated in preparation for this possible load scenario, particularly focusing on the costs and risks associated with interprovincial licencing requirements and water rentals. Level 3 studies should then proceed if warranted.

- **Coal supply possibilities:** In the event that the loads of this scale develop and coal also becomes available from developed Yukon sources, coal generation technology should be reviewed in the event that timing permits to determine the potential for an economic and environmentally sound coal development at sizes below 20 MW, sized as appropriate to fit the industrial loads being developed at that time.
- **Other activities regarding DSM and wind:** If loads of this scale and duration develop, further consideration will be given to DSM programming focused on both the reduction of system peak demand and energy conservation, and development of new wind generation (if attractive sites near established utility grids can be identified).

Actual development of new hydro sites (or any other new generation site) in each case will involve investments greater than $3 million, so YUB review will be sought prior to project commitment. In addition, for larger scale developments, planning and feasibility work may exceed the $3 million level, so there is the potential for YUB review at this earlier stage as well.

5.5.3 Proposed Activities Regarding Scenario 3: A 40 MW WAF Industrial Scenario

If industrial loads are committed on WAF before 2016 of more than about 20-25 MW (150 or more GW.h/year) for a period through to at least 2030, resulting in forecast baseload WAF diesel generation

[35] Present estimates of the costs are $50-$100 million generation capital cost (2005$) with potential generation planning costs of $5-$10 million prior to a decision to proceed with construction.

[36] No further work should proceed on Surprise Lake so long as the community continues its plans to develop micro-hydro at the site.

energy of more than about 150 GW.h/year to be required until at least 2030, then planning activities can reasonably proceed to consider commitments before 2016 to develop new hydro site or coal generation resources of 20-30 MW to provide 130-150 GW.h per year of long-term energy (20 or more years) to WAF.

- **Load uncertainties and low probabilities today:** The industrial loads required to reach the above levels at this time involve significant uncertainties and low probabilities.
- **New medium scale hydro site development (20-30 MW, 130-150 GW.h/year):** The development of generation and transmission to serve these loads, based on currently identified potential hydro sites (Primrose and Finlayson), would involve substantial generation capital costs ($179-$191 million (2005$), excluding transmission, as well as very large planning costs (about $20 million) prior to a decision to proceed with construction. Such costs are likely at or beyond the limits of YEC's current financial capabilities and involve material costs and risks related to investments in feasibility and planning long before final decisions to proceed can occur or plants brought on-line.
- **Coal supply thermal generation possibilities:** Coal resource options of this scale could involve far less capital than comparable new hydro sites, provided that coal supply as such was otherwise available from developed Yukon sources. The scale at 20 MW (140/GW/h/year[37]), however, is still very small for coal thermal technology and would require careful Level 2 and 3 screening and feasibility assessments to confirm its potential feasibility.

For potential generation projects related to the above scales, it is not apparent today that there is sufficient likelihood of this major development scenario arising to justify major investment at this time in planning and feasibility studies for medium new hydro or small coal plants. Accordingly, no specific planning activities are recommended at this time. Future decisions with respect to the level of effort and expense in this area will reflect YEC's ongoing assessment of the probabilities of the required loads developing. For projects of this scale, even early planning and feasibility work (at least on hydro sites) will exceed the $3 million level, in which case YUB review will be sought before proceeding with specific planning commitments of $3 million or more.

5.5.4 Proposed Activities Regarding Scenario 4: A 120 to 360 MW WAF Pipeline Scenario

The Scenario 4 pipeline loads at this time involves significant uncertainties as regards timing and magnitudes. However, given the implications of this industrial development for all aspects of Yukon power utility activities, and its clear possibility to come into service within the 20-year period for the

[37] The present estimate of the costs are $ 61 million thermal plant capital cost (2005$), excluding transmission or coal resource development costs, with potential generation planning costs of $6 million or more prior to a decision to proceed with construction.

current Resource Plan, one key activity recommended for the near-term regarding Scenario 4 involves continued active monitoring of this development as well as active planning to identify and assess all potential related material impacts, options and opportunities, including:

- Major power supply options for the pipeline for compression (focusing initially on short listing and assessing at Level 1 knowledge large scale hydro site options and related transmission requirements).
- More modest power supply opportunities focused on compressor station "station service" loads.
- Options to use natural gas for power generation to serve cost effectively other incremental industrial loads.

The development of generation and transmission to serve these pipeline loads is likely well beyond the limits of YEC's current financial capabilities as well as involving material costs and risks related to investments in feasibility and planning long before final decisions to proceed can occur or plants brought on-line. Accordingly, prior to carrying out any planning activities beyond Level 1 assessment of any specific site or technology specific studies, it is proposed that Yukon Energy identify and assess options that would address this constraint, e.g., joint venturing with others, and/or options to secure external government or other financing.

5.5.5 Proposed "Pre-commitment" activities

Prior to any certainty developing regarding the industrial scenarios that may arise, it is proposed that Yukon Energy remain focused on certain key planning activities to ensure protection of the options to address new load requirements. Yukon Energy proposes the following activities in this regard:

- **Monitoring of Industrial load developments:** Yukon Energy will continue to monitor closely potential load development and related spin-off residential and commercial impacts, including necessary discussions with mineral exploration companies active in Yukon, key officials in Yukon government working with mines and other industrial developments, and relevant industry associations. Separately, YEC will maintain ongoing monitoring of potential Alaska Highway pipeline developments and factors that may impact electrical loads in Yukon (including potential for electrical compression).
- **Southern Lakes hydrology assessments:** Continued assessment and studies of the hydrology of the southern lakes area, including identification of potential for water control structures to enhance output of Whitehorse Rapids, as well as potential hydro generation sites.

- **Other existing hydro facility enhancements:** Continued focus on projects to enhance output of existing hydro generation facilities at Aishihik, Whitehorse and in certain cases, Mayo. This includes full Level 3 and 4 studies on the Aishihik 3rd turbine and updating Level 2 studies on Aishihik diversions. Where suitable, activities should be carried out in conjunction with other normal Supply Side Enhancement planning by Yukon Energy, such as re-runnering.
- **Level 1 and 2 assessments to identify preferred 5-30 MW scale Yukon hydro sites**: There is an option to invest in further surveying the potential of other Yukon based hydro generation sites to try to identify good sites in the 5-10 MW range (within about 50 km of existing high voltage transmission) and to advance credible candidates in the 5-30 MW range through Level 2 assessments (including ongoing monitoring of hydrology) in order to identify more clearly preferred sites to develop for possible loads within this range. However, this activity is costly and may require assessment of a number of sites. No activities in this regard are recommended today; however, in the event that at least one large industrial load (such as Red Mountain or Division Mountain) proceeds to advanced licencing and likely commitment stages, it is proposed that this initial work should proceed quickly to determine if the sites identified to date are indeed the best candidates or if there are other Yukon-based sites that should be seriously considered, and to identify specific projects for Level 3 feasibility assessments.
- **Ongoing monitoring of hydrology**: Active hydrology monitoring will proceed where feasible for all hydro sites likely to be serious candidates for future development within the 20 year planning period. The monitoring may be periodic (seasonal flow information, current cost of $1,000 per year per site) up to a full-time recording station (at a current cost of $30,000 (initial costs) plus ongoing costs of between $10,000 to $15,000 per year).

APPENDIX A:
POWER RESOURCE TECHNOLOGY OPTIONS

APPENDIX B:
HYDRO PROJECT OPTIONS

APPENDIX C:
AISHIHIK 3RD TURBINE ASSESSMENT

APPENDIX A:
POWER RESOURCE TECHNOLOGY OPTIONS

A.1 POWER RESOURCE TECHNOLOGY OPTIONS

This Appendix provides a brief overview of technology options for providing power resources, either through new generation (supply side) or through Demand Side Management.

A substantial review of power resource options and technologies was provided in the 1992 Yukon Resource Plan. More recent power resource technology overviews have been prepared for northern conditions, most notably the Alaska Power Association overview titled *New Energy for Alaska* published in March 2004 (available online at http://www.areca.org/areca/energy_sys.htm) and a more site-specific review[1] "*Galena Electric power – A Situational Analysis (*pre-publication draft)" (available online at http://www.iser.uaa.alaska.edu/Publications/ Galena_power_draftfinal_15Dec2004.pdf) .

For each technology option reviewed, the scope of consideration from the 1992 Resource Plan is noted, as well as more recent information from either the Alaska studies, or other Yukon specific information compared to 1992.

A.1.1 DIESEL

The 1992 Resource Plan was directed, as per OIC 1992/92 to consider "contracts and commitments for non-diesel fuel generation". At the time, diesel generation was being used for a substantial part of the WAF supply. As such, diesel was not reviewed as a supply option, but was reviewed as the "base case" for comparison of non-diesel alternatives.

Diesel generating units have relatively low capital costs (approximately $1 million per MW), and high operating costs. Consequently, diesel units are typically well-suited to meeting reserve capacity requirements and short-term capacity needs during system peaks. Diesel is also well suited to isolated regions where loads are small (such as the Yukon isolated communities), where loads do not have very long lives (such as temporary applications or short lived mines) or where the heat from the operation of the diesels is of economic value (such as in certain industrial operations). Since diesel units can be turned off when they are not needed (and because of the relatively low capital costs), diesel units provide a relatively lower risk source of supply if loads are uncertain (as load decreases can be met with cost increases from putting the unit on standby).

[1] The draft was published in December of 2004, and provides an overview of generation options for an Alaskan community of 800 people. The options considered for Galena included: diesel, coal, nuclear, and a grid connection.

Diesel is expensive for utility operations running to provide sustained energy on a regular basis throughout the year.

Since 1992, efficiencies of new diesel units have occurred. The 1992 resource plan was based on efficiency of 3.7 kW.h/year and the most efficient units now in service on WAF are cited at 3.9 kW.h/litre (installed in early 1990s). However, the more recent Alaska studies cite potential efficiencies in the 4.18 kW.h/litre range for the most efficient new units (15.8 kW.h/gallon) at maximum efficiency. This maximum may be unattainable over any sustained operating period with normal start-up, shut-down, load variations, and other factors, but does reflect improvements since the 1992 review.

A.1.2 HYDRO

Hydro options were studied extensively as part of the 1992 Resource Plan Submission. In addition to the information provided in the main Resource Plan document in 1992, a separate binder (Supply Side: Binder A), contained detailed information on hydro options evaluated by the utilities.

Hydro generating plants have relatively high capital costs and very low operating costs; as a result, sustained operation of such facilities over an extended time period in a year can often yield lower unit costs for energy generation than would occur with diesel generation units. Hydro options have the potential to meet the needs of the Yukon under industrial development scenarios.

Hydro options for the Yukon are identified in detail in *Chapter 5: Industrial Developments and Opportunities*, and significant specific characteristics and issues related to hydro are discussed in particular in *Section 5.3: Options*., and *Appendix B: Hydro Project Options*.

A.1.3 WIND

At the time of the 1992 Resource Plan, the Yukon utilities had no wind generation in operation, but wind power was identified as a potential future supply option. Since that time, Yukon Energy, with the support of Yukon Development and the Government of Yukon, has gained considerable experience with wind generation for utility supply. This includes operation of two turbines on Haeckel Hill on WAF (a Bonus 150 of 150 kW installed in 1993 and a Vestas V47 of 660 kW installed in 2000) as well as numerous wind

monitoring projects throughout Yukon[2]. At this time, Yukon is consistently cited as a leader in assessing the commercial potential and technical considerations of wind generation in northern climates.

Key issues with respect to wind generation are capital costs (particularly for smaller units), capacity limitations and wind availability. Capital costs for wind generation have been declining in recent years, but remain quite high for installation in Yukon, where major new support systems can be required (transmission and roads are typically required to install wind generation in new sites, which are typically high elevations sites in Yukon). Wind is also not a form of reliable capacity to utility systems, as it is not dispatchable and is an intermittent resource, consequently wind does not make a contribution towards planning for meeting the peak commitments of a utility. Wind is well suited, however, to larger hydro-based systems that have material storage (such as WAF) once material expensive diesel generation begins to be dispatched.

More important to wind economics, the feasibility of wind is very sensitive to wind regime and availability. Utility industry experience indicates that wind economics essentially require a capacity factor of 30%[3] while high grade commercial installations may be higher. By comparison, wind turbines installed in Yukon have only been able to achieve an average capacity factor of 22% given the wind regime and other operational factors (such as rime icing, which can substantially reduce wind output) and a Community Wind Resource Assessment program run by YDC has surveyed a number of sites in Yukon (focused on potential customer wind installations) with capacity factors of 2% to a little over 10%. Two utility focused projects were investigated at Destruction Bay and Old Crow. Each was found to have an uneconomic wind regime compared to project costs.

Wind generators can be installed reasonably quickly (outside of the time to order new units, which today have significant lead times due to market demand). Capital costs risks related to wind primarily relate to associated infrastructure (such as roads and transmission lines needed to access the proposed site).

Capital costs for new wind generators continue to reduce in price fairly substantially. However, the scale of new wind turbine models is also growing, and is now approaching a range that would not be able to be easily integrated into Yukon systems other than WAF (1.5 MW or more per unit). On WAF, future industrial loads that push the system onto material diesel generation may enable commercial

[2] Sites at Mt. Sumanik, Destruction Bay, Haines Junction, Tagish, Whitehorse, Dawson City, and Ferry Hill have been undertaken since the early 1980s. Three locations suitable for wind generation were identified in the WAF area: Haeckel Hill, Mount Sumanik and Flat Mountain. Monitoring of potential commercial wind sites continues, including under the Yukon Development Community Wind Resource Assessment Program.

[3] p. 8, Yukon Energy Resources: Wind. March 1997.

development of wind as a complement to other resources reviewed in this plan. Given the rapid evolution of the wind industry and technology, updated assessment of the potential for wind will need to made once potential industrial loads become further defined.

In the north, the Northwest Territories Power Corporation has excluded wind generation from their resource planning for the current time, as a result of the challenges of operating wind turbines. In Alaska a number of remote communities have developed wind generation to supplement isolated diesel, but there are not utility wind turbines on the major interconnected systems. Also, the challenges associated with wind regime (capacity factor), as well as infrastructure costs (including transmission, as well as installation costs requiring major cranes) are noted to be a barrier.

A.1.4 BIOMASS

As of the 1992 Resource Plan, biomass had been studied for the generation of power in the Watson Lake region[4].

Biomass use for thermal generation is subject to the economic constraints related to the fixed costs (including fixed operating and maintenance costs). These costs do not fall dramatically for smaller scale operations or loads. In these circumstances, economic viability hinges on large and constantly running facilities.

As a general principle, biomass generation does not typically become economic unless three key conditions are met. These same conclusions have also recently been cited as preconditions for biomass electricity generation by the Alaska Energy Authority and in some cases the Yukon Cabinet Commission on Energy[5].

1. The fuel (typically wood) must be available from a source that would otherwise have to pay to dispose of it. Economic biomass generation is not typically possible with a wood product that has a cost to harvest, or even (in at least some cases) that can be delivered to the plant for free; there has to be savings from avoided disposal costs.

[4] A 6 MW steam-fired turbine had been assessed (assuming the Watson Lake sawmill was in operation) and determined to have too long a pay back period. See in particular the Yukon Cabinet Commission on Energy publication entitled "Wood", September 1997.

[5] Wood-Fired Boilers for Rural Communities, Online: http://www.uaf.edu/aetdl/presentationsre02.html. Also the 1998 Yukon Cabinet Commission on Energy "Principles of Supply Options for the Yukon" noted "Although abundant in supply, wood is not generally seen as a cost effective way to generate electrical power unless it has little or no cost as a fuel source".

2. The wood-fired power displaces diesel power.
3. There is a substantial market for power and heat.

To date, proposals discussed in Yukon do not meet these three key criteria.

In the Yukon, one biomass proposal received to date involves a waste wood generation facility at Haines Junction. However, that proposal was largely focused on burning wood that was previously killed by beetle infestation which will likely not be useable by the time the loads develop. A 2002 Canadian Forest Service annual Forest Health Survey found that the infestation was slowing. Standing wood tends to start to lose its heating value within three years of dying, and the bulk of the deadfall is now more than three years old.

Further information on biomass can be found in *Chapter 5: Industrial Development Scenarios and Opportunities.*

A.1.5 COAL

Coal-fired generation was examined in detail in the 1992 Resource Plan.

The economics of coal generation are very sensitive to various factors, such as the quality of the coal and emissions standards, which can materially impact the capital costs required for the plant (for example, ash handling and dealing with sulphur in the coal). The practical minimum size coal development considered for Yukon has been 20 MW which roughly equates to 144 GW.h/year.

Technologies for use of coal have been advancing at a rapid pace, particularly in regards to reducing emissions. Recent studies in Alaska have also summarized and assessed the potential for small coal developments, including Atmospheric Fluidized Bed Combustion[6]. Although a number of studies were cited, no successful small scale (1-10 MW) electrical utility coal projects are known to be in service in the north.

Key to development of environmentally sound coal generation in Yukon is the development of indigenous coal deposits independently of power generation requirements.

[6] "Galena Electric Power – a Situational Analysis" as noted above.

Further information on coal can be found in *Chapter 5: Industrial Development Scenarios and Opportunities.*

A.1.6 COAL-BED METHANE

Coal-bed methane generation was not studied in the 1992 Resource Plan.

Coal-bed methane generation produces electricity by using a methane gas from coal seams and fractures in coal beds, to produce electricity with conventional turbines. In order for coal-bed methane to be economic, the site must be close to a population base. In Yukon, no developed resources for coal-bed methane are available.

The Alaska resource study considered the potential for coal bed methane. No utility generation from coal bed methane is in service in Alaska today. The Alaska summary document identified high exploration and drilling costs, and the disposal of water as the main challenges associated with coal-bed methane generation.

A.1.7 NATURAL GAS

Natural gas was not reviewed in 1992.

Natural gas as a source for power is only available where commercial sources of gas can be delivered. Currently gas in not available in Yukon for utility purposes. Natural gas is in use in Inuvik, NWT for both domestic use (home heating) and power generation via reciprocating engines.

The availability of gas in Yukon would provide opportunities for a dramatic shift in the power resource framework for Yukon. Gas is a flexible resource that easily allows for “scalable” generation (from small 30 kW micro-turbines through massive turbines of hundred of MW, and including reciprocating engines of the size range is use in Inuvik of 2-3 MW).

However, given the limitations of gas availability in Yukon today, there is no option for gas generation to meet near-term requirements (Chapter 4) but serious investigation is required of opportunities to use gas (or maintain the option to use gas when it arrives) under Chapter 5 scenarios. If in the near-term Yukon Energy pursues new diesel generating units, consideration will be given to the potential to secure units that can later be converted to natural gas or can be run as dual fuel units.

Alaska has devoted considerable time and energy to natural gas generation given the availability of gas in many key communities. This information and experience will be of significant value to Yukon should gas become available during the period covered by the Resource Plan.

A.1.8 GEOTHERMAL

Geothermal generation was not studied in the 1992 Resource Plan.

Using heat energy from a geothermal resource is practical only if the geothermal occurrence and the energy need are located in close proximity. Thus, the development of geothermal applications in the Yukon will first occur where geothermal resources are found close to populated areas. A major well registry, mapping and resource analysis project is presently underway which will assemble the existing and available information on the groundwater and ground-source heat potential in all Yukon communities.

Known geothermal resources in the Yukon are too low in temperature to produce steam that could be used to generate electricity on a cost-competitive basis. While geothermal temperatures in the range of 100°C to 180°C are required, Yukon geothermal resources have so far been identified in only the 15°C to 55°C range. As a result, the Yukon's geothermal resources are best suited for heat energy applications such as space or district heating.

The recent reviews from Alaska noted similar concerns with respect to location of geothermal resources in relation to loads, and high capital costs of installing geothermal generation.

A.1.9 HYDROGEN

Hydrogen generation was not studied in the 1992 Resource Plan.

Yukon Energy has assessed hydrogen as an option for energy storage for electrical power. Given current hydro surpluses, the potential exists for electrolysis during off-peak or summer seasons for storage and use during peak times (or for isolated system generation or other non-utility purposes). However, given the technical complexity including issues related to storage and transportation, and the capital costs of hydrogen systems, hydrogen has not been considered a feasible resource option at this time.

Similar conclusions from Alaska indicate "feasibility is unknown, and the prospects without further advances in technology and market development are poor"[7].

A.1.10 SOLAR

Solar generation was not studied in the 1992 Resource Plan.

Given the angle of the sun, the intensity of the sunlight received closer to the Arctic Circle is less than in southern jurisdictions. Solar radiation is greater in the summer time, when there is currently a hydro surplus in the Yukon. As such, solar power does not provide any potential value to the Yukon in the near term, but has the potential to provide value in future if it is used to offset diesel generation.

Solar power is characterized by high initial or capital costs, and potentially low operating and maintenance costs. In isolated areas where grid power is not an option, residential and small commercial applications for mining camps, lodges, especially those with higher or solely summertime use, solar power may be considered a viable option.

The recent work in Alaska similarly concluded in respect of solar generation that "this technology is generally not cost-competitive for utility use when other alternatives are available"[8].

A.1.11 NUCLEAR

Nuclear generation was not studied in the 1992 Resource Plan.

Nuclear generation was studied for the Alaskan community of Galena based on a 10 MW Toshiba 4S reactor, which was to be provided for free from the manufacturer as a North American "Reference Case". Nuclear power was found to have the potential to be cost-competitive compared to diesel or coal, assuming that diesel and coal costs result in higher operating costs. The rising cost of diesel fuel has the potential to increase the economic attractiveness of nuclear generation.

The primary uncertainties with respect to nuclear power in Alaska are security and technical feasibility. In Galena, it was estimated that a minimum of four, and a maximum of 34 guards would be required. The proposed reactor is also a new technology for North America and will likely not available on a commercial basis for many years.

[7] "New Energy for Alaska" Alaska Power Association. March 2004.
[8] "New Energy for Alaska" Alaska Power Association. March 2004.

For Yukon, there is no commercial availability for the type of nuclear generation studied for Galena, and its future commercial availability is unknown. However many characteristics (size, life, efficiency, cost) of the project considered for Galena could be very attractive for consideration in Yukon. Other relevant considerations (including security and waste disposal) will clearly need substantial further attention before the true potential for nuclear in Yukon can be assessed.

A.1.12 DEMAND SIDE MANAGEMENT

DSM options were studied extensively as part of the 1992 Resource Plan Submission. In addition to the information provided in the main document, a separate binder (Demand Side: Binder B), contained detailed information on DSM options evaluated by the Utilities. The approach to DSM in 1992 reflected the situation that existed at that time; the Faro Mine was still in operation. A summary of the approach to DSM was outline at page 8 of the Demand Side Management binder, "In the Yukon, significant opportunities exist for Energy (GWh) savings because of the high cost of diesel generation. However, savings opportunities through reduction in peak Demand (MW) are relatively small due to the low capital cost for installing new diesel generation facilities. The priority, therefore, for DSM programs in the Yukon at this time relates to strategic reduction in energy use." Given the closure of the Faro Mine, there is no longer an incentive to decrease annual energy use. Consequently, the focus of the 1992 DSM plan does not correspond with Yukon Energy's current needs.

Yukon has been actively and aggressively engaged in DSM activities of various types since 1992, and in particular since 2000. Major emphasis from entities such as ESC, YDC and Natural Resources Canada has focused on reducing loads on isolated diesel systems, reducing non-electrical energy consumption (such as oil heating) as well as major efforts by Yukon Energy to grow the WAF loads via Secondary Sales (with surplus hydro, the most pertinent WAF DSM programs focus on selling this renewable resource that would otherwise be wasted, rather than reducing consumption).

In the near-term in Yukon, the electrical system requirements are almost entirely related to peak capacity (Chapter 4). Most non-industrial DSM programming is generally more successful at energy reductions than capacity reductions. As such, DSM has limited potential to address utility requirements in the near-term. In addition, DSM activities in the near-term that lower peak demand levels, but reduce utility sales which are currently being made from surplus hydro will be an adverse rate driver in Yukon (as lost revenue from reduced sales will outweigh cost savings from reduced system peaks).

Over the longer term, and under the various industrial scenarios (Chapter 5), DSM activities have the potential to contribute to savings from diesel fuel generation. As such, DSM activities will in all likelihood become an important utility focus should such scenarios arise. However, as a major supply option, there are limits to the scale of savings available from DSM. For example, under the 25 MW scenario diesel consumption on WAF proceeds rapidly to more than 100 GW.h per year – given a current firm non-industrial WAF sales of 250 GW.h/year, it is not possible for DSM to provide the resources needed to address this scenario, and therefore major displacement of diesel must come from supply-side resources (such as new hydro generation).

Information on Yukon DSM is provided in greater detail in *Section 2.4.5: Demand Side Management and the Energy Solutions Centre.*

A.2 LITERATURE REVIEWED

A.2.1 HYDRO

BC Hydro's 2002 Small Hydro Assessment in Yukon and northern BC.

Yukon Economic Development. Yukon Energy Resources: Hydro. March 1997.
The article provided an overview of hydro generation in Yukon, and issues affecting development. The article indicated that facilities smaller than 20 MW as the most likely to succeed.

A.2.2 WIND

Yukon Development Corporation & Yukon Energy Corporation. The Winds of Change: The Story of Wind . Generation in the Yukon. March 2001.
The report summarizes the history of wind generation in the Yukon and the history of Yukon Energy's experimental turbines at Haeckel Hill. YEC installed Bonus 150 kW MARK III in 1993 at Haeckel Hill in 1993. However, the report indicates that even with the special modifications that had been made to the Bonus before it was installed, there are still some problems, especially the lower temperatures and rime icing. The capacity factor of the turbine is 21%. The Vestas V47-660 kW was installed in 2000. YEC forecast a capacity factor of 23% for the Vestas.

Yukon Economic Development. Yukon Energy Resources: Wind. March 1997.

The article provides an overview of wind development in Yukon, and factors affecting development. The report indicates that wind velocities are greater at higher elevations; and that wind has the greatest velocities in the winter months, correlating with the period of peak electrical demand. However, rime icing is a significant factor impacting reliability and production levels during the winter peak.

A.2.3 BIOMASS

Wood-Fired Boilers for Rural Communities, Online: http://www.uaf.edu/aetdl/presentationsre02.html

Yukon Economic Development. Yukon Energy Resources: Wood. March 1997.

The article provided an overview of Yukon's wood fuel resources and the factors affecting development. The report indicated that wood fuel is a source of residential heating fuel, and supports existing small industries in sawmilling and firewood cutting. Further potential for wood fuel, including limited export and as a means of producing electricity were also identified.

A.2.4 COAL

Yukon Economic Development. Yukon Energy Resources: Coal. March 1997.

The article provides an overview of Yukon's coal resources, and the factors impacting development. The local markets identified for coal, included power generation and industrial heating.

A.2.5 LITERATURE REVIEWED ASSESSING MULTIPLE GENERATION TECHNOLOGIES

A number of publications were reviewed that provided an overview of generation and/or demand side management options for the Territory. These publications are outlined below.

New Energy for Alaska. Alaska Power Association. March 2004.

The publication includes an examination of a number of alternative energy sources, including: battery energy storage systems; biomass power; clean coal; coal bed methane; cogeneration; diesel engine efficiency; fuel cells; geothermal; hydroelectric power; hydrogen; microturbines; solar; tidal energy; and wind turbines. Given the similarities between Alaska and the Yukon, the analysis provided relevant comparisons for the Yukon.

Galena Electric Power – a Situational Analysis (Draft Final Report). Prepared for the U.S. Department of Energy. December 2004.

The economics of electrical power generation options for the City of Galena, Alaska were identified. Given the similarities between Alaska and the Yukon, the analysis provided relevant comparisons for the Yukon.

Economic Development from Renewable Energy: Yukon Opportunities. Provided by Pembina Institute. October 1999.

The report summarizes the energy conservation and efficiency, key renewable energy resources, and their application in the Yukon. The economic benefits, environmental and social aspects of renewable energy, and strategic direction for renewable energy in the Yukon were examined.

Yukon Government Cabinet Commission on Energy. Energy Efficiency for the Yukon, 1998.

The report provided an overview of the potential for greater energy efficiency in the Yukon.

Yukon Government Cabinet Commission on Energy. Green Power Fund. 1998.

The report provided an overview of a Green Power Fund for the Yukon.

Yukon Government Cabinet Commission on Energy. Principles of Supply Options for the Yukon, 1998.

The report provided an overview of principles of supply options for the Yukon.

Yukon Economic Development. Yukon Energy Resources: Alternatives. March 1997.

Generation resources were identified and examined, including: solar energy, geothermal energy and refuse-derived energy.

Yukon Economic Development. Yukon Energy Resources: Oil & Gas. March 1997.

The article provides an overview of oil and gas generation in the Yukon, and the factors affecting their development. The article explored development activities, and environmental issues.

APPENDIX B:
HYDRO PROJECT OPTIONS

B.1 HYDRO PROJECT OPTIONS

Yukon Energy has developed an inventory of many potential hydro sites in Yukon and in northern BC that have been studied in the past (primarily by NCPC or Government of Canada, and reviewed from time to time by Yukon Energy). Based on the inventory of sites studied in the past, Appendix B reviews specific potential hydro sites over a range of sizes.

The projects in this chapter reflect the primary alternatives identified to date based on review of the numerous studies conducted in Yukon. In selecting the projects noted in this chapter, location was used as a key screening factor, as well as information available on the relative attractiveness of the various sites (as reflected in part in the rough qualitative and quantitative factors considered in the various Level 1 work on the projects, including potential integrated system benefits).

Rough assumptions to date are that hydro projects in the 1-4 MW range cannot support any material transmission costs beyond simple connection (i.e., must be basically on the established transmission, preferably 138 kV) while 5-10 MW projects may be able to support transmission of 50 km (to perhaps as high as 100 km at a maximum). Projects in the 10-30 MW range may be able to allow for transmission somewhat over 100 km.

For the large to very large projects (30-60 MW and 60+ MW) there has not been any serious effort to screen based on incremental transmission costs, as this can only likely be usefully considered once loads have been identified and required upgrades or additional circuits to existing transmission can be incorporated into the assessment – such planning is not possible in the absence of further information about potential loads.

No screening is applied in this section based on environmental or socio-economic considerations. Such considerations would become key considerations for projects that can progress through an initial "technical" screening of the type outlined in this Appendix and Chapter 5.

The hydro sites reviewed in this Appendix are summarized in Table B-1 and shown on the map in Figure B-1.

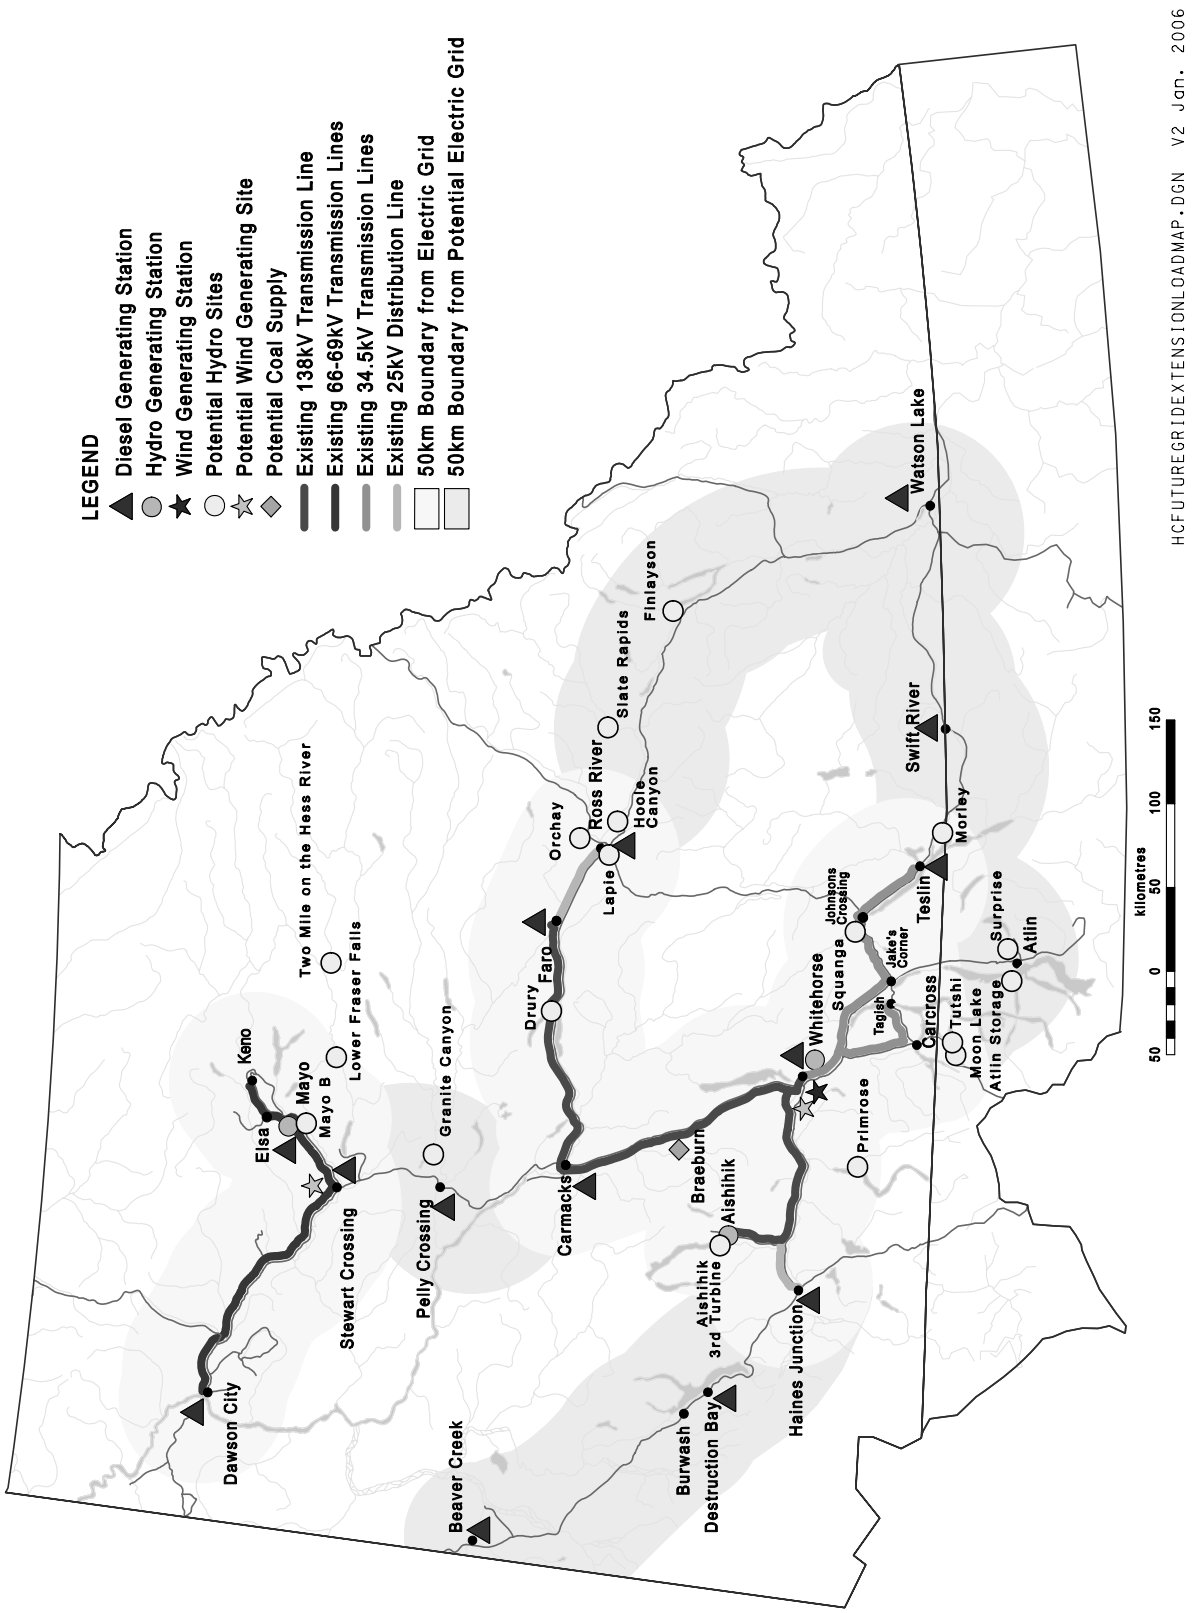
Table B-1:
Potential Hydro Sites

	Grid	Installed MW	GWh	Capital Cost (2005$millions) (excl. trans.)	Trans. Distance (km)	Protected under Yukon land claims	In BC	Capital Cost LCOE (cents/KWh) excl. trans (2005$ real)
Existing Hydro Enhancements								
Aishihik Diversions	WAF	0	total of 24	n/a	0	X		n/a
Atlin Storage	WAF	2	9	n/a	0		X	n/a
Very Small Hydro Projects (1-4 MW)								
Drury	WAF	2.6	23	31	0	X		7.2
Squanga	WAF	1.75	8.3	12	5			7.7
Orchay	WAF	4.2	27	47	15			9.2
Morley	WAF	4	22	31	30	X		7.5
Lapie	WAF	2	10	14	8			7.4
Small Hydro Projects (5-10 MW)								
Moon	WAF	8.5	50	51	66		X	5.4
Surprise	WAF	8.5	50	50	100		X	5.3
Tutshi	WAF	7.5	50	79	25		X	8.4
Mayo B	MD	10	48	101	0			11.2
Medium Hydro Projects (10-30 MW)								
Primrose	WAF	28	141	191	100			7.2
Finlayson	WAF	17	129	179	230			7.4
Large Hydro Projects (30-60 MW)								
Hoole	WAF	40	275	412	100			8.0
Slate	WAF	42	252	422	172			8.9
Two Mile Canyon on the Hess	MD	53	280	380	n/a	X		7.2
Very Large Hydro Sites (60+ MW)								
Granite	WAF	80 (up to 250)	660	706	125	X		5.7
Fraser Falls	MD	100 (up to 450)	613	555	n/a			4.8
Yukon River *(such as Rink Rapid, Eagles Nest, Five Fingers)*	WAF	various 75-240	n/a	n/a	n/a			n/a

Many of the above hydro projects arise from studies carried out by NCPC prior to 1987. In many cases these projects have not been subsequently reviewed in sufficient detail to confirm technical, economic or environmental acceptability for Yukon Energy to pursue today.

The above table also notes that some of the potential hydro projects identified here are "protected" under the Yukon First Nations land claims. Protection under the land claims agreements does not preclude the requirement to consult and work with local First Nations should Yukon Energy determine a need to develop these projects to supply load requirements. Furthermore, the extent to which such "protection" in each case may or may not extend to the elevations required to reach the maximum outputs noted in this Appendix has not yet been confirmed (because, as noted, further work has not yet been carried out since the initial studies).

Figure B-1:
Map of Potential Supply Options



B.1.1 LEVELIZED COST OF ENERGY

A primary consideration in screening potential new projects is the basic generation cost of energy supplied by output from any new resource (with typical focus on overall unit cost per kW.h as opposed to cost per MW of capacity). For the purposes of initial screening, "levelized costs of energy" ("LCOE") can be used to determine the unit costs/kW.h at the project site of energy produced. Levelized costs reflect the costs of the plant amortized over its life (all kW.h units available to be produced by the plant) assessed on real dollar (2005$) economic terms (i.e., assuming the levelized unit cost after 2005 increases with inflation each year).

- LCOE focuses only on key generation cost components for a resource option as needed to screen or compare alternative resource options during preliminary assessment stages[1].
- LCOE for hydro supply projects accordingly focuses in most instances only on capital costs, as these tend to establish the primary overall generation cost for this option[2]. Operating and maintenance costs for large projects can be quite modest (0.5% of capital cost based on BC Hydro estimates) which would tend to increase the LCOE by about 9.4%. Smaller hydro project operating and maintenance costs may vary up to 1.0% to 1.5% of capital cost, which can increase LCOE by 18.8% to 28.3% over the levels quoted in Table B-1.
- In the case of other resource options which involve material fuel operating costs (e.g., diesel generation, or thermal generation using coal, wood biomass or natural gas) it is also necessary that the LCOE reflect fuel as well as capital costs (if the capital costs are also likely to be a key part of the option's overall costs).
- LCOE automatically takes into consideration variations in the economic lives of alternative resource options.
- LCOE implicitly assumes that all energy generated over the economic life of a resource option is sold at rates that fully recover the LCOE costs, i.e., this screening tool does not address the extent to which a resource option may be oversized to meet forecast loads, or otherwise mismatched with forecast loads (in terms of, say, seasonal consideration).

[1] In BC, transmission costs to interconnect a project are considered in the levelized costing, but not overall transmission system upgrades required outside of the simple connection to the generation. In Yukon, screening of hydro projects is intended to be a quick and relatively simple process, so transmission costs to interconnect stations are not specifically estimated but are approximated in the screening process by focusing, for each scale of project, on only those projects a reasonable distance from developed transmission systems.

[2] Hydro project operating costs are modest compared to capital costs (outside of special charges such as BC water rentals, which need to be separately considered).

Levelized cost of energy as it is used in this Resource Plan for hydro focuses exclusively on hydro capital costs (excluding transmission and excluding O&M), estimated in 2005$ (includes 25% for owner's costs and contingency). Levelized costs are calculated by dividing the 2005$ capital cost of the project by a 65 year energy output (kW.h) of the project, discounted each year at a real discount rate of 5.41%. The real discount rate is determined by a nominal discount rate of 7.52% (based on YEC's costs of capital – 40% equity at 9.05% and 60$ debt at 6.5%) and inflation of 2%[3].

B.2 EXISTING HYDRO ENHANCEMENTS

Opportunities to enhance existing hydro in Yukon include items identified in Chapter 4 (such as re-runnering, Aishihik 3rd Turbine, Marsh Lake Top Storage and other potential opportunities in the Southern Lakes) as well as the Aishihik Diversions projects.

B.2.1 AISHIHIK DIVERSIONS

One set of projects that Yukon Energy has protected under the First Nations land claims (Champagne and Aishihik First Nation and Kluane First Nation as required) is the potential diversion of Long Lake (maximum 4.6 GW.h), Hutshi Creek (maximum 1.8 GW.h) and Gladstone Lake (maximum 17.7 GW.h) into the Aishihik Lake and Canyon Lake systems (total maximum potential energy of 24.0 GW.h per year). These projects have the potential to add energy with no new capacity Considerable further work would be required on these project before their respective feasibility can be assessed, including work to update capabilities and considerations with respect to licencing.

B.2.2 ATLIN STORAGE

NCPC studied and assessed the potential to optimize the water regime on Atlin Lake (an important upstream source of water for the existing Whitehorse Rapids hydro plant) to allow improved winter flows on the Yukon River. Although various potential scales exist, one option involves managing the lake within the natural range. This variant is expected to be able to provide 2.0 MW of enhanced Whitehorse Rapids firm capacity, plus 9 GW.h of additional energy (depending on loads). No reliable updated cost estimates

[3] This is generally consistent with major utilities considering long-term generation options. Other LCOE approaches have been used at times by other utilities when comparing to IPP projects, which attempt to address disparities in the length of IPP contracts compared to project service lives, the availability of low-cost financing to Crown utilities compared to IPPs, before-tax versus after-tax costs of Crown utilities versus IPPs, and elimination of federal government subsidies that may distort economic choices and fail to recognize that subsidies are a cost to taxpayers (see, for example, the 2005 BC Hydro Resource Options Report, section 4), The intent of such processes is to incorporate "societal perspectives" rather than focus on ratepayer perspectives. The Yukon Energy Resource Plan focuses primarily on utility and ratepayer perspectives.

are available, and significant complications are expected with respect to required interprovincial licencing processes should the project be advanced.

B.3 VERY SMALL PROJECTS (1-4 MW)

Very small hydro projects in the range of 1-4 MW may be candidates for development under Chapter 5 forecasts under the 10 MW industrial scenario or larger (at the very maximum that the 10 MW scenario can handle).

B.3.1 DRURY

Drury is a proposed 2.6 MW, 23 GW.h project that capitalizes on the head between Drury Lake and the confluence of Drury Creek with Little Salmon Lake. Drury was assessed in 1992, and remains the preferred candidate for scenarios with capacity and energy requirements consistent with Drury's output. The project has a capital cost of $31 million (2005$).

On a simple LCOE basis the costs of Drury are about 7.2 cents/kW.h (2005$, real). This includes all capital costs of the generating project including interest, depreciation and return on equity, but excludes transmission, incremental operating and maintenance costs and taxes.

The 2.6 MW is a firm winter capacity number based on the assumption that the plant would be developed to operate at a very high load factor throughout the year (e.g., include all necessary storage to allow firm winter supplies). If a more variable and flexible operating regime were to be considered for Drury, additional capacity above 2.6 MW could be installed (larger capacity configurations up to 5.2 MW and 29 GW.h have also been recently considered, at a cost of $37 million – a gain of 2.6 MW and about 6 GW.h). Alternate project layouts and sizes must be evaluated to determine the optimum scheme.

The plant would interconnect with the 138 kV line which follows the highway from Carmacks to Faro and would give rise to very little transmission costs.

Yukon Energy has the Drury site protected under the Yukon First Nation land claims agreements.

B.3.2 SQUANGA

A small potential site at Squanga Creek, at 1.75 MW and 8.3 GW.h at a rough capital cost of $12 million for a run-of-river version (2005$). This creek is near Johnson's Crossing with a steep final drop into the Teslin River, where the project would be located. Yukon Energy did work on Squanga as part of the 1992

Resource Plan, focusing on a run-of-river design with primarily summer supply (only 500 kW of firm winter capacity). In 1992 the potential for year-round storage was also noted, but little recent study of the potential for this variation had taken place.

The simple LCOE of Squanga is about 7.7 cents/kW.h (2005$, real). This includes all capital costs of the generating project including interest, depreciation and return on equity, but excludes transmission, incremental operating and maintenance costs and taxes.

In 1996 during the call for Expressions of Interest, Yukon Energy received an IPP proposal to develop Squanga at a similar run-of-the-river (limited winter capacity) configuration. Since that time, Yukon Energy/Yukon Development have been approached by private IPP developers interested in developing the Squanga site and YDC worked with one private outfit (via the Green Power Fund) with respect to further work. Continuing issues with Squanga relate to its limited ability as studied to provide winter capacity, and its location on a weak transmission link (the 34.5 kV system towards Teslin).

B.3.3 MORLEY, LAPIE AND ORCHAY

Three other sites in this size range that were recommended by the YUB for further water monitoring in 1992 (but not further assessment work) were Morley (past Teslin, 4 MW, 22 GW.h, $31 million (2005$)), Lapie (near Ross river, 2 MW, 10 GW.h, $14 million (2005$)) and Orchay (near Ross River, 4.2 MW, 27 GW.h, $47 million (2005$)). In each case, YEC has conducted water monitoring, but not undertaken the additional work required to advance the projects to the level of Drury in terms of technical assessment. In each case, projects may be limited by transmission, as they are not located on or near the 138 kV system.

Simple LCOE for these projects (excluding transmission, incremental operating and maintenance costs and taxes) varies from 7.4 cents/kW.h (Lapie) to 7.5 cents/kW.h (Morley) to 9.2 cents/kW.h (Orchay) (2005$, real).

Yukon Energy has the Morley site protected under the Yukon First Nation land claims agreements.

B.4 SMALL PROJECTS (5-10 MW)

Small hydro projects in the range of 5-10 MW may be candidates for development under Chapter 5 forecasts under the 25 MW industrial scenario or larger. These projects may also be part of a development plan under the larger 40 MW scenario.

B.4.1 MOON HYDRO SITE

The proposed Moon Lake project would have a capacity of 8.5 MW with 50 GW.h of annual generation at an estimated capital cost of $51 million (2005$). Potential exists for increasing the energy capability by the diversions of other small watersheds into Moon Lake. Additionally, the capacity could be increased to take greater advantage of the seasonal storage capability (other versions of Moon have been cited at as large as 14.6 MW for primarily winter peaking operation).

The simple LCOE of Moon is about 5.4 cents/kW.h (2005$, real). This includes all capital costs of the generating project including interest, depreciation and return on equity, but excludes transmission, incremental operating and maintenance costs and taxes (also excludes water rentals – see below).

Moon Lake is located in northern BC on the east shore of Tutshi Lake, approximately 45 km south of Carcross, Yukon. Moon Lake provides the opportunity for seasonal storage of water (like Aishihik) focused on allowing summer flows to be stored for use during the winter. Due to the distance from the 138 kV transmission grid (about 66 km), a reasonably substantial amount of new transmission would be required[4].

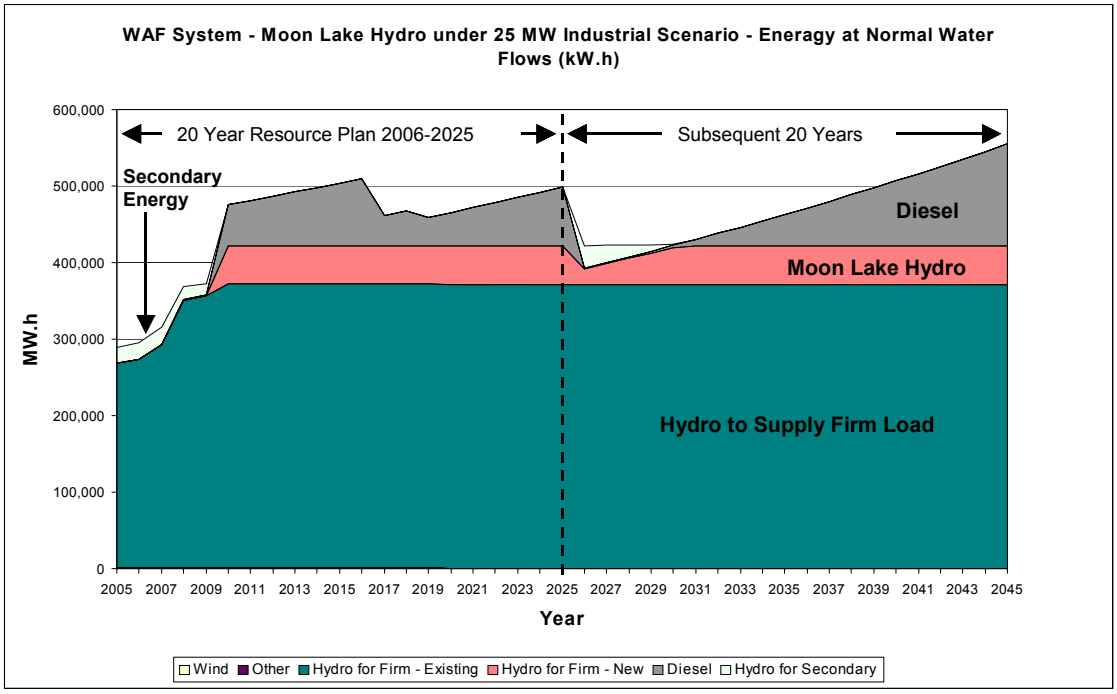
Because the Moon Lake project is located in BC, it would be subject to economic disadvantages due to material "water rental" payments and potentially property and school taxes that would be due to the BC government, as well as potentially more complicated licencing and regulations. The economic feasibility of operating in BC would need to be thoroughly assessed before proceeding with this project. Water rental payments to the BC government, for example, can likely add in the range of 0.5 cents/kW.h to the LCOE of the project.

In 1996, during the call for Expressions of Interest, Yukon Energy received a proposal from a local developer to either develop Moon Lake for Yukon Energy, or to develop the project as an IPP.
If developed in response to the 25 MW Industrial Development Scenario 2 (see Chapter 5: Section 5.2.2), it will become relevant to consider in detail the load fit of Moon to the loads to be developed. Under the 25 MW scenario loads, Moon would see full use of its energy output through 2045, with the exception of the 2026-2029 period (when surplus Moon hydro would arise, from 22 GW.h in 2026 reducing to 6 GW.h

[4] Although this transmission connection has not been priced, at a standard pricing of about $130,000 per km, plus substations, the rough capital cost could equate to $10 million. If this transmission line is solely providing a connection to Moon, the extra costs could increase the LCOE by 1.1 cents/kW.h

in 2029) as noted in Figure B-2. The impact of this 4 year surplus energy period is an increase in the LCOE of Moon over 65 years from 5.4 cents/kW.h (if all output could be used) to 5.6 cents/kW.h[5].

Figure B-2:
WAF Energy Requirements under 25 MW Scenario with Moon Lake Hydro



B.4.2 SURPRISE LAKE HYDRO SITE

In 1992, Surprise Lake was considered one of the key options for Yukon Energy in this size range. It was studied extensively in the early 1990's and a joint venture was contemplated with YEC, YECL and Synex to develop the project. It is an 8.5 MW project (50 GW.h) in two powerhouses estimated at $50 million (2005$).

In earlier review, significant concerns arose with respect to transmission requirements (more than 100 km from Jake's Corner to the site near Atlin, plus issues related to the 34.5 kV connection to Jake's Corner), regulatory requirements (due to location in BC), and economics due to material "water rental" payments and property and school taxes that would be due to the BC government as well as the local community.

[5] Full screening of Moon under a 25 MW scenario could therefore result in LCOE of 5.6 cents/kW.h for hydro capital costs reflecting "load fit", plus about 18.8% for hydro O&M based on 1% of capital cost (reflecting small projects, about $500,000 per year (2005$)), plus 1.1 cents/kW.h for transmission, plus 0.5 cents/kW.h for BC water rentals (ignoring taxes) for a total LCOE of 8.25 cents/kW.h (2005$, real).

More recently, the local community has indicated they are proceeding with a much smaller variant of the project to supply power solely to BC Hydro at Atlin. This development would likely preclude any future development of the full project as contemplated by Yukon Energy, and the project has been discarded by Yukon Energy as a likely development for Yukon needs.

B.4.3 TUTSHI AND OTHER HYDRO SITES IN THE SOUTHERN LAKES

There are a number of sites in the southern lakes that may provide opportunities for new generation, such as on the Tutshi River (7.5 MW installed, 50 GW.h, $79 million (2005$), LCOE of 8.4 cents/kW.h[6] plus water rentals to BC government). These projects serve to provide new generation as well as potentially enhance management of flow to the existing Whitehorse Rapids plant which provides added generation benefits (both capacity and energy). Yukon Energy is currently undertaking a hydrology study of this area along with site identification of potential water management structures or generating stations. Until that work is complete, all potential generation projects remain at the very initial stages of study.

Similar to Moon, a development of Tutshi under the 25 MW scenario would give rise to at least four years of surplus energy from 2026-2029. However, the actual annual flow patterns, flexibility and storage potential of Tutshi (and its associated impacts on Whitehorse Rapids) have not been recently assessed, and it is possible that surplus hydro would arise for more than four years if the plant output is not as able to be tailored to fit WAF loads as a Moon or other existing flexible resources such as Aishihik. The impact on LCOE from this surplus hydro under optimum conditions (a very flexible output from Tutshi) is an increase from 8.4 to 8.6 cents/kW.h; however the impact could be considerably more under a less flexible output.

B.4.4 MAYO B

The existing hydro site at Mayo has the potential to be enhanced by various changes in configuration, either to develop further head below the existing reservoir or an expansion of capacity utilizing the same head. This leads to multiple potential alternatives. However, as a supply option to WAF, these various projects are only of relevance if the Carmacks-Stewart transmission line is previously in service. The full capability of various potential Mayo enhancements to supply an interconnected WAF and MD system (as opposed to MD on its own) has not been fully studied, and should be re-examined in the event that the interconnection proceeds.

[6] As above, excludes transmission, incremental operating and maintenance costs and taxes.

One configuration alternative considered is a 10 MW, 48 GW.h, $101 million (2005$) variation based on a separate conveyance route from the existing reservoir to a new plant lower in elevation than the existing plant, which would be able to operate in parallel with the existing plant. This concept has an initial LCOE of 11.2 cents/kW.h. Various other concepts require further study. However, although work is still in preliminary stages, it must be recognized that it is possible no credible facility enhancements of this type exist at Mayo.

B.4.5 LACK OF OTHER YUKON-BASED HYDRO PROJECTS

There are very limited other potential hydro projects in the broad 5-15 MW size range identified in Yukon (as opposed to BC). One is near Faro, involving a diversion of the Anvil Creek and Rose Creek (9 MW, 70 GW.h, no reliable recent cost estimates available). Other identified projects are in the vicinity of Ross River (Prevost Canyon) or Pelly Crossing (Mica Creek) but have little to no reliable updated assessment of capital costs, transmission constraints and other key feasibility variables. Given the economic disadvantages of projects in BC (due to water rentals and taxes), it would be beneficial to secure generating station options in Yukon.

B.5 MEDIUM PROJECTS (10-30 MW)

Medium sized hydro projects have potential fit to the 40 MW industrial development scenario. However, key limitations arise with respect to the requirement for projects of this size once the mines close, as well as the risks of premature mine closures.

B.5.1 PRIMROSE/KUSAWA/TAKHINI HYDRO SITE

The potential Primrose generating station involves a number of potential concepts that were studied as alternatives to the Aishihik GS when it was constructed (studied in 1962, 1968, 1975, some more recent reviews). In general terms, the project involves developing hydro generation to capture the head between the high elevation Primrose Lake or Rose Lake and either Kusawa Lake or Takhini Lake.
Variations considered to date extend from about 19 MW to 30 MW and 100 to 180 GW.h. The primary concept reviewed to date is 28 MW, 141 GW.h/year estimated at $191 million (2005$). The LCOE under this scenario, consistent with the approaches used above, is about 7.2 cents/kW.h (2005$, real).

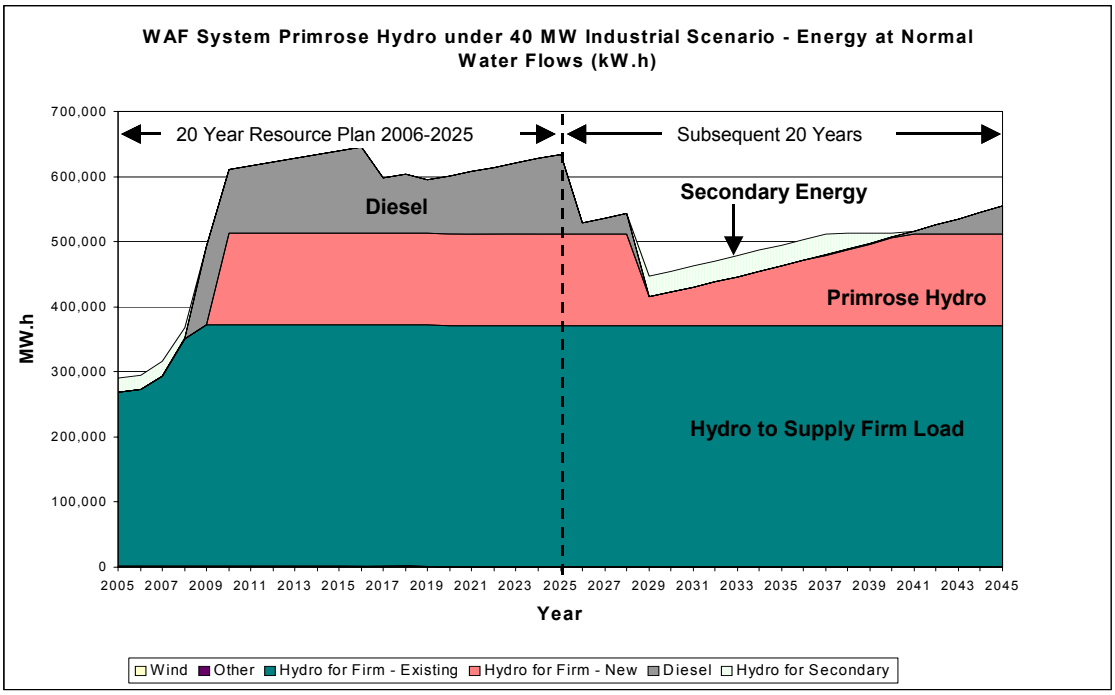
The site has reasonable access to developed transmission (less than 100 km, potential impact on LCOE of about 0.5 cents/kW.h). However, the site is located within an area that may be encompassed by a Park or special conservation area (subject to ongoing discussions with Yukon Government and the Kwanlin Dun, Champagne and Aishihik, and Carcross Tagish First Nations), which may limit development

opportunities. Primrose is not "protected" by notation under the Yukon First Nations land claim agreements. In addition, the Primrose River is glacial fed and carries large amounts of silt, which may pose technical problems for a generating station.

The project is located in Yukon, so would not be subject to economic disadvantages of BC locations due to "water rental" payments or property and school taxes, as well as the potentially more complicated interprovincial licencing regulations.

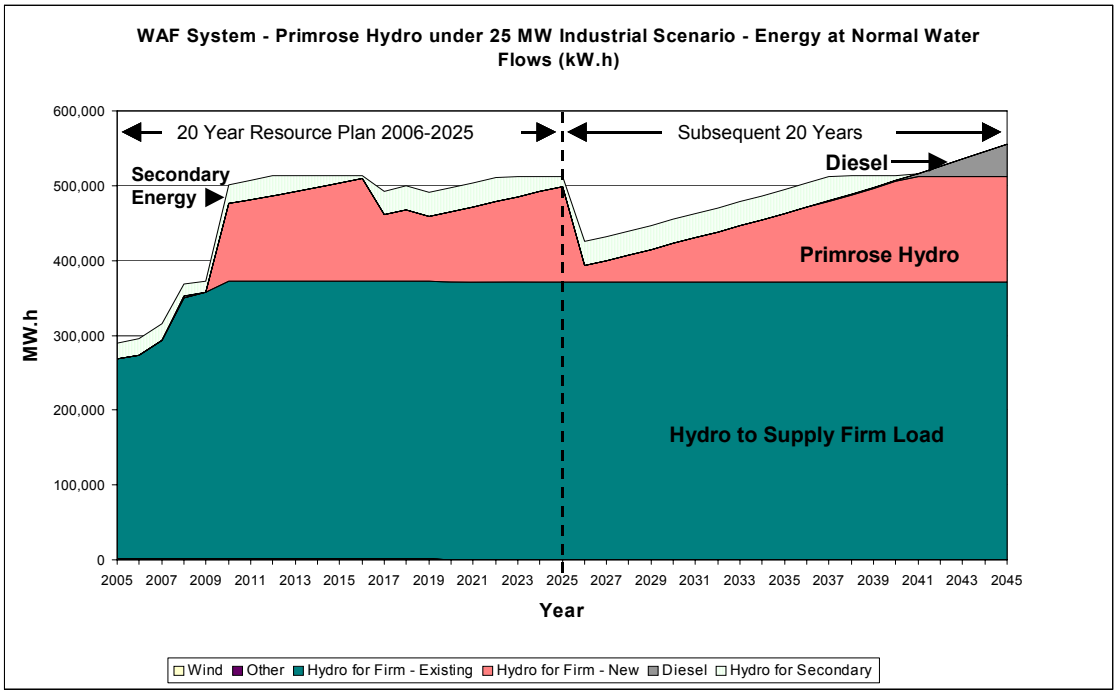
The key issues with Primrose or other hydro sites under the 40 MW scenario is the lack of load following closure of the mines, and the resulting potential for material surplus energy at that time (and potential consequent adverse rate impacts) as noted in Figure B3. In particular, were Primrose to be developed to service the 40 MW Industrial Scenario 3 (see Chapter 5: Section 5.2.3), its output would be fully utilized from the date of in-service to 2028. Starting in 2029 the facility would be in excess of WAF needs (about 2/3 of its output would be surplus), and the hydro surplus would extend through 2040. The consequent impact on project LCOE over 65 years is an increase from 7.2 to 7.7 cents/kW.h.

Figure B-3:
WAF Energy Requirements under 40 MW Scenario with Primrose Hydro



In contrast, were Primrose to be brought into service under the 25 MW industrial scenario, as noted in Figure B-4, the size would be well in excess of the system requirements in many years, and the consequent impact on LCOE would be an increase from about 7.2 cents/kW.h to over 9.0 cents/kW.h.

Figure B-4:
WAF Energy Requirements under 25 MW Scenario with Primrose Hydro



B.5.2 FINLAYSON HYDRO SITE

This potential project is on the Finlayson River, at Frances Lake well past Ross River near the Robert Campbell highway. It is potentially a 17 MW generating station (very high load factor, at 129 GW.h/year), and has a substantial transmission requirement (about 230 km). No recent reviews have been done of the potential costs of the station, but simple escalations from earlier capital cost estimates indicate potentially $179 million (2005$) (equivalent to an LCOE of 7.4 cents/kW.h in 2005$, real).

Finlayson is located in the Kaska area which has not signed a final agreement, so the status of any protection is not available.

Other larger hydro generating sites also exist in this area, along with significant future mining potential (Wolverine, Kudz Ze Kayah, others) which may enable a major system development along the Robert

Campbell highway at some point in the future. However, as a lone supply option, Finlayson is unlikely to be economic due to the substantial transmission requirements (which could add more than 1.2 cents/kW.h to the above LCOE).

B.6 LARGE PROJECTS (30-60 MW)

Large sized hydro projects have limited potential under any of the industrial load scenarios, with the exception of potential service to a limited number of compressors under the Alaska highway pipeline case.

B.6.1 HOOLE

Hoole is located on the Pelly River east of Ross River and is in the Kaska First Nations area which does not have final agreement on any protection for potential hydro sites. The project is a 40 MW, 275 GW.h/year facility at an estimated $412 million capital cost (2005$). Resulting LCOE is 8.0 cents/kW.h (2005$, real).

B.6.2 SLATE

Slate is similarly on the Pelly River east of Ross River, and is also in the area without final agreements as yet on protected sites (Kaska). The project is a 42 MW, 252 GW.h/year facility at an estimated $422 million capital cost (2005$). The resulting LCOE is 8.9 cents/kW.h (2005$, real))

B.6.3 HESS

Two Mile Canyon on the Hess is located east of Mayo and is protected in the Yukon land claims agreements. It is only of value to WAF if Stewart-Carmacks interconnection in place. The project is a 53 MW, 280 GW.h/year with an estimated $380 million capital cost (2005$). The resulting LCOE is 7.2 cents/kW.h (2005$, real)).

B.7 VERY LARGE PROJECTS (60 MW+)

Very large hydro projects have the potential to service most or all of the potential Alaska highway pipeline loads.

B.7.1 GRANITE CANYON

On the Pelly River (east of Pelly Crossing), Granite Canyon is a site that was studied by NCPC under a number of different concepts and sizes. Although the site is protected under the Yukon final agreements,

the extent to which development of the site can be accommodated within the "protection" areas has not yet been determined. Possible development concepts previously studied range from 80 MW (660 GW.h/year and $706 million capital cost (2005$)) or up to 250 MW or more. The LCOE is about 5.7 cents per kW.h (2005$, real) for the 80 MW version excluding transmission.

B.7.2 FRASER FALLS

On the Stewart River east of Mayo, possible concepts range from 100 MW up to 450 MW; the smallest version (100 MW, 613 GWh/year) has been estimated (2005$) to cost about $555 million, with LCOE for generation at about 4.8 cents per kW.h (2005$, real), excluding transmission costs.

B.7.3 VARIOUS OTHER LARGE YUKON RIVER SITES

Other sites have been identified on the Yukon River, well downstream of Whitehorse, ranging from 100 MW to 500 MW. No costs are available at this time for these options.

APPENDIX C:
AISHIHIK 3RD TURBINE ASSESSMENT

C.1 AISHIHIK 3RD TURBINE ASSESSMENT

Yukon Energy has reviewed the economics of a potential Aishihik 3rd turbine project under various assumptions, focused on a 65 year life. The assessment reviews five cases, as summarized in Chapter 4:

- **Section C-2:** Aishihik 3rd Turbine at 2009 under Base Case Loads
- **Section C-3:** Aishihik 3rd Turbine at 2009 under Base Case with 10 MW Mine Loads
- **Section C-4:** Aishihik 3rd Turbine at 2009 assuming earlier in-service (2007) of Marsh Lake Fall/Winter Storage under Base Case Loads
- **Section C-5:** Aishihik 3rd Turbine at 2009 assuming earlier in-service (2007) of Marsh Lake Fall/Winter Storage under Base Case with 10 MW Mine Loads
- **Section C-6:** Aishihik 3rd Turbine at 2011 assuming earlier in-service (2007) of Marsh Lake Fall/Winter Storage under Base Case Loads
- **Section C-7:** Aishihik 3rd Turbine at 2009 assuming earlier in-service (2007) of Marsh Lake Fall/Winter Storage and (2008) of Carmacks-Stewart (CS) under Base Case with 10 MW Mine Loads

In each case, there are two sets of tables presented:

- **Overall Project Economics (IRR based on cash flows):** The first indicates an overall cash flow analysis of the project, focused on determining the Internal Rate of Return (IRR) of the project (e.g., focused on one-time capital costs rather than "accounting" costs of depreciation or return on rate base used for ratemaking). This is basically the equivalent of the analysis of the Mayo-Dawson Transmission Line project provided in Table 5.4 of the YEC 2005 Required Revenues and Related Matters Application.
- **Ratepayer Impacts (NPV based on annual impacts on ratepayers):** The second table indicates the overall project lifetime NPV, the project NPV during the period of the current Resource Plan (2006-2025) and the annual impacts on ratepayers.

In each case, the economics do not include assessment of the expected beneficial impacts on secondary sales, particularly in the early years of the project[1].

A summary of the cases is provided in Table C1.

[1] Once the WAF system grows to the point of having "diesel on the margin" and no annual surplus hydro, all secondary sales will be interrupted, so no further impacts on secondary sales will occur as a result of the project; for a few years prior to the point of diesel on the margin, the 3rd Turbine project may also reduce the availability of secondary sales, as there will be less "surplus" hydro due to the 3rd Turbine allowing more of the water to be used to avoid peaking diesel.

Table C-1:
Summary of Aishihik 3rd Turbine Assessment Cases (2005$, $000s)

	IRR lifetime (%)	Ratepayer Costs/(Savings) (NPV) lifetime	Ratepayer Costs/(Savings) (NPV) 20 years	Years until beneficial rate impact
Section C2: Turbine in 2009 – Base Case Loads	10.81%	(4,075)	57	8
Section C3: Turbine 2009 – Base Loads with 10 MW Mines	16.31%	(7,854)	(3,722)	2
Section C4: Turbine 2009 – Base Loads – Marsh Lake Storage in service	9.95%	(3,104)	1,028	9
Section C5: Turbine 2009 – Base Loads with 10 MW Mines – Marsh Lake Storage in service	14.44%	(6,726)	(2,594)	3
Section C6: Turbine 2011 – Base Loads – Marsh Lake Storage in service	10.96%	(3,779)	291	7
Section C7: Turbine 2009 – Base Loads with 10 MW Mines – Marsh Lake Storage and Carmacks-Stewart in service	14.91%	(7,258)	(3,126)	3

C.2 AISHIHIK 3RD TURBINE AT 2009 UNDER BASE CASE LOAD

Table C-2A: Lifetime Economic Analysis of Aishihik 3rd Turbine (65 years) - IRR based on cash flows ($000s)
Diesel prices at $0.65/litre in 2005$, inflation at 2% per year, all present values to 2005, no assessment of benefits due to secondary sales - Base Case load forcast

	Project Benefits															Project Costs			Net Costs
	Baseload diesel without project (MW.h)	Baseload diesel with project (MW.h)	Change in Baseload Diesel (MW.h)	efficiency (kW.h.litre)	litres saved (000s)	Peaking diesel without project (MW.h)	Peaking diesel with project (MW.h)	Change in Peaking Diesel (MW.h)	efficiency (kW.h.litre)	litres saved	total litres saved	Fuel cost savings (65 cents/litre in 2005$ plus inflation)	Diesel O&M Cost savings (1.6 cents/kW.h 2005$)	Secondary Sales Revenus Benefits	Total project benefits	Capital Costs	O&M costs	SubTotal - Costs	Total Costs less Benefits (savings)

C.5 AISHIHIK 3RD TURBINE AT 2009 ASSUMING EARLIER IN-SERVICE (2007) OF MARSH LAKE FALL/WINTER STORAGE UNDER BASE CASE WITH 10 MW MINE LOADS

Table C-5A: Lifetime Economic Analysis of Aishihik 3rd Turbine (65 years) with Marsh Lake Fall/Winter Storage - IRR based on cash flows ($000s)

Diesel prices at $0.65/litre in 2005$, inflation at 2% per year, all present values to 2005, no assessment of benefits due to secondary sales - **Base Case load forecast with Mines**

	Project Benefits														Project Costs			Net Costs
	Baseload diesel without project and with Marsh Lake (MW.h)	Baseload diesel with project (MW.h)	Change in Baseload Diesel (MW.h)	efficiency (kW.h.litre)	litres saved (000s)	Peaking diesel without project and with Marsh Lake (MW.h)	Peaking diesel with project (MW.h)	Change in Peaking Diesel (MW.h)	efficiency (kW.h.litre)	litres saved	total litres saved	Fuel cost savings (65 cents/litre in 2005$ plus inflation)	Diesel O&M Cost savings (1.6 cents/kW.h 2005$)	Secondary Sales Revenus Benefits	Total project benefits	Capital Costs	O&M costs	SubTotal - Costs	Total Costs less Benefits (savings)

C.6 AISHIHIK 3RD TURBINE AT 2011 ASSUMING EARLIER IN-SERVICE (2007) OF MARSH LAKE FALL/WINTER STORAGE UNDER BASE CASE LOADS

Table C-6A: Lifetime Economic Analysis of Aishihik 3rd Turbine (65 years) with Marsh Lake Fall/Winter Storage - IRR based on cash flows ($000s)

Diesel prices at $0.65/litre in 2005$, inflation at 2% per year, all present values to 2005, no assessment of benefits due to secondary sales - Base Case load forecast

	Project Benefits															Project Costs			Net Costs
	Baseload diesel without project and with Marsh Lake (MW.h)	Baseload diesel with project (MW.h)	Change in Baseload Diesel (MW.h)	efficiency (kW.h.litre)	litres saved (000s)	Peaking diesel without project and with Marsh Lake (MW.h)	Peaking diesel with project (MW.h)	Change in Peaking Diesel (MW.h)	efficiency (kW.h.litre)	litres saved	total litres saved	Fuel cost savings (65 cents/litre in 2005$ plus inflation)	Diesel O&M Cost savings (1.6 cents/kW.h 2005$)	Secondary Sales Revenus Benefits	Total project benefits	Capital Costs	O&M costs	SubTotal - Costs	Total Costs less Benefits (savings)

GLOSSARY OF TERMS

BASELOAD DIESEL GENERATION:

Diesel generation operated to provide energy, due to a shortfall in annual energy (kW.h) from hydro (or other low variable cost generating sources).

BULK ELECTRICAL SUPPLY:

The generation and transmission part of an electrical grid that delivers power to the distribution system(s).

CAPACITY:

The load for which a generating unit, generating station or other electrical apparatus is rated either by the user or by the manufacturer.

COST OF SERVICE:

The total cost incurred to provide utility service, including expenses, taxes and return on investment. The cost of service may be thought of as an annual revenue requirement.

DEMAND:

The rate of flow of electricity demanded at one point in time and the maximum size (capacity) of facilities required to serve the demands of electric customers, usually expressed in kilowatts.

ENERGY:

The consumption of electricity over a period of time by customers of an electric system, usually expressed in kilowatt hours.

FIRM CAPACITY:

Capacity which is intended to have assured availability to the customers to meet all or a portion of the load requirements.

FIXED COST:

Those costs that do not vary with the number of kilowatt hours supplied. Examples would be depreciation and return on investment.

GIGAWATT:

One gigawatt equals 1,000 megawatts.

INDUSTRIAL CUSTOMER:

Defined in OIC 1995/90 as:

a) "major industrial customer" means a customer engaged in manufacturing, processing, or mining, whose peak demand for electricity exceeds 1 MW, but it does not include an isolated industrial customer;

b) "isolated industrial customer" means a customer engaged in manufacturing, processing, or mining and whose electrical service is not inter-connected with electrical service provided to any other customer.

KILOWATT:

One kilowatt equals 1,000 watts, where a watt is an electrical unit of real power or rate of doing work. One kilowatt is equivalent to approximately 1.34 horsepower.

KILOWATT HOUR:

The basic unit of electric energy equal to one kilowatt of power supplied to or taken from an electric circuit steadily for one hour. One kilowatt hour equals 1,000 watt hours.

LOAD FACTOR:

The average load of a customer, a group of customers, or the system divided by the maximum load (usually expressed as a percentage). For example, assuming 48 kWh of usage for the day, the average is 48/24 or 2 kW. If the maximum capacity available is 4 kW, the load factor is 2/4 or 50%.

LOAD FORECAST:

The forecast energy and demand requirements of the customers (usually on a monthly or annual basis).

MAXIMUM CONTINUOUS RATING:

The generation output rating in megawatts that a generating unit can sustain on a continuous basis.

MEGAWATT:

One megawatt equals 1,000 kilowatts.

PEAKING DIESEL GENERATION:

Diesel generating operated over short-term periods (hours to days) to aid in meeting the peak demand (MW) for electricity, typically during daytime hours.

RE-RUNNERING:

The replacement of turbines at an existing hydro generating station with a modern, more efficient design.

RESERVE:

Excess generation capacity that is maintained to safeguard against losses of supply due to unexpected equipment failures.

RUN OF RIVER:

Hydro projects that do not have any material storage, and must generate power based on river flows at any given point in time.

SECONDARY ENERGY:

Energy sold on an interruptible basis for service to heating loads.

POWER PURCHASE AGREEMENT

This Agreement dated September 1, 2010 is:

Between:

YUKON ENERGY CORPORATION, a Yukon Territory corporation, having an office at P.O. Box 5920, #2 Miles Canyon Road, Whitehorse, Yukon Territory, Y1A 6S7

("**YEC**")

and:

ALEXCO KENO HILL MINING CORP., a British Columbia corporation, having an office at 1150 - 200 Granville Street, Vancouver, British Columbia, V6C 1S4

("**AKHM**")

and:

ELSA RECLAMATION & DEVELOPMENT COMPANY LTD., a Yukon Territory corporation, having an office at 1150 - 200 Granville Street, Vancouver, British Columbia, V6C 1S4

("**ERDC**")

and:

ALEXCO RESOURCE CORP., a British Columbia corporation, extra-provincially registered in the Yukon Territory, having an office at 1150 - 200 Granville Street, Vancouver, British Columbia, V6C 1S4

("**AXR**")

Background:

A. AKHM and ERDC are each wholly owned subsidiaries of AXR, and AXR, AKHM, and ERDC are therefore Affiliates of each other.

B. Alexco is developing the Initial Mine Facilities with the intent of commencing milling operations at the Initial Mill Site and mining operations at the Initial Mine Site in 2010, and of developing other Mines and Mills in the District in the future;

C. YEC has agreed to sell to Alexco and Alexco has agreed to purchase from YEC Grid Electricity required by Alexco to operate the Mine Facilities in the District; and

D. The Parties have agreed to enter into this Agreement to set out their respective rights and obligations with respect to the sale and purchase of Grid Electricity by YEC to Alexco for Mine Facilities in the District.

Agreements:

The Parties agree:

PART 1
DEFINITIONS AND INTERPRETATION

1.1 Definitions

In this Agreement:

(a) **"Accrued Decommissioning Fund"** means a separate account to be set up by YEC under Part 11;

(b) **"Accrued Decommissioning Fund Amount"** means the amount standing to the credit of the Accrued Decommissioning Fund from time to time;

(c) **"Act"** has the meaning in Section 7.1;

(d) "**Affiliate**" has the meaning set out in the *Business Corporations Act* (Yukon Territory);

(e) **"Alexco"** refers collectively to AXR, AKHM, ERDC, and all Alexco Affiliates who become a Party to this Agreement under Section 4.5;

(f) **"Alexco Forecasts"** has the meaning in Section 4.2;

(g) **"Alexco Power Bill"** means the monthly bill sent by YEC to Alexco under Section 6.1;

(h) **"ampere"** means a unit of measurement of electric current, which is the rate that electrons flow in a wire (one ampere is 6.023 x 1023 electrons per second);

(i) **"Business Day"** means any day which is not a Saturday, Sunday, or a statutory holiday in the Yukon Territory or the Province of British Columbia;

(j) **"Capital Cost"** means all of YEC's reasonably incurred costs and expenses incurred in the design, engineering, procurement, construction, and commissioning of the Mine Facilities Spurs and YEC's costs and expenses reasonably incurred to negotiate and conclude this Agreement;

(k) **"Commencement of Delivery"** means, for any Mine Facility, the later of:

(i) the Mine Facilities Operation Date; and

(ii) if delivery of Grid Electricity by YEC at the Point of Delivery for that Mine Facility has not yet commenced, the date on which YEC provides written notice to Alexco that, in the reasonable opinion of YEC, the Mine Facilities Spurs for that Mine Facility are commissioned and are available for YEC to provide Grid Electricity to that Mine Facility from the Transmission Facilities and the Mine Facilities Spurs;

(l) **"Commercial Operation Cessation Date"** means the date on which:

(i) a Mine Facilities Shut Down Date has occurred for all Mine Facilities; or

(ii) Alexco no longer requires, acting reasonably under normal market and operating conditions, a combined Electric Demand at the Points of Delivery in excess of 1,000 kW;

(m) **"Commercial Operation Date"** means the first date on which Alexco actually receives Grid Electricity from YEC for a combined Electric Demand at the Points of Delivery in excess of 1,000 kW;

(n) **"Confidential Information"** has the meaning in Section 15.1;

(o) **"Decommissioning Costs"** means all decommissioning and other costs to be incurred by YEC and agreed to be recovered from Alexco (including, without limitation, costs to take down and remove facilities and costs to restore any property under applicable law, less credits for recovery sales of any materials removed and sold) reasonably required to remove such parts of the Mine Facilities Spurs to be decommissioned after a Mine Facilities Shut Down Date as YEC at that time may require to be decommissioned;

(p) **"Decommissioning Cost Payment"** means a payment to be made by Alexco to YEC under Section 11.2(c), that YEC will deposit in the Accrued Decommissioning Fund;

(q) **"Defaulting Party"** has the meaning in Section 10.1;

(r) **"Dispute"** means any dispute, difference, or disagreement between the Parties:

(i) as to the meaning, application, or implementation of this Agreement; or

(ii) as to whether an Event of Default has occurred;

(s) **"District"** means the entire area as shown in Figure C-1 in Schedule C;

(t) **"Electric Demand"** means the capacity at which Grid Electricity is delivered by YEC to Alexco for mining, processing, or manufacturing expressed in kV.A or kW, averaged over a rolling 15 minute period following YEC billing and metering practice for industrial customers receiving Grid Electricity;

(u) **"Electric Energy"** means electric energy, expressed in kW.h, delivered by YEC to Alexco under this Agreement;

(v) **"Electricity"** means Electric Energy and Electric Demand delivered by YEC to Alexco under this Agreement;

(w) **"ESRs"** means the Electric Service Regulations applicable to YEC, or any future replacement terms and conditions applicable to YEC, as approved by the YUB;

(x) **"Estimated Decommissioning Costs"** means, for any Mine Facilities Spur or part thereof, an amount equal to 25% of the Capital Costs incurred by YEC for that Mine Facilities Spur or part thereof;

(y) **"Event of Default"** has the meaning in Section 10.1;

(z) "**Event of Insolvency**" means any one or more of the following:

(i) if a Party files a petition for reorganization or for an arrangement under any applicable bankruptcy law or under any similar laws, now or hereafter in effect, is adjudged by a court of competent jurisdiction bankrupt, becomes insolvent, makes an assignment for the benefit of its creditors, admits in writing its inability to pay its debts generally as they become due, is dissolved, or suspends payment generally of its obligations;

(ii) if a petition is filed proposing the adjudication of a Party as a bankrupt or its re-organization under any applicable bankruptcy law or any similar law, now or hereafter in effect and:

A. the Party consents to the filing thereof;

B. the petition is not discharged or denied within 60 days after the filing thereof; or

C. the petition is not diligently defended against; and

(iii) if a receiver, receiver-manager, trustee, monitor, or liquidator (or other similar official) is appointed to take charge of all or substantially all of the business or assets of a Party and:

A. that Party consents to such appointment; or

B. the appointment is not discharged or withdrawn, or action is not taken by that Party to secure the discharge of that official, within 60 days after the appointment;

(aa) **"Firm Mine Rate"** means the rate set out in Schedule A, as may be amended by YUB from time to time;

(bb) **"Fixed Charge"** means the fixed charge rate as set out in Schedule A, as may be amended by the YUB from time to time;

(cc) **"Force Majeure"** means any event or circumstance suffered by a Party which is not within the reasonable control of the Party claiming Force Majeure and includes, without limitation:

(i) acts of God, including wind, ice and other storms, forest fires, lightning, floods, earthquakes, volcanic eruptions, and landslides;

(ii) strikes, lockouts, and other industrial disturbances, it being acknowledged that the settlement of strikes, lockouts, and other labour disturbances depends upon the agreement of employees and other third Persons and therefore is not wholly within the discretion of the Party involved;

(iii) epidemics, war (whether or not declared), terrorism, blockades, acts of public enemies, acts of sabotage, civil insurrection, riots, and civil disobedience;

(iv) acts or omissions of Governmental Authorities; and

(v) explosions and fires;

(dd) **"Government Approvals"** means all licences, permits, consents, authorizations, or approvals from, withholding of objection on the part of, or filing, registration or qualification with, any and all Governmental Authorities required for any particular decision, act, or event;

(ee) **"Governmental Authority"** means the government of Canada, the government of the Yukon Territory, a municipality or other political subdivision thereof, and any entity exercising executive, legislative, judicial, regulatory, or administrative functions including, without limitation, the YUB, if applicable;

(ff) **"Grid Electricity"** means Electricity delivered under this Agreement by YEC to Alexco from the Transmission Facilities, through the Mine Facilities Spurs to the Mine Facilities;

(gg) **"Initial Mill"** means the mill to be financed, designed, engineered, procured, and constructed by Alexco on the Initial Mill Site;

(hh) **"Initial Mill Site"** means those lands and premises to be used for the Mill that is to be located at Christal Lake, near Keno City, Yukon Territory as shown in Figure B-1 in Schedule B, including any related lands and premises and facilities to be used by Alexco to secure Grid Electricity at the Point of Delivery at the Initial Mill Site;

(ii) **"Initial Mine"** means the mine to be financed, designed, engineered, procured, and constructed by Alexco on the Initial Mine Site;

(jj) **"Initial Mine Facilities"** means the Mine Facilities for the Initial Mine and the Initial Mill;

(kk) **"Initial Mine Facilities Spurs"** means the Mine Facilities Spurs for the Initial Mine Facilities;

(ll) **"Initial Mine Site"** means those lands and premises used for the Mine that is located at as shown in Figure B-2 in Schedule B, including the related lands and premises and facilities currently used, and used in the future, by Alexco to secure Grid Electricity from YEC at the Point of Delivery at the Initial Mine Site;

(mm) "**Interest Rate**" means the interest rate charged by the lead banker of YEC from time to time on unsecured commercial loans made to YEC or if YEC does not have any unsecured commercial loans outstanding at such time, the variable nominal interest rate per annum being the prime interest rate of Canadian Imperial Bank of Commerce (or its successor) for Canadian dollar commercial loans in Canada as publicly declared from time to time as its prime rate;

(nn) "**kV**" means a kilovolt and one kilovolt equals 1,000 volts;

(oo) "**kV.A**" means a kV ampere and one kV ampere equals 1,000 volt-amperes;

(pp) "**kW**" means a kilowatt and one kilowatt equals 1,000 watts;

(qq) "**kW.h**" means a kW hour, the common unit of electrical energy, equal to one kilowatt of power supplied to or taken from an electric circuit for one hour;

(rr) **"Major Industrial Customer"** means a customer of YEC, or of any other regulated electric utility in the Yukon Territory, engaged in manufacturing, processing, or mining whose electrical service is inter-connected with electrical service provided to any other customer of such electric utilities and whose peak Electric Demand exceeds 1,000 kW or any future replacement definition or replacement service capacity threshold applicable to manufacturing, processing or mining activities of Alexco, as approved by the YUB;

(ss) **"Maximum Electric Demand"** means the maximum Electric Demand for Mine Firm Electricity that YEC is be obligated to deliver to Alexco at the Points of Delivery under Part 4;

(tt) "**Mill**" means any one or more mills developed and owned by Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5. and located at the Mill Site that YEC agrees to provide Grid Electricity to under Section 4.5;

(uu) **"Mill Sites"** means those lands and premises to be used for the Initial Mill Site, and those lands and premises and facilities in the District to be similarly used by Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, for any future Mill that Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, develops in the District and that YEC agrees to provide Grid Electricity under Section 4.5, and **"Mill Site"** means any one of them;

(vv) "**Mine**" means any one or more mine projects developed and owned by Alexco, or one of Alexco's Affiliates who becomes a Party to this Agreement under Section 4.5, and located at the Mine Site that YEC agrees to provide Grid Electricity to under Section 4.5;

(ww) "**Mine Facilities**" means the Mills, the Mines, and any substations or facilities financed, designed, engineered, procured, and constructed by Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, to connect a Mill or a Mine to the Mine Facilities Spurs at a Point of Delivery to receive Grid Electricity from YEC under this Agreement, and **"Mine Facility"** means any one of them;

(xx) "**Mine Facilities Closure Date**" for any Mine Facility means the date that the Mine Facility has permanently ceased commercial operation;

(yy) "**Mine Facilities Operation Date**" for any Mine Facility means, as specified in a prior written notice provided by Alexco to YEC, the date on which Alexco wishes the commercial operation for that Mine Facility to occur;

(zz) **"Mine Facilities Shut Down Date"** with respect to a particular Mine Facility is the date provided by Alexco in writing to YEC on which YEC is to initiate permanent termination of any further delivery of Grid Electricity to that Mine Facility under this Agreement;

(aaa) **"Mine Facilities Spurs"** means the YEC transmission connections from the Transmission Facilities to the Points of Delivery, including any transmission line spurs and related switches, fuses, meters, transformers, or other equipment connecting the Transmission Facilities to the Points of Delivery, and "**Mine Facility Spur**" means any one of them;

(bbb) **"Mine Firm Electricity"** means Grid Electricity delivered by YEC to the Mine Facilities on a firm basis;

(ccc) "**Mine Sites**" means those lands and premises to be used for Initial Mine Site, and those lands and premises and facilities in the District to be similarly used by Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, for any future Mine that Alexco, or one of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, develops in the District and that YEC agrees to provide Grid Electricity to under Section 4.5, and **"Mine Site"** means any one of them;

(ddd) **"MV.A"** means thousands of kV amperes;

(eee) **"MW"** means a megawatt, being the electrical unit of power which is equal to 1,000 kW or 1,000,000 watts;

(fff) **"MW.h"** means a MW hour, being the electrical energy equal to one megawatt of power supplied or taken from an electric circuit for one hour;

(ggg) **"Non-Defaulting Party"** has the meaning in Section 10.2;

(hhh) **"ohm"** means a unit of resistance and impedance. One ohm is the resistance of a conductor such that a constant current of one ampere produces a voltage of one volt between the ends of the conductor;

(iii) **"Parties"** means YEC and Alexco and, in the case of Alexco, includes any of Alexco's Affiliates who become a Party to this Agreement under Section 4.5, and **"Party"** means either of them;

(jjj) **"Person"** means an individual, firm, partnership, body corporate, or other legal entity, a government or any department or agency thereof, a trustee, any unincorporated organization and the heirs, executors, administrators, or other legal representatives of an individual, as the case may be;

(kkk) "**Point of Delivery**" means the point at a Mine Facility at which Mine Facilities Spurs are connected to the Mine Facility, with YEC's meter to be located at the Mine Facility side of the YEC disconnect switches and on the primary side of any transformation equipment used as part of the Mine Facilities Spurs and **"Points of Delivery"** means all such points;

(lll) **"Power Factor"** means the ratio at any Point of Delivery of the highest metered kW demand in a billing period to the highest metered kV.A demand in that same billing period;

(mmm) **"Service Charge"** means the late payment charge on any overdue account of YEC as provided for in the ESRs;

(nnn) **"Term"** has the meaning in Section 2.1;

(ooo) **"Transmission Facilities"** means YEC's 69 kV Mayo-Keno transmission facilities located north of Mayo, Yukon Territory, or any future replacement transmission facilities at similar or higher voltage;

(ppp) **"volt"** means the unit of electromotive force or voltage that if steadily applied to having a resistance of one ohm will produce a current of one ampere;

(qqq) **"watt"** the electrical unit of power and the rate of energy transfer when one ampere is passing across one volt; and

(rrr) **"YUB"** means the Yukon Utilities Board.

1.2 Schedules

The following Schedules are attached to and form a part of this Agreement:

Schedule A – Firm Mine Rate;

Schedule B –Initial Mine Facilities Spurs requirements for the Initial Mill Site and the Initial Mine Site; and

Schedule C - Map of District.

1.3 Interpretation

Under this Agreement:

(a) references to voltage are approximate;

(b) words importing the masculine gender include the feminine and neuter genders, and Persons, and words in the singular include the plural, and vice versa, wherever the context requires;

(c) all references to designated Parts and Sections are to the designated Parts and Sections of this Agreement;

(d) using separate Parts and Sections, providing a table of contents, and inserting headings are for convenience only and will not affect how this Agreement is interpreted;

(e) unless otherwise indicated, any reference to a currency is a reference to Canadian currency;

(f) except where otherwise specified, any reference to a statute includes a reference to such statute and to its regulations, with all amendments in force from time to time, and to any statute or regulation that may be passed which has the effect of supplementing or superseding the statute or regulation; and

(g) any reference to a Person includes a reference to any Person that is a successor to that Person.

PART 2
DURATION

2.1 Term

This Agreement will commence as of the date of this Agreement and, unless terminated earlier under this Agreement, will terminate on the date when a Mine Facilities Shut Down Date has occurred for all Mine Facilities and when decommissioning has been completed for all Mine Facilities Spurs and all of the Accrued Decommissioning Fund Amount has been used, set off, or refunded under Section 11.3 (the "**Term**").

PART 3
INITIAL ACTIVITIES

3.1 Filing with YUB

Upon execution and delivery of this Agreement, YEC will proceed diligently to file an application with the YUB seeking YUB approval of the Fixed Charge of $7,289 per month as set out in Schedule A. YEC will provide the YUB with such supporting documentation as required by the YUB for such application. Alexco will support the YEC application to YUB as YEC may reasonably require to obtain the approval of the YUB under this Section 3.1.

3.2 Initial Mine Facilities Spurs

Upon execution and delivery of this Agreement, YEC will exercise commercially reasonable efforts to design, engineer, procure, construct, and commission the Initial Mine Facilities Spurs so as to be able to provide Commencement of Delivery at the Initial Mill Site and the Initial Mine Site as soon as is reasonably possible on or before the Commercial Operation Date anticipated by Alexco, acting reasonably, or such date thereafter as is reasonably possible, and to supply Grid Electricity to the Initial Mill and the Initial Mine.

3.3 Initial Mine Facilities

Upon execution and delivery of this Agreement, Alexco will exercise commercially reasonable efforts, to finance, design, engineer, procure, and construct the Initial Mine Facilities on a timely basis to reach the Commercial Operation Date anticipated by Alexco, acting reasonably, as soon as reasonably practicable and not later than June 30, 2011. Alexco's current estimate of the commissioning of the Initial Mine Facilities is mid-September, 2010. Alexco's current estimate of the actual commercial operation of the Initial Mine Facilities is mid-October, 2010. Alexco will from time to time provide written notice to YEC of Alexco's progress under this Section 3.3 and Alexco's best estimate of the likely Commercial Operation Date and as soon as practical. Alexco will provide written notice to YEC of the Mine Facilities Operation Date for the Initial Mine Site and the Mine Facilities Operation Date for the Initial Mill Site. Alexco will ensure that the Initial Mine Facilities will be able to receive Grid Electricity from YEC at each Point of

Delivery on the Mine Facilities Operation Date for that facility and Alexco will receive Grid Electricity from YEC on the Commencement of Delivery for these Points of Delivery. YEC will provide written notice to Alexco of the date of the Commencement of Delivery for each Point of Delivery for the Initial Mine Facilities. The Parties will use commercially reasonable efforts to cooperate and coordinate their activities as described in this Section 3.3 to ensure the actual commencement of delivery of Grid Electricity at each Point of Delivery occurs at a time mutually agreed to by the Parties.

PART 4
ELECTRICITY

4.1 Electricity to be Made Available

From the Commencement of Delivery for the Initial Mill, YEC will deliver to Alexco and Alexco will purchase from YEC Grid Electricity as Mine Firm Electricity at the Firm Mine Rate until the Commercial Operation Cessation Date has occurred, subject to the Maximum Electric Demand and Electric Energy as follows:

(a) for the periods from the Commencement of Delivery for the Initial Mill until the first anniversary of the Commencement of Delivery for the Initial Mill Maximum Electric Demand of not more than 2,300 kV.A and Electric Energy of approximately 11,800 MW.h/year of Electric Energy at an average monthly peak Electric Demand of 1,850 kV.A, allocated to the following by Points of Delivery:

(i) **Point of Delivery at the Initial Mill:** Maximum Electric Demand of up to 1,550 kV.A and Electric Energy of approximately 7,600 MW.h/year; and

(ii) **Point of Delivery at the Initial Mine:** Maximum Electric Demand of up to 750 kV.A and Electric Energy of approximately 4,200 MW.h/year;

(b) thereafter, Maximum Electric Demand of up to 2,610 kV.A and Electric Energy of approximately 13,400 MW.h/year with the allocation to the Point of Delivery at the Initial Mill of Maximum Electric Demand of approximately 1,760 kV.A and of Electric Energy of approximately 8,800 MW.h/year.

4.2 Alexco Forecasts

Alexco will provide to YEC annual written forecasts ("**Alexco Forecasts**") of the Grid Electricity requirements of the Mine Facilities at the Points of Delivery for each of the succeeding five calendar years, so as to allow YEC to forecast the future Electric Demand and Electric Energy loads on its facilities. The Alexco Forecast will be provided to YEC eight months in advance of each calendar year end (unless otherwise agreed to by YEC in writing), starting upon execution and delivery of this Agreement, and will include load patterns showing the characteristics of the expected Mine Firm Electricity, including the characteristics for Electric Demand and Electric Energy on a monthly basis. Alexco will advise YEC in writing forthwith of any material change to the Alexco Forecasts for Mine Firm Electricity, including the

characteristics for Electric Energy or Electric Demand. During the first week of each month after Commencement of Delivery, Alexco will advise YEC by written notice of its estimated daily requirements for Mine Firm Electricity during the following month.

4.3 Points of Delivery

YEC will deliver Grid Electricity to Alexco and Alexco will receive Grid Electricity from YEC at the Points of Delivery.

4.4 Maximum Electric Demand

YEC's obligation to supply Mine Firm Electricity to Alexco will not exceed the Maximum Electric Demand in effect at any time at any Point of Delivery. Notwithstanding such Maximum Electric Demand, if Alexco receives from YEC Mine Firm Electricity Electric Demand in excess of the Maximum Electric Demand, Alexco will pay for the billing demand charge on all metered kV.A billing demand recorded at the Firm Mine Rate.

4.5 Increase in Maximum Electric Demand, new Point of Delivery, or Addition of Affiliate

(a) If Alexco:

(i) requires an increase to its Maximum Electric Demand in excess of that under Sections 4.1(a) or (b);

(ii) requires a new Point of Delivery for a new Mine Facility; or

(iii) wishes to add an Affiliate and that Affiliate's Point of Delivery and Electric Demand as a Party to this Agreement;

then Alexco will provide YEC with such written information and documentation as YEC may reasonably require for the:

(iv) amount of the requested increase in Electric Demand and the period of time during which the increase in Electric Demand is required;

(v) related increase in Mine Firm Electricity Electric Energy requirement;

(vi) specifications of any new Point of Delivery for such increase in Electric Demand; and

(vii) details of Alexco's Affiliate that wishes to be a Party to this Agreement;

together with such other information YEC may reasonably require to determine any related new Mine Facilities Spurs and related new Capital Costs and Points of Delivery;

(b) after receipt of the written information and documentation under Section 4.5(a), YEC will have a reasonable period of time to determine whether or not the Transmission Facilities and YEC's other facilities have the ability to supply and maintain that increased Electric Demand, Points of Delivery, or Affiliates requested by Alexco under Section 4.5(a) and what, if any:

(i) new Mine Facilities Spurs or other facilities and related new Capital Costs are estimated to be required;

(ii) potential requirement for an increase in the Mine Firm Rate related to such increase; and

(iii) potential new Decommissioning Costs provisions required for the Mine Facilities Spurs or other facilities;

and after having made a determination under this Section 4.5(b), YEC will forthwith provide written notice to Alexco of YEC's determination under this Section 4.5(b);

(c) following such written notice by YEC to Alexco under Section 4.5(b), if the Parties are unable to agree on the matters set out under Section 4.5(b) within a period of 90 days from the date of such written notice by YEC to Alexco, no increase in Maximum Electric Demand, addition of Points of Delivery, or addition of Affiliates will occur. For greater certainty the Parties' failure to agree on the matters set out in Section 4.5(b) will not be a Dispute and will not be subject to Part 12. For further greater certainty, the foregoing in no way limits the rights of, or remedies available to, either Party generally under applicable law or regulation, including but not limited to any rights to refer such failure to agree to a Governmental Authority;

(d) if the Parties are able to agree on the matters set out in Section 4.5(b) within 90 days then the Parties will enter such written amendments to this Agreement as the Parties may reasonably require to reflect such agreements, including without limitation, in the case of the addition of an Affiliate as a Party to this Agreement a written agreement under which such Affiliate agrees to be jointly and severally liable with Alexco and Alexco agrees to be jointly and severally liable with the Affiliate to perform the obligations of the other under this Agreement. If the Parties are unable to execute and deliver such agreements within a period of 120 days of the written notice under Section 4.5(b), no amendments to this Agreement will occur. For greater certainty the Parties' failure to agree on such written agreements will not be a Dispute and will not be subject to Part 12. For further greater certainty, the foregoing in no way limits the rights of, or remedies available to, either Party generally under applicable law or regulation, including but not limited to any rights to refer such failure to agree to a Governmental Authority.

4.6 Alexco Standards for Usage of Electricity

Alexco will regulate its electrical load so that the Power Factor for the Mine Facilities at any Point of Delivery is maintained within a reasonable operating range, as agreed to by the Parties from time to time, acting reasonably. Alexco will operate its equipment and use the Grid Electricity at the Mine Facilities so as not to endanger any of YEC's plant or equipment or cause any unacceptable fluctuations of YEC's electrical system. Alexco will comply with reasonable standards of operation as provided by YEC to Alexco by written notice from time to time. If Alexco fails to comply with these requirements or standards of operation so as to endanger any of YEC's plant or equipment or cause any unacceptable fluctuations on YEC's electrical system, YEC may by written notice to Alexco require that Alexco remedy the situation. Should Alexco fail to immediately comply with this Section 4.6 upon receiving such written notice regarding any Point of Delivery, YEC may immediately suspend the supply of Grid Electricity to Alexco at such Point of Delivery and continue such suspension until the situation is remedied. Upon receipt of such written notice Alexco may provide written notice to YEC that Alexco wishes YEC to operate any such equipment endangering YEC's plant, or equipment, or electrical system at Alexco's sole cost and expense. Upon receipt of such written notice YEC will provide written notice to Alexco as to whether YEC will operate such equipment and in such case Alexco will indemnify and save harmless YEC against any costs, damages, or losses associated with such operations.

4.7 ESRs

The ESRs apply to the Parties with regard to Grid Electricity delivered by YEC to Alexco under this Agreement including, without limitation, the provisions regarding the responsibility and liability of each Party. If there is an inconsistency between the ESRs and this Agreement the ESRs will govern.

4.8 Commercial Operation Cessation Date

Alexco will provide written notice to YEC of a Commercial Operation Cessation Date within 30 days of the occurrence of such Commercial Operation Cessation Date.

PART 5
CAPITAL COSTS

5.1 Initial Mine Facilities Spurs Capital Costs for Connecting Initial Mill and Initial Mine

(a) As at the date of this Agreement, the YEC estimate for the Capital Costs related to the Initial Mine Facilities Spurs to connect the Initial Mill and the Initial Mine is $330,000, and the YEC estimate for the Capital Costs to negotiate and conclude this Agreement is $100,000. Within 30 days of the execution and delivery of this Agreement, YEC will invoice Alexco for 50% of such estimated Capital Costs, and within 15 days of receipt of said invoice Alexco will pay the invoice to YEC.

(b) YEC will invoice Alexco for, and within 15 days of receipt of said invoice Alexco will pay to YEC, the amount by which the actual Capital Costs related to the Initial Mine Facilities Spurs exceeds the related amount invoiced under Section 5.1(a), within 30 days of the date on which YEC provides written notice to Alexco that, in the reasonable opinion of YEC, the Initial Mine Facilities Spurs for the Initial Mill and the Initial Mine are commissioned and are available to provide Grid Electricity to Alexco from the Initial Mine Facilities Spurs under this Agreement.

(c) YEC will invoice Alexco for, and within 15 days of receipt of said invoice Alexco will pay to YEC, the amount by which the actual Capital Costs related to the negotiation and conclusion of this Agreement exceeds the related amount invoiced under Section 5.1(a), as and when such actual Capital Costs are incurred and are invoiced to or paid by YEC.

(d) If the final actual Capital Costs for either the Initial Mine Facilities Spurs or the negotiation and conclusion of this Agreement are less than the related amount invoiced under Section 5.1(a), within a reasonable period of time of that determination YEC will set the difference off against any other amounts owed by Alexco to YEC under this Agreement or will refund the difference to Alexco.

5.2 Capital Costs for Other Mine Facilities Spurs

Alexco will pay to YEC the Capital Costs for any new Mine Facilities Spurs that YEC agrees to develop after the Initial Mine Facilities Spurs, as provided for in Section 4.5, with payment by Alexco to YEC of 50% of YEC's estimated costs for such facilities prior to YEC starting to order equipment for, or to construct, such new Mine Facilities Spurs, and with the balance of such Capital Costs to be paid by Alexco to YEC within 30 days of notice by YEC that such new Mine Facilities Spurs are commissioned and available to receive Grid Electricity to provide to Alexco. When the actual Capital Cost for such new Mine facilities Spurs is determined by YEC to be greater or less than the amount paid to date by Alexco, YEC will so notify Alexco in writing as soon as practical thereafter and an appropriate adjustment will be made between the Parties from the date such determination is made.

PART 6
BILLING/PAYMENT AND SECURITY

6.1 Alexco Power Bill

As soon as practicable following the last day of each month after the Commencement of Delivery for the Initial Mill, YEC will deliver the Alexco Power Bill to Alexco in writing setting out the amount payable to YEC by Alexco under this Agreement for all Electricity delivered by YEC to Alexco during such month. Alexco will pay YEC the amount set out in each Alexco Power Bill within 15 Business Days of the date of delivery of the Alexco Power Bill to Alexco. Electricity provided by YEC to Alexco will be charged to Alexco at the rates provided for in this Agreement. If permitted by the ESRs or YUB, the Electric Demand and Electric Energy at the

Points of Delivery will be totalled and only one bill will be issued for such Points of Delivery. If Alexco's Affiliates become a Party to this Agreement under Section 4.5 the amounts payable by such Affiliate will be included on the Alexco Power Bill and will be payable by Alexco and such Affiliate jointly and severally under this Part 6.

6.2 Canadian Funds

All payments by Alexco to YEC will be made in Canadian funds to an office or banker of YEC, as YEC may direct to Alexco in writing, at Whitehorse, Yukon Territory.

6.3 Failure to Render Invoice

Failure to render an invoice within the time periods set out in this Agreement will not abrogate YEC's right to receive payment of the Alexco Power Bill, Capital Cost, Decommissioning Costs, or other amounts payable under this Agreement.

6.4 Late Payment

Any payment to be made by Alexco to YEC under this Agreement that remains unpaid, in whole or in part, when due will be subject to a late payment charge at a rate of interest equivalent to the Service Charge calculated on the amount unpaid from the due date of payment until payment is made in full.

6.5 Prepayments

Any payments to be made by Alexco to YEC under this Agreement may be prepaid by Alexco at any time in whole or in part without penalty.

6.6 Taxes

All sales taxes, excise taxes, or similar charges payable on Electricity delivered to Alexco under this Agreement will be added to the Alexco Power Bill and paid by Alexco under Section 6.1.

6.7 Fixed Charge

Each time that a Major Industrial Customer proposes to commence for the first time to receive Grid Electricity from the Transmission Facilities, YEC will determine on a reasonable basis a proposed amended Fixed Charge applicable to Alexco reflecting an allocation of costs relating to the Transmission Facilities among the new Major Industrial Customer, Alexco, and all other Major Industrial Customers receiving Grid Electricity from the Transmission Facilities at that time. YEC will then, on a timely basis, make application to the YUB seeking the YUB approval of such proposed amended Fixed Charge. YEC will provide the YUB with such supporting documentation as required by the YUB for such application, and will use commercially reasonable efforts to obtain the approval of the YUB for such proposed amended Fixed Charge for Alexco, and Alexco will use commercially reasonable efforts to support such application by YEC.

PART 7
METERING

7.1 Metering

The Electricity purchased by Alexco under this Agreement will be measured and recorded at the Points of Delivery by revenue meters having one hour integrating intervals, which meters, will be types approved for revenue metering by Industry Canada and will comply with the *Electricity and Gas Inspection Act* (the "**Act**").

7.2 Testing

YEC will test its metering equipment under Section 7.1 and field test the metering installation in compliance with the Act. If requested to do so by Alexco, YEC will make additional tests or inspections of such installations, the expense of which will be paid by Alexco, unless Alexco has confirmed by such testing that the metering is faulty in which case such testing will be paid for by YEC. YEC will give reasonable written notice to Alexco of the time when any such test or inspection is to be made. Alexco may have representatives present at such test or inspection. Any component of such installations found to be defective or inaccurate will be adjusted, repaired, or replaced by YEC to provide accurate metering. If a meter is found not to be functioning within the prescribed limit of error, the Electricity purchased will be determined under the Act.

7.3 Backup Metering

Alexco may, at its cost and expense, install a backup metering system to check YEC's metering system performance and, if so, Alexco will own, operate, and maintain this system, at Alexco's sole cost and expense.

7.4 Costs

All costs and expenses incurred by YEC, beyond normal reading and testing of meters and other costs that YEC is to pay under Section 7.2, in complying with its obligations under this Section 7.2 will be invoiced separately to Alexco by YEC and will be paid by Alexco upon receipt.

PART 8
FORCE MAJEURE

8.1 Force Majeure

Subject to Section 8.3, neither Party will be liable to the other Party for any delay in or inability of the first Party to perform its obligations under this Agreement if any such delay or inability is a direct result of Force Majeure.

8.2 Notice of Force Majeure

If a Party suffers a Force Majeure it will promptly notify the other Party in writing and within 10 days of becoming so aware will give written notice to the other Party:

(a) describing the Force Majeure in reasonable detail and stating, to the extent reasonably practicable at such time, its estimate of the duration of the Force Majeure;

(b) setting out in reasonable detail the obligations under this Agreement which it is unable to perform or will be delayed in performing as a direct result of the Force Majeure;

(c) containing particulars of the circumstances causing the Party to be unable to perform or delayed in performing its obligations under this Agreement as a direct result of the Force Majeure; and

(d) describing what needs to be done and what will be done to end the Force Majeure.

During a Force Majeure a Party invoking the Force Majeure will exercise commercially reasonable efforts to end the Force Majeure.

8.3 Exclusions

A Party may not invoke Force Majeure:

(a) for lack of money or credit;

(b) if the Force Majeure is the result of a breach by the Party seeking to invoke Force Majeure of a permit, certificate, licence, approval, or of any applicable laws, regulations, or orders;

(c) if the Party seeking to invoke Force Majeure has failed to use commercially reasonable efforts to prevent or remedy the situation and remove, so far as possible and with reasonable dispatch, the effects of the Force Majeure; or

(d) if the Force Majeure was caused by a breach of, or default under this Agreement or a wilful or negligent act or omission by the Party seeking to invoke Force Majeure.

If a Party is required to perform an obligation by a certain date or with a specified time period and the Party is delayed in performing that obligation by a Force Majeure the date or time for the performance of that obligation will be extended by a period of time equal to the length of the Force Majeure.

PART 9
REPRESENTATIONS AND WARRANTIES

9.1 YEC Representations and Warranties

To induce Alexco to enter into this Agreement YEC hereby represents and warrants to Alexco as of the effective date of this Agreement, upon each of which representations and warranties Alexco specifically relies, as follows:

(a) **YEC Corporate Organization and Authority:** YEC has been duly incorporated and is a validly existing corporation under the laws of the Yukon Territory, is in good standing with respect to all required filings in the office of the Registrar of Companies and has the full corporate power and capacity to execute and deliver this Agreement and perform its obligations under this Agreement.

(b) **Authorization, Consents, and Enforceability:** The execution and delivery of this Agreement by YEC and the consummation by YEC of the transactions contemplated hereby have been duly authorized by the Board of Directors of YEC and this Agreement constitutes valid and binding obligations of YEC, enforceable against YEC in accordance with its terms, subject to the availability of equitable remedies and enforcement of creditors' rights generally.

(c) **Compliance:** The entering into and compliance by YEC with this Agreement is legal, does not violate any provisions of any requirement of law and does not result in any breach of any of the provisions of, or constitute a default under any charter document, by-law, unanimous shareholder agreement, loan agreement, or other agreement or instrument to which YEC is a party or by which it is or its property may be bound.

9.2 Alexco Representations and Warranties

To induce YEC to enter into this Agreement Alexco hereby represents and warrants to YEC as of the effective date of this Agreement, upon each of which representations and warranties YEC specifically relies, as follows:

(a) **Alexco Corporate Organization and Authority:** Each of AXR, AKHM, and ERDC has been duly incorporated and is a validly existing corporation under the laws of the Province of British Columbia with respect to AXR and AKHM and the laws of the Yukon Territory with respect to ERDC and is in good standing with respect to all required filings in the office of the Registrar of Companies and has the full corporate power and capacity to perform business in the Yukon and to execute and deliver this Agreement and perform its obligations under this Agreement.

(b) **Authorization, Consents, and Enforceability:** The execution and delivery of this Agreement by AXR, AKHM, and ERDC and the consummation by AXR, AKHM, and ERDC of the transactions contemplated hereby have been duly

authorized by the respective Boards of Directors of AXR, AKHM, and ERDC and this Agreement has been duly executed and delivered by AXR, AKHM, and ERDC and constitutes valid and binding obligations of AXR, AKHM, and ERDC, enforceable against AXR, AKHM, and ERDC in accordance with its terms, subject to the availability of equitable remedies and enforcement of creditors' rights generally.

(c) **Compliance:** The entering into and compliance by AXR, AKHM, and ERDC with this Agreement is legal, does not violate any provisions of any requirement of law and does not result in any breach of any of the provisions of, or constitute a default under any charter document, by-law, loan agreement, or other agreement or instrument to which AXR, AKHM, or ERDC is a party or by which they or their property are or may be bound.

PART 10
DEFAULT

10.1 Event of Default

Each of the following events constitutes an "**Event of Default**" for a Party in question (the "**Defaulting Party**"):

(a) an Event of Insolvency of such Party; or

(b) any representation or warranty of such Party contained in this Agreement being untrue in any material respect unless the default is of a nature that can be cured and it is cured within 30 days, or such reasonable time period as may be required given the default, following receipt by the Defaulting Party of written notice from the other Party specifying the nature of the default and requiring that the default be cured; or

(c) any default (other than defaults of a non-material nature) by such Party in the performance or observance of any of the covenants, agreements, and obligations on its part to be performed or observed under this Agreement, unless the default is of a nature that can be cured and it is cured within 30 days, or such reasonable time period as may be required given the default, following receipt by the Defaulting Party of written notice from the other Party specifying the nature of the default and requiring that the default be cured.

10.2 Remedies

If an Event of Default under Section 10.1 occurs, any Party not in default (the "**Non-Defaulting Party**") may do one or more of the following:

(a) pursue any remedy available to it in law or equity, it being acknowledged by the Parties that specific performance, injunctive relief (mandatory or otherwise), or other equitable relief may be the only adequate remedy for an Event of Default; or

(b) if the Event of Default is curable, take all actions in its own name or in the name of the Defaulting Party as may reasonably be required to cure the Event of Default, in which event all payments, costs, and expenses incurred therefore will be payable by the Defaulting Party to the Non-Defaulting Party on demand with interest at the Interest Rate; or

(c) waive the Event of Default, provided any waiver of the particular Event of Default will not operate as a waiver of any subsequent or continuing Event of Default; or

(d) in the case of an Event of Default by Alexco under Section 6.1 YEC may suspend or discontinue the supply of Grid Electricity to Alexco but no such suspension or discontinuance by YEC will relieve Alexco of its obligations under this Agreement, including the obligation to make payment of any sum, nor will any such suspension or discontinuance constitute or be deemed to constitute rescission of this Agreement.

PART 11
DECOMMISSIONING

11.1 Decommissioning Costs

Alexco will be responsible for all Decommissioning Costs incurred by YEC. Alexco will provide YEC with written notice within 15 days of the occurrence of a Mine Facilities Closure Date at any Mine Facility. Alexco will exercise commercially reasonable efforts to provide YEC with not less than six months prior written notice of an anticipated Mine Facilities Shut Down Date at any Mine Facility, and will provide YEC with immediate written notice if Alexco reasonably anticipates that a Mine Facilities Shut Down Date will occur at any Mine Facility within less than six months time. Subject to receiving reasonable written notice of the Mine Facilities Shut Down Date for a Mine facility, on or before the Mine Facilities Shut Down Date for a Mine Facility YEC will provide written notice to Alexco of the parts of the Mine Facilities Spur to be decommissioned as soon as is feasible after the Mine Facilities Shut Down Date, and after such date YEC will exercise commercially reasonable efforts to carry out and complete such decommissioning as soon as is reasonably feasible.

11.2 Accrued Decommissioning Fund

YEC will establish the Accrued Decommissioning Fund account, and Alexco will make the Decommissioning Cost Payment to YEC, as follows:

(a) YEC will deposit the Decommissioning Cost Payment for any Mine Facilities Spur into the Accrued Decommissioning Fund, and invest the Accrued Decommissioning Fund at 6.5% interest per annum to fund YEC's regulated rate base during the Term under this Part 11;

(b) after the determination of the final Capital Cost incurred by YEC for a Mine Facilities Spur for any Mine Facility, YEC will inform Alexco in writing of the

Estimated Decommissioning Costs of the Mine Facilities Spur for that Mine Facility;

(c) at the same time as Alexco provides written notice to YEC (or a determination is made under this Section 11.2) of the Mine Facilities Closure Date for any Mine Facility, Alexco will make a Decommissioning Cost Payment to YEC equal to the Estimated Decommissioning Costs for those parts of the Mine Facilities Spur for that Mine Facility for which YEC has given written notice to Alexco under Section 11.1;

(d) if Alexco fails to notify YEC in writing of the occurrence of a Mine Facilities Closure Date for any Mine Facility, YEC may provide Alexco with written notice of Dispute on this matter.

11.3 Application of Accrued Decommissioning Fund and Payment of Decommissioning Costs

After the Mine Facilities Shut Down Date for a Mine Facility, the Accrued Decommissioning Fund Amount will be used to pay the actual Decommissioning Costs for those parts of the Mine Facilities Spur for that Mine Facility for which YEC has given written notice to Alexco under Section 11.1. If the actual Decommissioning Costs exceed the Accrued Decommissioning Fund Amount for such parts of that Mine Facilities Spur, Alexco will pay to YEC the amount of the excess. Such excess costs will be invoiced by YEC within 10 Business Days of the end of the month in which the costs are incurred. Alexco will pay YEC the amount set out in each such invoice on or before the 15th Business Day after the invoice is received. If the Accrued Decommissioning Fund Amount for such parts of that Mine Facilities Spur exceeds the actual Decommissioning Costs, YEC will:

(a) set the excess, if any, off against any other amounts owed by Alexco to YEC under this Agreement; and

(b) then refund the remaining excess, if any, to Alexco within 15 Business days after the actual Decommissioning Costs are determined by YEC.

PART 12
DISPUTE RESOLUTION

12.1 Confidentiality of Process.

The Parties will maintain the dispute resolution process set out in this Part 12 as confidential and such process will not be disclosed, unless otherwise required by law, by any Party to any other Person unless previously discussed and agreed to in writing by the Parties. For greater certainty, no part of the dispute resolution process will be open to the public.

12.2 Stages.

Disputes that arise among the Parties will progress, until resolved, through the following stages of the dispute resolution process:

Step 1: Within 10 days of one Party providing written notice to the other Parties that a Dispute exists, the Presidents of each of the Parties, or their nominees in the first instance or themselves if they cannot resolve the Dispute, will meet and make good faith efforts to resolve the Dispute through collaborative negotiation by:

(i) identifying underlying interests;

(ii) isolating points of agreement and disagreement;

(iii) exploring alternative solutions;

(iv) considering compromises or accommodations; and

(v) taking any other measures that may assist in resolution of the Dispute.

Step 2: If the Presidents of each of the Parties are unable to resolve the Dispute themselves within 30 days of the written notice under Step 1, either Party may give written notice to the other Party of a desire to commence mediation and the Parties will jointly appoint a mutually acceptable mediator within 30 days after the date that such notice is given. If the Parties are unable to agree upon the appointment of a mediator within 30 days after a Party has given notice of a desire to mediate the Dispute, either Party may apply to the British Columbia Mediator Roster Society for appointment of a mediator. The Parties agree that the mediation will be conducted under the Mediation Rules of the British Columbia Mediator Roster Society.

Step 3: If a Dispute has not been resolved through mediation under Step 2 within 30 days of the appointment of a mediator, either Party, by notice in writing to the other Party, may refer such unresolved Dispute to binding arbitration under the *Arbitration Act*, (R.S.Y., 2002, c.8). The Parties will agree upon an Arbitrator within 30 days of the notice of arbitration being provided, failing which the Arbitrator will be selected under the *Arbitration Act*, (R.S.Y., 2002, c.8). The decision of the arbitrator will be final and binding on the Parties.

12.3 Availability of Argument.

In any Dispute, a Party may raise any defence or argument that it would otherwise have been able to raise at law, equity, or otherwise, had the Dispute been referred to a court of competent jurisdiction, including a defence that the Dispute is statute-barred by the *Limitation of Actions Act*, (R.S.Y., 2002, c.139).

12.4 No Further Claims.

When Disputes are settled among the Parties to the Agreement under this Part 12:

(a) no further claim may be made; and

(b) no further compensation will be payable by any Party,

for the same Dispute.

12.5 Continued Payment

Pending resolution of any Dispute, Alexco will continue to pay to YEC any sums payable under this Agreement and YEC may avail itself of its remedy under Section 10.2(d) in relation to a failure by Alexco to do so.

PART 13
INDEMNITY

13.1 Limitation of Liability

No Party will be liable to the other Party in contract, tort, warranty, strict liability, or any other legal theory for any indirect, consequential, incidental, punitive, or exemplary damages arising under or in connection with this Agreement or in connection with the failure to perform or observe obligations under this Agreement. No Party will have any liability to the other Party except under, or for breach of, this Agreement provided, however, that this Section 13.1 is not intended to constitute a waiver of any rights of one Party against the other Party for matters which are unrelated to this Agreement.

13.2 Indemnification

(a) Alexco will indemnify and save YEC harmless for any loss or damage to property, death, or injury to Persons (or any claim against YEC in respect thereof) and all expenses relating thereto (including without limitation reasonable legal fees) suffered or incurred by YEC in connection with this Agreement resulting from any negligence or wilful default of Alexco in connection with the performance of its obligations under this Agreement or a breach by Alexco of its obligations under this Agreement. The indemnity will not extend to any loss, damage, death, or injury (or any claim in respect thereof) or any expenses relating thereto to the extent that it was caused by the negligence or wilful default of YEC or the failure of YEC to take reasonable steps in mitigation thereof. Notwithstanding anything to the contrary contained in the preceding sentence, nothing in this Section 13.2(a) will apply to any loss, damage, cost, or expense in respect to which, and to the extent that, YEC is compensated under any insurance, agreement, or through any other means.

(b) YEC will indemnify and save Alexco harmless for any loss of or damage to property, death or injury to person (or any claim against Alexco in respect thereof) and all expenses relating thereto (including without limitation reasonable legal fees) suffered or incurred by Alexco in connection with this Agreement from any negligence or wilful default of YEC in connection with the performance of its obligations under this Agreement or a breach by YEC of its obligations under this Agreement. The indemnity will not extend to any loss, damage, death, or injury (or any claim in respect thereof) or any expenses relating thereto to the extent that it was caused by the negligence or wilful default of Alexco or the failure of Alexco to take reasonable steps in mitigation thereof. Notwithstanding anything to the contrary contained in this preceding sentence, nothing in this Section 13.2(b) will apply to any loss, damage, cost or expense in respect of which, and to the extent that, Alexco is compensated under any insurance, agreement, or through any other means.

(c) If such injury or damage results from the joint or concurrent negligent or intentional acts of the Parties each will be liable under this indemnification in proportion to its relative degree of fault.

13.3 Assertion of Claims

Neither Party will be entitled to assert any claim for indemnification until such time as all claims of such Party for indemnification under this Agreement exceed an amount equal to $10,000, in the aggregate, at which time all claims of such Party for indemnification under this Agreement may be asserted; provided, however, that when such claims have been asserted the same rule will apply in respect of future claims. Notwithstanding the preceding sentence, either Party may assert a claim for indemnification regardless of amount upon the expiry or earlier termination of this Agreement or if such claim would otherwise be barred by the *Limitation of Actions Act*, (R.S.Y., 2002, c.139).

13.4 Defence of Claims

The indemnified Party will have the right, but not the obligation, to contest, defend, and litigate any claim, action, suit, or proceeding by any Person alleged or asserted against such Party in respect of, resulting from, related to, or arising out of any matter for which it is entitled to be indemnified under this Agreement, and the reasonable costs and expenses thereof will be subject to the indemnification obligations of the indemnifying Party under this Agreement provided, however, that if the indemnifying Party acknowledges in writing its obligations to indemnify the indemnified Party in respect of loss to the full extent provided by Section 13.2, the indemnifying Party will be entitled, at its option, to assume and control the defence of such claim action, suit, or proceeding at its expense and through counsel of its choice if it gives prompt notice of its intention to do so to the indemnified Party and, reimburses the indemnified Party for the reasonable costs and expenses incurred by the indemnified Party prior to the assumption by the indemnifying Party of such defence, and provides reasonably adequate security for any judgment for costs that might be imposed on the indemnified Party. The indemnified Party will not be entitled to settle or compromise any such claim action, suit, or proceeding without the prior

written consent of the indemnifying Party, which consent will not be unreasonably withheld or delayed. The indemnified Party will have the right to employ its own counsel and such counsel may participate in such action (but the fees and expenses of such counsel will be at the expense of such indemnified Party), provided that the:

(a) employment of counsel by such indemnified Party has been authorized in writing by the indemnifying Party;

(b) indemnified Party will have reasonably concluded that there may be a conflict of interest between the indemnifying Party and the indemnified Party in the conduct of the defence of such action;

(c) indemnifying Party will not in fact have employed independent counsel reasonably satisfactory to the indemnified Party to assume the defence of such action and will have been so notified by the indemnified Party; or

(d) indemnified Party will have reasonably concluded and specifically notified the indemnifying Party either that there may be specific defences available to it which are different from or additional to those available to the indemnifying Party or that such claim action, suit, or proceeding involves or could have a material adverse effect upon it beyond the scope of this Agreement.

If Sections 13.4(a), (b), (c), or (d) are applicable, then counsel for the indemnified Party will have the right to direct the defence of such claim, action, suit, or proceeding on behalf of the indemnified Party and the reasonable fees and disbursements of such counsel will constitute legal or other expenses under this Agreement.

PART 14
ASSIGNMENT

14.1 Assignment

Neither Party may assign this Agreement without the prior written consent of the other Party, such consent not to be unreasonably withheld.

14.2 Sale of the Transmission Facilities

If YEC disposes of all or any interest in the Transmission Facilities, the Mine Facilities Spurs or YEC's other assets required to meet YEC's obligations under this Agreement, YEC will ensure that the obligation to sell Grid Electricity from the Transmission Facilities or the Mine Facilities Spurs, on the same basis as provided for in this Agreement will continue and be assumed by the purchaser of such interest, for the Term. YEC will require, as a condition of the closing of the disposition of such interest, that the purchaser sign an agreement in a form satisfactory to Alexco, acting reasonably, which provides that the purchaser agrees to be bound by this Agreement.

14.3 Sale of the Mine Facilities

If Alexco disposes of all or any interest in the Mine Facilities, Alexco will ensure that the obligation to purchase Grid Electricity from YEC on the same basis as provided for in this Agreement will continue and be assumed by the purchaser of the Mine Facilities for the Term. Alexco will require as a condition of the closing of the disposition of the Mine that the purchaser sign an agreement in a form satisfactory to YEC, acting reasonably, which provides that the purchaser agrees to be bound by this Agreement for the Term.

PART 15
CONFIDENTIALITY

15.1 Confidentiality.

Except as required by law, and subject to Section 15.1, a Party will not disclose to a third person who is not a Party any information, data, or documents, supplied by one Party to the other Parties under this Agreement (collectively, the **"Confidential Information"**) without the consent of the other Party, such consent not to be unreasonably withheld.

15.2 Exceptions.

Section 15.1 will not:

(a) extend to information that is already in the public domain or becomes, after having been disclosed to a Party, generally available to the public unless the disclosure was made directly or indirectly by a Party in breach of this Agreement;

(b) prevent a Party from divulging Confidential Information in confidence to its Affiliates and to its or their officers, directors, employees, agents, or other representatives on a "need-to-know" basis;

(c) prevent a Party from divulging Confidential Information in confidence to third parties (provided the third party is subject to similar confidentiality restrictions), in order to permit the operation of the Mine or the Transmission Facilities, as the case may be, in the ordinary course, all on a "need-to-know" basis;

(d) prevent a Party from divulging Confidential Information to the extent required by applicable legislation or stock exchange requirements;

(e) prevent a Party from divulging Confidential Information to the extent necessary in connection with any dispute resolution commenced under this Agreement or any litigation commenced in respect of this Agreement;

(f) prevent a Party from divulging Confidential Information to the extent necessary, in confidence, to any financial institution for the purpose of obtaining financing for such Party or any of its Affiliates;

(g) prevent a Party from divulging Confidential Information to the extent required by any Governmental Authority having jurisdiction to require the production of such Confidential Information; and

(h) prevent a Party from divulging Confidential Information to the extent necessary, in confidence, to a prospective purchaser of the Mine or the Transmission Facilities or YEC's other assets required to meet YEC's obligations under this Agreement, as the case may be, on a "need to know" basis.

If any Party is required to disclose Confidential Information under Sections 15.2(d), (e), or (g), such Party will advise the other Party in writing in advance of any such disclosure where reasonable so that the other Party may take such action as they consider necessary to maintain the confidentiality of such Confidential Information, and will take reasonable steps to limit the extent of the disclosure and to make such disclosure confidential under the applicable legislation, stock exchange rules, or rules of any governmental or regulatory authority having jurisdiction, as the case may be.

15.3 Survival

The obligations of confidentiality in Section 15.1 will survive the termination or expiry of this Agreement indefinitely, and any Party who ceases to be a Party will continue to be bound by such obligations following such termination or expiry.

15.4 Injunctive Relief

Each Party acknowledges that all Confidential Information is proprietary to the disclosing Party and that breach of this Agreement by a Party may result in irreparable injury to the other Party. Accordingly, in the event of any breach of Section 15.1 by a Party, the other Party will be entitled to seek and obtain an order of specific performance, restraining order, or injunctive relief, in addition to any other legal or equitable remedies provided under this Agreement.

PART 16
GENERAL

16.1 Notices

Except as otherwise provided in this Agreement, any notice, direction, demand, request, or document required or permitted to be given by any Party to any other Party under this Agreement will be in writing and deemed to have been sufficiently given if signed by or on behalf of the Party giving the notice and delivered or transmitted by facsimile to the other Party's address or facsimile number as shown below:

To YEC:

Yukon Energy Corporation
P.O. Box 5920, #2 Miles Canyon Road
Whitehorse, YT Y1A 6S7

Attention: President

Facsimile: 867-393-5323

with a copy to:

Davis LLP
2800 - 666 Burrard Street
Vancouver, BC V6C 2Z7

Attention: John Landry

Facsimile: 604-605-3588

To Alexco:

Alexco Resource Corp.
1150 - 200 Granville Street
Vancouver, BC V6C 1S4

Attention: Clynton R. Nauman, CEO, President

Facsimile: 604-633-4887

with a copy to:

Fasken Martineau DuMoulin LLP
2900 - 550 Burrard Street
Vancouver, BC V6C 0A3

Attention: Kai Alderson

Facsimile: 604-631-3232

or to such other address or facsimile number or to the attention of such other official or individual as a Party will have most recently notified the other Party of in the manner hereinbefore provided. Any such notice, direction, request, or document will conclusively be deemed to have been received by the intended recipient on the date of delivery or transmission, as the case may be, except that if it is not received at such address or at the facsimile device by 5:00 P.M. on a Business Day (at the place of receipt) it will conclusively be deemed to have been received by the intended recipient on the next Business Day immediately following its receipt at such address or at such facsimile device.

16.2 Coordination of Communications

Each Party agrees to cooperate with the other Parties in order to coordinate all press, news, or other releases to private or public media groups in connection with this Agreement. Each Party will use all reasonable efforts to allow the other Parties to review such releases in advance of release and will comply with all reasonable requests from the other Parties as to the content or manner of publication of such releases.

16.3 Amendment

The only amendments, which may be made to this Agreement are amendments in writing which have been approved by the Parties.

16.4 Governing Law and Language

This Agreement will be governed by and construed under the laws of the Yukon Territory and applicable Canadian law and will be treated in all respects as a Yukon Territory contract.

16.5 Submission to Jurisdiction

Each of the Parties will:

(a) submit to the jurisdiction of the Yukon Territory courts;

(b) if not incorporated or registered in the Yukon Territory appoint an agent to receive service of any process in the Yukon Territory; and

(c) if any appointed agent is required, notify the others of the name and address of its appointed agent.

16.6 Severability

Each provision of this Agreement is intended to be severable and if any provision is illegal or invalid, such illegality or invalidity will not affect the validity of this Agreement or the remaining provisions.

16.7 Entire Agreement

(a) This Agreement and any other arrangement in writing between any of the Parties, which is entered into substantially contemporaneously with this Agreement constitute the entire agreement between the Parties relating to the subject matter of this Agreement and supersedes all prior negotiations and agreements, whether written, oral, implied or collateral, between the Parties, provided, however, that any confidentiality agreements, or confidentiality provisions contained in any agreements, executed between the Parties in connection with the transactions contemplated in this Agreement will continue in full force and effect and will survive any termination of this Agreement.

(b) No representation or inducement whether made by statement or delivery of data or other information of any kind or nature whatsoever and whether in writing, orally or in any other manner conveyed by any Party to any other Party survives the execution of this Agreement unless expressly made in this Agreement.

16.8 Further Assurances

As and so often as any Party may reasonably require, the Parties agree to execute and deliver further and other documents, assurances and conveyances as may be necessary to properly carry out the intention of this Agreement.

16.9 Successors and Assigns

This Agreement enures to the benefit of and will be binding upon the Parties and their respective permitted successors and permitted assigns.

16.10 Waivers

No provision of this Agreement may be waived except by a written instrument and any waiver of a provision:

(a) is valid only in respect of the specific instance to which it relates and is not a continuing waiver; and

(b) is not to be construed as a waiver of any other provision.

16.11 Time

Subject to Part 8, time is of the essence of this Agreement.

16.12 Counterparts

This Agreement may be executed in any number of counterparts with the same effect as if the Parties had signed and delivered the same document. All counterparts will be construed together and will constitute one and the same agreement. This Agreement will be duly executed and delivered if facsimile signature pages are exchanged by the Parties.

16.13 Joint and Several

The obligations, representations, and warranties of Alexco under this Agreement are joint and several obligations of each of AXR, AKHM, and ERDC.

This Agreement is executed in multiple originals effective as of the day and year first written above.

SCHEDULE A

FIRM MINE RATE

RATE SCHEDULE 39

INDUSTRIAL PRIMARY

AVAILABLE: Throughout the service areas of Yukon Energy Corporation (**"YEC"**) served by the Whitehorse-Aishihik-Faro and Mayo-Dawson systems.

APPLICABLE: To all major industrial customers engaged in manufacturing, processing or mining with an electric service capacity in excess of 1,000 kW.

RATE: Charges in any one billing month will be the sum of the following:

(a) Demand Charge of $15.00/kV.A of Billing Demand

(b) Energy Charge of 7.60¢/kW.h for all energy used.

(c) Fixed Charge

For service to Alexco mine and mill sites, the Fixed Charge each month will equal $7,289 as required under the Power Purchase Agreement (the **"PPA"**) dated September 1, 2010 between YEC and Alexco Resource Corp.(**"Alexco"**) for existing transmission connection to the mine and mill sites.

PEAK SHAVING CREDIT: For customers with an established Winter Contract Load in good standing, a Peak Shaving Credit in each billing month equal to 50% of the Demand Charge times the Peak Shaved Load.

MINIMUM MONTHLY BILL: The minimum monthly bill will be the sum of the Demand Charge and the monthly Fixed Charge, less any applicable Peak Shaving Credit.

PEAK SHAVED

Davis:5203362.15
DM_VAN/262912-00049/7651578.3

LOAD: Peak Shaved Load in any billing month is the amount by which then nominated Winter Contract Load is less than the Billing Demand for the month.

BILLING DEMAND: The Billing Demand will be the greater of:

(a) the highest metered kV.A demand recorded in the current billing month; or

(b) the highest metered kV.A demand recorded in the previous 12-month period including the current billing month, excluding the months April through September; or

(c) the contract minimum demand.

WINTER CONTRACT LOAD: A customer may, by six month written notice to YEC, nominate a Winter Contract Load at not less than two-thirds of the customer's contract maximum demand subject to the following conditions:

a) the customer will thereby contract with YEC not to exceed the nominated Winter Contract Load whenever the temperature at Whitehorse is below -30 degrees Centigrade, based on YEC informing the customer by phone, fax or e-mail as to forecast and actual winter temperatures at Whitehorse as provided for in paragraph (b) below;

b) YEC will inform the customer at least one hour in advance, and not more than one day in advance, of a forecast temperature at Whitehorse being below -30 degree Centigrade; thereafter, until YEC informs the customer otherwise, the customer will be responsible for ensuring that its metered kV.A demand does not exceed the Winter Contract Load during any hour when the actual temperature at Whitehorse is below -30 degrees Centigrade; YEC will inform the customer forthwith when the temperature at Whitehorse is no longer forecast to be below -30 degree Centigrade within the next 24 hours;

c) the customer agrees that the contract for the nominated Winter Contract Load will continue until terminated by

written notice of not less than 12 months by the customer to YEC;

d) if during such contract period for the Winter Contract Load the customer's metered kV.A demand recorded, after YEC has provided notice as specified in paragraph (b) above, exceeds the Winter Contract Load when the temperature at Whitehorse is less than -30 degrees Centigrade, the Winter Contract Load contract will be terminated forthwith, the customer will forthwith be required to repay to YEC all Peak Shaving Credits determined within the previous 12 billing months, and the customer will also pay for that billing month to YEC as penalty an amount equal to four times the Demand Charge on the metered kV.A demand recorded in excess of the Winter Contract Demand; in addition, YEC reserves the right if so required to meet system loads when the temperature at Whitehorse is less than 30 degrees Centigrade during the then current month and the following 12 months to interrupt electricity supplied to the customer in excess of the previous Winter Contract Load.

BASE LOAD ENERGY:

A Base Load Energy amount per month may be established for a customer of 90% of forecast use when YEC expects to require diesel fuel generation to service use in excess of such a Base Load Energy amount. At such time, Rate Schedule 39 will be submitted to the Yukon Utilities Board for amendment to adjust the Energy rate as required for a two part rate that yields the same overall energy charge at forecast energy use, with all energy consumed in excess of the Base Load being charged at a rate reflecting the incremental cost of service using diesel fuel generation and all other energy being charged at the reduced rate required to yield the same overall energy charge at forecast energy use.

RATE MODIFICATIONS APPLICABLE:

For fuel adjustment rider, see Rider F. Rider F applied to energy charges only, set to $0.0 for fuel price forecast filed November 20, 2006.

Davis:5203362.15
DM_VAN/262912-00049/7651578.3

ELECTRIC SERVICE REGULATIONS:

The Electric Service Regulations approved by the Yukon Utilities Board form part of this rate schedule and apply to YEC and every customer supplied with electric service by YEC in the Yukon Territory. Copies of the Electric Service Regulations are available for inspection in the offices of YEC during normal working hours.

SCHEDULE B

The Point of Delivery for the:

(a) Initial Mill Site is shown in Figure B-1 as the Keno Hill Mill Site Substation; and

(b) Initial Mine Site is shown in Figure B-2 as the Bellekeno Mine Drop Point.

The Mine Facility Spur for the Initial Mill Site includes a 69 kV transmission line of approximately 1.65 km connecting the Transmission Facilities to the Initial Mill Site as shown in Figure B-1.

INTRODUCTION

Yukon Energy's 2011 Resource Plan addresses generation and transmission priorities in Yukon for the 20-year planning period (2011-2030), focusing on:

- Resource options for implementation over the first five years (2011-2015); and
- Planning activities for implementation during the first five years to protect longer-term legacy resource development options for potential start of construction before or after 2021.

The 2011 Resource Plan updates the review of overall planning priorities and options as last provided in the 2006 Resource Plan. It was drafted in late 2011 based on then available information. Overall load forecasts and analysis of specific project options are subject to ongoing updates. As reviewed in the 2006 Resource Plan, several additional planning stages are required beyond the Resource Plan prior to any Yukon Energy decision to proceed with construction for any preferred project[1].

The Overview summarizes the 2011 Resource Plan document. Where relevant, the Overview also notes more recent information that may modify the earlier analysis.

Background on 2011 Resource Plan Process

The first activity Yukon Energy undertook preparing this latest 20-year resource plan was to seek input from First Nations and other governments, stakeholders and the public through meetings, workshops and a three-day energy planning charette held in March 2011.

The charette brought together Yukoners from all walks of life along with nationally and intentionally-recognized energy experts. Information and knowledge was shared and the participants provided a great deal of input in terms of what Yukon's energy future should look like.

Dr Mark Jaccard led off the proceedings by clarifying his experience regarding energy planning and urged participants to thoughtfully consider all of the choices available and to examine the alternatives from the point of view that all options have impacts and risks and all require trade-offs.

[1] Subsequent planning stages include: the final feasibility assessment, costing, design and contract arrangements (and related tendering to obtain final estimated costs); consultation with First Nations and others; all required external reviews, approvals and agreements (includes where relevant YESAB, DFO, YWB and other regulatory authorities as required, as well as seeking YUB review of near-term projects over $3 million).

Dr. Jaccard also talked to the gathering about how we determine and provide affordable energy:

- What role energy has in economic development;
- Future demand and supply; and
- The need to examine multiple objectives.

Along with providing a list of potential energy options that required further investigation and analysis, the charrette participants also helped Yukon Energy formulate four principles around which to base future energy decisions. They include:

- Reliability;
- Affordability;
- Flexibility; and
- Environmental Responsibility.

With these four principles as the lens through which all possible energy options were considered, Yukon Energy prepared later in 2011 a draft of a new 20-year resource plan that is summarized in this Overview for Yukoners to review.

Yukon Energy recognizes that the 2011 Resource Plan, as with its predecessor, is a living document that continues to evolve.

Yukon Energy has continued in fall 2011 and 2012 to date, for example, to hold workshops to examine in more detail specific resource options, including waste to energy, biomass, liquefied natural gas, and energy conservation. As noted in this Overview, new load forecast scenarios have also been developed since the draft 2011 Resource Plan to reflect updated information.

Yukon Energy will continue to use the draft 2011 Resource Plan to frame priorities and options for ongoing new assessments and analysis, without going back to amend or revise the draft as prepared in 2011.

All papers, reports, presentations and records from the energy charrette and workshops have been made available to the public on Yukon Energy's web site.

Yukon Energy Corporation
20-Year Resource Plan: 2011-2030 **July 2012**

Outline of Overview

The Overview summarizes the 2011 Resource Plan as follows:

- Current Challenges and Opportunities;
- Background on Yukon Power System;
- Future Yukon Power Requirements – Overview;
- Range of Resource Supply Options;
- Yukon Utilities – Default Diesel Portfolio Requirements;
- Near-Term Resource Options to Default Diesel;
- Longer-Term Resource Options to Default Diesel; and
- Summary Conclusions & Recommended Plans.

The Overview summarizes the 2011 Resource Plan as drafted in late 2011. Where relevant, the Overview also notes more recent information that may modify the earlier analysis. Updated load forecasts that Yukon Energy is currently using, for example, are provided in the Appendix A. Ongoing examination of specific resource options continues, using updated information and analysis as required.

Yukon Energy will review the Overview and draft 2011 Resource Plan with the public, and report on the results of this review, including any resulting adjustments to recommended plans for ongoing priority attention.

1.0 CURRENT CHALLENGES AND OPPORTUNITIES

Unprecedented growth is expected in Yukon-wide electricity requirements over the next decade, creating new generation challenges:

- **Near-Term Challenges** – To move quickly to meet new grid energy requirements emerging today with options that cost materially less than diesel generation while continuing the planning needed to develop longer-term Yukon power resources.

- **Longer-Term Opportunities** – Development as soon as feasible in future of hydro and other Yukon power resources to supply growing Yukon loads with reduced costs and emissions.

The 2011 Resource Plan assesses resource options in the context of current forecasts for overall Yukon energy and capacity requirements (i.e., off-grid as well as on-grid for all major power loads), agreed upon resource planning principles[2], and the assumption that Yukon Energy is proceeding with a robust and aggressive Demand Side Management/Supply Side Enhancement (DSM/SSE) program in response to Yukon Utilities Board Directives, government policy considerations and stakeholder comments.

Key challenges related to new generation requirements in Yukon include:

- **Higher Costs** – Higher costs to secure safe and reliable new resource supplies from utility operations on or off the grid will increase rates throughout Yukon. Electricity prices in Yukon today are relatively low due to legacy hydro. On Yukon's isolated grid, planning and capital costs are borne by ratepayers (no opportunity to 'overbuild' and sell to another market).

- **Higher Greenhouse Gas ("GHG") Emissions** – Higher GHG emissions from increased electricity generation in Yukon on and off the grid (including utility and non-utility operations) will challenge Yukon's ability to secure overall GHG emission reductions.

- **Flexibility Required** – The isolation of Yukon's electrical system requires flexibility to address a wide range of challenges, including: seasonal variations in loads and existing hydro generation; annual changes in grid hydro generation due to varying water conditions; development and/or shut down of major mine loads; and potential changes in competitive generation option costs due to new resource supplies becoming available (e.g., development of accessible natural gas in Yukon).

[2] The four key planning principles agreed to by the March 2011 Energy Charrette participants are reliability, affordability, flexibility and environmental responsibility.

2.0 BACKGROUND ON YUKON POWER SYSTEM

Yukon's centres continue to have residential and commercial electric rates that are lower than other northern centres in Canada, reflecting extensive reliance on low cost legacy hydro generation.

Figure 2-1 provides a map of existing power infrastructure, active and potential mine developments, the potential Alaska Highway Pipeline, and future power supply options in Yukon over the planning period. Areas within a 50 km boundary from the current and potential future electric grids are identified (based on the current southern highway structure).

Current and committed generation capacity in Yukon includes approximately 138 MW of installed generation on the integrated grid (approximately 92 MW YEC hydro, 0.8 MW YEC wind, 37 MW YEC diesel, 1.3 MW YECL hydro, and 6.8 MW of YECL diesel) and 8.4 MW of diesel generation in five separate off-grid diesel-served communities supplied by YECL (5.3 MW in Watson Lake, 2.0 MW in three Small Diesel zone communities along the Alaska Highway, and 1.1 MW in Old Crow).

The current integrated Yukon grid reflects material Yukon Energy developments since the 2006 Resource Plan, including completion in 2011 of the Carmacks-Stewart Transmission Project to connect the Whitehorse-Aishihik-Faro (WAF) grid and the Mayo-Dawson (MD) grid, expansion of Mayo hydro capacity from 5 to 15 MW (Mayo B project), and the 7 MW enhancement of the Aishihik hydro facility. As a result of substantial federal and Yukon funding contributions, in 2012 these new grid power assets are already yielding ratepayer cost savings due to displacement of otherwise required costly diesel generation.

Grid capacity planning is required to not exceed a Loss of Load Expectation (LOLE) of 2 hours per year and, for non-industrial loads, to provide capacity adequate to accommodate loss of the system's largest generating or transmission-related generation resource (the "N-1" standard). Current capacity planning also provides for sufficient winter peak capacity reserve to accommodate loss of the Aishihik transmission line connection to Whitehorse.

Off-grid mine development has recently commenced at the Wolverine mine located south east of Ross River. The 2011 Resource Plan highlights many other potential off-grid mine developments over the next decade (locations for these projects are noted on Figure 2-1).

Figure 2-1: Existing Yukon Power Infrastructure, Potential Supply Options, and Active & Potential Mine Loads

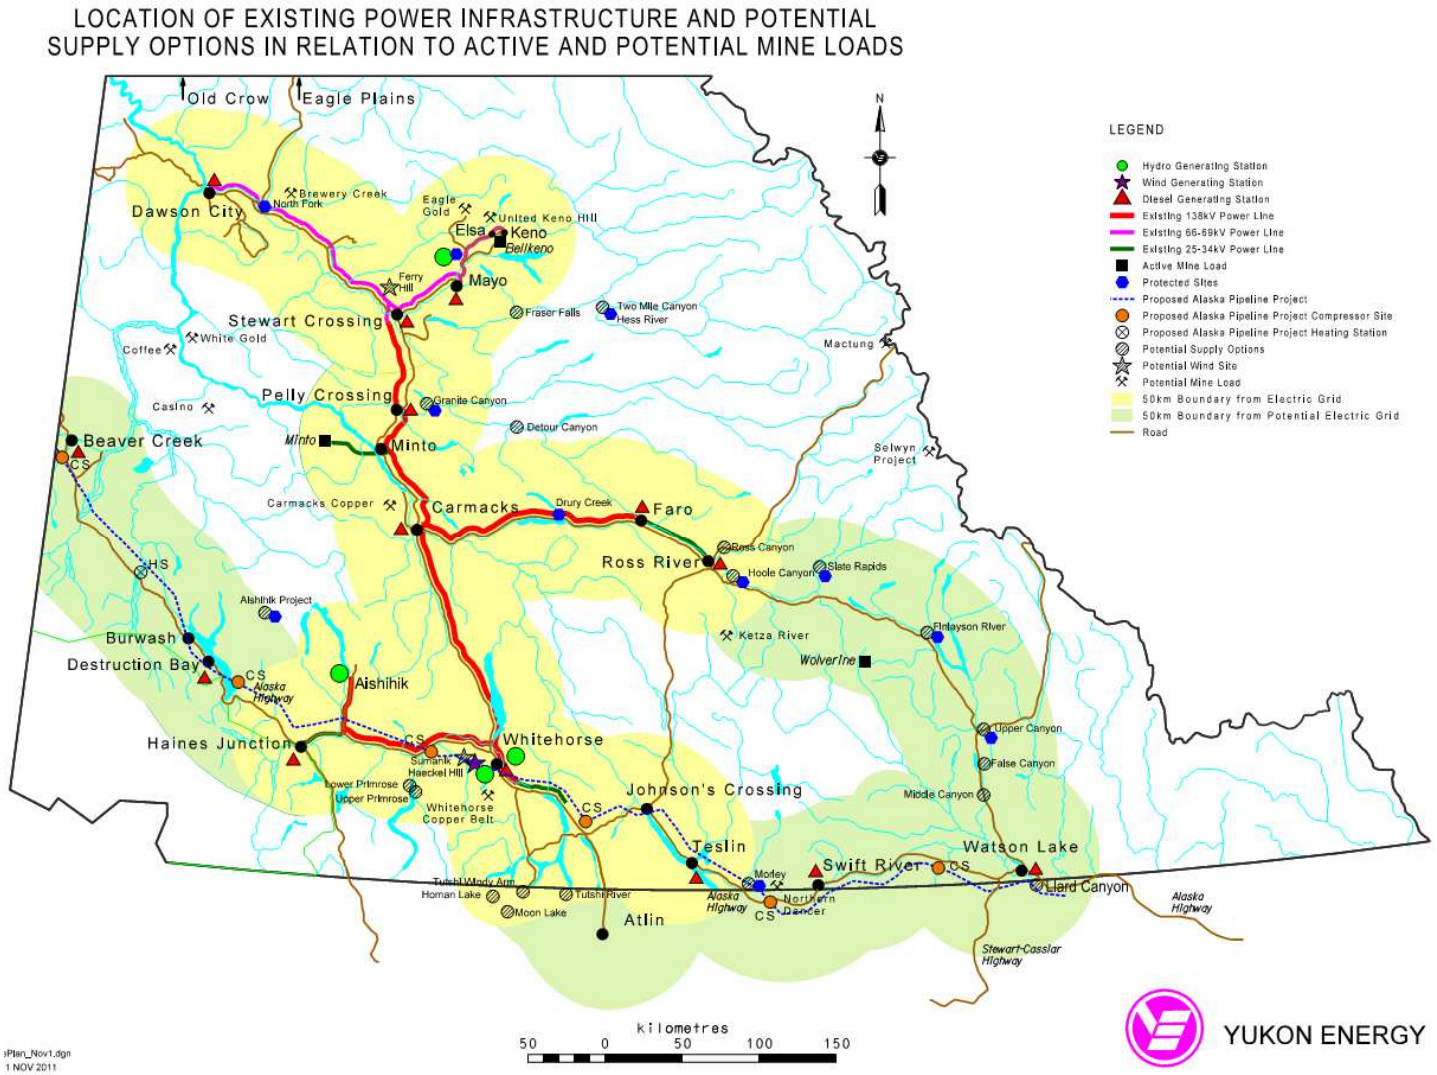

Figure 2-2 reviews historical power generation (1995-2010) by source for the WAF and MD grids. The following load changes are highlighted over this period:

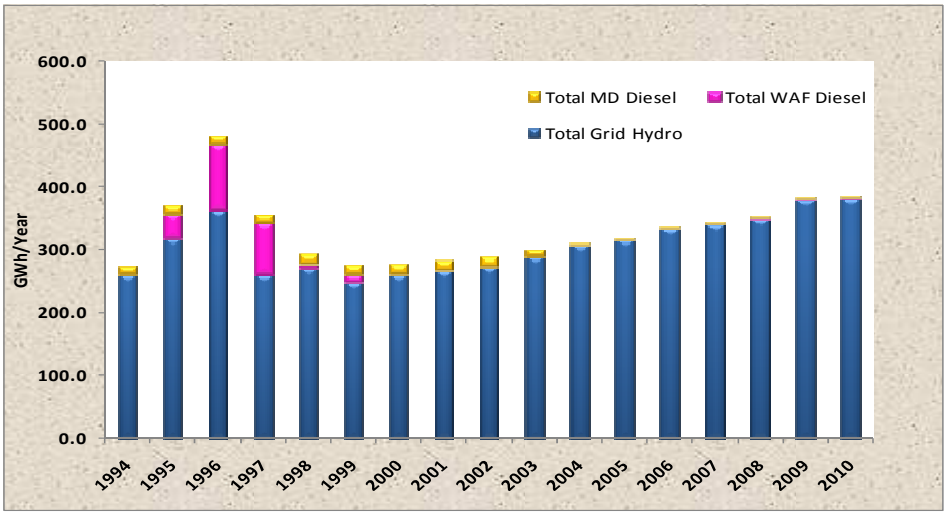
- WAF – Faro mine closure in 1998 (82-100 GW.h/yr diesel immediately before shut down; no material diesel needed after shut down, except for low water year of 1999).
- WAF – Load growth since 1998 to the point that diesel generation starting to be needed again (impacts of non-industrial load growth plus recent Minto mine connection).
- Mayo Dawson – Grid expansion (15 GW.h/yr diesel reduction) – now connected to WAF.

Figure 2-2: Yukon Grid Generation – 1995-2010 (GW.h/year)



Grid Generation by Source (GW.h/year)	1995	1996	1997	1998	2000	2003	2005	2009	2010
Total Grid Hydro & Wind (Incl Fish Lake)	317.5	362.3	259.6	270.3	259.5	288.3	315.5	379.3	380.5
Total WAF Diesel	39.5	104.6	81.8	7.2	0.7	0.3	0.1	2.1	2.7

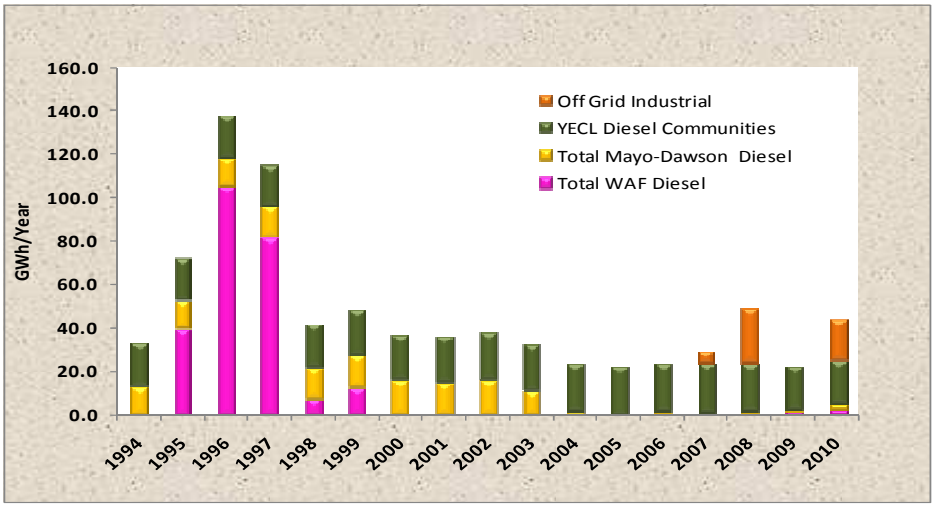
Figure 2-3 reviews historical (1995-2010) annual diesel generation and GHG emissions for the grid and off-grid loads. The following load changes are highlighted over this period:

- After closure of the Faro mine in 1998, off-grid communities accounted for almost all of the Yukon diesel generation.
- Off-grid Diesel Communities – YECL communities today at about 20 GW.h/yr (approximately 70.5% in Watson Lake).
- Off-grid Industrial – No off-grid mine loads until Wolverine in 2010 (19 GW.h that year).

Figure 2-3: Yukon Grid & Off-Grid Diesel Generation – 1995-2010 (GW.h/year)



Diesel Generation (GW.h/year)	1995	1996	1997	1998	2000	2005	2008	2009	2010

3.0 FUTURE YUKON POWER REQUIREMENTS – OVERVIEW

Overall, forecast Yukon power requirements highlight the extent to which off-grid mine loads are expected to grow and dwarf grid loads within the next 5 to 10 years. To the extent this occurs, a fundamental shift will occur in Yukon power generation – affecting near-term opportunities for new fuel or other resource supply development options, ongoing Yukon GHG emissions, and potential options for future grid expansion concurrent with development of new longer-term legacy supply options in Yukon.

Figure 3-1 shows potential off-grid mine loads over a longer-term 40 year period (2011-2050) as projected in the 2011 Resource Plan. These off-grid mine loads are forecast to grow rapidly, surpassing grid loads as soon as the 2015-2020 time period, potentially exceeding 1,500 GW.h/year by 2020, and potentially continuing at over 1,300 GW.h/year for more than 20 years (beyond 2040) for new mines such as Casino, Selwyn and Northern Dancer. Off-grid projects are currently expected to rely upon diesel or LNG resource supply options for on-site power generation.

Figure 3-1 also shows over this same 40-year period (2011-2050) the existing Yukon grid system capability to supply potential grid loads as projected in the 2011 Resource Plan. Highlights from this figure include:

- Non-industrial grid load is projected in the 2011 Resource Plan to grow after 2010 at an annual rate of 2.26% based on recent trends[3].
- Grid connected mine loads are assumed in the 2011 Resource Plan to include Minto and Alexco (which are currently connected to the grid) plus Whitehorse Copper Tailings (assumed to be connected in 2013), Victoria Gold (assumed in the 2011 planning to be connected in late 2013) and Carmacks Copper (assumed in the 2011 planning to be connected in late 2014)[4].

[3] The 2011 Resource Plan forecasts were prepared using 2010 actual results and do not reflect current YEC forecasts for 2012 and 2013 based on more recent information. Based on current forecasts through 2013 and 2.26% annual growth thereafter (and grid loss now assumed at 8.7%), grid non-industrial loads would be about 7.7 GW.h/yr higher in 2015 than projected in the earlier 2011 Resource Plan (with similar increases for subsequent years). See Appendix A to this Overview for current load forecasts.

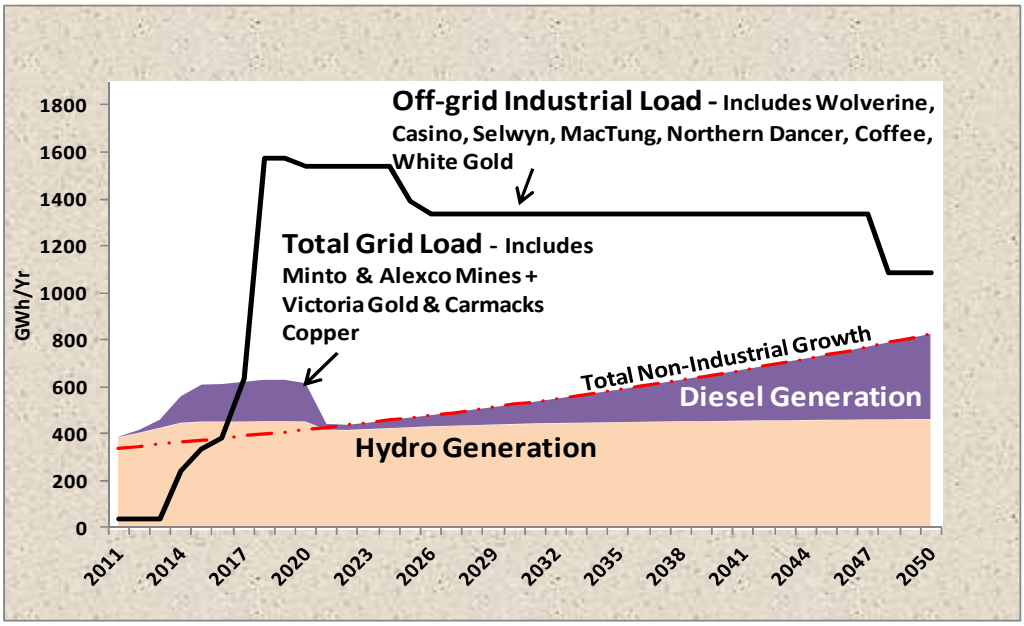
[4] Changes in expected grid mine load forecasts since the 2011 Resource Plan forecasts were prepared include: Minto load growth occurring later in 2012; somewhat lower Alexco loads and higher Whitehorse Copper Tailings mine loads by 2014; delay in connection of Victoria Gold load until start of 2015 and expectation that this load will peak in summer and extend for a longer life than the seven years assumed earlier. No specific timing is currently forecast for Carmacks Copper mine connection to the grid, although the mine's developer (Copper North Mining Corp.) has recently announced (April 26, 2012) plans to submit a proposal to YESAB in Q3, 2012 based on design changes for the plans for development and closure of the project, and expects to submit plans for the Quartz Mining Licence amendment, revised Closure Plan, and a new Water Use Licence application immediately thereafter. Other potential future mine connections to the grid include Brewery Creek (potentially starting in 2013), Rau Gold and Ketza River.

- Forecast grid diesel generation reflects the extent to which forecast grid loads exceed long-term average generation from existing and committed grid hydro and wind generation[5].
    - Assuming no new resource supply developments, forecast grid diesel generation requirements exceed 150 GW.h/yr (2015-2020) with Victoria Gold and Carmacks Copper.
    - Grid mine loads are forecast in Figure 3-1 to stop by the early 2020s; thereafter, ongoing diesel growth reflects only non-industrial growth; in light of this impact, the 2011 Resource Plan tests the sensitivity of new resource options to different potential extensions of related grid diesel requirements to 2025 and 2030.

The 2011 Resource Plan forecasts as highlighted in Figure 3-1 were used in the initial 2011 analysis, as summarized in this Overview, to provide the initial assessment of overall options and priorities. However, expected grid mine loads continue to evolve. Mine and non-industrial grid load forecasts have been updated for the 2012/2013 Yukon Energy General Rate Application filed in April 2012 - and based on this information, updated near-term grid load forecasts have been prepared (see Appendix A to this Overview). These updates assist in ongoing near-term planning for specific new resource project options.

[5] In these assessments, long-term average annual generation capability is assumed for existing hydro and wind resources (annual hydro generation capability is adjusted as required to reflect higher capability at higher annual grid load levels).

Figure 3-1: Existing System Capability to Supply Potential Grid Load & Potential Off-Grid Mine Loads: 2011-2050[6] Excludes DSM/SSE - 2011 Resource Plan



***Scenario B - Base Case Load Forecast with Victoria Gold, Carmacks Copper & WHCT**

* 2011 diesel generation is based on long term forecast (not actuals)

** Assumes connection of Carmacks Copper and Victoria Gold to grid

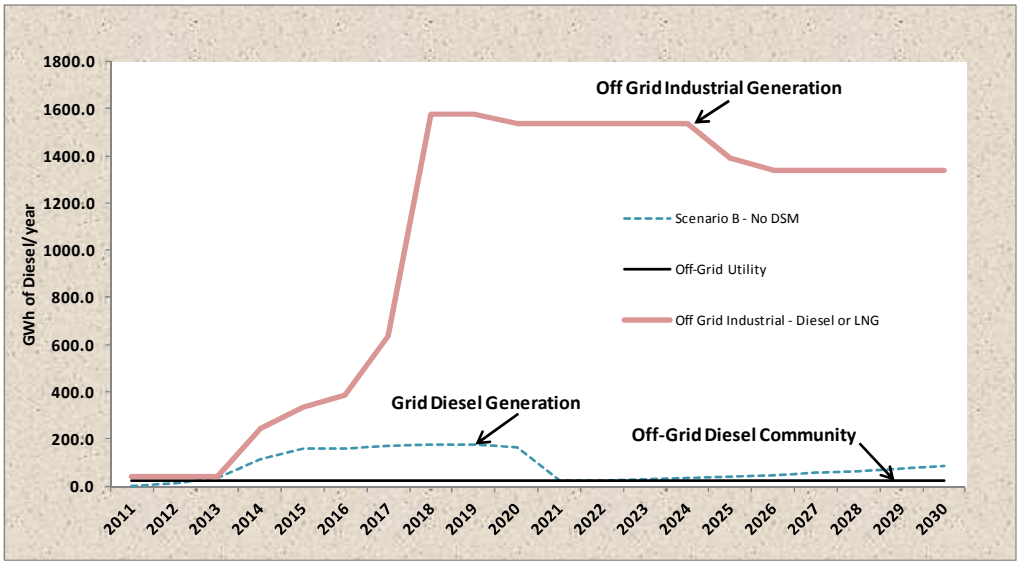
***Assumes Casino develops using LNG with combined cycel power generation & other off grid mines develop using diesel

Figure 3-2 shows non-renewable generation during the 20-year planning period (2011-2030) for all grid and off-grid loads (forecast off-grid diesel community generation and potential off-grid mine diesel) with an accompanying table showing related GHG emissions. The figure and table further highlight the extent to which potential off-grid mine diesel or LNG generation could dwarf grid diesel generation by as soon as 2018-2019.

[6] Potential Alaska Highway Pipeline Project compressor station power loads not included in the above figure could potentially add 1,470 GW.h/year of additional equivalent energy requirements (six compressor stations). Forecasts prepared in 2011 noted that this could occur by approximately 2020/21 and be sustained over 25 years in the event that GHG emissions initiatives support electrification initiatives. Ongoing events in 2012 suggest that this project may be materially delayed.

As noted above, forecast grid diesel generation reflects the extent to which forecast grid loads exceed long-term average generation from existing and committed grid hydro and wind generation. Absent DSM/SSE and new mine loads connected to the grid after forecast mine loads end, Figure 3-2 indicates that on-grid diesel generation is forecast to grow from being minimal in 2011 to 40 GW.h by 2025, i.e., almost twice as large as the off-grid diesel community generation. Continuation of recent non-industrial grid load growth is forecast (without DSM/SSE) to result in 83 GW.h of grid diesel generation by 2030.

Figure 3-2: Total Yukon Non-Renewable Generation (Grid & Off-Grid): 2011-2030
Excludes DSM/SSE - 2011 Resource Plan



Diesel* Energy Requirement	2011	2015	2020	2025	2030
Grid Diesel (YEC - Scenario B-no DSM/SSE)

* Includes LNG for Casino mine

4.0 RANGE OF RESOURCE SUPPLY OPTIONS

The 2011 Resource Plan identifies and assesses near-term (i.e., can be committed before 2015) as well as longer-term (i.e., can start construction before 2021) resource options in Yukon. Table 4-1 provides an overview of resource options considered at Yukon Energy's March 2011 Charrette.

- **Near-term options** are identified, i.e., potentially available to start construction before 2015. In addition to diesel and DSM/SSE, these include the following resource options:
    - Hydro enhancements – Limited potential added supply from Mayo Lake storage[7], Marsh Lake storage, Aishihik licencing, Gladstone Diversion (cannot meet timing for short-term).
    - Thermal-Biomass – Wood biomass has potentially large supplies, relative to near-term needs (10 to 25 MW); municipal waste-to-energy (WTE) for up to 2.2 MW.
    - Thermal-LNG – Liquid natural gas (LNG) from BC gas source (potentially unlimited supply relative to Yukon needs over the planning period).
    - Wind – Ferry Hill or Mount Sumanik opportunities (up to 21 MW and about 56 GW.h/yr)
- **Longer-term options** are screened into the "hydro" greenfield site options potentially available to start construction by 2021 versus "other" options that require information, technology or other external action to be considered potentially available before 2021.
    - Longer-term hydro – Subject to adequate connected loads being committed and adequate ongoing resource planning being carried out prior to 2015, includes up to 70 GW.h/yr of small hydro (<10 MW) at 20-23 c/kW.h, over 2,070 GW.h/yr of medium hydro (11-60 MW) at less than 15 c/kW.h, and over 4,700 GW.h of large hydro (>60 MW) at less than 15 c/kW.h.
    - Other longer-term – Includes geothermal (needs exploration), nuclear (needs cost-effective proven technology, permitting experience), solar (needs cost-effective proven technology for Yukon market conditions), pipeline/natural gas (needs commitments by others re: Alaska Highway Pipeline [plans first gas by 2020, full gas by 2021], and/or potential Eagle Plain gas development), and grid connect to BC or Alaska (needs commitments by others).
- **Yukon Energy's resource planning principles** are also used to characterize at a high level each option as regards reliability, affordability, flexibility and environmental responsibility.

[7] The 2011 Resource Plan assumes that Mayo Lake Storage (1 metre of added bottom storage) is approved prior to assessing new resource options. The earliest in service for this project is currently estimated to be after winter 2013/14.

Yukon Energy Corporation
20-Year Resource Plan: 2011-2030 **July 2012**

Table 4-1: Range of Resource Supply Options & Initial High Level Characterization

		RELIABILITY Reliable winter peak capacity, & reliable development (timing & cost)	AFFORDABILITY c/kW.h ($2010) if fully utilized	FLEXIBILITY Ratepayer cost risks re Mine Load Reductions	ENVIRONMENTAL RESPONSIBILITY Env. impact mitigation - reduction of GHG Emissions
NEAR-TERM potentially available start to construction before end of 2014 (available no later than 2017)	DSM/SSE	MEDIUM - depends on uptake and type of DSM/SSE	HIGH - <10 c/kW.h	MEDIUM – reasonably flexible; curtailable as/when needed	HIGH
	Diesel – existing default option	HIGH - low cost peaking & reserve capacity on system; low regulatory risk	LOW- approx. 30 c/kW.h	HIGH – low capital cost; save fuel & operating cost when load not there (summer/mine shutdown)	LOW- higher GHG & emissions than any other option
	Hydro Enhancements	MEDIUM – reliable winter energy but high regulatory risk	HIGH <10 c/kW.h	MEDIUM – reasonable flexible; - winter storage; long-term value	HIGH
	Thermal - Biomass (incl. waste)	HIGH - baseload energy & capacity (no development planning to date)	MEDIUM - approx 15 c/kW.h; Scalability issues	LOW – not flexible – high capital cost; intended for yr-round energy supply	HIGH
	Thermal - Liquid Natural Gas (LNG)	HIGH - peaking & reserve capacity; low regulatory risk	MEDIUM/HIGH – < 15 c/kW.h	HIGH - low capital cost; save fuel & operating cost when load not there (summer/mine shutdown)	MEDIUM – 30% to 50% lower GHG emissions than diesel
	Wind	LOW – not add reliable peaking/ reserve capacity; not dispatchable; but low regulatory risk	MEDIUM – approx 15 c/kW.h; includes storage	LOW – not flexible – high capital cost & not dispatchable	HIGH
LONG-TERM HYDRO (greenfield) potentially available to start construction before 2021	Small Hydro (< 10 MW)	MEDIUM – reasonably reliable; medium regulatory risk	LOW to MEDIUM(15 to> 20 c/kW.h)	LOW – not flexible; high capital costs req's sustained demand (30+ yrs)	MEDIUM- HIGH – minimal emissions; large footprint
	Medium Hydro (11 to 60 MW)	MEDIUM – reasonably reliable; high regulatory risk	LOW to MEDIUM (10 to 20 c/kW.h)	LOW – not flexible; high capital costs req's sustained demand (30+ yrs)	MEDIUM- HIGH – minimal emissions; large footprint
	Large Hydro (> 60 MW)	MEDIUM – reasonably reliable; high regulatory risk	HIGH – 5 to 11 c/kW.h	LOW – not flexible; high capital costs req's sustained demand (30+ yrs)	MEDIUM – HIGH – minimal emissions; large footprint
OTHER LONG-TERM (require information, technology or other external action to be considered potentially available before 2021)	Geothermal (exploration)	HIGH re: energy & capacity LOW re: development risk as depends on successful exploration	HIGH - low cost to build and operate LOW– high exploration costs	LOW – not flexible; high capital cost req's sustained demand; Not dispatchable	HIGH – minimal emissions/ footprint
	Nuclear	HIGH – baseload energy & capacity	UNKNOWN	LOW – capital intensive; req's sustained demand;	LOW-MEDIUM – low emissions; nuclear-specific env. issues
	Solar	LOW - not dispatchable, dependant on sun availability	LOW - high cost at this time 20 to 60 c/kW.h & req storage	LOW - capital intensive; req's sustained demand;	HIGH
	Pipeline/ Nat gas	HIGH - provides peaking & reserve capacity; low reg. risk	MEDIUM to HIGH (high cost to establish)	HIGH - low capital cost; save fuel & operating costs when no loads	MEDIUM - lower GHG emissions than diesel
	Grid Connection (B.C. or Alaska)	MEDIUM-HIGH	LOW – high cost to provide	LOW - capital intensive; may enhance greatly flexibility in Yukon	MEDIUM-HIGH – offers clean energy options

Note: "Affordability" in this table is assessed assuming adequate load to fully utilize the resource, e.g., greenfield large hydro lifecycle costs of 5 to 11 cents/kW.h assume full use of the resource throughout a 65 year life. In practice, project feasibility for each option depends on forecast lifecycle costs (LCOE) based on forecast utilization of the option over its life.

5.0 YUKON UTILITIES – DEFAULT DIESEL PORTFOLIO REQUIREMENTS

The 2011 Resource Plan grid load forecasts indicate that the major near-term challenge is to reduce costs and GHG emissions by displacing diesel energy generation that would otherwise be required between 2014 and 2021. Higher costs for default diesel generated by Yukon Energy and Yukon Electrical will affect rates for utility customers throughout Yukon due to integrated and equalized rate setting directives to the Yukon Utilities Board.

Diesel is currently the "default" generation resource option in Yukon, i.e., diesel is the reliable, established and available supply option against which other new supply options must be assessed. The Default Diesel Portfolio option retains established diesel generation capacity on and off the grid (with unit replacements as required), and assumes new capacity is supplied only through new diesel units as required at relatively low capital costs. In effect, this option assumes that all forecast grid electrical energy and capacity requirements beyond those that can be supplied by currently existing or committed hydro and wind generation are reliably and flexibly met through diesel generation.

After an overview of overall default diesel portfolio costs and GHG emissions, Section 5 reviews load forecast scenarios for grid diesel generation requirements for energy and capacity. Key features of the Yukon grid default diesel use are then reviewed which drive flexibility requirements and ability to utilize new resources effectively, i.e., grid seasonality in diesel generation and annual variability in diesel generation due to annual changes in hydro generation. The sensitivity of grid diesel energy forecasts to a range of possible mine connection loads is outlined, and future off-grid diesel generation is also reviewed for utility communities and mines.

Default Diesel Portfolio Costs & GHG Emissions

The concerns raised by the Default Diesel Portfolio option are high costs and high GHG emissions, each of which derive from the use of diesel fuel[8].

Forecast grid generation accounts for a small portion of total GHG emissions forecast for the Yukon power generation sector[9]. This is the situation today (2011) and is forecast to remain the likely reality throughout the 20-year forecast period. Over the next several years prior to 2020, off-grid industrial load and related emissions are forecast to increase dramatically, effectively dwarfing on-grid load and GHG

[8] Costs are also required to replace all existing diesel capacity (and to provide added capacity as needed) during the planning period. However, with regard to meeting these capacity planning requirements, diesel is a low cost option with minimal site-related environmental impact concerns.

[9] See Figure 3-2 shows total Yukon non-renewable generation (grid and off-grid) GHG emissions during the planning period under each grid load scenario without DSM/SSE; the figure includes off-grid utility communities and existing plus potential off-grid industrial (mines).

emissions. Addressing the GHG emission challenge related to off-grid loads also raises new power planning considerations well beyond those addressed in the 2006 Resource Plan. The potential near-term surge in off-grid mine development, however, also raises the opportunity to examine new renewable resource development options for commitment prior to 2021 to expand the grid and help to supply power requirements for major new industrial developments.

Grid Diesel Requirements Load Scenarios with and without DSM/SSE - Energy

Each grid load scenario provides projections with no DSM/SSE and also with DSM/SSE that is assumed to secure a 67% reduction in annual non-industrial grid load growth each year starting in 2013[10].

Forecast utility grid (integrated WAF and MD grids) diesel energy generation requirements for the 2011 Resource Plan (GW.h and incremental energy costs/year) are provided in Figure 5-1 for the following three grid scenarios focused on near-term (i.e., to 2015) mine load connection prospects[11,12]. Existing diesel capacity on the grid is more than adequate to supply forecast energy requirements under each of these near-term load scenarios.

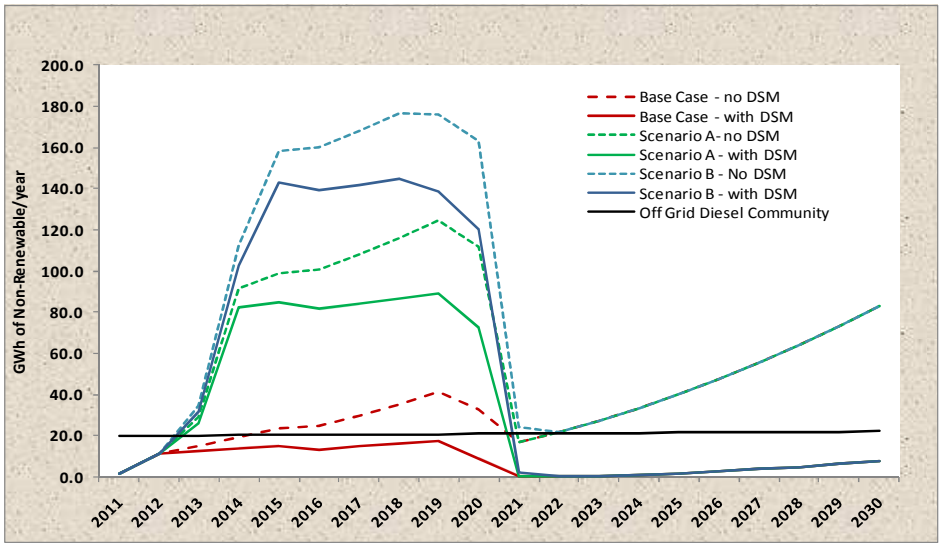
- **Base Case** – Includes non-industrial loads growing at recent rates (2.26%/year) and current connected mines (Minto and Alexco – forecasts assume these mines remain on the grid until around 2020).
- **Scenario A** – Adds Victoria Gold mine to the grid Base Case in late 2013 (based on then available information, forecast assumes on grid for about 7 years, i.e. until end of 2020).
- **Scenario B** – Adds the potential Carmacks Copper mine and Whitehorse Copper Tailings mine to the grid Scenario A (based on then available information, forecasts assume on grid until 2021).

[10] This range of potential diesel generation requirements is used to test the sensitivity of new supply options to potential DSM/SSE program impacts (DSM/SSE costs and programs are being addressed later in 2012 after completion of current studies and program development). DSM is also being addressed with industrial customers and is anticipated to provide some load reductions beyond those shown (potentially in the order of 10% of grid mine loads). Pending completion of current DSM/SSE studies, the 2011 Resource Plan assumes that DSM/SSE programs incur an average annual cost equal to 7.5c/kW.h (2010$) of assumed energy load reduction.

[11] Figure 5-1 also shows forecast off-grid utility diesel generation requirements. Forecast diesel generation fuel and O&M costs reflect approved 2009 incremental diesel generation costs by rate zone escalated at inflation (2% per year) after 2010. Incremental grid diesel generation costs for fuel and O&M (2010$) are assumed at 28c/kW.h (escalated at general inflation assumed at 2%/year), reflecting YEC's approved 2009 GRA fuel prices (e.g., 96 cents per litre at Whitehorse) and a 50/50 average of estimated costs for existing and new units (range of unit efficiencies and O&M cost). Diesel fuel prices in 2011 were generally higher than the approved 2009 fuel prices; however, based on October 2011 NYMEX futures, future diesel prices would be slightly lower than assumed in the Resource Plan (NYMEX futures based prices about 3% lower in 2012, 5% lower by 2015 and 6% lower by 2018).

[12] All loads (including mine loads) as forecast in 2011 based on then available information. Changes since the 2011 Resource Plan was prepared include: Minto load growth occurring later in 2012; somewhat lower Alexco loads and higher Whitehorse Copper Tailings mine loads by 2014; delay in connection of Victoria Gold load until start of 2015 and expectation that this load will peak in summer and extend for a longer life than the seven years assumed earlier. See Appendix A to this Overview for updates.

Figure 5-1: Diesel Energy Requirements (Grid & Off-Grid Utility)
Resource Plan Scenarios 2011 Resource Plan[1]



Diesel Energy Requirement	2011	2015	2020	2025	2030
Base Case (GWh)					
with DSM/SSE	1.5	15.2	8.7	1.8	7.5
without DSM/SSE	1.5	23.7	32.5	40.3	82.8
Scenario A (GWh)					
with DSM/SSE	1.5	84.9	72.5	1.8	7.5
without DSM/SSE	1.5	98.9	112.0	40.3	82.8
Scenario B (GWh)					
with DSM/SSE	1.5	142.9	120.6	1.8	7.5
without DSM/SSE	1.5	158.1	163.3	40.3	82.8
Off Grid Diesel Community (GWh)	19.9	20.4	20.9	21.5	22.1
Diesel Energy Cost (Fuel & O&M)					
Base Case ($ millions)					
with DSM/SSE	0.4	4.7	3.0	0.7	3.1
without DSM/SSE	0.4	7.3	11.1	15.2	34.5
Scenario A ($ millions)					
with DSM/SSE	0.4	26.3	24.8	0.7	3.1
without DSM/SSE	0.4	30.6	38.3	15.2	34.5
Scenario B ($ millions)					
with DSM/SSE	0.4	44.2	41.2	0.7	3.1
without DSM/SSE	0.4	48.9	55.8	15.2	34.5
Off Grid Community ($ millions)	5.9	6.6	7.5	8.6	9.9

[1] See Appendix A to this Overview for current updated diesel energy and other forecasts prepared since the 2011 Resource Plan.

Under each of the above grid scenarios, a robust and successful DSM/SSE program would see minimal diesel generation (and consequently minimal diesel cost impacts and diesel displacement opportunities) after shut down of connected mine loads (i.e., with assumed DSM/SSE and Scenario A or B assumed mine closures after 2020, there is less than 10 GW.h of required diesel generation annually over the period from 2021 to 2030). In contrast, no DSM/SSE program (or unsuccessful DSM/SSE programming over the period) would see much greater rate impacts and diesel displacement opportunities after 2020 (i.e., between 22 GW.h to 83 GW.h per year (2022-2030) under all "no DSM/SSE" scenarios that assume closure of connected mines after 2020-2021).

Grid Season Generation – Impacts on Diesel Generation

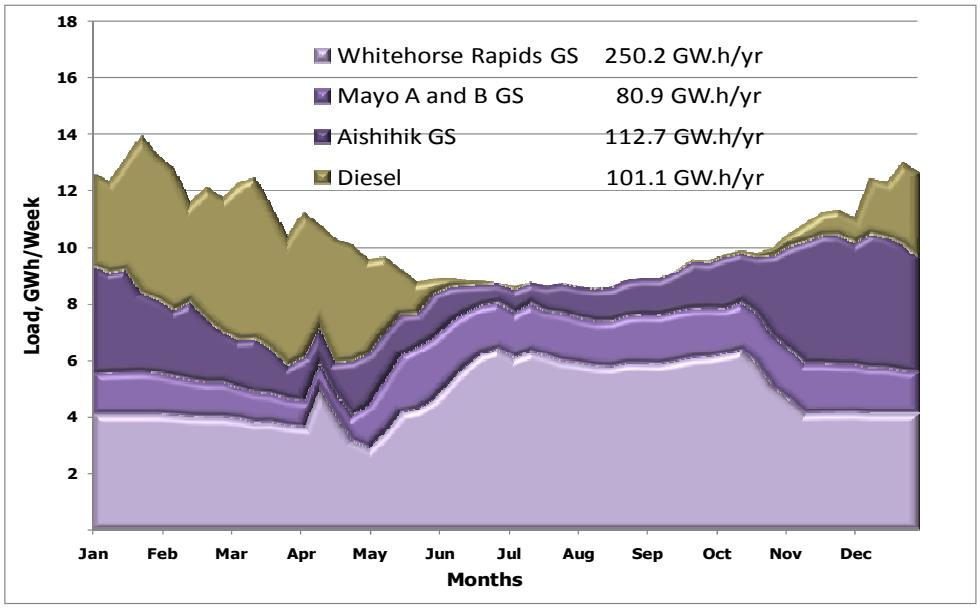
Diesel generation on the Yukon grid occurs in winter. As reviewed in Figure 5-2, with Scenario A 2015-2016 load and no DSM/SSE, 69% of annual near-term diesel generation forecast under average water conditions occurs in four winter months (December to March), and only 2% occurs in the five summer/fall months (June to October). Concentration of forecast diesel generation outside the summer/fall remains a key feature of the Yukon grid under a wide range of load and water conditions.

This concentration of grid diesel generation outside the summer/fall months reflects two factors: seasonal variation in grid loads (which are higher in winter than in summer) and seasonal variation in grid hydro generation for existing and committed facilities (hydro generation typically is higher in summer and fall as compared to winter/spring months). The seasonal concentration of grid diesel generation also reflects a key feature of Default Diesel, i.e., its flexibility to be utilized only when needed, reflecting both the technology (i.e., portable/storable fuel that is readily available) and its relatively low capital cost.

In contrast, Figure 5-3 shows seasonal generation at the Scenario A 2015-2016 load with a new 21 MW of wind generation providing 56 GW.h/year with year-round operation (reflects maximum near-term potential wind development at Ferry Hill). In an average water year, 88% of this new wind is used to displace diesel generation (this result is sensitive to assumed grid load and scale of wind generation):

- 49 GW.h of diesel displaced (70% directly displaced in winter, 30% through use of incremental stored hydro due to impact of wind's summer generation);
- 52 GW.h of diesel energy generation requirements remain on the grid under the assumed load and scale of wind capacity; and
- Unlike diesel, the 21 MW of new wind generation is dependent at all times on wind availability and therefore does not contribute to grid reliable capacity requirements (i.e., diesel or other new reliable capacity is needed to address diesel unit retirements plus added capacity requirements from growth).

Figure 5-2: YEC Grid Electricity Seasonal Generation by Source: Mean Flows (average of all water years) at Scenario A 2015-16 Load without DSM/SSE Grid Load Net of Fish Lake and Wind



GW.h	Jan-Mar	April	May	June-Oct	Nov	Dec	Annual

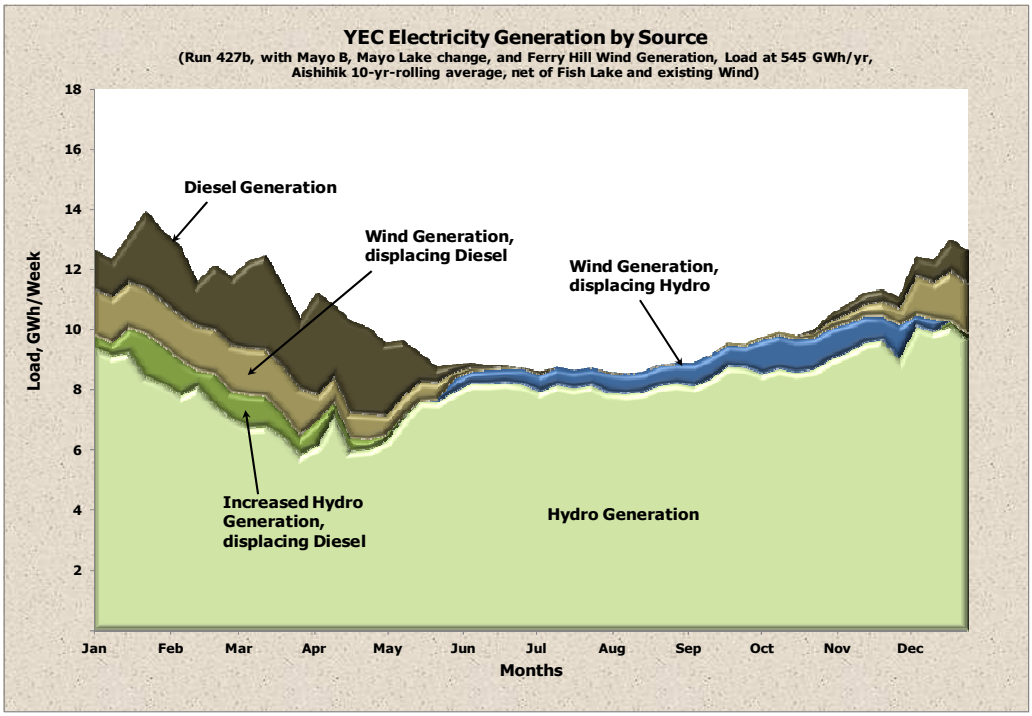
	29%	*8%*	*8%*	*37%*	*8%*	*9%*	*100%*

Notes: Weekly grid generation by source in Figure 5-2 from January to December is based on long-term average water flows and the Scenario A grid 2015-2016 load without DSM/SSE (assumes yet-to-be approved Mayo Lake project with amended licence for one metre of enhanced bottom storage):

- Seasonal loads (peak in winter and are lowest in summer).
- Current hydro generation supply (tends to peak in summer/fall, constrained in winter/spring).
- Diesel energy generation for average year is concentrated in winter months (60% in four months of December to March), and only 2% in five summer/fall months (June to October).
- Diesel energy generation forecast for average year at 101 GW.h (reflects impact of potential load growth by 2015/16, i.e., much lower grid diesel generation today based on average year).
- Diesel provides critical reliable grid capacity requirements to meet peak winter loads and reserve when hydro capacity can be constrained on the current grid, e.g., reliable winter hydro capacity approximates 24 MW at Whitehorse (out of 40 MW installed) and 11 MW at Mayo (out of 15 MW installed).

Figure 5-3: YEC Grid Electricity Seasonal Generation by Source: Mean Flows (average of all water years) with 21 MW Wind Project Displacing Diesel and Displacing Hydro at Scenario A 2015-16 Load Without DSM/SSE



Grid Generation at 545 GW/h load* (GW.	Without Wind Project	With 21 MW Wind Project	Change
Grid Load	545.0	545.0	
Grid Generation			
Hydro*	443.9	437.3	(6.6)
Diesel	101.1	51.9	(49.2)
Wind*	-	55.8	55.8
Total	545.0	545.0	

* Existing Wind and Fish Lake generation not included.

Breakdown of Wind Generation Impacts (GW.h/yr)	
Directly Displacing Diesel	34.6
Directly Displacing Hydro	
Stored Hydro Displacing Diesel	14.6
Spilled Hydro (not required)**	6.6
Total Wind Project Generation	55.8

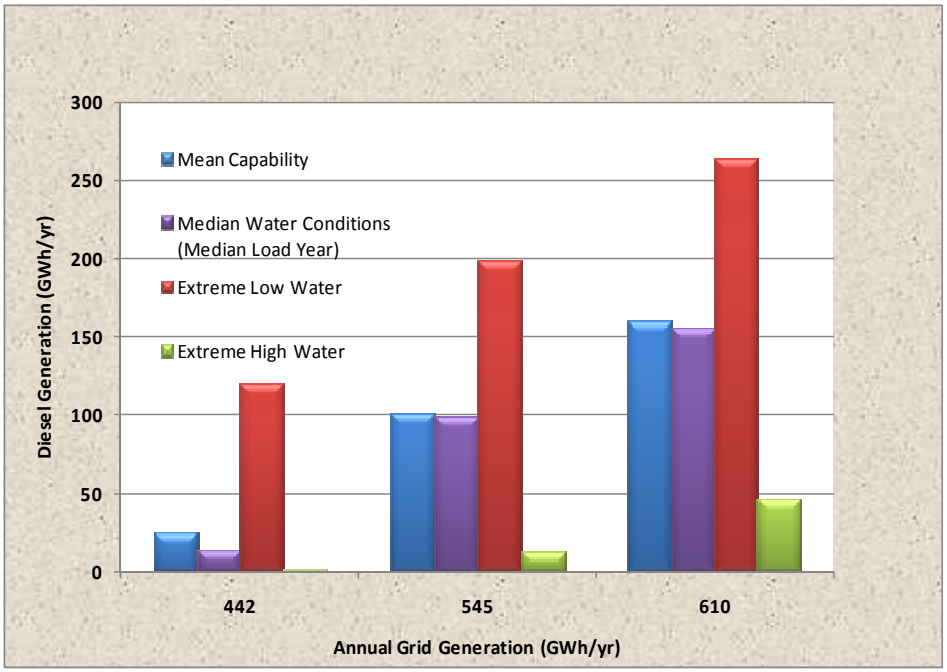
Total Displaced Diesel = 34.6 + 14.6 = 49.2 GW.h

**This figure provides an example that illustrates impacts this supply option would have on the existing generation system;
This does not suggest YEC would operate the system in a manner that results in hydro being displaced by other forms of more costly generation

Annual Diesel Variability Due to Annual Hydro Generation Fluctuations

Figure 5-4 demonstrates the high variability that exists on the current Yukon grid regarding annual diesel generation requirements at any assumed grid load level. By way of example, at the Scenario A 2015-2016 load without DSM/SSE assumed in Figures 5-2 and 5-3, diesel generation can potentially range in any year from 13 to 199 GW.h/year, depending on water flow impacts on grid hydro generation.

Figure 5-4: YEC Annual Grid Diesel Generation Variability at Different 2015-2016 Grid Loads (GW.h/yr)



Annual Diesel Generation (GW.h/yr)	Annual Grid Load (GW.h/yr)		
	442	545	610
Mean Capability	24.6	101.1	160.2
Median Water Conditions (Median Load Year)	13.6	98.6	155.7
Extreme Low Water	119.7	198.8	263.8
Extreme High Water	0.1	13.0	46.2

Notes:

- The range of annual grid loads reflects approximate forecast 2015-16 loads ranging from Base Case (442 GW.h - no new mines) to Scenario A (545 GW.h – connect Victoria Gold) and Scenario B (610 GW.h – connect Victoria Gold, Carmacks Copper and Whitehorse Copper Tailings).
- An "extreme" or "median" year reflects one year out of 364 cases (28 water years and 13 load years). "Averaged load year" (which not shown above) is average annual value for a water year calculated over all 13 load years. For the 545 GW.h/year grid load, the extreme low water diesel generation for Averaged Water Year would require 166.7 GW.h/year diesel generation (reflects 1996 water year of record), and the extreme high water diesel generation for Averaged Water Year would require 34.1 GW.h/year diesel generation (reflects 1992 water year of record).

Range of Possible Connected Mine Loads

The 2011 Resource Plan recognizes that a wide range of possible variations in connected mine loads may occur over the 20-year planning period, including delays in connection of specific loads, extensions in the

life of any connected loads, earlier-than-expected mine shutdowns, new connections not currently forecast and expansions or contractions in connected loads.

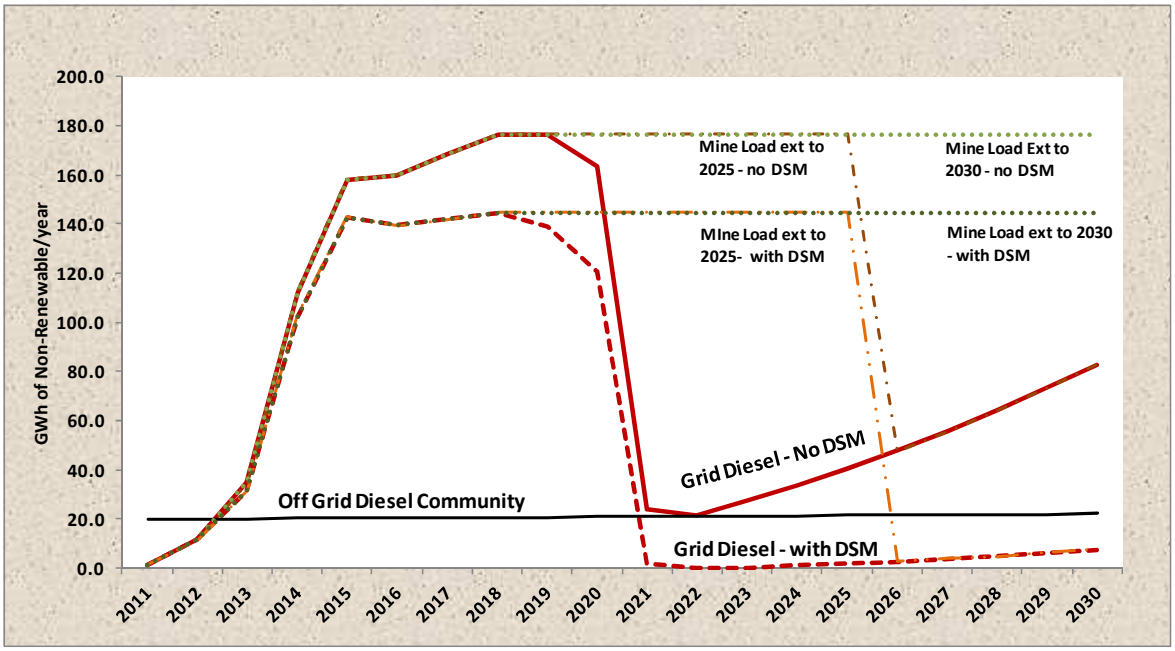
- Beyond looking at a range of near-term mine connections (e.g., Base Case, Scenario A and Scenario B loads), resource option sensitivity for displacing grid diesel generation is also tested for different potential extensions of connected mine loads beyond the 2020 date after which the forecasts show shut down of connected mine loads (sensitivity is tested separately as shown in Figure 5-5 for extensions of related grid diesel requirements to 2025 and 2030).

- The potential for connection to the grid of material new off-grid mine loads (beyond those included in Scenario A and B) has been forecast to be very limited:

    - Off-grid industrial diesel or other fossil fuel power generation at the Wolverine mine (37 GW.h/year) already exceeds utility diesel generation (grid and off-grid). This load is over 270 km from the grid, and connection was never considered to be a practical option given this distance and an expected 10 year mine life.
    - There are currently only a limited number of potential new mine opportunities located within 50-100 km of the 69-138 kV grid (e.g., potentially Brewery Creek, Rau Gold, and Ketza River); although none of these mine loads were included in the 2011 grid load forecasts, the developer of the Brewer Creek mine (Predator Mining Group Inc.) informed YEC that it would like to discuss connection to the grid potentially as soon as mid 2013 with a load of approximately 3.7 MW.

- Opportunities exist in the longer-term (i.e., commitments prior to 2021) to connect to the grid one or more of the major new off-grid mine loads that are driving potential off-grid diesel/LNG generation on a multi-decade basis as shown earlier in Figure 3-1. However, as noted, these mine loads are not being planned on the basis of any grid connection – and any potential grid connection in future will be contingent on new larger-scale renewable resources being developed that can supply a major share of the new off-grid power requirements on a timely and cost-effective basis. Looking at the largest of these potential off-grid mine loads (Casino), this opportunity translates into the challenge of developing new renewable resource options within the next decade that are less costly than the LNG (or natural gas fuelled generation if pipeline or Eagle Plain gas becomes available) that is currently planned to supply this load.

Figure 5-5: Diesel Energy Requirements - Sensitivity Tests re: Mine Load Extensions



Forecast Grid Diesel Requirements - Capacity

In addition to supplying energy requirements, diesel generating units are important for meeting grid capacity planning requirements, i.e., the required capacity to meet firm winter peak load requirements with adequate reserve. As reviewed in Table 5-1, over the 20-year planning period all of Yukon Energy's existing diesel generation capacity (37 MW) is forecast to be replaced due to expected retirements. The following highlights are noted from Table 5-1:

- There are no forecast new grid capacity requirements in 2011 under any of the resource planning scenarios.
- By 2015, with DSM/SSE, there is no new grid capacity required under the Base Case scenario, and between 9.6 MW to 17.6 MW of new capacity required under Scenario A and Scenario B loads respectively (at a diesel capacity replacement cost of approximately $15.7 million to $28.7 million)[13].
- By 2020, with DSM/SSE, 8.8 MW of new grid capacity is required under the Base Case scenario (at a diesel capacity replacement cost of $15.8 million). New capacity required under Scenario A

[13] Cumulative diesel capacity spending to date after 2010 to meet capacity planning requirements (escalated dollars – assumed cost of $1.5 million/MW [$2010]).

and Scenario B loads is 17.9 MW and 25.9 MW respectively (at a diesel capacity replacement cost of $30.6 million to meet Scenario A loads and $43.6 million to meet Scenario B loads).

- By 2025, with DSM/SSE, under all scenarios 27.6 MW of new capacity is required at a diesel capacity replacement cost of between $47.0 million and $52.1 million.
- By 2030, with DSM/SSE, under all scenarios 37.1 MW of new capacity is required at a diesel capacity replacement cost of between $67.0 million and $72.1 million.

Table 5-1: New Diesel Grid Capacity Requirements for Resource Plan Scenarios: 2011-30*

	2011	2015	2020	2025	2030
New Diesel Capacity Requirement (MW)					
With DSM/SSE

Scenario B	0.0	34.0	59.4	76.3	112.2

1. Cumulative diesel capacity spending to date after 2010 to meet capacity planning requirements (escalated dollars - assumed cost of $1.5 million/MW [$2010]).

*See Appendix A to this Overview for current updated diesel grid capacity requirement forecasts prepared since the 2011 Resource Plan.

Forecast timing for new diesel capacity will be affected by diesel unit retirements and new capacity requirements during the 2013-2020 period related to different load scenarios[14]. This 2011 Resource Plan analysis assumes that the 25 km line L172 between Takhini and Whitehorse is appropriately reinforced within the next few years so as to provide no line constraint, i.e., absent such reinforcement, additional capacity would be required in Whitehorse.

Off-Grid Utility Diesel Generation Requirements

Off-grid utility community diesel energy power generation requirements are forecast to grow very slowly based on recent trends for the diesel rate zone communities served by Yukon Electrical (Watson Lake, three small diesel communities, and Old Crow). Off-grid utility community diesel generation exceeds grid diesel generation under the Base Case forecast with DSM/SSE. Off-grid utility community diesel capacity requirements are not addressed at this time.

Potential Off-Grid Mine Diesel Requirements

Potential off-grid mine diesel/LNG energy generation forecasts indicate that unprecedented potential off-grid industrial power load growth before 2020 could easily dwarf current projected utility gird and off-grid diesel generation (see earlier Figure 3-1). Current forecasts indicate that industrial off-grid diesel and/or LNG power generation could potentially exceed 330 GWh/year by 2015 and 1,545 GW.h/year by 2020, and remain above 1,300 GW.h per year beyond the planning period (2030); by comparison, total grid load served by hydro, wind and diesel generation as projected in 2020 under Scenario B with no DSM/SSE is 614 GW.h/year, i.e., about 36% of the potential off-grid industrial generation by that date.

The larger potential off-grid longer-life mines which constitute most of the potential projected off-grid industrial load over the planning period (e.g., Casino, Selwyn, Mactung and Northern Dancer) are not currently considering connection to the Yukon grid in order to meet load requirements. The largest of these potential industrial loads (Casino project) is planning to use LNG at costs well below the cost of diesel, and Northern Dancer is also looking at the LNG option.

[14] Forecast new default diesel capacity requirements by year on the grid for each load scenario reflect forecast peak loads under the grid load scenarios, forecast generation unit retirements, and Yukon Energy's grid capacity planning requirements to meet peak winter loads. During the 2015-2020 period connected mine loads as assumed in Scenarios A and B of the 2011 Resource Plan are expected to be sufficient potentially to affect capacity planning requirements (under updated assessments, this is assumed to occur under the Loss of Load Expectation [LOLE] planning requirements when industrial loads exceed 13 MW), while in other years the N-1 requirement (currently loss of the Whitehorse transmission connection to the Aishihik hydro plant) based on non-industrial loads is expected to determine new default diesel capacity requirements.

6.0 NEAR-TERM RESOURCE OPTIONS TO DEFAULT DIESEL

Portfolio options examine the extent to which alternative resource combinations could effectively reduce grid diesel generation under different forecast load scenarios. Diesel generation is assumed to be retained in each portfolio to supply all generation requirements not supplied by other resources.

Near-Term Resource Options to Default Diesel

Non-diesel resource options potentially available for in service by late 2014 that were selected for near-term portfolios include Marsh Lake Storage (6.4 GW.h/year potential), Wood Biomass Thermal (15 MW)[15], Waste to Energy (WTE) Thermal (2.2 MW)[16], Wind (21 MW)[17], and Liquid Natural Gas (LNG)[18]. In contrast, Gladstone Diversion (36.6 GW.h/year potential) likely cannot be committed before 2016 at the earliest, but could potentially constitute a resource for in-service by late 2017.

Each of these near-term options were assessed in the 2011 Resource Plan based on then available information – recognizing that further feasibility work is required in each case to confirm costs and supply capabilities, and also to determine whether or not the option is feasible to be committed by the dates currently assumed.

- LNG and Wood biomass are options where sourcing fuel supply remained a significant issue at the time of the 2011 Resource Plan analysis, and it was recognized that further pre-feasibility analysis is required prior to relying on either of these options for near-term supply[19]. Ongoing work by YEC is focusing on confirming least-cost options whereby LNG supplies can be secured as required by late 2014[20].

- Feasibility information for Marsh Lake Storage and Gladstone Diversion confirms the relatively low cost offered by each of these hydro enhancement options – however, each of these hydro

[15] Resource Plan analysis determined that any larger scale Wood Biomass plant would be more costly under forecast grid loads (the plant scale exceeds forecast grid requirements for a thermal plant running throughout the year). In contrast, a 10 MW plant might merit review under lower Scenario A loads. Wood Biomass plants smaller than 10 MW (e.g., 3 MW) are being examined as possible pilot projects (see Section 8 of this Overview).

[16] The 2.2 MW scale was assessed to be an optimum scale based on projected available municipal solid waste (MSW) resource supplies and potential access to low cost wood biomass "waste" supplies to supplement MSW supplies.

[17] A smaller 10.5 MW option was examined, but was slightly less cost-effective at forecast loads than the 21 MW option (the latter option reflected estimated wind resource that could be developed at Ferry Hill).

[18] LNG capacity is adapted as required to the specific assumed load forecast (assumes BC based LNG supply not limited).

[19] It was assumed that LNG and wood biomass options could likely be committed before 2015 if selected for development, subject to sufficient studies and planning being carried out in a timely manner to resolve various feedstock supply issues. The 2011 Resource Plan (Section 6.1) reviewed recent studies that YEC has participated in with the developer of the Casino mine project to confirm the feasibility of near-term LNG supply chain options to Yukon from Kitimat or Fort Nelson, B.C.

[20] See YEC web site for: (a) January 2012 LNG Workshop background paper and presentations; (b) December 2011 Biomass background study and presentations.

projects is subject to material timing uncertainties related to regulatory and permitting processes, and further Yukon Energy planning work on Gladstone Diversion is also subject to securing local First Nation support for the project. Gladstone Diversion is examined as potentially being in-service by late 2017 (it is expected that this option cannot be committed before 2015 – the assessment examined the potential impact of securing this option by the end of 2017).

- Feasibility information is also available for Wind and WTE options – however, further feasibility work is required on each of these projects before commitments could be made to proceed with permitting activities[21].

Energy and Capacity Supply Capabilities

Overall, only a few of the available non-diesel resource options offer large scale energy generation supply potential relative to forecast Yukon diesel generation loads. Figure 6-1 highlights the gross energy supply capabilities of the near-term options relative to each of the forecast 2015-2019 grid diesel requirement load scenarios with and without DSM/SSE (the table below this figure reviews reliable capacity capabilities and capital costs for each resource supply option):

- **LNG** – LNG supply is the only option that can potentially displace all diesel energy loads as well as all new diesel capacity requirements at any near-term load.

- **15 MW Wood Biomass** – Gross energy capability of a 15 MW wood biomass option exceeds all but Scenario B diesel energy loads; however, after seasonal diesel requirements and annual hydro variability impacts are considered, this option's net energy displacement of diesel is much lower than the gross energy capability, e.g., assuming Scenario A with DSM/SSE, net energy diesel displacement approximates only 72 GW.h of the 119.6 GW.h annual gross energy. This option can displace only a portion of new diesel capacity requirements (at this scale of plant, the only identified potentially feasible locations are either in Whitehorse or in the Minto burn area).

- **Other Near-Term Options** – Gross energy capability of other near-term options only displace portions of Scenario A diesel requirements, and net energy capability to displace diesel is lower than gross capability, e.g., approximately 80% to 88% of WTE or Wind gross generation displaces diesel with Scenario A load; minimal contributions from Marsh Lake hydro and WTE; wind provides minimal capacity contribution.

In summary, LNG can provide flexible amounts of supply up to any load levels likely to be required and Wood Biomass can also provide relatively large amounts of annual generation (119.6 GW.h/year for a 15

[21] See YEC web site for October 2011 Waste to Energy Workshop background study and presentations.

MW plant, of which 72 GW.h would displace diesel generation under Scenario A loads with DSM/SSE)[22]. In contrast, maximum potential levels of annual generation are limited from Marsh Lake (6.4 GW.h/year), 2.2 MW WTE (17.1 GW.h/year), Gladstone Diversion (36.6 GW.h/year), and Wind (55.6 GW.h/year).

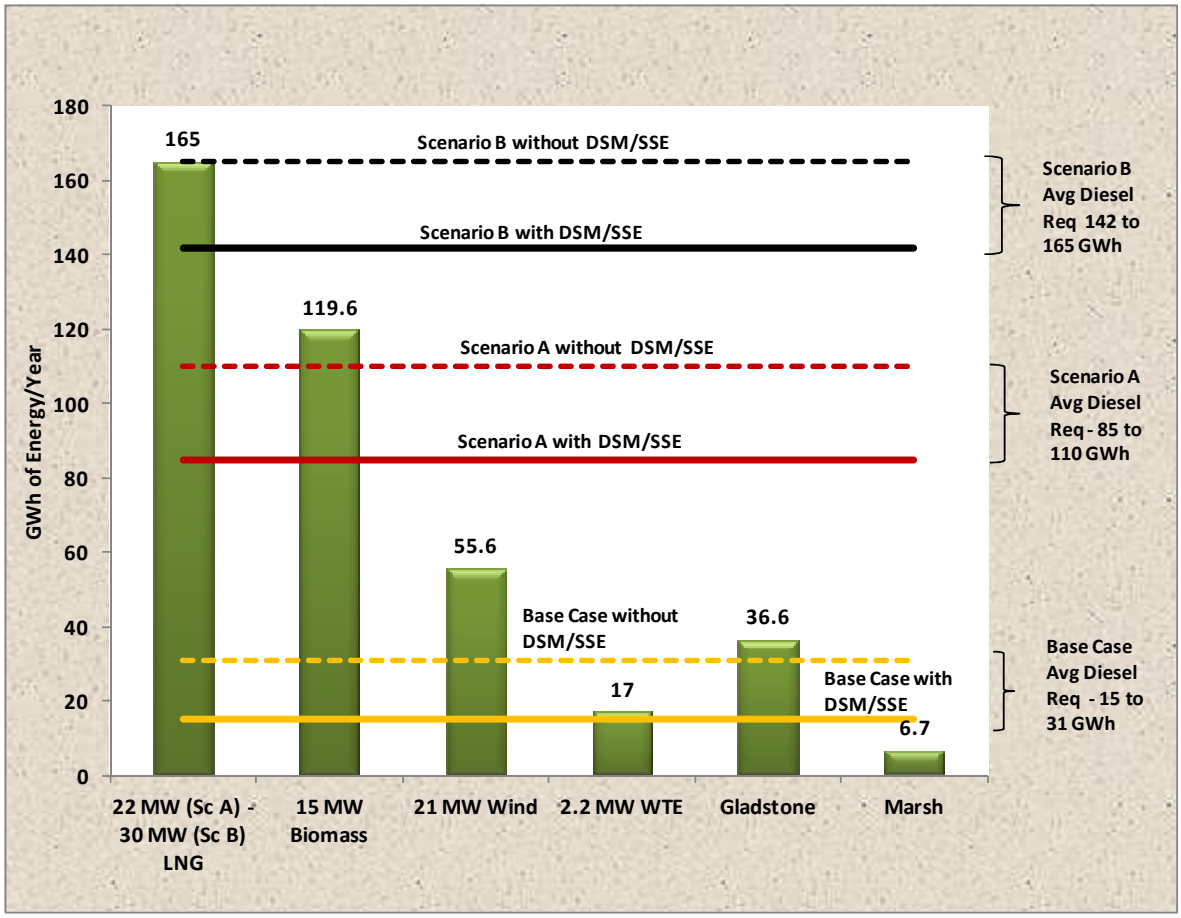
Ongoing studies are defining the economic potential for DSM and SSE as well as specific programs and costs. Pending completion of these studies, the 2011 Resource Plan assumes that a specific level of DSM/SSE will be implemented starting in 2013 for non-industrial grid loads[23] and tests the sensitivity of all non-diesel supply options to these potential DSM/SSE impacts. In summary, notwithstanding the materially higher diesel displacement opportunities and higher Default Diesel Portfolio costs with no DSM/SSE, comparative feasibility assessments of the different resource portfolio options under load scenarios with DSM/SSE were not generally changed by consideration of load scenarios with no DSM/SSE[24]. Accordingly, the following summary overview analysis of resource and portfolio options typically focuses solely on review of load scenarios with DSM/SSE.

[22] Studies suggest that a 25 MW plant scale located in Whitehorse might also be feasible, with annual generation approaching 200 GW.h/year; however, under Scenario A loads with DSM/SSE, less than 15% of the annual biomass energy over the project life would displace diesel generation (even during the 2015-19 period with mine loads connected, less than 100 GW.h/yr of the wood biomass generation would be used to displace diesel generation).

[23] Although the timing and level of future DSM/SSE remains uncertain, preliminary study results suggest that future DSM/SSE load reduction impacts over the period to 2030 may be within 50-75% of DSM/SSE assumed in the 2011 Resource Plan.

[24] Higher loads assuming no DSM/SSE tend to improve cost savings for all non-diesel portfolio options when compared with the Default Diesel Portfolio, and reduce somewhat the penalties faced by non-flexible options such as Wind when grid loads drop due to mine closures. Portfolios that include Gladstone Diversion tend in particular to show improved (lower) present value costs over the planning period with higher loads assuming no DSM/SSE. However, the overall cost ranking of LNG Transition Portfolio Options relative to Minimum GHG Portfolio Options or the Default Diesel Portfolio is not materially changed without DSM/SSE.

Figure 6-1: Gross Energy Supply Capabilities by Near-Term Option (GW.h/yr During 2015-2019) – Compared to Diesel Requirements by Load Scenario with and without DSM/SSE (Net Energy Displacement of Diesel may be less than Gross Energy)



Notes: Reliable Capacity capability (up to 37 MW new grid capacity needed by 2030 with Scenario A load with DSM/SSE):

- **Diesel, LNG** – Each can provide all of the firm capacity required (capital cost of $1.5 million/MW assumed; for LNG cost of $1.8 million/MW for combined cycle).
- **Wood Biomass** - Option assumes 15 MW of firm capacity (capital cost of $5.7 million/MW).
- **Waste-to-Energy (WTE)** - 2.2 MW of firm capacity (capital cost of $17.7 million/MW).
- **21 MW Wind** – Wind generation does not provide any reliable capacity; the option includes 5 MW of DRUPS (diesel rotary uninterruptible power) to enhance reliability, and this adds 5 MW to reliable capacity. Wind option capital cost of $3.6 million/MW for 26 MW (wind & DRUPS).
- **Gladstone and Marsh** – Gladstone Diversion hydro adds minimal or no reliable capacity (due to Aishihik Transmission line vulnerability); Marsh Lake hydro storage adds about 1 MW reliable capacity. Overall capital costs are estimated at $40 million for Gladstone and $10.5 million for Marsh Lake storage. Earliest potential in-service for Gladstone is late 2017.

2015-2020 Average Annual Costs per kW.h

New resource supply options display widely varying annual ratepayer cost impacts per kW.h during the 2015-2020 period with assumed connected mine loads (see Figure 6-2 for annual ratepayer costs per kW.h with Scenario A loads and DSM/SSE, assuming average annual hydro generation):

- **LNG and Hydro Enhancements (Marsh & Gladstone) are lowest cost** – LNG and hydro enhancements cost less than 20 c/kW.h each year relative to diesel fuel and O&M (new diesel units) at approximately 30 c/kW.h or higher (LNG fuel and O&M cost is lowest at 11 to 13 c/kW.h)[25].

- **Wind and WTE slightly lower cost than Diesel** – Wind and WTE cost typically between 25 and 30 c/KW.h[26]; these capital intensive options are sensitive to load decline that is forecast starting in 2020 (lower loads result in higher average costs per KW.h).

- **Wood Biomass costs more than Diesel** – Wood biomass costs at or slightly below 35 c/kW.h until 2020, when costs rise above 35 c/kW.h[27]; this is a capital intensive option that is sensitive to load decline as forecast starting in 2020 (lower loads result in higher average costs per kW.h).

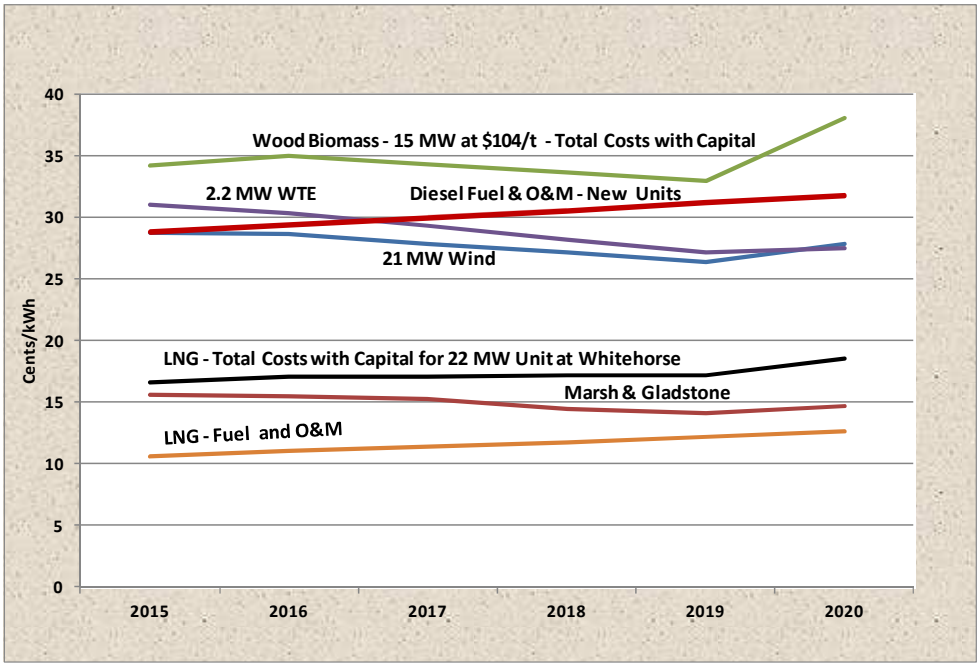
In summary, LNG is a flexible low capital cost option where unit fuel costs determine overall annual costs per kW.h. In contrast, higher capital costs per MW for other options result in costs per kW.h being sensitive to option scale and assumed grid loads.

[25] Forecasts assume diesel fuel and O&M cost escalation at 2% year (fuel price as approved by YUB in place in 2010). LNG costs assume 22 MW combined cycle generation units at Whitehorse (50% energy efficiency [6.562 Mcf/MW.h] and 44% average annual plant capacity factor) with LNG supplied by truck from Kitimat at cost of 2.7 cents per kW.h (2010$) for all LNG supply costs other than LNG fuel; cost of LNG fuel at assumed natural gas price in BC plus $3/MMBtu (2010$) to reflect conversion costs and impact of export pricing; assumed BC gas price at $5.5/MMBtu in 2015 ($6.07/MMBtu after inflation), $6.60/MMBtu in 2020 ($8.05/MMBtu after inflation) and $7.45/MMBtu in 2030 ($11.07/MMBtu after inflation). Although combined cycle provides opportunity for waste heat sales in Whitehorse, no waste heat revenue offsets assumed with LNG option in this analysis.

[26] Assumes use 25,000 ODT/year of MSW plus 3,800 ODT/year wood biomass at Whitehorse WTE plant, with district heat net revenues, tipping fees and other revenues of $3.3 million per year (2010$). See Figure 6-3.

[27] Wood Biomass plant assumed to be located adjacent to grid in Minto burn area with wood biomass requirement of 0.7 ODT/MW.h at an average cost (2010$) of $104/per ODT. Assume 2%/year inflation of costs.

Figure 6-2: Average Annual Costs per kW.h for Near-Term Resource Options – 2015-2020 (Scenario A Load with DSM/SSE – Cost Inflation at 2%/yr; higher for LNG)



Annual Cost (cents/kW.h)	2015	2016	2017	2018	2019	2020
Diesel Fuel & O&M - new units	29	29	30	31	31	32
Wood biomass 15 MW at $104/t						
Total Costs	34	35	34	34	33	38
Fuel + O&M	19	20	20	20	20	24
21 MW Wind	29	29	28	27	26	28
2.2 MW WTE	31	30	29	28	27	28
LNG - total costs with capital	17	17	17	17	17	19
LNG - fuel & O&M	11	11	11	12	12	13
Marsh & Gladstone	16	15	15	14	14	15

Note: Assumes 2%/yr inflation for 2010$ costs, except for LNG fuel cost which assumes specific real escalation of the 2010$ natural gas price as well as overall inflation at 2%/yr (per footnote 24 at page 28). All costs assume average annual hydro generation each year during the period.

Lifecycle Costs per kW.h (LCOE)

Resource options are more effective in displacing grid diesel generation to the extent that they can be focused in the priority diesel generation periods (winter/spring) and flexible to address relatively wide variability in annual hydro generation capability[28].

Figure 6-3 provides, by option, forecast lifecycle costs of energy (LCOE) per kW.h (2010$) of generation used to displace forecast diesel over the economic life of each option[29]. Separate LCOE forecasts for Scenario A load with DSM/SSE, for sensitivity tests for mine load diesel displacement extended to 2025 and 2030, and for full utilization of all generation to displace diesel are summarized below:

- **Forecast LCOE with no mine loads after 2021** – Only LNG and Marsh Lake & Gladstone have LCOE less than 30 c/kW.h (13.1 c/kW.h for Marsh/Gladstone and 18.4 c/kW.h for LNG); the highest LCOEs are Wind option (40 c/kW.h) and Wood Biomass (60.8 c/kW.h).

- **Forecast LCOEs decline as mine load diesel displacement is extended** – With mine loads extended to 2025, only LNG and Marsh Lake & Gladstone have LCOE less than 20 c/kW.h (10.1 c/kW.h for Marsh/Gladstone and 15.2 c/kW.h for LNG), and the highest LCOEs are Wind (26.5 c/kW.h) and Wood Biomass (37.1 c/kW.h) – with mine loads extended to 2030, further LCOE declines occur without changing the cost ranking of the options.

- **Full Utilization LCOE do not reflect forecast diesel displacement** – Forecast LCOEs with no mine loads after 2021 are much higher than Full Utilization LCOE which assume all generation can always be fully used to displace diesel, e.g., 53% higher for LNG (Forecast LCOE vs. Full Utilization LCOE), 111% higher for Marsh/Gladstone, 133% higher for WTE, 176% higher for Wind and 285% higher for 15 MW Wood Biomass.

  Figure 6-4 demonstrates how Full Utilization generation varies from Forecast net diesel displaced with Scenario A loads for a Wind option over a 25 year economic life (highlights the impact of mine shutdown when the resource has no flexibility to limit its ongoing generation or costs).

In summary, LNG and Hydro Enhancements (Marsh Lake & Gladstone Diversion) have the lowest LCOE, and Wood Biomass has the highest LCOE, under all Scenario A cases examined in Figure 6-3.

[28] This reality reflects the lack of grid connection in Yukon to external markets - and the resulting need to ensure where feasible that local generation matches the local grid load requirements (as surplus generation cannot otherwise be usefully used or sold). See Section 5 regarding grid hydro seasonal load and supply characteristics, as well as annual hydro supply variability. In the end, resource options for the grid in Yukon are valued based on ability to displace diesel generation, i.e., generation that is surplus to diesel displacement needs has little if any value to ratepayers.

[29] LCOE and present value cost assume discount rate of 6.56%/year for new generation assets based on YEC's 2009 GRA approved return on equity and cost of new long-term debt. Assumed project life varies by resource option, e.g., 20-years for LNG, 25 years for WTE and Wood Biomass and Wind, 65 years for Hydro enhancements.

Figure 6-3: Forecast Lifecycle Cost of Energy (LCOE - 2010$) by Near-Term Option - Scenario A Load with DSM/SSE

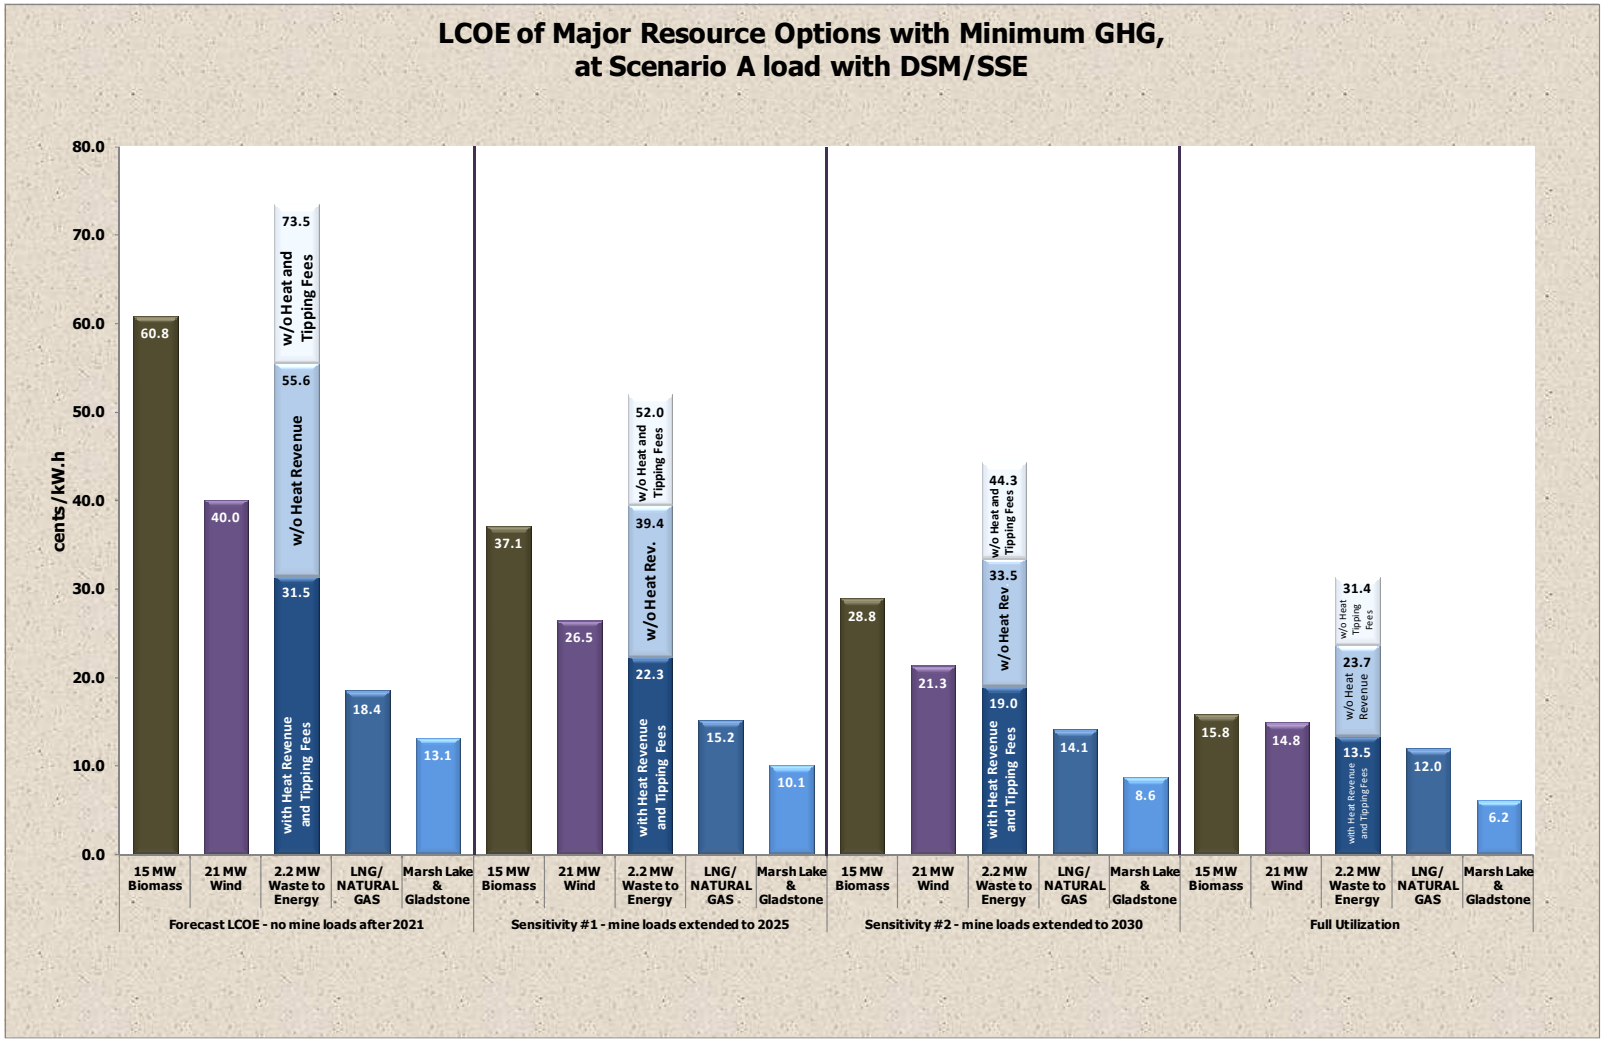


Figure 6-4: Wind Project: Displacing Diesel and Hydro at Scenario A Load with DSM/SSE (current forecast mine life, no mine loads after 2021)

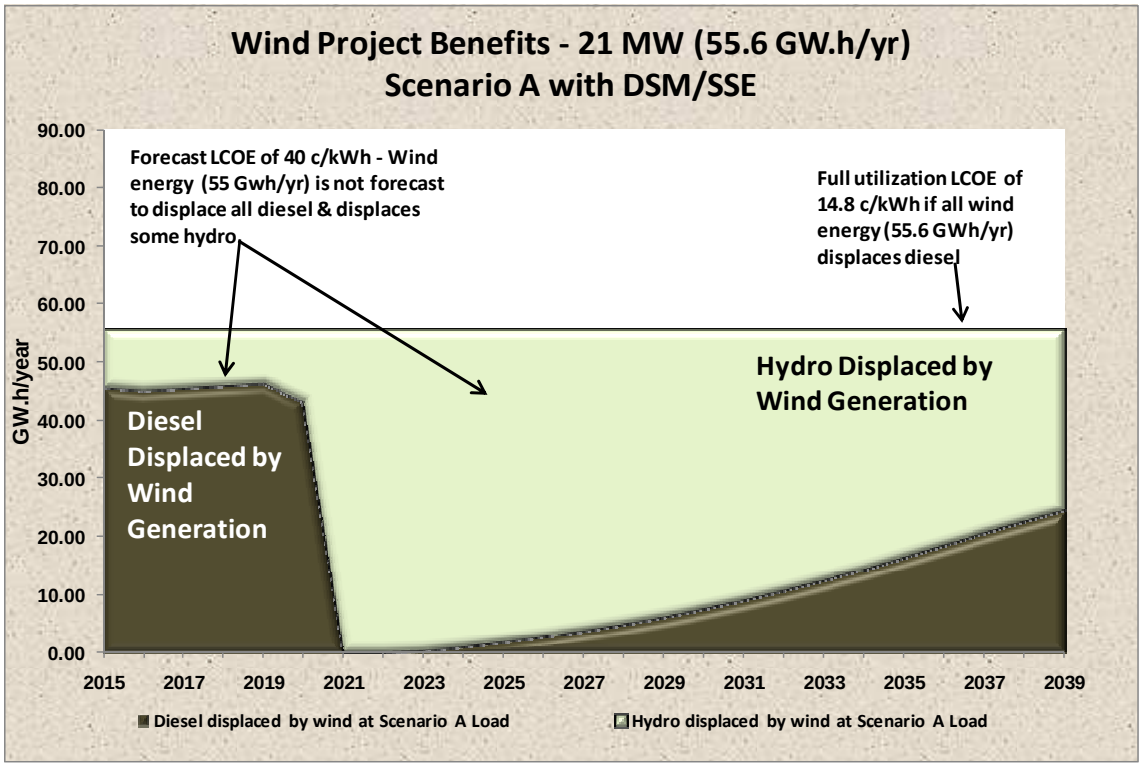

Near-Term Portfolio Options to Default Diesel

Alternative portfolios including each of the above near-term resource options have been reviewed considering grid economic impacts, Yukon greenhouse gas emissions impacts and long-term development considerations. Near-term cost and rate impacts vary significantly depending in large part on the capital intensive nature of each resource option and its flexibility relative to major forecast load reductions after 2020 under all resource plan forecast scenarios.

Table 6-1 provides an overview of different resource portfolio near-term options indentified in the 2011 Resource Plan (Scenario A grid loads with DSM/SSE are assumed for this table)[30].

[30] The same Resource Portfolio Options apply for Scenario B loads with DSM/SSE, and for Scenario A or B loads with no DSM/SSE, subject to the LNG plant being 30 MW capacity rather than 22 MW capacity. Base Case Portfolio Options are more limited due to smaller scale of the diesel displacement loads, e.g., with DSM/SSE the options are Marsh Lake Storage & 2.2 MW WTE for Minimum GHG Portfolio, and LNG 4 MW or Marsh Lake Storage & LNG 4 MW for LNG Transition Portfolio [if no DSM/SSE, LNG plant scale increased to 8 MW]; for Base Case loads, LNG options assume simple cycle power plant (40% energy efficiency) and reliance on LNG availability in Yukon to supply off-grid mine loads.

In addition to the Default Diesel Portfolio, the following Portfolio Options are identified (resource options assumed to be in operation by start of 2015, except for Gladstone Diversion [assumed in operation by start of 2018]):

1. Minimum GHG Portfolio Options:
    a. Marsh Lake Storage & 15 MW Wood Biomass (89-92% reduction of grid diesel GHG for 2015-2019 period)[31].
    b. Marsh Lake Storage, Gladstone Diversion & 21 MW Wind (60-61% reduction of grid diesel GHG for 2015-17 period and 84-85% for 2018-19 period [after Gladstone]).
    c. Marsh Lake Storage, 21 MW Wind & 2.2 MW Waste-to-Energy (WTE) (70-74% reduction of grid diesel GHG for 2015-2019 period).
2. LNG Transition Portfolio Options:
    a. Marsh Lake Storage & LNG (22 MW) (52% reduction of grid diesel GHG for 2015-2019 period).
    b. LNG (22 MW) (48% reduction of grid diesel GHG for 2015-2019 period).

Table 6-1 compares the present value (PV) incremental generation costs of each Portfolio option over the 20-year planning period and the Forecast LCOE (levelized cost of energy over project life)[32].

- LNG Transition Portfolios have a much lower PV cost and Forecast LCOE than Default Diesel.
    - LNG Portfolio PV costs at 65-66% of PV costs for Default Diesel Portfolio.
    - LNG Forecast LCOE at 47-51% of Default Diesel Portfolio Forecast LCOE (61-66% if compare only with diesel fuel and O&M costs).
- LNG Transition Portfolios have a much lower PV cost and Forecast LCOE than any of the Minimum GHG Portfolio Options.
    - Minimum GHG Portfolio PV costs 110-120% of PV costs for Default Diesel Portfolio.
    - Minimum GHG Portfolio Forecast LCOE at 80-109% of Default Diesel Portfolio Forecast LCOE (104-141% if compare only with diesel fuel and O&M costs).

[31] The Wood Biomass resource option is typically assumed to operate year round – however, it is assumed to be flexible enough to shut down when grid annual load drops to very low levels after 2020 (as a result, the material O&M cost of $72.8/MW.h (2010$) is saved, providing this option with PV cost savings relative to other Minimum GHG resource options which do not have this flexibility).
[32] PV cost and LCOE assume discount rate of 6.56%/year based on YEC's 2009 GRA approved return on equity and cost of new long-term debt. PV cost excludes assumed $35.4 million PV cost for DSM/SSE over this period, which is common to all Portfolio options. Forecast LCOE for a specific resource option is cents per kW.h of forecast diesel displaced [2010$] over the assumed economic life of that resource option and assuming forecast diesel generation under Scenario A with DSM/SSE.

Table 6-1: Overview of Resource Portfolio Near-Term Options Scenario A with DSM/SSE: 2011-2030

	PV Cost million[1]	Forecast LCOE[2]	Capital Cost (2010$)		O&M Cost (2010$)		Reliable Capacity	Total Capacity	Energy Capability	Diesel Required/ Displaced

Diesel Capacity	11.4		1.5	22.6			15.1	15.1		
Total	109.6			62.9			37.1	37.1		

Notes: 1. PV = Present Value cost over 20-year planning period (2011-2030). Excludes $35.4 million PV cost for DSM/SSE.
2. Forecast LCOE = Levelized Cost of Energy (cents/ kW.h of forecast diesel displaced [2010$]) over project life.

The LNG resource option has much lower incremental capital costs than the wood biomass or wind resource options examined, and much lower capital costs per MW than each of the Minimum GHG resource options. LNG, WTE and Wood Biomass resource options each provide reliable capacity equal to their plant capacity – in contrast, Wind and Gladstone each provide little if any reliable capacity benefits.

Comparative Rate Impacts for Near-Term Portfolio Options

The Default Diesel Portfolio shows material increases in grid diesel energy requirements by 2015 under all load scenarios. Assuming DSM/SSE, diesel fuel and O&M cost increases from 2011 to 2015 are projected at $4.3 million with Base Case loads, $25.9 million with Scenario A loads and $43.8 million with Scenario B loads (see Figure 5-1 and accompanying table). Increased revenues from new loads will offset some, but not all, of these increased costs - resulting in upward pressure on rates.

Unlike the Default Diesel Portfolio, LNG portfolio options allow major new incremental loads to occur by 2015 under Scenario A or B without requiring material rate increase impacts. As reviewed in Figure 6-2, average annual costs in 2015 with Scenario A loads and DSM/SSE are projected at 17 cents/kW.h with LNG (including capital costs) as compared to 29 cents/kW.h with diesel (fuel and O&M costs, excluding capital costs).

The Minimum GHG Portfolio options show varying rate impacts during 2015-2020 depending on the assumed load scenario. Overall, however, costs for these options during 2015-2019 are at best only slightly lower than diesel - and in several instances are higher than diesel fuel and O&M costs (see Figure 6-2).

After 2020 with Scenario A or B and DSM/SSE, the assumed drop in grid loads (when mine loads are forecast not to be connected, based on the then available information) at the outset could slightly reduce Default Diesel Portfolio rate impacts, but ongoing load growth by 2030 would lead to renewed rate increase pressures[33]. After the loss of the mine loads, LNG Transition Portfolio Options would continue to have lower rate impacts than any of the other non-diesel portfolio options - however, until later in the period (close to 2030) the Default Diesel Portfolio with these greatly reduced loads could have slightly lower rate impacts than the LNG Transition Portfolio Options[34].

A sensitivity test assuming connected mine loads continue to 2030 at sufficient levels to prevent a drop in grid diesel generation under the Default Diesel Portfolio indicates that the least cost LNG Transition

[33] Loss of mine loads leads to loss of all revenues from these loads, as well as reduced diesel costs as shown in Figure 5-1. All Portfolio Options, including Default Diesel, include assumed costs for DSM/SSE as well as capacity installed that are not reduced by mine load reductions.

[34] In cases with no DSM/SSE, the LNG Transition Portfolio Options would have lower rate impacts than Default Diesel in all years of the planning period (as well as lower rate impacts than any of the Minimum GHG Portfolio Options).

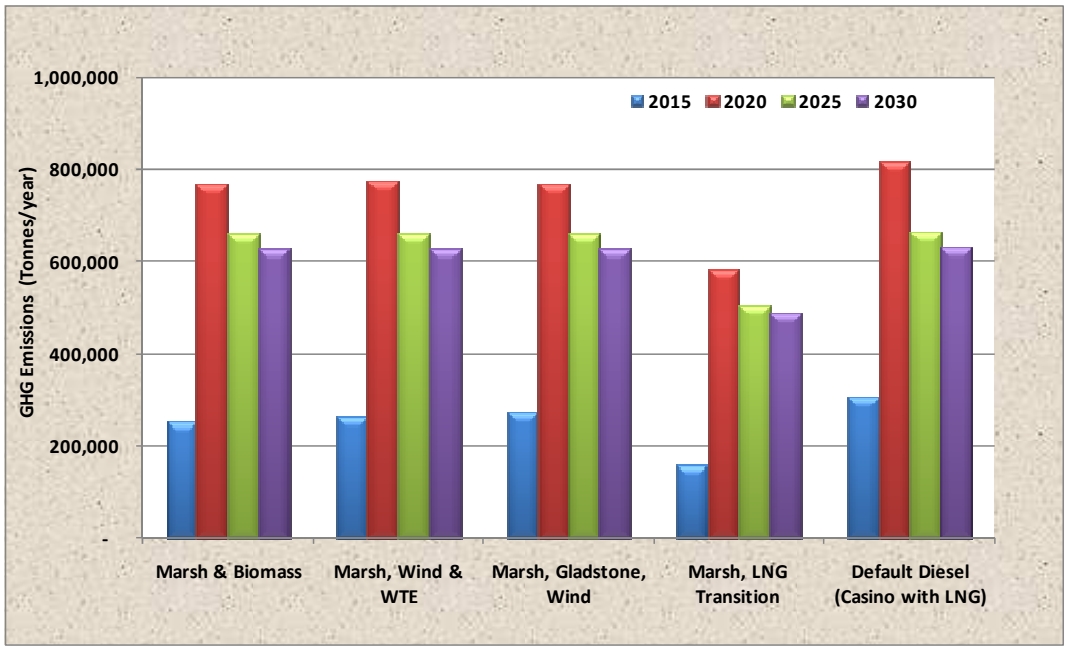
Portfolio Option continues through 2030 to show potential rate impacts that are materially lower than the potential rate impacts for all Minimum GHG Portfolio Options as well as the Default Diesel Portfolio.

Comparative GHG Emission Impacts for Near-Term Portfolio Options

LNG is the only non-diesel portfolio option examined for the near-term that can be used off-grid to reduce reliance on diesel (i.e., either off-grid communities or industrial customers).

Figure 6-5 demonstrates that when off-grid industrial and utility diesel community load opportunities are fully considered, near-term LNG supply development in Yukon as part of the LNG Transition approach has the potential to achieve far lower overall GHG emission levels from power generation in Yukon during the next 5-10 years than can be secured by grid-focused Minimum GHG Emissions Portfolio Options.

Figure 6-5: Portfolio Option Yukon GHG (tonnes/year) – 2015-2030
Grid Scenario A with DSM/SSE, Off-grid Diesel Community, & Off-Grid Mines



Total Yukon GHG Emissions (Tonnes/Year)[1]

	2015	2020	2025	2030
Marsh & Biomass	252,384	767,010	661,267	625,287
Marsh, Wind & WTE	263,266	775,226	661,267	625,287
Marsh, Gladstone, Wind	270,569	769,132	661,267	625,287
Marsh, LNG Transition[2]	158,844	582,266	505,355	488,089
Default Diesel (Casino with LNG)	306,067	815,235	662,522	630,560

1.Grid Scenario A with DSM/SSE, Off Grid Diesel Communities, & Off Grid Mines
2. Assumes LNG simple cycle at Watson Lake, LNG combined cycle at all mines.

The specified resource portfolios are examined in Figure 6-5, with any requirements not met by the specified resources assumed to be supplied by diesel generation under each portfolio. LNG is the only resource option other than diesel that can be applied in the near-term to off-grid as well as on grid requirements. The analysis excludes potential LNG impacts to reduce diesel and oil products in Yukon transportation and heating end uses (the largest GHG generating sectors in Yukon today).

- Yukon GHG emissions are materially lower in each time period with LNG than with any other resource option; reflects ability to apply LNG to off-grid diesel displacement.
- Overall LNG accessibility for all potential Yukon uses is facilitated by co-ordinated near-term planning and actions.

7.0 LONGER-TERM RESOURCE OPTIONS TO DEFAULT DIESEL

Greenfield Hydro Opportunities

A range of greenfield hydro resource project opportunities are potentially available to start construction before 2021, subject to appropriate planning and development of loads sufficient to fully utilize these resources[35]. These opportunities offer potential to establish sustainable lower cost electricity as well as low GHG emissions in a way similar to that secured by earlier legacy hydro developed in response to earlier major Yukon industrial mine developments.

Table 7-1 summarizes the available hydro sites by size of project, indicating key features as currently estimated (potential installed capacity, annual energy, capital cost and levelized lifecycle cost at full utilization)[36]. Total potential supply exceeds 6,800 GW.h/year at full utilization levelized cost (including transmission) below 15 cents per kW.h.

- **Hydro Options at less than 10 cents/kW.h** – Nine sites or schemes are identified with estimated Full Utilization LCOE's (2009$) below 10 cents per kW.h and over 4,390 GW.h per year of average annual sustainable energy (net of duplication among sites); four of these sites are Medium scale (11-60 MW) that could together provide over 850 GW.h/year; the other sites are Large scale (>60 MW).

- **Hydro Options at 10-15 cents/kW.h** – A further eight sites or schemes are identified with Full Utilization LCOE's between 10 and 15 cents per kW.h and over 2,000 GW.h of additional average annual sustainable energy; five of these sites are Medium scale (over 850 GW.h/year); the other sites are Large scale (>60 MW).

- **Other Medium Scale Hydro Options** – A further two Medium scale sites located north of the Watson Lake area are identified with Full Utilization LCOE's under 15 cents per kW.h if exceptionally high transmission cost estimates to connect to the existing grid are excluded from consideration. Together, these sites could provide over 375 GW.h per year of additional average annual sustainable energy.

[35] The geothermal option is identified in the 2011 Resource Plan as "other long-term options" in Yukon that might provide both low cost and low GHG emissions at some point during the planning period – however, beyond monitoring of related activities (e.g., geothermal exploration and confirmation drilling), the 2011 Resource Plan does not consider specific planning activities for the next five years. Similarly, monitoring of ongoing activities is all that is considered today with regard to potential development in the future of a natural gas pipeline, Eagle Plains gas, or transmission connection to the BC grid and/or Alaska.
[36] See Figure 1-2 for map showing the location of identified load and resource supply options.

Development of such longer-term renewable resource options is subject to connecting new grid loads that could fully utilize the specific resource options over 20-30 or more years.

- Potential off-grid mine developments prior to 2021 relying on fossil fuel generation are identified that could potentially exceed 1,500 GW.h/year and remain above 1,300 GW.h/year through 2045 in the event that three of these multi-decade off-grid mines are developed, i.e., the Casino Property west of the CSTP grid (940 GW.h/year), the Selwyn project located to the east of the WAF grid in the passes close to the border with NWT (147 GW.h/year), and the Northern Dancer project located near the Alaska Highway east of Teslin (200-300 GW.h/year).

- If the Alaska Highway Pipeline project proceeds, gas compressors for this project could potentially add 1,470 GW.h/year of additional equivalent energy requirements (six compressor stations) by approximately 2020/21 that would also be sustained over 25 years in the event that GHG emissions concerns support electrification initiatives.

Table 7-2 identifies potential off-grid mine loads and/or pipeline compressor loads that could radically change the electricity generation sector in Yukon during the next 5 to 10 years. These potential new loads offer the opportunity to plan for new legacy hydro development opportunities concurrent with actual development of new major mines or other major new loads. The following possible development packages are noted:

- **Develop Southern Lakes Grid Connection** – These are not low cost options; development of some of these options might be considered if Gladstone is not able to proceed and loads remain uncertain.

- **Develop Grid East of Ross River** – Potential options to consider in connection with Selwyn/Mactung mine loads, which offer 20+ years of load.

- **Develop Southern Grid to East Near Alaska Highway** – Potential options to consider in connection with Northern Dancer mine load and/or Alaska Highway Pipeline compression loads which offer 20+ years of load.

- **Develop Central & Western Yukon Grid** – Potential options to consider in connection with Casino and other mine loads south of Dawson City, which offer 20+ years of load.

Protecting the option to start construction for such projects before 2021 is contingent upon sustaining sufficient site specific planning processes as required throughout the next five year period through 2015. Figure 7-1 sets out proposed planning activities that would need to be pursued during the next five to ten years to protect the ability to start construction prior to 2021.

Coordination with LNG Transition Portfolio Option

The LNG Transition Portfolio Option is a near-term rather than a long-term legacy resource option for Yukon. The intent is to displace LNG use with appropriate renewable resource options when it is cost effective to do so, i.e., when sustained high utilization can be effectively achieved for renewable options so as to secure Forecast Utilization LCOEs that are equivalent to or less than LNG costs.

LNG Transition Portfolio Options are expected to show escalating costs as natural gas prices increase at a rate faster than general inflation. By 2020, the initial year costs for a new hydro development with a levelized cost (2010$) of 10 cents/kW.h might potentially correspond to the then current costs for LNG-supplied generation - in which case, subject to securing sufficient long-term load, the transition from LNG to new hydro could occur relatively smoothly[37].

At such time as new hydro develops, LNG grid generating unit capacity no longer needed for baseload energy generation can be retained for peaking, low water and emergency/grid reliability use. These units are flexible as to the range of such uses - and will likely be dual fuel in nature such that they can also use diesel fuel if so required. Furthermore, when new hydro is developed LNG supplies are expected to continue to be provided in Yukon to meet remaining off-grid power loads as well as other sector loads such as transportation[38]. Introduction of LNG/natural gas supplies in Yukon will also likely create longer-term development of natural gas use in the transportation and heating sectors.

[37] Figure 6-2 shows annual costs per kW.h during the period of forecast connected mine loads (2015-2020), indications that LNG annual costs (with capital) during this period remain well below annual costs for all renewable options other than the hydro enhancement options (Marsh Lake Storage and Gladstone Diversion) - by 2020, LNG costs in escalated dollars approximate 19 c/kW.h (13 cents for fuel and O&M only).

[38] These same considerations apply in the event that natural gas supplies come to be available directly in Yukon through the Alaska Highway Pipeline Project and/or Eagle Plain gas development. LNG liquefaction facilities may need to be moved to (or developed in) Yukon - but ongoing LNG requirements are anticipated to remain for off-grid power uses and other sectors.

Table 7-1: Summary of Potential Hydro Sites

		Installed Capacity (MW)	Annual Energy (GWh)	Capital Cost (Million $2009)	Levelized Cost (c/kWh)
Small Hydro Projects <10MW)					
20-23 c/kWh	Moon Lake	5.8	32.9	126.8*	19.9
	Tutshi River	4.2	30.3	135.5*	23.1
	Tutshi (Windy Arm)	5.9	39.4	164.9*	21.6
	Pine Creek at Atlin	3.5-8	23-52	NA	NA
Medium Hydro Projects (<60 MW)					
< 10 c/kWh	Hoole Canyon with Storage	40.4	275	460.1	8.6
	Granite Canyon Small	60.0	400	670.3	8.7
	Slate Rapids	41.6	266	505.6	9.8
	Finlayson	17.0	128.9	233.7**	9.4
10 to 15 c/kWh	Ross Canyon	30	181	495.0	14.1
	False Canyon	58	370	1,036.3**	14.5
	Two Mile Canyon	53.1	280	696.5	12.9
	Combined Slate Rapids[1] & Hoole	50.1	351.1	728.9	10.7
	Slate Rapids[1] (powerhouse at foot of dam	22.3	156.3	441.4	14.6
Other[2]	Middle Canyon	38.0	200	773.5***	20.0
	Upper Canyon	25.2	176.6	677.2***	19.8
Large Hydro Project (>60 mW)					
< 10 c/kWh	Granite Canyon High	254.0	1,783	1,680.7	4.9
	Fraser Falls Low	100.0	700	1,340.4	9.9
	Granite Canyon Low	80.0	600	934.8	7.3
	Fraser Falls High	300.0	2,100	2,540.6	6.3
	Combined Slate Rapids & Hoole	69.4	459	849.7*	9.6
10 to 15 c/kWh	Detour Canyon	65.0	435	1,057.0	12.6
	Detour Canyon w storage At Pelly Lakes	100.0	585	1,301.0	11.5
	Liard Canyon	93.5	659	1,554.6**	12.2

Notes:

1. Powerhouse at foot of dam

2. Excluding exceptionally high transmission costs to connect to existing grid, these sites would be under 15 cents per kW.h.

* Transmission costs to connect to grid are 18% of cost for Tutshi (Windy Arm), 21% of cost for Combined Slate Rapids & Hoole Canyon, and 26-27% of cost for Moon Lake & Tutshi River.

** Transmission costs are 33% of cost for Liard Canyon, 36% of cost for Finlayson, and 38% of cost for False Canyon.

*** Transmission costs to connect to existing grid are estimated at 54-55% of cost for these sites.

Table 7-2: Yukon Industrial Load Opportunities and Potential Hydro Sites

POTENTIAL INDUSTRIAL LOAD OPPORTUNITIES

Developing low cost/low emission hydro options depends on connecting new grid loads that could adequately utilize the resource for 20-30 years

DEVELOP SOUTHERN LAKES GRID CONNECTIONS

Timing for development of these projects in the next decade will depend on whether or not Gladstone is developed, future grid loads and definition of distinct hydro project opportunities

DEVELOP GRID TO EAST OF ROSS RIVER

SELWYN (147 GWh/yr) **& MACTUNG**
30+ year load in service 2014/15 - A medium hydro project in the 17-30 MW range (129 to 181 GWh/yr) to the east of the northern WAF grid could match all or most of the Selwyn load

DEVELOP SOUTHERN GRID TO EAST NEAR ALASKA HWY

NORTHERN DANCER (200-300 GWh/yr) - a 30 year load in service in 2017 to east of Teslin. A medium hydro project to serve this load could provide basis for extension of grid in south-east portion of Yukon

PIPELINE COMPRESSOR - Marsh Lake - 245 GWh/yr load per compressor in service in 2020/21 - Could provide anchor load for a medium hydro project in 266-280 GWh range (25 year load)

PIPELINE COMPRESSOR - Alaska Hwy - 245 GWh/yr load per compressor in service in 2020/21; May provide an opportunity to develop sites and transmission in east Yukon such as Liard Canyon (25 year load); Liard Canyon may also support develpment of NORTHERN DANCER

DEVELOP CENTRAL & WESTERN YUKON GRID

CASINO MINE (940.8 GWh/yr)
20-30 year load in service in 2018-19 - A large hydro project in the 69-100 MW range (450-700 GWh/yr) reasonably near the CSTP grid could match a large share of the Casino Load

POTENTIAL HYDRO DEVELOPMENT OPPORTUNITIES

		Installed Capacity (MW)	Annual Energy (GWh)	Levelized Cost (c/kWh)
Small Hydro Projects (<10MW)				
	Southern Lakes Projects			
20-23 c/kWh	Moon Lake	5.8	32.9	19.9
	Tutshi River	4.2	30.3	23.1
	Tutshi (Windy Arm)	5.9	39.4	21.6
	Pine Creek at Atlin	3.5 to 8	23-52	N/A
Medium Hydro Projects (<60 MW)

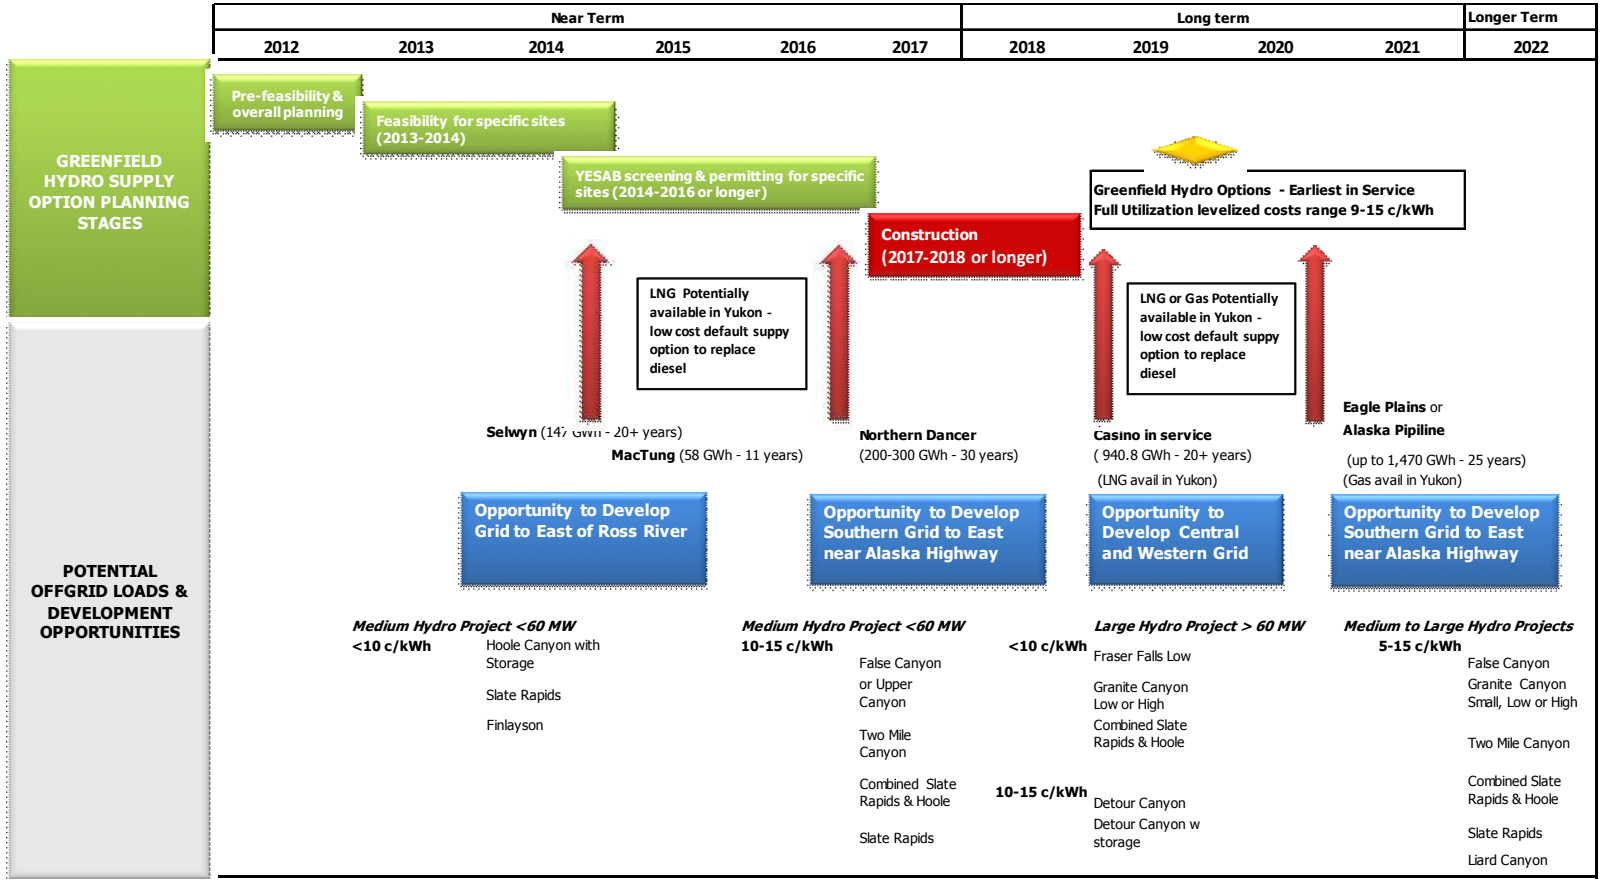
	Slate Rapids	41.6	266	9.8
	Finlayson	17	128.9	9.4
10-15 c/kWh	Ross Canyon	30	181	14.1
Medium Hydro Projects (<60 MW)				
10 to 15 c/kWh	False Canyon	58	370	14.5
	Middle Canyon*	38	200	20.0
	Upper Canyon*	25.2	176.6	19.8
	Two Mile Canyon	53.1	280	12.9
8.7 10 to 15 c/kWh	Combined Slate Rapids & Hoole	50.1	351.1	10.7
	Granite Canyon Small	60	400	8.7
	Slate Rapids	22.3	156.3	14.6
Large Hydro Project (> 60 MW)				
10-15 c/kWh	Liard Canyon	93.5	659	12.2
Large Hydro Project (> 60 MW)				
< 10 c/kWh	Granite Canyon Low	80	600	7.3
	Fraser Falls Low	100	700	9.9
	Granite Canyon High	254	1783	4.9
	Fraser Falls High	300	2100	6.3
	Combined Slate Rapids & Hoole	69.4	459	9.6
10 to 15 c/kWh	Detour Canyon	65	435	12.6
	Detour Canyon w storage	100	585	11.5

*Transmission costs to connect to existng grid are 54-55% of levelized cost.

Figure 7-1: Overview of Planning Activities for Greenfield Hydro Supply Option Development - 2011-2021



8.0 SUMMARY CONCLUSIONS & RECOMMENDED PLANS

Overview of Options

Figure 8-1 summarizes near-term options examined in the 2011 Resource Plan in the context of Yukon Energy's four key planning principles. Conservation/efficiencies (DSM/SSE) programs are being developed as an option to be pursued in combination with other selected resource options.

Figure 8-1: Near-Term Resource Supply Options[39]

OPTIONS	**Reliability** Winter Peak Capacity; Development Timing & Cost	**Affordability** Potential lifecycle cost per kWh if fully used	**Flexibility** Ratepayer Risk re: Mine Load Reductions	**Environmental Responsibility** Env. Mitigation; GHG Emission Reduction
Southern Lakes (Marsh Lake) Hydro Enhancement	**Medium**	**High**	**Medium**	**High**
Gladstone Diversion Hydro Enhancement	**Medium**	**High**	**Medium**	**High**
Conservation / Efficiencies	**Medium**	**High**	**Medium**	**High**
Biomass	**High**	**Medium**	**Low**	**High**

Wind	**Low**	**Low**	**Low**	**High**
Diesel	**High**	**Low**	**High**	**Low**

Table 8-1 provides an overview of the near-term resource options identified for potential construction start on the grid before 2015 (including a 3 MW wood biomass pilot plant option[40]), and the longer term resource options identified for potential construction start before 2021. The Gladstone Diversion project is excluded from the near-term options on the basis that construction start is not feasible before 2015, and

[39] See Table 4-1 for more detail.

[40] The 2011 Resource Plan examined various wood biomass plant options, ranging from 10 MW to 25 MW and at different locations to accommodate potential wood biomass supply (e.g., Whitehorse for 25 MW plant; 10 to 15 MW plant in Minto burn area option). Based on feedback from the workshop held on wood biomass, this option has been scaled back to a 2-3 MW wood biomass pilot plant option. Yukon Energy is currently developing a partnership with the Champagne and Aishihik First Nations and Dakwakada Development Corporation to examine opportunities for a small-scale (2-3 MW) wood biomass pilot project, potentially with existing wood operations at Haines Junction, and to seek funding support for this pilot plant.

earliest in-service is in late 2017. Table 8-2 provides a more detailed overview of the near-term resource option capabilities and costs under both Scenario A and B grid loads with DSM/SSE.

In the near-term, LNG is identified in the 2011 Resource Plan as the only near-term option that can totally displace Default Diesel on the grid during 2015-2019 with forecast Scenario A or B loads (e.g., with forecast diesel generation ranging from 85 to 143 GW.h/year with DSM/SSE). Excluding the relatively small energy impact Marsh Lake Storage hydro enhancement option (approximately 6 GW.h/year), LNG is also the lowest cost near-term option, with costs per kW.h of diesel displaced less than half the cost of diesel. Wood Biomass ranks second behind LNG in diesel displacement capability, but is the highest cost near-term option (with costs per kW.h of diesel displaced higher than the cost of diesel). The only other near-term option with potential ability to displace more than 50% of Scenario A diesel generation requirements (i.e., Wind) has 2015-2019 costs per KWh only slightly lower than diesel, and forecast LCOE costs that are higher than diesel under Scenario A or B loads with the assumed DSM/SSE.

In contrast to the near-term options, longer term hydro options are identified in the 2011 Resource Plan that offer a wide range of annual energy capability (e.g., options in Table 8-1 range from 33 to over 450 GW.h/year), with several options also having estimated Full Utilization LCOE at less than 10 cents/kW.h. The 2011 Resource Plan outlines the requirements for successful development of these longer term options, including securing appropriate long-term loads as required to adequately utilize such options over 20-30 or more years and sustaining sufficient and successful site specific planning processes over the next five years to protect the ability for potential construction start before 2021.

Tables 8-1 and 8-2 also show the extent to which each near-term resource option's economic feasibility (i.e., comparative LCOE) is affected by the option's flexibility to adapt to Yukon's isolated grid and the expected range of load and hydro generation conditions on this grid.

- LNG, Wood, Wind and Waste-to-Energy options, for example, show minimal variation in estimated LCOE when full utilization is simply assumed of all electricity generated for each option, e.g., LCOEs (2010$) for these options range from 12 c/kW.h for LNG to 17 c/kW.h for the 3 MW Wood Pilot.

- However, when Scenario A forecast loads (which are well in excess of Base Case loads) and expected hydro conditions on Yukon's isolated grid are considered, LNG is the only option with an LCOE at less than 20 c/kW.h for diesel displaced, and the 3 MW Wood Pilot is the only other option with an LCOE less than diesel fuel and O&M cost at 28 c/kW.h. Higher LCOEs for Wind, 15 MW Wood Biomass and 2.2 MW Waste-to-Energy options in this instance reflect relative

inflexibility to adapt to an assumed sharp drop in mine loads on the grid after 2020 as well as seasonal and annual variability in hydro generation on the grid.

LNG Transition Option Near-Term Benefits

In summary, the 2011 Resource Plan indicates that the LNG Transition Portfolio option provides a range of potential benefits relative to the other near-term grid generation options available for potential commitment before 2015:

- LNG is superior to diesel in terms of cost (affordability) and emissions (environmental responsibility); relative to near-term renewable resource options, LNG is less costly while also providing high reliability, flexibility and diversity of potential Yukon uses on and off-grid.
- Where established, LNG would displace diesel as the default option in Yukon (although dual fuel units could also cost effectively retain flexibility to use diesel if and when advantageous). Lower cost LNG fuel would affect the assessment of future resource choices and also incremental pricing and rate setting in the rate zones where it is utilized, i.e., run out rates for higher use levels could be set based on LNG costs rather than diesel fuel costs.
- Other potential development benefits include:
    - LNG is the only option to offer material reductions in near-term rate increase impacts relative to diesel under Scenario A or B loads, as well as the non-diesel option with the lowest rate impacts in the event that currently assumed mine closures reduce grid loads after 2020.
    - LNG provides a cost effective contribution to grid capacity planning requirements, and the planned retirements of all of YEC's diesel plant over the 20-year planning period.
    - As a result of the above impacts, LNG is the only option to offer opportunity to reduce present value diesel costs during the planning period under Scenarios A and B (projected reductions at 35% under Scenario A and 41% under Scenario B).
    - Overall, LNG offers high flexibility with ability to be turned off and ability to accommodate load changes; it can provide cost effective baseload generation and backup capacity, and can be cost effectively developed concurrently with hydro enhancements such as Marsh Lake Storage and Gladstone Diversion.
    - The LNG Transition Option can accommodate optimum timing for Gladstone diversion, other potential hydro enhancements or greenfield developments, and wind development

in response to confirmation of longer-term grid loads needed to secure reduced Forecast LCOE for these various renewable resource options.

- LNG is the only portfolio option that can be used off-grid to reduce reliance on diesel (i.e., off-grid communities such as Watson Lake and mines at various off-grid locations). This option can also be used to reduce GHG emissions in other sectors where GHG emissions impacts are more significant (e.g., transportation).

In order to pursue the LNG option for near-term development for power generation in Yukon by late 2014, Yukon Energy is pursuing further feasibility work to determine the optimum way to secure the LNG, the required timing and all related costs (including assessment of potential options for LNG supply chain development jointly with other interests to meet broader near and longer term Yukon opportunities). Feasibility work is also being pursued to optimize the specific Yukon Energy generation capacity and technology for power generation using LNG (including assessment of the optimum combination of combined cycle and simple cycle units in response to different potential load scenarios).

Resource Portfolios - Combining Options

Combining projects on the Yukon grid can dilute the benefits and raise LCOEs relative to what is shown for individual options.

For example, the Scenario A (with DSM/SSE) LCOE is 11.4 c/kW.h for Marsh Lake storage on its own and 8.0 c/kW.h for Gladstone Diversion on its own (see Table 8-1) - however, combining these two hydro enhancement projects results in a higher overall LCOE at 13.1 c/kW.h for the combined projects.

Similarly, LCOEs (2010$)per kW.h of displaced diesel generation for various renewable resource options under Scenario A loads are significantly higher when combined with the assumed DSM/SSE than when assessed without DSM/SSE[41]:

- Marsh Lake Storage LCOE: 11.4 c/kW.h with DSM/SSE, 8.6 c/kW,h without DSM/SSE.
- Gladstone Diversion LCOE: 12.0 c/kW.h with DSM/SSE, 6.5 c/kW,h without DSM/SSE.
- 2.2 MW Waste to Energy: 31.5 c/kW.h with DSM/SSE, 17.6 c/kW,h without DSM/SSE.
- 3 MW Wood Pilot: 35.4 c/kW.h with DSM/SSE (with assumed shut down in 2020), 22.7 c/kW,h without DSM/SSE (no shut down).
- 15 MW Wood Biomass LCOE (with assumed shut down after 2020): 40.1 c/kW.h with DSM/SSE, 17.8 c/kW,h without DSM/SSE.

[41] LNG LCOE for Scenario A also slightly reduced (18.4 c/kW.h with DSM/SSE, 14.0 c/kW.h without DSM/SSE).

- 21 MW Wind with 5 MW DRUPS: 40.0 c/kW.h with DSM/SSE, 19.6 c/kW.h without DSM/SSE.

In summary, dilution of benefits and higher LCOEs that result from combining projects highlight once again the extent to which load and hydro conditions on the isolated Yukon grid can critically affect economic assessment of resource option portfolios.

Table 8-1: Overview of Resource Options - Capabilities and Costs

	Capital (2010$ million)	Capacity (MW)	Energy Capability (Average GWh/yr)	2015-2019 Diesel Required/ Displaced (GWh/yr)	2015-2019 Annual Costs (cents/kW.h diesel displaced)	LCOE (2010 c/kWh) Scenario A	LCOE (2010 c/kWh) Extend 2019 load to 2030	LCOE (2010 c/kWh) Full Utilization

* Shut down after 2020

Note #1: 10.5 MW wind option was slightly less cost-effective at forecast loads.

Graphic Comparisons of Near-Term Options

Figures 8-2, 8-3 and 8-4 compare key features of the near-term options and Gladstone Diversion under Scenario A loads with DSM/SSE, highlighting each option's comparative diesel displacement capability (GW.h/year) during 2015-2019. DSM/SSE (conservation/efficiency) option impacts as assumed in the 2011 Resource Plan are also included for broad comparison[42].

Figures 8-2 and 8-3 compare lifecycle costs per kW.h (LCOE) and capital cost for each option, with Figure 8-3 showing the extent to which LCOE is reduced for each option under Scenario A if the 2019 grid loads are extended to 2030.

- Based on total capital costs ($2010) as shown in Figures 8-2 and 8-3, the wind and large scale biomass options require considerably higher capital costs than other near-term options, and LNG provides far greater diesel displacement than any other option requiring similar capital costs.
- Based on LCOE (2010$) for Scenario A loads with DSM/SSE as shown in Figure 8-2, near-term options with forecast lifecycle costs that are less the diesel include conservation/efficiency, hydro enhancements (Marsh Lake and Gladstone Diversion) and LNG; near-term option options with forecast lifecycle costs that are more than diesel include the biomass and wind options.
- Comparison of Figure 8-2 and 8-3 LCOE for any option highlights sensitivity to major changes in grid loads over the planning period, e.g., the wind and biomass options show significantly lower LCOE's if the 2019 grid loads are assumed to be extended to 2030.

Figure 8-4 focuses on impacts in the 2015-2019 period, comparing costs per kW.h and percentage savings in diesel fuel and O&M costs for each option.

- Differences in cost per kW.h of diesel displaced for the first few years of operation (2015-19) reflect normal utility costing (e.g., capital costs charged per year decline over the project life).
- Comparative near-term diesel fuel and O&M cost savings for ratepayers reflect diesel displacement capability as well as near-term cost saving capability per kW.h relative to diesel generation for each option, and highlight LNG's overall cost saving benefits relative to other near-term options.

[42] These figures show the maximum potential DSM/SSE (conservation/efficiency) diesel displacement impacts assumed in the 2011 Resource Plan for non-industrial load reduction during the 2015-2019 time period. As noted in Appendix A, pending completion of current DSM/SSE planning, it is considered that likely DSM/SSE over the period to 2030 will be 50% of this maximum. In the near-term period from 2015 to 2019, DSM/SSE will be in an initial implementation phase and accordingly may be less (relative to the 2011 Resource Plan maximums) than levels expected to be achieved by 2030.

Recommended Plans

Based on the 2011 Resource Plan, Yukon Energy's recommended plans for the period prior to 2015 include the following (in addition to implementing cost-effective DSM/SSE pursuant to the separate ongoing planning process currently underway with other parties):

1. **LNG Transition Option:** Subject to successful completion of current assessments, determine whether Yukon Energy is able to establish LNG generating capability in Whitehorse prior to 2015 with sufficient capacity to displace grid diesel generation under current Base Case grid load forecasts, and determine the feasibility of utilizing LNG in the event that material additional near-term grid loads occur such as those assessed in Scenarios A and B. This action is being undertaken to implement LNG as a transition option that is able to meet current forecast loads with the least cost option available for near-term implementation, i.e., prior to 2015, and with reduced GHG and other emissions relative to diesel generation.

2. **Near-term Hydro Enhancements:**

    a. Complete the required environmental, engineering and remediation studies related to the Marsh Lake Storage hydro enhancement project and make a determination whether it is feasible and cost effective to proceed once this information is available.

    b. Plan within the next 6 to 12 months to reach a final determination regarding whether Gladstone Diversion is feasible to pursue further at this time, based on discussions with local First Nations and regulators.

3. **Future Development:**

    a. **Wind:** Finish current Ferry Hill wind monitoring in order to have this project shelf-ready to pursue through regulatory submissions and other development activity at such time as grid loads and other relevant conditions indicate that this project would be cost-effective to implement. Continue to examine for initial development the feasibility of smaller wind projects in the range of 10 MW to meet suitable grid loads.

    b. **Greenfield Hydro Sites:** Continue to carry out planning studies to identify and plan priority longer-term greenfield hydro development opportunities as recommended in the 2011 Resource Plan, including Hoole and Finlayson sites, and seek funding support for these activities.

4. Other Longer-Term Resource Planning:

a. **Geothermal:** Carry out scaled down geothermal investigations and look for funding support for geothermal exploration and studies, and seek funding support for these activities.

b. **Grid Extensions:** Continue to explore opportunities to extend the grid within Yukon, and to connect the Yukon grid to British Columbia and/or Alaska (including Skagway). A watching brief with regard to grid extensions to BC or Alaska and other potential longer-term resource options.

c. **Wood Biomass:** Identify and pursue opportunities for a small scale (e.g., 2 to 3 MW) wood biomass pilot project, potentially in association with existing wood operations at Haines Junction, and seek funding support for this pilot project.

d. **Other Options:** Continue watching briefs with regard to other resource options, including:
   i. Solar (cost-effective proven technology development suited to Yukon market conditions); and
   ii. Pipeline/natural gas (commitments by others regarding Alaska Highway Pipeline and/or potential Eagle Plain or other Yukon natural gas development).

APPENDIX A: UPDATED NEAR-TERM GRID LOAD SCENARIOS

The 2011 Resource Plan grid load scenarios are updated on an ongoing basis. As at spring 2012, four load scenarios are currently applicable for Yukon Energy grid generation and capacity planning (see Table A-1):

1. Load scenarios without connection of major new mines:

    a. **Base Case:**[43]

        i. GRA forecast loads for 2012 and 2013;
        ii. non-industrial growth after 2013 at 2.26%/year less 50% of DSM/SSE assumed in 2011 Resource Plan;
        iii. Minto generation load at 46.7 GW.h/yr (same as 2013) until 2019, and 23.4 GW.h in 2020 until mid-year (no load thereafter);
        iv. Alexco generation load at 21.7 GW.h/year 2014-16 (as compared to 15.9 GW.h/yr forecast in 2013); 15.0 GW.h/yr assumed 2017-2020 (no load thereafter); and
        v. Whitehorse Copper Tailings (WHCT) at 9.3 GW.h/yr 2014-2018 (as compared to 5.2 GW.h/yr in 2013) and 4.1 GW.h in 2019 (no load thereafter).

    b. **Base Case with Brewery Creek:** Base Case with the added connection, starting January 2014, of Brewery Creek mine with generation load assumed of 20.5 GW.h/yr in 2014 and 33.88 GW.h/yr thereafter until the end of 2023[44].

2. Load scenarios with connection of major new mines:

    a. **Scenario A:** Base Case with Brewery Creek and Victoria Gold mine, starting January 1, 2015 with generation load of 103.3 GW.h/yr that continues until the end of 2024 (no load thereafter)[45].

[43] The Base Case loads are expected to be reviewed in future to consider higher near-term non-industrial load growth (related to increased use of electric heat, consideration of Whistle Bend subdivision development impacts, and expected DSM/SSE timing which may indicate lower DSM/SSE impacts in near-term), and more recent information on Minto, Alexco and WHCT loads. The current Base Case does not consider Capstone's June 2012 announcement of Phase VI Pre-feasibility study results that extend Minto mine life to 2022. PPA negotiation for WHCT has not yet commenced.

[44] Negotiation of a PPA with Brewery Creek has not yet commenced. The load forecast includes expansion as provided by WHCT plans. This mine has expressed interest in connection in second half of 2013.

[45] PPA negotiations are ongoing with Victoria Gold (an earlier LOI set out principles for connection to the grid). It is assumed that Victoria Gold will pay all costs required for grid connection, plus upgrade of the Mayo-Keno line. The timing for connection of this mine remains uncertain (but will not be earlier than the Q1 2015 assumed in Scenario A).

b. **Scenario B:** Base Case with Brewery Creek, Victoria Gold and Carmacks Copper mine, starting January 1, 2015 with generation load of 56.5 GW.h/yr that continues until the end of 2020 (no load thereafter)[46].

[46] Carmacks Copper has recently re-started its regulatory review processes, with an announced filing of a revised application planned this fall with YESAB, followed shortly thereafter with revised filing with the YWB. PPA discussions occurred in the past, and have been restarted – Carmacks Copper will be required to pay all costs required for grid connection plus a contribution to CSTP capital costs. The timing for connection of this mine remains uncertain, but could potentially occur during 2015 or (perhaps more likely) during 2016.

Diesel Energy Requirement (GWh)	2012	2015	2020	2025	2030
Base Case	11.5	27.0	24.4	24.5	51.9
Base Case with Brewery Creek	11.5	45.5	47.1	24.5	51.9
Base Case with Brewery Creek and Victoria Gold	11.5	135.2	128.8	24.5	51.9
Base Case with Brewery Creek, Victoria Gold and Carmacks Copper	11.5	187.1	181.0	24.5	51.9

Figure A-1 and table provide the forecast diesel generation requirement during the 20-year planning period for each of the load scenarios.

1. The numbers are based on updated load for 2012-2030.
2. Diesel requirement numbers are long-term average diesel.
3. Model run with Aishihik 10-year rolling average rule, Mayo Lake assumed in-service by winter 2013/14 (more recent information suggests earliest in-service is now winter 2014/15).

Diesel generation forecasts for each load scenario reflect long-term average hydro generation, i.e., the average hydro generation over 28 recorded water year conditions at the assumed load, as estimated by the power benefits model used by YEC for grid generation planning. Table A-2 and the Figure A-2 below it provide a detailed review of potential diesel generation variability for the year 2015 under each load scenario for each of the 28 water years (the figure shows the annual load duration curve for diesel for each load scenario).

Table A-2: Forecast Diesel Generation Variability (GW.h) Depending on Water Year Conditions - Load Scenarios for 2015 and 28 Water Years of Record

Average Annual Diesel Generation (Averaged Load Years for 28 Water Years)

Water Year	2013 GRA - load at 430.4 GW.h	2015 Base Case - load at 449.1 GW.h	2015 Base Case w Brewery Creek - load at 483 GW.h	Average diesel generation required (GW.h) Scenario A - 2015 load at 586.2 GW.h	Scenario B - 2015 load at 642.7 GW.h

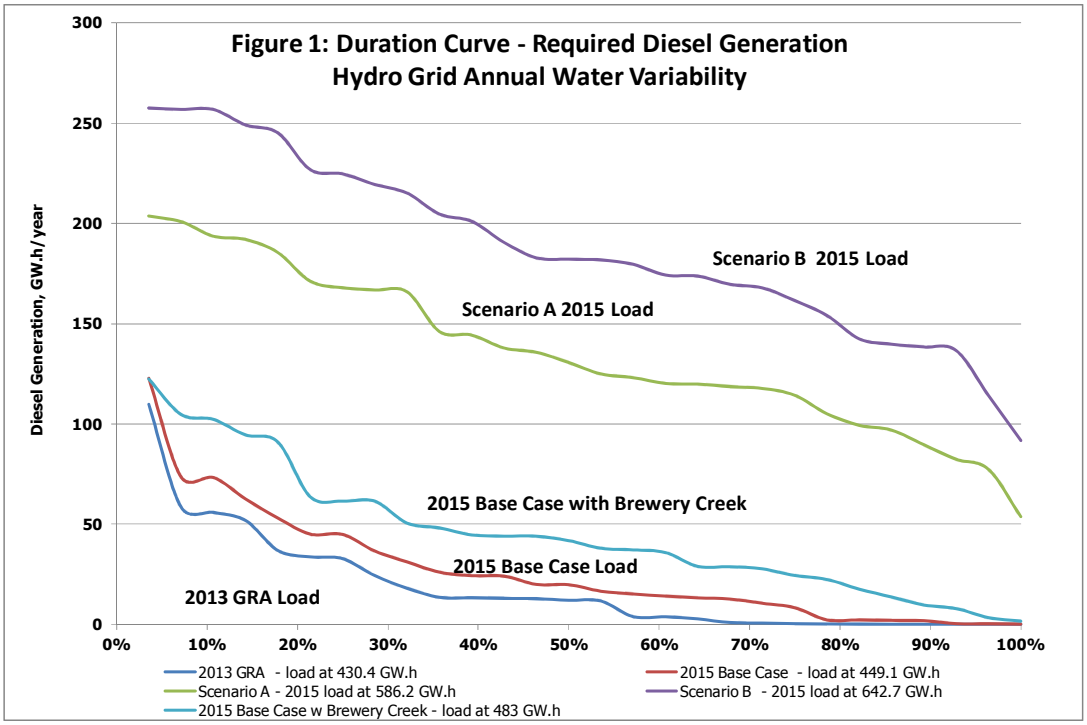
Figure A-2: Duration Curve – Required Diesel Generation Hydro Grid Annual Water Variability



Projected annual grid capacity MW surplus (shortfall) under each load scenario is provided in Table A-3, assuming existing plant and planned diesel unit retirements and applying YEC's approved N-1 and LOLE capacity planning criteria. These shortfalls assume that L172 is re-enforced (with by twinning or by provision for the 35 kV system to be able to by-pass this line between Takhini and McIntyre substations).

The following are noted regarding assumed diesel unit retirements, using projected shortfalls under the Base Case to demonstrate the impact of assumed retirements:

- 2015 Base Case shortfall of 3.3 MW: reflects following 8 MW of diesel unit retirements:
    - Mirrlees WD#1 and WD#2 retired in 2014/2015 (2011 Resource Plan rating of 3.50 and 4.5 MW=8 MW total).
    - Replacing one of these units with at least the same capacity would totally resolve the 2015 shortfall.
- 2020 Base Case shortfall of 15.7 MW: reflects following 13.11 MW of diesel unit retirements:
    - The above Mirrlees retirements (8 MW) plus.
    - Dawson retirement of 3 units (total 2.56 MW retired in 2017, 2018 and 2020).
    - Mayo retirement of 2 units (total 1.7 MW in 2019).
    - Faro retirement of 1 unit (0.85 MW in 2019).
- 2025 Base Case shortfall of 38.1 MW: reflects following 28.61 MW of diesel unit retirements:
    - The above 13.11 MW retired by 2020 plus.
    - Whitehorse retirement of 4 units (total 11.5 MW - last Mirrlees (4.5 MW) and 3 EMDs).
    - Faro Mirrlees unit (4.0 MW in 2021).
- 2030 Base Case shortfall of 51.5 MW: reflects following 34.41 MW of diesel unit retirements:
    - The above 28.61 MW retired by 2025 plus.
    - Whitehorse CAT (3.0 MW in 2026).
    - Faro CAT (2.8 MW in 2027).

EXECUTIVE SUMMARY

The Yukon Bureau of Statistics conducted the Electricity Values Survey in the spring of 2016 on behalf on the Yukon Energy Corporation (YEC). The purpose of the survey was to generate information on Yukon residents' preference for factors that would be affected by future electricity generation in Yukon. The survey also aimed at understanding Yukon residents' preferences and values relating to energy use.

A stratified random sample representing one-third of total eligible Yukon households was selected to complete the phone survey. The overall response rate for the survey was 63.2%, indicating the results are a good representation of all Yukon households.

Respondents ranked four major factors in order of importance to YEC's future projects. Environmental Protection was ranked first by 44% of respondents, followed by Cost (23%), Reliability (21%), and Social Responsibility (8%).

In contrast to the importance given to YEC's projects, when respondents were asked to rank five factors that influence their own home heating system selection, cost was the most important factor (chosen first by 45% of respondents) to influence a respondent's home heating selection. Respondents' selection of home heating system was more influenced by cost than all four other factors (safety, environmental concerns, comfort, and ease of maintenance) combined.

Respondents ranked statements on Environmental Protection in order of importance. 'Reduce pollution to land, water, and air, other than greenhouse gas emissions' was ranked first by 30% of households, followed by 'Reduce impacts on species' habitats and wildlife populations at risk' (24%), and 'Reduce impacts on Earth's atmosphere' (23%). 'Minimize the amount of land affected by a new energy project' was ranked last (12%).

While Social Responsibility was the factor least ranked first of the four major factors, a question asking respondents to rank statements relating to social responsibility revealed that one-third of Yukon households ranked 'Enhancing economic growth and creating jobs' as the most important social responsibility.

When asked if they would support specific Yukon Energy initiatives even if it meant a potential increase in electricity rates, respondents answered 'Yes' at the following percentages:

- An effort to reduce impact on species' habitats and wildlife populations at risk (81%)
- An effort to reduce GHG emissions in energy production (78%)
- An effort to create local jobs (73%)
- An effort to maintain access to wilderness recreation (73%)
- An effort to reduce power outages in your area (71%)
- An effort to not compromise traditional pursuits as a way of life (69%)
- An effort to enhance economic growth for Yukon (57%)
- A decision to supply electricity to mines (46%)

In ranking three energy sources in order of preference for Yukon's future, 59% of the responding households chose renewable energy as their preferred future energy source. About one-third (31%) preferred energy conservation as a future energy source, while only 5% preferred fossil fuels as a future energy source.

If YEC is required to choose a fossil fuel for future back-up generation, slightly over half of Yukon households (51%) would prefer the use of natural gas. Only 14% would prefer diesel fuel.

At 47%, fuel oil is the most prevalent primary home heating source in Yukon. Electricity (baseboard, furnace or boiler) is the second most prevalent primary home heating source and is used by a quarter (25%) of households. Of those who did not already use electricity as a primary or additional home heating source, only 18% had considered switching to electric heat.

Most households (41%) did not have an additional home heating source. Of households that did have additional home heating sources (59%), wood was the most common (36%) additional home heating source followed by electricity (31%). While fuel oil was the most commonly used primary source of heat, it was not commonly used (13%) as an additional home heating source.

A little over three-quarters of the respondents (76%) said their electricity bills are affordable, while 55% thought Yukon's current electricity rates are reasonable. Almost all respondents (97%) claimed they make efforts to reduce their energy use; however, a little over three-quarters (77%) of respondents said they 'always' or 'frequently' check the energy efficiency rating when purchasing a new appliance or electronic device.

Eighty-five percent of all households experienced at least one power outage in 2015. About two-thirds of the households felt it necessary to have back-up heating and/or a generator in case of power outages.

Most (61%) respondents were confident that YEC is able to plan and develop sustainable energy sources to meet future needs. About a fifth (19%) of the respondents said that that they do not have confidence in YEC's ability.

INTRODUCTION

The Electricity Values Survey 2016 was conducted by the Yukon Bureau of Statistics (YBS) on behalf of the Yukon Energy Corporation (YEC). The objective of the survey was to generate information on Yukon residents' perspectives on factors that need to be considered in planning for Yukon's future electricity needs. The results of the survey will be used in YEC's 2016 Resource Plan – a document that outlines how to meet Yukon's electricity needs for the next 20 years (2016 to 2035).

The Electricity Values Survey 2016 was designed to collect information primarily on Yukon residents' preference for factors that can potentially be affected by Yukon's future electricity generation. For instance, how would Yukon residents balance their preference between environmental protection, cost, reliability, and social responsibility, knowing that choosing any energy option requires trade-off? The survey questionnaire also included modules aimed to understand Yukon residents' interests and values relating to energy use so that they can be reflected in YEC's 2016 Resource Plan.

YBS conducted the survey using a Computer Assisted Telephone Interviewing (CATI) system. A stratified random sample[1] of 4,534 households representing one-third of the total eligible Yukon households (13,591) was selected to complete the CATI survey[2]. Only one person per household could complete the survey and the respondent was selected with a regressive eligibility criterion[3] based on their availability during the call. The overall weighted[4] response rate for the survey was 63.2% indicating that the results are a good representation of Yukon households.

The results of a survey with a response rate of 70% or greater are considered excellent, while those derived from a survey with a response rate between 60% and 70% are considered of good quality. Results from a survey below 60% response rate tend to have high margins of error. However, for highly important public opinion research involving key policy or resource allocation decisions, Canada's federal government departments target a response rate of 40% to 60%[5].

Appendices to this report contain the following information:

Appendix A: Results and summary tables of survey responses,
Appendix B: Survey response rates and survey delivery details, and
Appendix C: Survey questions.

The following analyses[6] provide a summary of results by survey question (or group of related questions). The results of the ranking questions are presented as percentages of first ranking as well as weighted averages of all rankings[7].

---

[1] All Yukon households were stratified by geography and household size (i.e., the number of household members) and random sample was drawn from each stratum. Smaller communities were allocated with a relatively bigger proportion of samples.

[2] The distribution of the valid sample was checked against that of the initial sample and the survey universe by stratum to ensure randomness of the sample with valid contact information.

[3] The most senior person, or the next senior person, or in their absence, an adult who is at least 18 years old.

[4] The distribution of the responses was checked against that of the sample by stratum, and the sample weights were calibrated to adjust for non-response.

[5] http://www.tpsgc-pwgsc.gc.ca/rop-por/rapports-reports/comitephone-panelphone/page-06-eng.html

[6] All graph values are represented as percentages of the sum of respondents based on weighted frequencies.

[7] Geometrically declining weights are applied to progressively reducing preferences to calculate weighted averages.

PART 1: UNDERSTANDING THE PUBLIC'S VALUES REGARDING YEC INITIATIVES

A critical part of YEC's resource planning work is to gather input from Yukoners so that the Corporation can create a plan reflecting Yukoners' values in terms of the territory's energy future. Since all energy options have impacts on often competing preferences and require trade-offs, YEC wanted to understand how the public would rank various factors in terms of their importance. Four broad categories of factors included Environmental Protection, Cost, Reliability, and Social Responsibility. Each survey question in this section is related to one or more factors in these categories.

FACTORS TO BE CONSIDERED FOR YEC'S FUTURE PROJECTS

Respondents were asked to rank four factors in order of importance for YEC's future projects. As shown in Figure 1, the four factors were ranked in order of importance as follows:

- Environmental Protection: 44.4% ranked first (weighted average of all rankings: 34.3%);
- Cost: 22.7% ranked first (weighted average of all rankings: 24.1%);
- Reliability: 21.0% ranked first (weighted average of all rankings: 22.5%), and
- Social Responsibility: 7.7% ranked first (weighted average of all rankings: 14.6%).

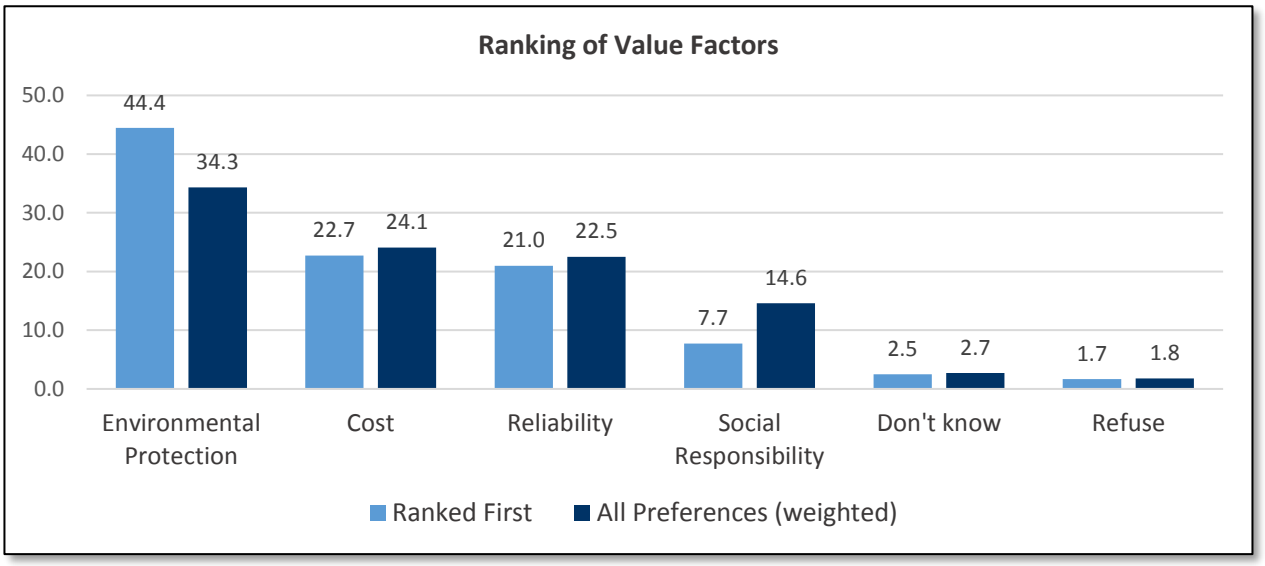

Figure 1. Ranking of factors that respondents would like YEC to consider in deciding on future projects.

Of those Yukon households that value *Environmental Protection* as the most important factor, 32.5% ranked the reduction of risk of pollution to land, water and air other than greenhouse gases as the most important form of environmental protection, followed closely by reduction of impacts on Earth's atmosphere (30.5%). Even with a potential increase in electricity rates, 71.0% households of this group would support YEC's effort to create local jobs. However, only 52.5% households would support YEC's effort to enhance economic growth. While ranking statements on *Social Responsibility*, 27.1% of this group ranked maintaining traditional pursuits as the most important *Social Responsibility*, and 23.9% chose economic growth and job creation as the most important. This group was split almost evenly between Yes (40.9%) and No (41.5%) when asked if they would support YEC's decision to supply

electricity to mines even with a potential increase to electricity rates. In addition, 57.0% of this group preferred renewable energy as the most important type of future energy source for Yukon. For 38.4% of this group, *cost* was the most important factor that influences their home heating selection, while only 18.7% identified *environmental concerns* as the most important factor.

Of households that value *Cost* as the most important factor, 31.2% ranked the reduction of pollution to land, water and air other than greenhouse gases as the most important form of environmental protection. Even with an increase in electricity rates, 76.4% of this group would support an effort to reduce impact on species' habitats and wildlife populations at risk, 75.8% would favour creation of local jobs, and 52.5% would support YEC's decision to supply electricity to mines. Most households (43.8%) in this group chose economic growth and job creation as the most important *Social Responsibility*. Further, 64.1% of this group preferred renewable energy as future energy source for Yukon and for 59.9%, *cost* was the most important factor that influences their home heating selection.

Of households that value *Reliability* as the most important factor, 32.4% ranked the reduction of pollution to land, water and air other than greenhouse gases as the most important form of environmental protection. Even with an increase in electricity rates, 77.2% of the respondents in this group would support efforts to reduce power outages in their areas and 75.8% would favour creation of local jobs. Majority of the households in this group (44.6%) ranked economic growth and job creation as the most important *Social Responsibility*. In addition, 61.4% of this group ranked renewable energy as the most important type of future energy source for Yukon and 51.4% said *cost* was the most important factor that influences their home heating selection.

Of households that value *Social Responsibility* as the most important attribute, 31.7% ranked the reduction of impacts on species' habitats and wildlife populations at risk as the most important form of environmental protection. Even with an increase in electricity rates, 84.9% of this group would support an effort to reduce impact on species' habitats and wildlife populations at risk, and 79.7% would favour an effort to reduce greenhouse gas emissions in energy production. Of this group, 34.4% ranked economic growth and job creation as the most important *Social Responsibility*. Further, 57.7% of this group ranked renewable energy as the most important type of future energy source for Yukon and for 31.7%, *cost* was the most important factor that influences their home heating selection.

ENVIRONMENTAL PROTECTION

Respondents were asked to rank statements on *Environmental Protection* in order of their importance. The statement 'reduce pollution to land, water and air, other than GHG emissions' was ranked first by 29.5% (weighted average of all rankings: 26.7%) of households (Figure 2). This was followed by 'reduce impacts on species' habitats and wildlife populations at risk' (23.7%; weighted average: 24.3%) and 'reduce impacts on earth's atmosphere specifically relating to GHG emissions' (22.6%; weighted average: 20.9%). 'Minimize the amount of land affected by a new energy project' was the least important to households at 12.1% (weighted average: 15.1%).

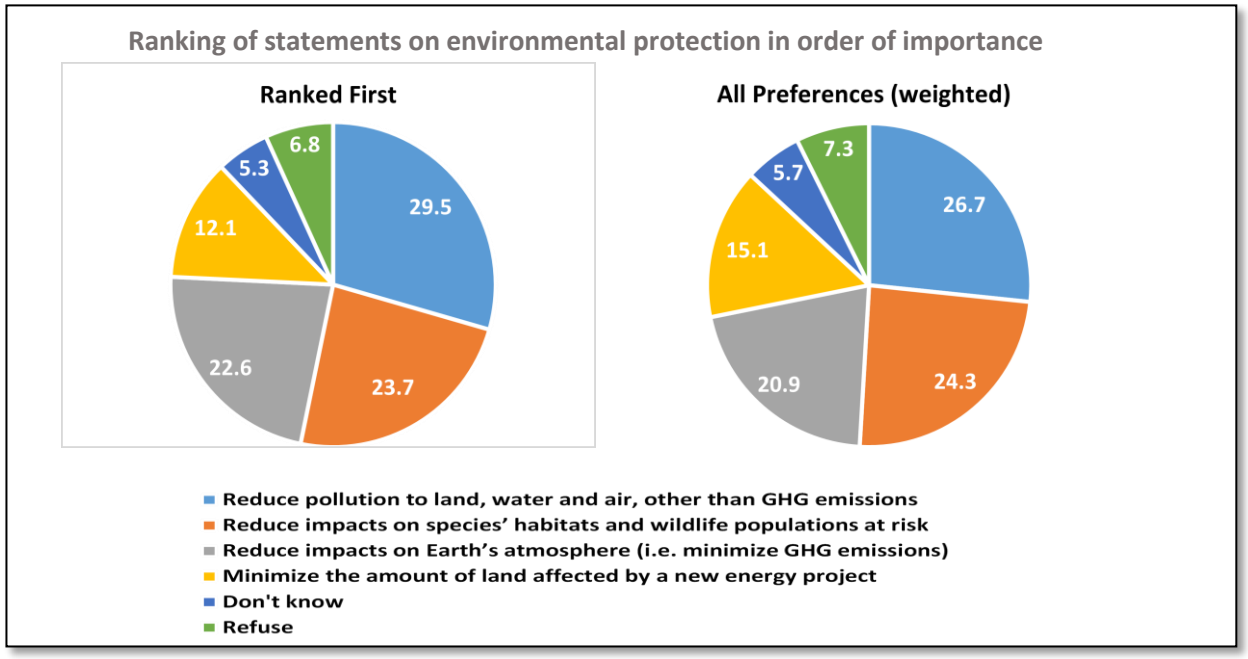

Figure 2. Ranking of preference for environmental protection in respondents' order of importance.

ELECTRICITY AFFORDABILITY, REASONABILITY OF RATES, AND CONSERVATION EFFORTS

Respondents were asked simple questions on the affordability of their electricity bills, the reasonability of the electricity rate, and their efforts to reduce enrgy use. While a little over three-quarters of the respondents (76.4%) said that their electricity bills are affordable, 54.7% thought that Yukon's current electricity rates are reasonable (Figure 3). Almost all respondents (96.9%) claimed that they make efforts to reduce their energy use.

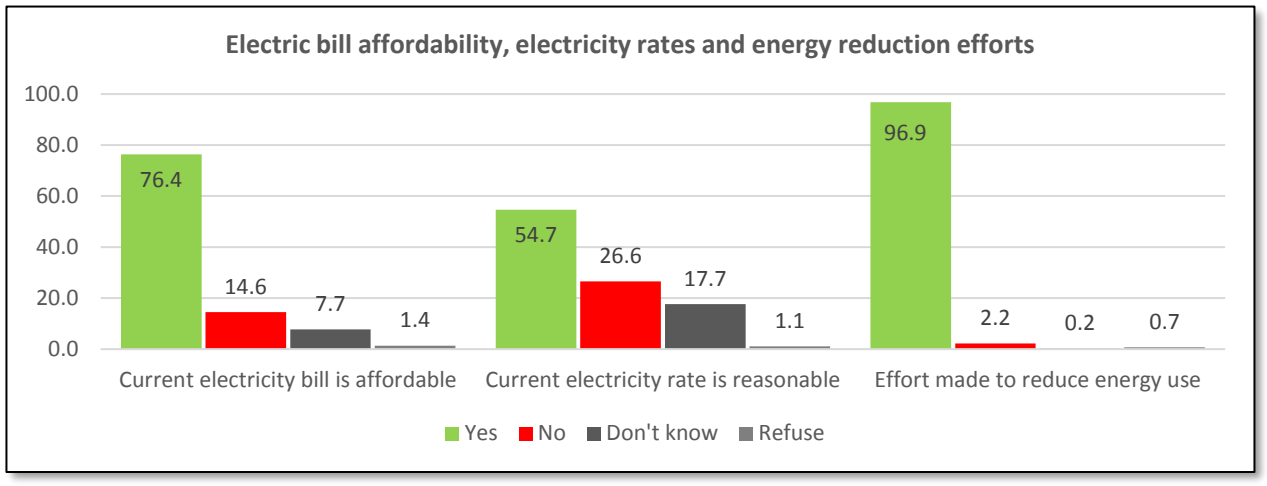

Figure 3. The affordability of electricity bills, the reasonability of current electricity rates, and efforts to reduce energy use.

SUPPORT FOR YEC INITIATIVES

Respondents were asked, even with a potential increase in electricity rates, whether they would support YEC's initiatives to protect environment, maintain social responsibility, and enhance reliability in project planning. The results are presented in Figure 4.

As shown in the figure, 80.7% Yukon households would support YEC's efforts to protect environment, even with a potential increase in electricity rates. While 73.4% households would support initiatives that would create local jobs, only 57.1% would favour initiatives to enhance economic growth. About three-quarters of households (73.1%) would support initiatives to maintain access to wilderness recreation, about two-thirds (68.6%) would support initiatives not to compromise traditional pursuits, and 71.0% would support initiatives to reduce power outages. The support for YEC's decision to supply electricity to mines was the lowest at 46.0%.

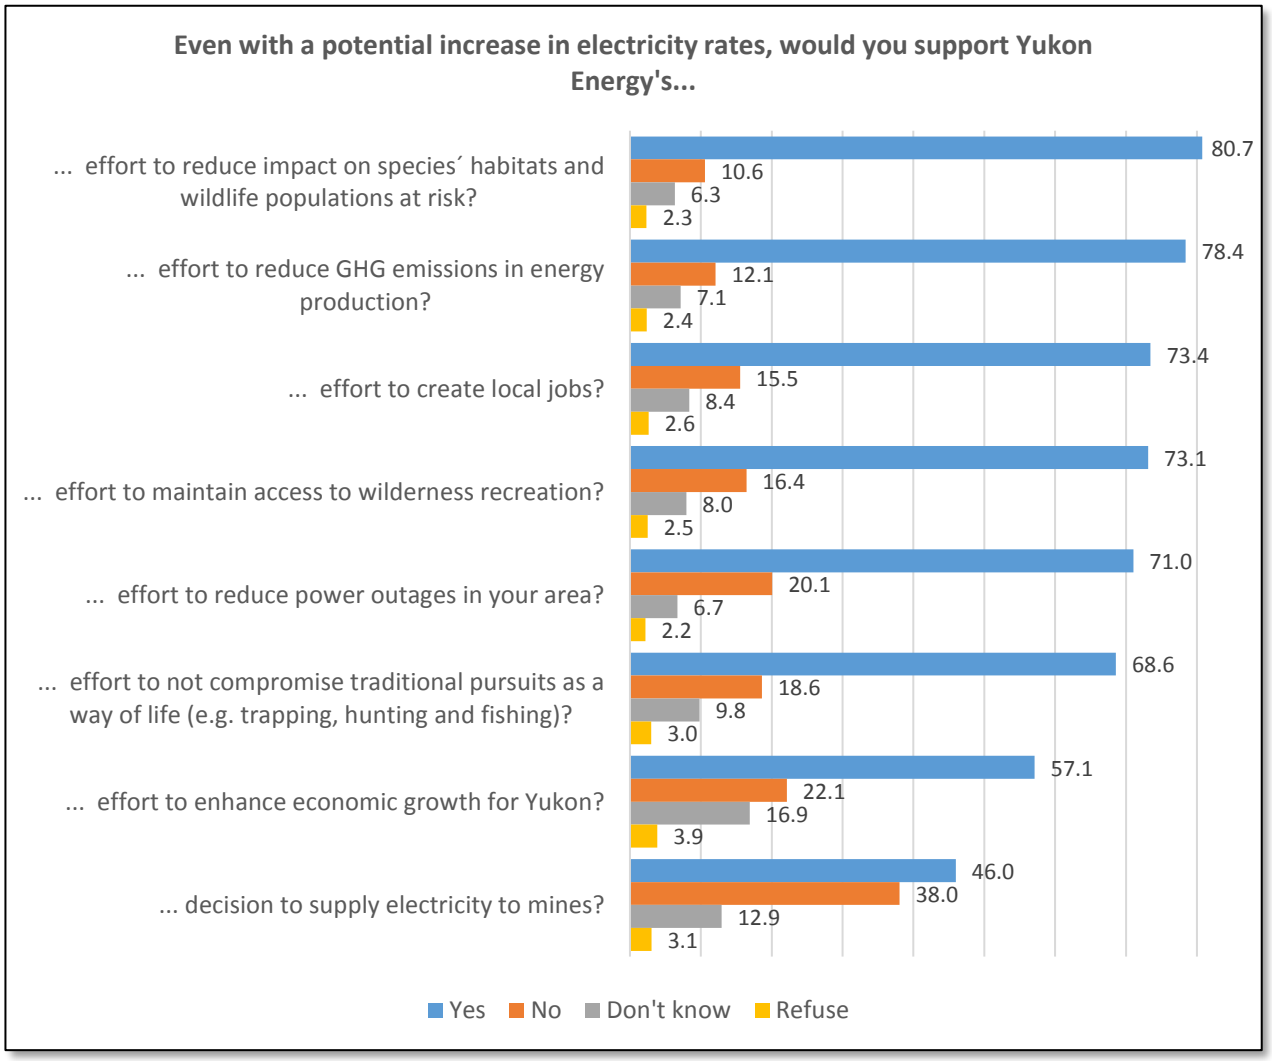

Figure 4. Extent of support to YEC initiatives even with a potential increase in electricity rates.

POWER OUTAGES AND BACK-UP HEATING

Respondents were asked if they had experienced power outages in 2015. While 84.5% of all households experienced at least one power outages in 2015, 64.6% of those households experienced at least one outage that lasted more than an hour (Figure 5). About two-thirds of the households (67.2%) felt it necessary to have back-up heating and/or a generator in case of power outages (Figure 6).

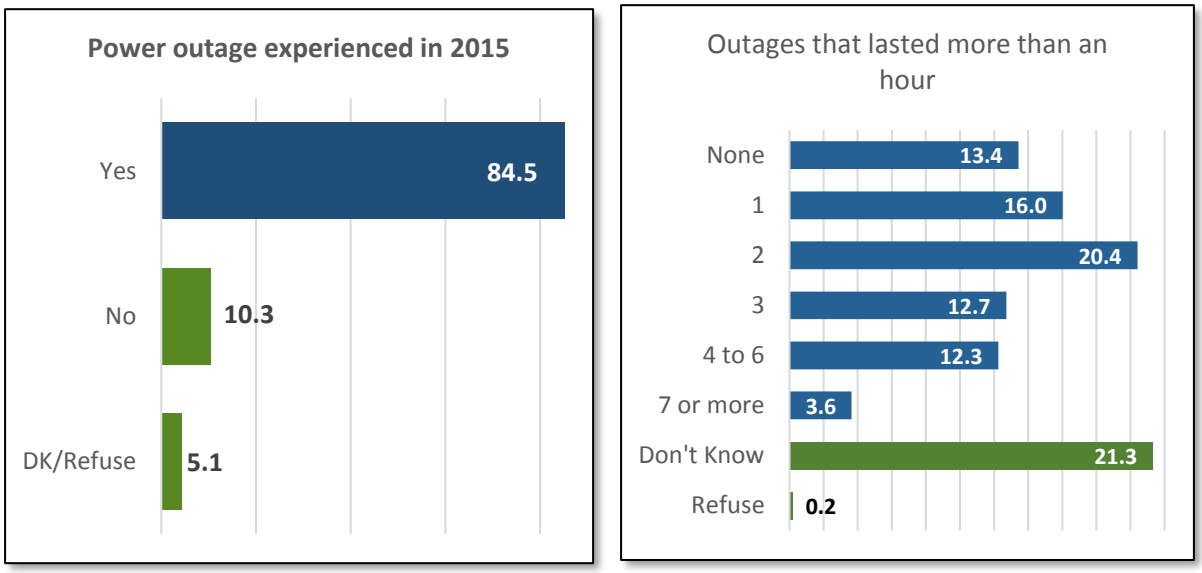

Figure 5. Respondents' experience of power outages in 2015.

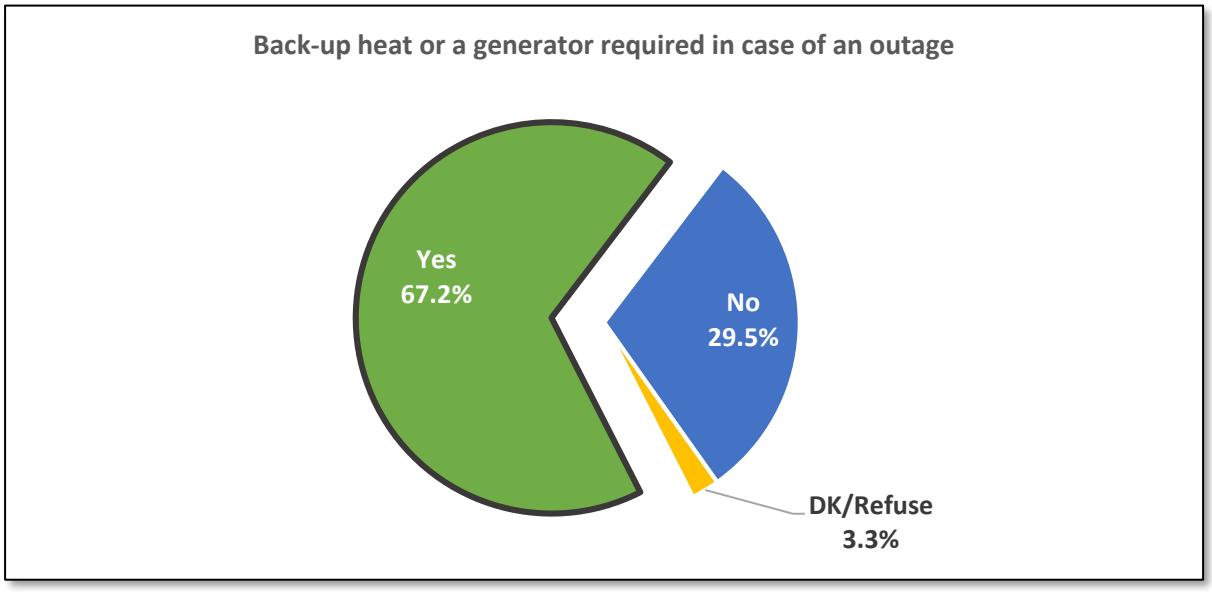

Figure 6. Necessity of back-up heating and/or a generator in case of a power outage.

SOCIAL RESPONSIBILITY

The survey asked the respondents to rank the following statements concerning social responsibility in order of importance:

- Enhance economic growth and create jobs;
- Do not compromise traditional pursuits (e.g. trapping, hunting and fishing);
- Maintain access to wilderness recreation; and
- Conservation of historical sites to protect Yukon culture.

Based on the responses, one-third of Yukon households (33.3%; weighted average of all rankings: 25.2%) ranked 'enhance economic growth and create jobs' as the most important *Social Responsibility*, while about one-fifth (20.2%; weighted average: 21.0%), ranked 'do not compromise traditional pursuits' as the most important (Figure 7). The next in order were maintaining access to wilderness recreation (16.7%; weighted average: 20.0%), and conservation of historical sites to protect Yukon culture (14.8%; weighted average of all rankings: 17.5%).

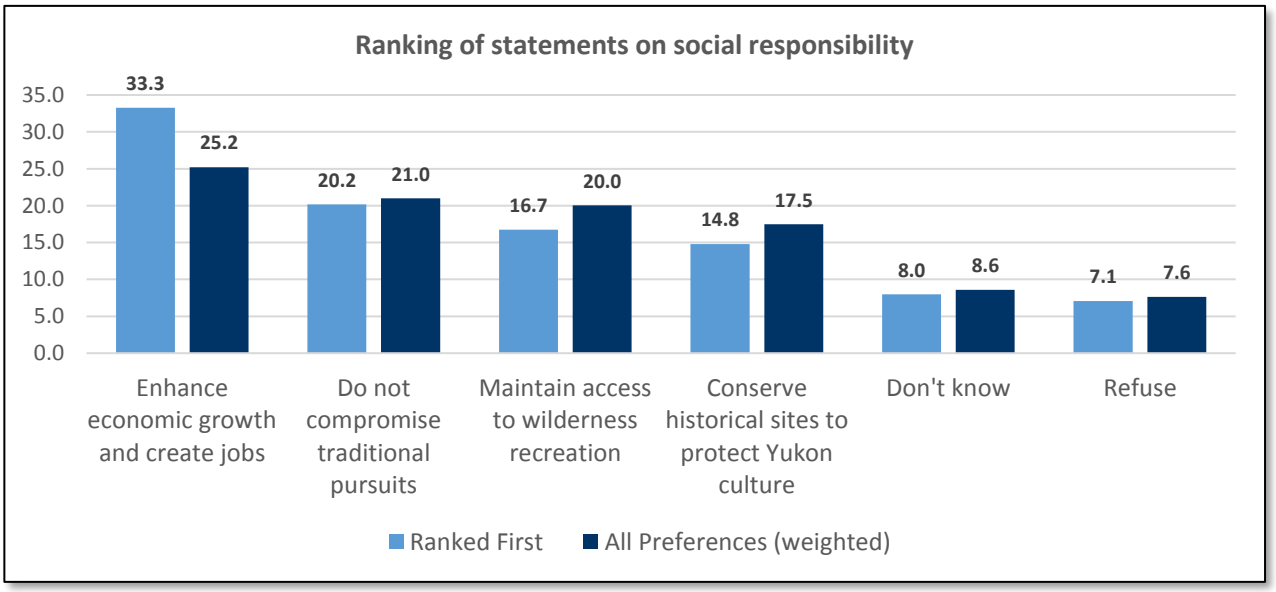

Figure 7. Ranking of statements relating to social responsibility in order of importance.

PREFERRED FUTURE ENERGY SOURCE FOR YUKON

When asked to rank three energy sources (fossil fuels, renewable energy and energy conservation) in order of preference, 59.2% (weighted average of all rankings: 44.1%) of the responding households chose renewable energy as their preferred future energy source (Figure 8). About one-third (31.0%; weighted average: 34.2%) preferred energy conservation as a future energy source, while only 4.6% (weighted average of all rankings: 16.3%) preferred fossil fuels as a future energy source.

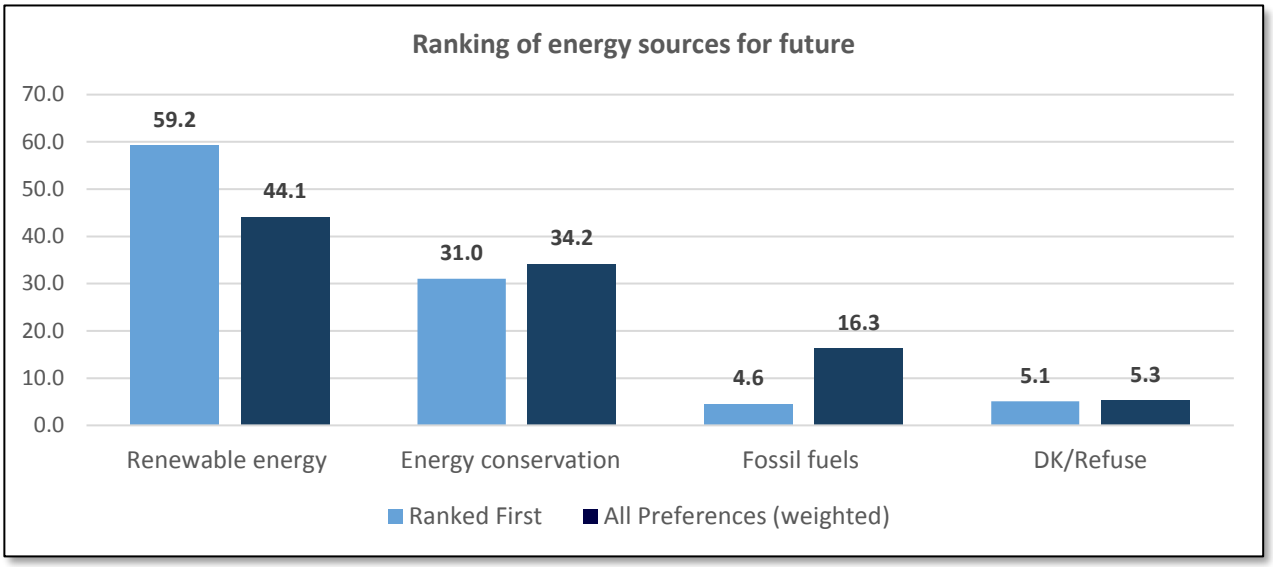

Figure 8. Ranking of energy sources for Yukon's future in order of preference.

ENERGY EFFICIENCY

Respondents were asked how often they consider the item´s energy efficiency rating when purchasing a new appliance or electronic device. A little over three-quarters (76.8%) of the respondents said they always or frequently check energy efficiency rating when purchasing a new appliance or electronic device, while 10.0% of the respondents never or rarely check (Figure 9).

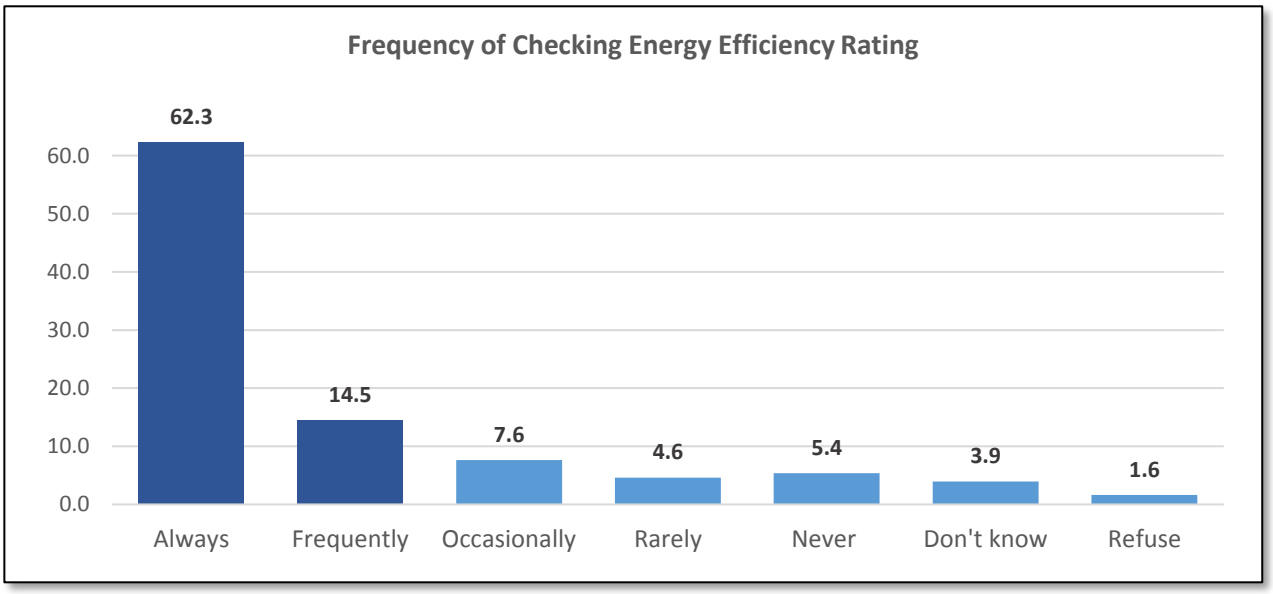

Figure 9. Frequency of checking energy efficiency rating before purchasing a new appliance or electronic device.

HOME HEATING SOURCES

Respondents were asked about their primary home heating sources as listed on their home insurance. At 46.5%, fuel oil is the most prevalent primary home heating source in Yukon. Electricity (baseboard, furnace or boiler) is the second most prevalent primary home heating source used by almost a quarter (24.5%) of the households (Figure 10a). Other primary sources, not listed in the question, included diesel, pellet stove, solar, forced air, kerosene heater, propane hot water heat, heat pump and exchange, Toyostove, pellet boiler, radiant heat, electro-thermal storage unit, and external wood boiler.

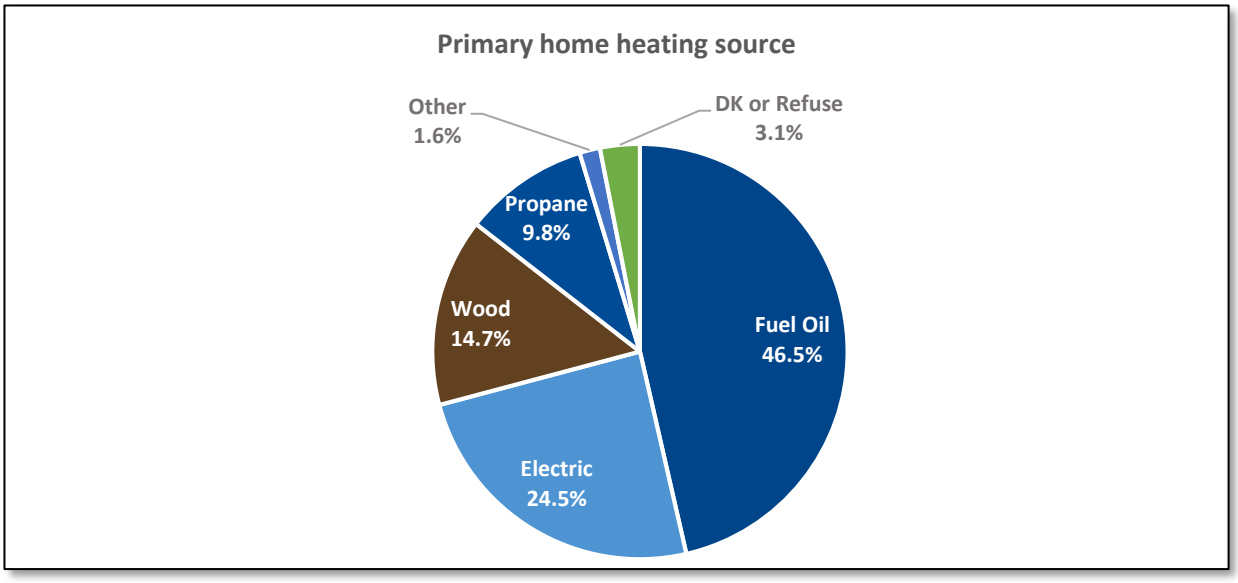

Figure 10a. Primary home heating sources as listed on home insurance.

In response to the question about additional home heating sources, most respondents (41.2%) said they did not have an additional home heating source. Of households that had additional home heating sources (58.9%), wood was the most common (35.5%) additonal home heating source followed by electricity (30.6%), as shown in Figure 10b. While fuel oil was the most commonly used (46.5%) primary source of heat, it was not so commonly used (12.9%) as an additional home heating source. Other additional home heating sources (3.3%) included pellet stove, fireplace, solar, diesel, generator, kerosene heater, Toyostove, oil, infrared heater, propane system, hot water heat, sauna, forced air, boiler system, candles, monitor, portable electrical heater, and hydronic.

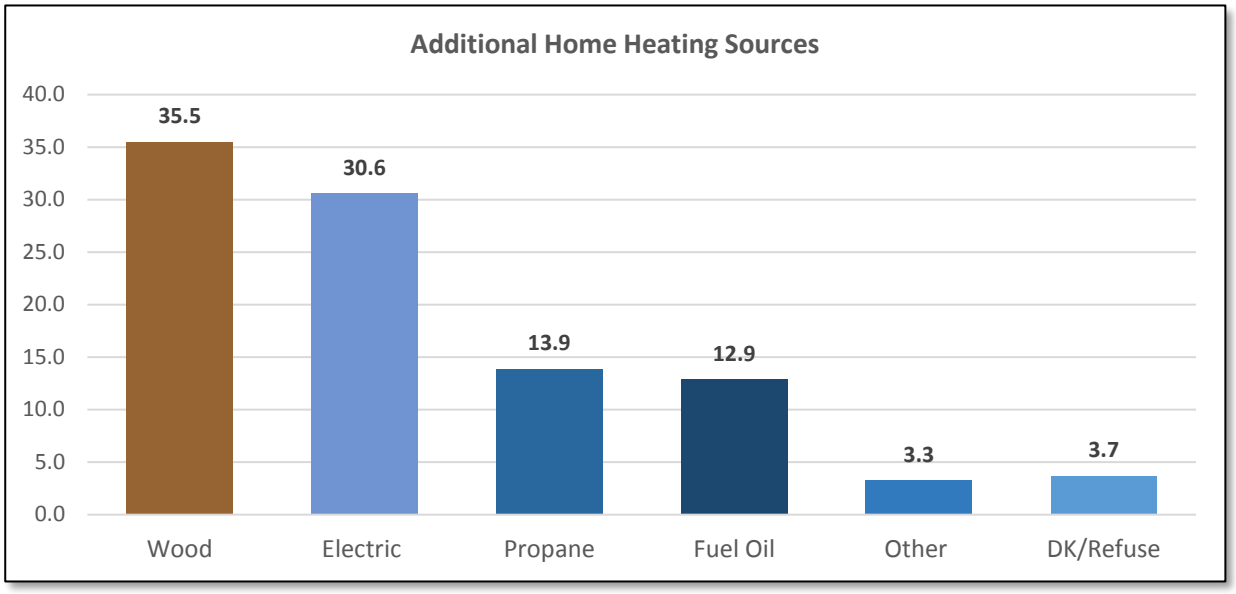

Figure 10b. Additional home heating sources (Note: respondents were allowed to choose multiple responses and percentages are derived from the sum of all reported additional home heating sources).

Responding households with oil or propane as a home heating source were asked if they have considered switching to electric heat. Of those who did not already use electricity as a primary or additional home heating source, 73.4% had not considered switching to electric heat, while 18.1% had (Figure 11).

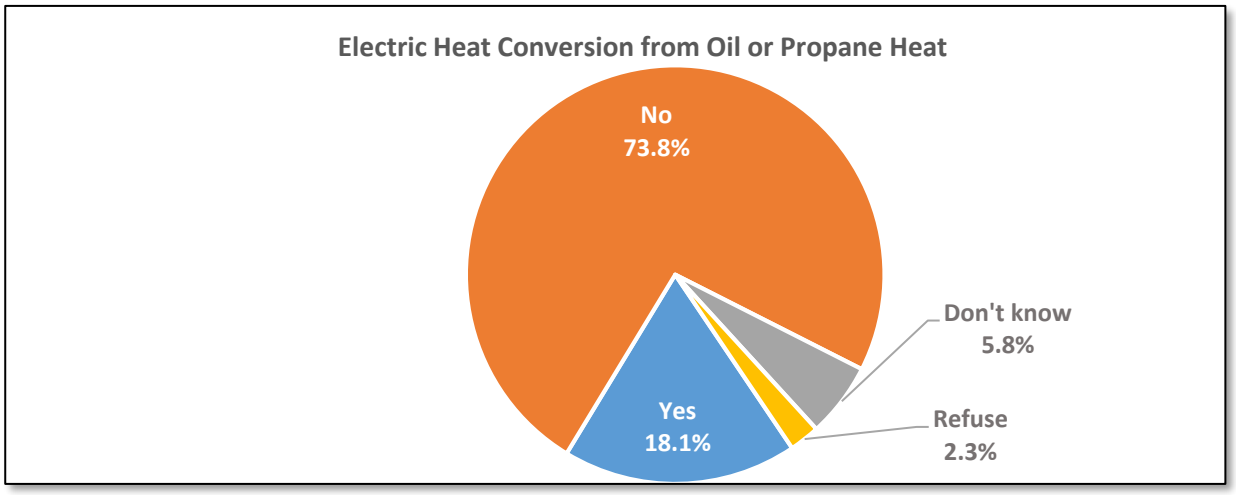

Figure 11. Respondents' consideration of switching to electric heat.

HOME HEATING SELECTION

Respondents were asked to rank five factors that influence their home heating system selection. Of the five given factors, cost was the most important (45.1%; weighted average of all rankings: 31.0%) to influence a respondent's home heating selection, distantly followed by safety (15.2%; weighted average: 16.7%), environmental concerns (11.2%; weighted average: 13.5%), comfort (9.5%; weighted average: 13.9%) and ease of maintenance (6.7%; weighted average of all rankings: 11.9%). In terms of first ranking (light blue bars in the chart below), respondents' selection of home heating system is more influenced by cost than all four other factors combined (Figure 12).

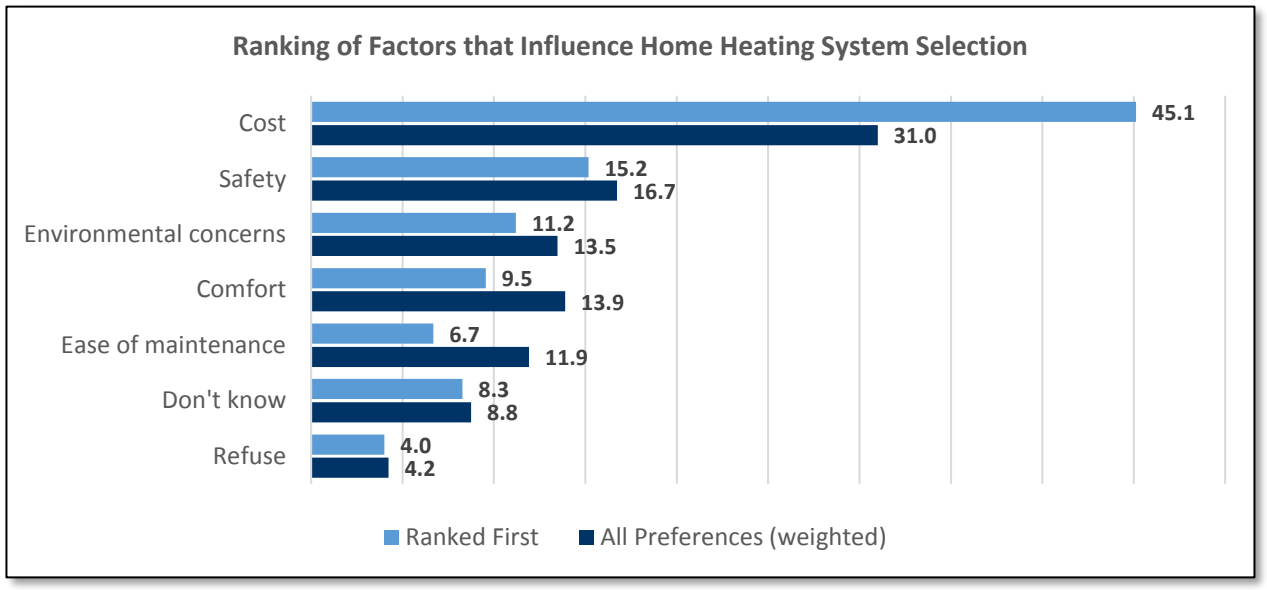

Figure 12. Ranking of factors that influence respondents' home heating system selection.

PART 2: FOCUS ON UNDERSTANDING THE SUPPORT FOR YEC INITIATIVES

This section of the survey generated information on two topics: to understand the Yukoners' preference for the type of fossil fuel for future back-up generation and to find if Yukoners have confidence in YEC's ability to plan and develop sustainable energy sources to meet future needs.

YUKON'S FUTURE BACK-UP GENERATION FOSSIL FUEL CHOICE

Respondents were asked about their preference of fossil fuel if YEC is required to choose a fossil fuel for future back-up generation. Slightly over half of Yukon households (50.7%) would prefer the use of natural gas if YEC is required to choose a fossil fuel for future back-up generation (Figure 13). Only 14.0% would prefer diesel fuel. About a quarter of the responding households did not know how to respond to this question, while 10.6% refused to provide a response.

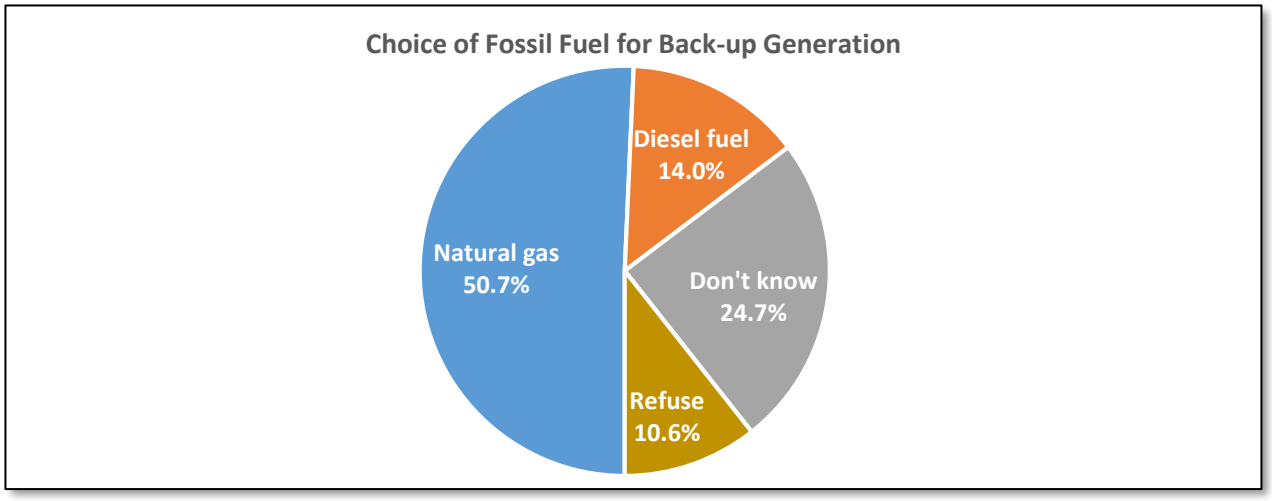

Figure 13. Respondents' preference of fossil fuel if YEC is required to choose a fossil fuel for future back-up generation.

CONFIDENCE IN YEC TO PLAN AND DEVELOP SUSTAINABLE ENERGY SOURCES

Respondents were asked if they have confidence in YEC to plan and develop sustainable energy sources to meet future needs. Most (61.2%) respondents were confident that YEC is able to plan and develop sustainable energy sources to meet future needs (Figure 14). About a fifth (19.2%) of the respondents said that that they do not have confidence in YEC's ability, while 17.2% either did not know or refused.

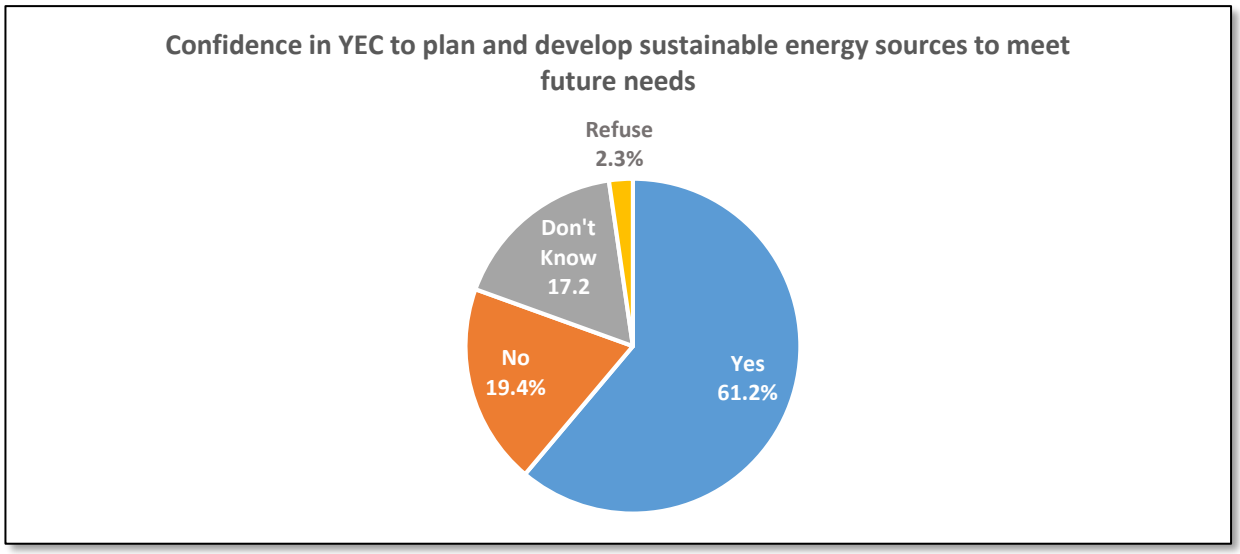

Figure 14. Respondents' confidence in YEC's ability to plan and develop sustainable energy sources to meet future needs.

PART 3: DEMOGRAPHICS OF THE RESPONDENTS

The survey was a household survey designed to collect responses primarily from head of the household or the next senior person in the household. Therefore, the demographic characteristics of the respondents of this survey may not match those of Yukon's total population.

RESPONDENTS' AGE GROUPS

More female (55.1%) than male respondents (42.7%) completed the survey. The largest proportion (28.0%) of the respondents were in the age group of 60 years or more, followed by the 30-39 years age group at 21.1% and the 50-59 years age group at 20.8% (Figure 15). As expected, the smallest respresented age group was 18-29 years.

Since the survey was designed to collect responses primarily from household heads or the next senior person, the age distribution of the respondents is not expected to match that of the population, especially those in the 18-29 years and the 60+ years age groups. However, the percentages of respondents in the age groups 30-39 years (21.1%), 40-49 years (17.6%) and 50-59 years (20.8%), are roughly comparable to the relevant population percentages (19.7%, 17.2% and 20.3%, respectively).

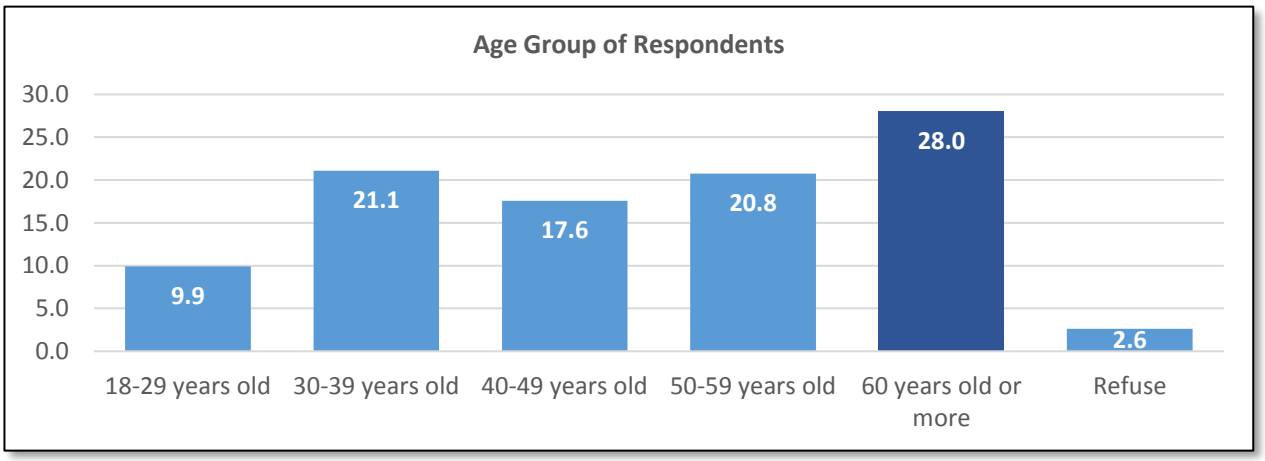

Figure 15. Age groups of the respondents.

RESPONDENTS' EDUCATION LEVELS

Nearly all respondents had at least a high school (or general education) diploma (Figure 16). About a quarter (24.2%) of the respondents had a bachelor's degree, while 11.8% had a graduate degree.

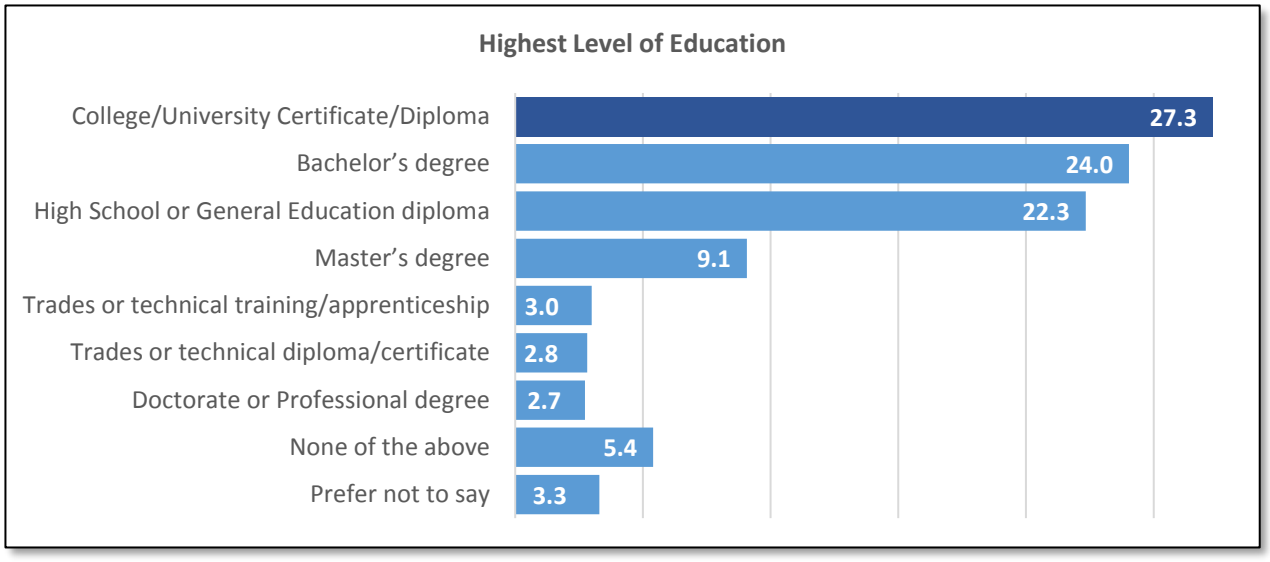

Figure 16. Levels of education of the respondents.

INCOME GROUPS OF RESPONDING HOUSEHOLDS

Almost 60% of respondents had an annual gross household income of greater than $50,000; about half of them had a household income of more than $100,000 (Figure 17). Of the demographic questions, this question had the highest refusal rate at 16.0%.

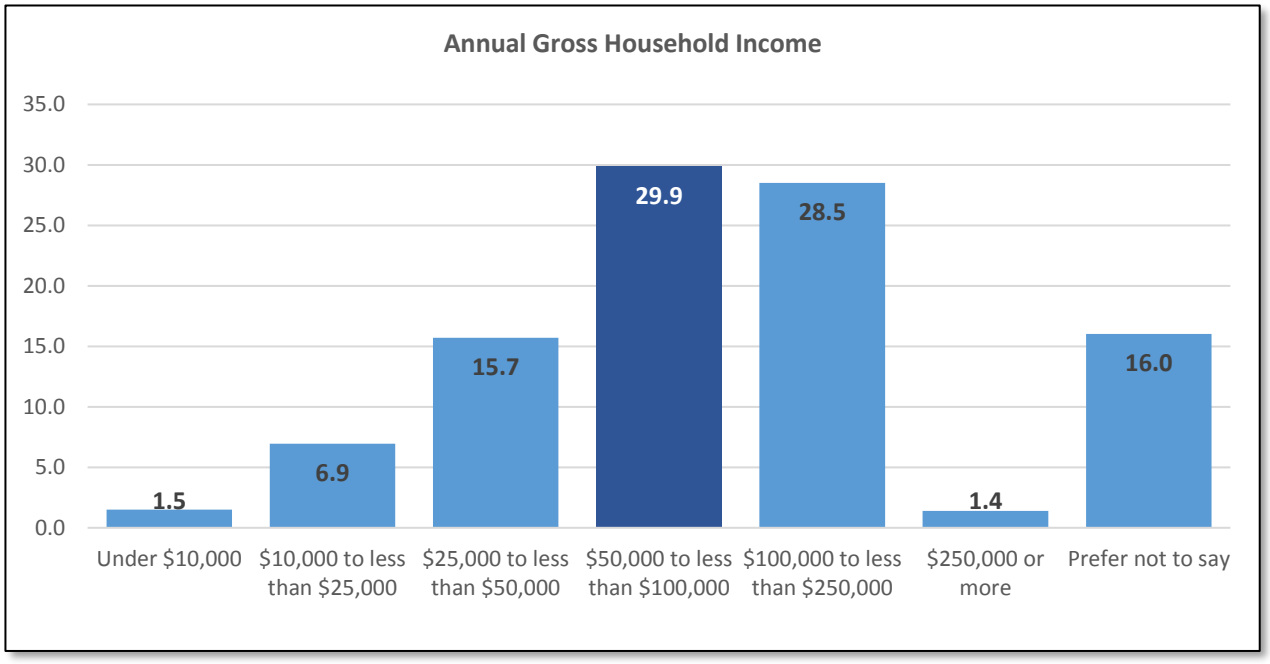

Figure 17. Responding households by annual gross household income.

RESPONSE BY ABORIGINAL GROUPS

Of the 14.5% of respondents who identified themselves as Aboriginal, 22.5% identified themselves as non-Yukon First Nations and 14.1% identified themselves as Metis (Figure 18). The ratio of Aboriginal respondents is less than the proportion of Aboriginal population in Yukon (23.1%). However, a comparison of the results of Aboriginal respondents to those of non-Aboginal respondents did not reveal any significant difference except the ranking order of the statements on social responsibility. Compared to non-Aboriginal respondents, Aboriginal respondents ranked 'do not compromise traditional pursuits' first at a higher rate (34.2% compared to 17.7%), and ranked 'enhance economic growth and create jobs' first at a lower rate (23.9% compared to 34.8%).

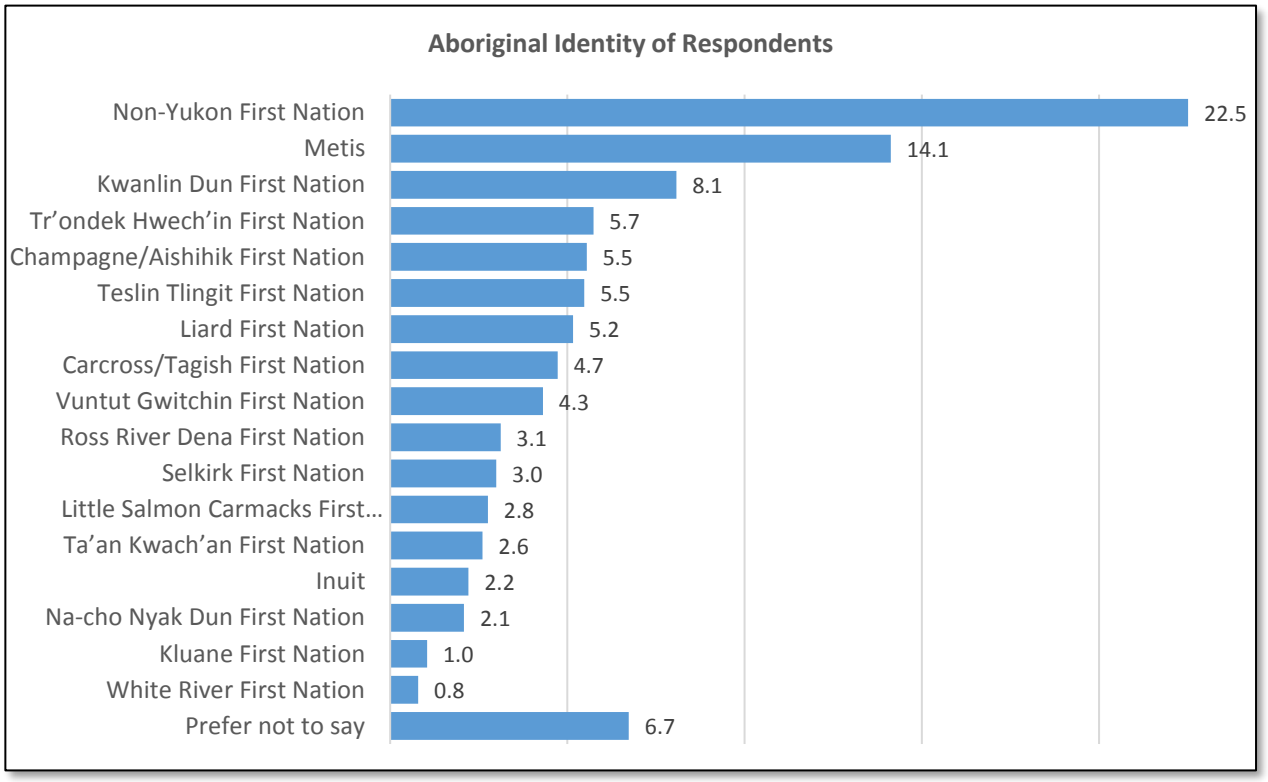

Figure 18. Respondents who identified themselves as Aboriginal.

RESPONSE BY COMMUNITY

Most respondents (76.4%) lived in Whitehorse and 22.8% of Yukon respondents lived in other Yukon communities. Less than 1% of respondents lived outside of Yukon or refused to reveal their Yukon community. A comparison of the results for Whitehorse and the rest of Yukon communities did not reveal any significant difference.

CONCLUSION

Through this survey, Yukoners ranked environmental protection as the most important factor for YEC's future project management goals, followed in order by cost, reliability, and social responsibility. However, personal home heating selection was influenced largely by cost (45.5%), followed by safety (15.2%), environmental concerns (11.2%), comfort (9.5%), and ease of maintenance (6.7%).When considering environmental protection, reducing the risk of pollution to land, water and air, other than greenhouse gases was of the most concern (29.5%).

Overall, respondents' current electricity bills were reported to be affordable (76.4%). However, when asked if current electricity rates were reasonable, there was more uncertainty; 54.7% thought rates were reasonable and 17.7% did not know. Most responding households (84.5) experienced a power outage in 2015, 65.1% of them reported one or more outages lasting more than an hour. In turn, 67.9% of the responding households felt it was necessary to have back-up heat source in case of an outage.

Based on the responses to this survey, Yukoners would generally support YEC's efforts to protect environment, enhance reliability, not compromise traditional pursuits, maintain access to wilderness, and create local jobs, even with a potential increase in electricity rates. However, respondents' support for YEC's efforts to economic growth was not overwhelming and they were divided on the issue of supplying electricity to mines if it leads to an increase in electricity rates.

For 56.3% Yukon households, the primary home heating source was fuel oil, followed by electricity for about a quarter of them. Most additional home heating sources were wood and electricity. Of households that did not have electric heating, 18.1% had considered switching to electric heat.

Most responding households (59.2%) selected renewable energy sources as the most preferred energy sources for Yukon's future, while 31.0% of them preferred energy conservation over new energy production. A little over half of the responding households would prefer natural gas, if YEC is required to use a fossil fuel for future back-up generation. Many of the respondents (61.2%) expressed their confidence in YEC's ability to plan and develop sustainable energy sources for the future.

APPENDIX A – SUMMARY TABLES

Q1. To help Yukon Energy choose new projects, please rank the following four factors in order of importance.	Percent			
	1st	2nd	3rd	4th
Environmental Protection	44.4	23.9	19.0	6.7
Cost	22.7	28.4	21.9	23.3
Reliability	21.0	21.8	33.8	18.5
Social Responsibility	7.7	21.1	20.0	46.1
Don't know	2.5	2.9	3.2	3.2
Refuse	1.7	1.9	2.1	2.1

Q2. For environmental protection, please rank which statement you consider more important.	Percent			
	1st	2nd	3rd	4th
Reduce impacts on Earth's atmosphere	22.6	16.3	22.1	21.8
Reduce risk of pollution to land, water and air, other than greenhouse	29.5	27.3	18.3	12.1
Reduce impact on species' habitats and wildlife populations at risk	23.7	28.6	26.3	6.7
Minimize the amount of land affected by a new energy project	12.1	13.9	18.2	44.2
Don't know	5.3	6.1	6.6	6.7
Refuse	6.8	7.8	8.5	8.6

Q3 Is your current electricity bill affordable?	Percent
Yes	76.4
No	14.6
DK	7.7
Refuse	1.4

Q4 Do you think that the current electricity rate in Yukon is reasonable?	Percent
Yes	54.7
No	26.6
DK	17.7
Refuse	1.1

Q5 Do you make efforts to reduce your energy use?	Percent
Yes	96.9
No	2.2
DK	0.2
Refuse	0.7

Q6 Even with a potential increase to electricity rates, would you support Yukon Energy's ...	Percent			
	Yes	No	DK	Refuse
... effort to enhance economic growth for Yukon?	57.1	22.1	16.9	3.9
... effort to create local jobs?	73.4	15.5	8.4	2.6
... effort to reduce power outages in your area?	71.0	20.1	6.7	2.2
... effort to reduce GHG emissions in energy production?	78.4	12.1	7.1	2.4
... effort to reduce impact on species´ habitats and wildlife populations at risk?	80.7	10.6	6.3	2.3
... effort to not compromise traditional pursuits as a way of life (e.g. trapping, hunting and fishing)?	68.6	18.6	9.8	3.0
... effort to maintain access to wilderness recreation?	73.1	16.4	8.0	2.5
... decision to supply electricity to mines?	46.0	38.0	12.9	3.1

Q7 Did you experience power outages in 2015?	Percent
Yes	84.5
No	10.3
DK	4.3
Refuse	0.9

Q8 Approximately how many power outages did you experience in 2015 that lasted more than one hour?	Percent
Less than an hour	13.4
1	16.0
2	20.4
3	12.7
4	5.3
5	3.9
6	3.1
7 or more	3.7
DK	21.3
Refuse	0.2

Q9 Do you feel it is necessary to have back-up heating and/or a generator at your home in case of power	Percent
Yes	67.2
No	29.5
DK	2.3
Refuse	1.0

Q10. With respect to social responsibility, please rank the statements in order of importance.	Percent			
	1st	2nd	3rd	4th
Enhance economic growth and create jobs	33.3	11.7	15.0	23.8
Do not compromise traditional pursuits as a way of life	20.2	24.2	20.4	16.8
Maintain access to wilderness recreation	16.7	27.3	23.8	14.5
Conservation of historical sites to protect Yukon culture	14.8	19.5	22.2	26.1
Don't know	8.0	9.2	9.8	10.0
Refuse	7.1	8.2	8.7	8.9

Q11. Please rank the next three energy sources for Yukon's future in terms of preference.	Percent		
	1st	2nd	3rd
Fossil fuels	4.6	11.9	78.1
Renewable energy	59.2	30.2	4.9
Energy conservation	31.0	52.3	11.2
Don't know	2.8	3.1	3.2
Refuse	2.3	2.5	2.6

Q12 When purchasing a new appliance/electronic device, how often do you consider the item´s energy	Percent
Always	62.3
Frequently	14.5
Occasionally	7.6
Rarely	4.6
Never	5.4
Don't know	3.9
Refuse	1.6

Q13 What is the primary heating source in your home as listed on your home insurance?	Percent
Electric (Baseboard, furnace or boiler)	24.5

APPENDIX B – YUKON ELECTRICITY VALUES SURVEY

YEC Electricity Values Survey 2016

Hello. May I speak to… [*read contact name(s) from label*…]?

- ❑ Yes → [*continue with introduction*]
- ❑ No → We are conducting the Electricity Values Survey.
  When would be a good time to call back? _____

My name is _____ and I am calling from Yukon Bureau of Statistics in Whitehorse. We are conducting the Electricity Values Survey on behalf of the Yukon Energy Corporation. The purpose of this survey is to collect your input on how to meet Yukon's future electricity needs. Your responses will be used in YEC's project planning.

Your household has been randomly selected to complete the survey. Participation in this survey is voluntary and your responses are confidential. Information collected through this survey is protected in accordance with the Statistics Act.

Questionnaire

Q1. To help Yukon Energy choose new projects, please rank the following four factors in order of importance.
[Interviewer: please read all factors, then ask respondent for 1st, 2nd, 3rd and 4th]

Factor	Ranking
a. Environmental Protection (i.e. healthy planet and environment)	
b. Cost (i.e. affordable bills, rates and fees)	
c. Reliability (i.e. uninterrupted power supply, reduced power outages)	
d. Social Responsibility (i.e. healthy communities, strong economy)	

☐ Don't know ☐ Refuse

Q2. For environmental protection, please rank which statement you consider more important.
[Interviewer: please restate the agreement scale after each statement]

Statement	Ranking
a. Reduce impacts on Earth's atmosphere (i.e. minimize greenhouse gas emissions)	
b. Reduce risk of pollution to land, water and air, other than greenhouse gas emissions	
c. Reduce impact on species' habitats and wildlife populations at risk (e.g. Chinook salmon)	
d. Minimize the amount of land affected by a new energy project (i.e. smaller projects have a lower footprint)	

☐ Don't know ☐ Refuse

Q3. Is your current electricity bill affordable?
☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q4. Do you think that the current electricity rate in Yukon is reasonable?
☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q5. Do you make efforts to reduce your energy use?
☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q6. Any new project initiative of Yukon Energy would likely involve costs and therefore, may affect electricity rates. Even with a potential increase to electricity rates, would you support:
[Interviewer: please ask respondent yes or no after each question]

Question	Yes	No	Don't Know	Refuse
a. Yukon Energy's effort to enhance economic growth for Yukon?	◯	◯	◯	◯
b. Yukon Energy's effort to create local jobs?	◯	◯	◯	◯
c. Yukon Energy's effort to reduce power outages in your area?	◯	◯	◯	◯
d. Yukon Energy's effort to reduce GHG emissions in energy production?	◯	◯	◯	◯
e. Yukon Energy's effort to reduce impact on species' habitats and wildlife populations at risk?	◯	◯	◯	◯
f. Yukon Energy's effort to not compromise traditional pursuits (e.g. trapping, hunting and fishing)?	◯	◯	◯	◯
g. Yukon Energy's effort to maintain access to wilderness recreation?	◯	◯	◯	◯
h. Yukon Energy's effort to conserve historical sites to protect Yukon culture?	◯	◯	◯	◯
i. Yukon Energy's decision to supply electricity to mines?	◯	◯	◯	◯

Q7. Did you experience power outages in 2015?
☐ Yes ☐ No → Go to Q9 ☐ Don't know → Go to Q9
☐ Refuse → Go to Q9

Q8. Approximately how many power outages did you experience in 2015 that lasted more than one hour?
_____ outages in 2015
☐ Don't Know ☐ Refuse

Q9. Do you feel it is necessary to have back-up heating and/or a generator at your home in case of power outages?
☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q10. With respect to social responsibility, please rank the statements in order of importance.
[Interviewer: please read all types, then ask respondent for 1st, 2nd, 3rd and 4th choice]

Statement	Ranking
a. Enhance economic growth and create jobs	
b. Do not compromise traditional pursuits (e.g. trapping, hunting and fishing)	
c. Maintain access to wilderness recreation	
d. Conservation of historical sites to protect Yukon culture	

☐ Don't know ☐ Refuse

Q11. Please rank the next three energy sources for Yukon's future in terms of preference.
[Interviewer: please read all types, then ask respondent for 1st, 2nd and 3rd choice]

Energy source	Ranking
a. Fossil fuels (such as diesel, natural gas).	
b. Renewable energy (such as hydro, wind, solar).	
c. Energy conservation (such as savings measures, efficiency) preferred over new energy production.	

☐ Don't know ☐ Refuse

Q12. When you purchase a new appliance or electronic device, how often do you consider the product's energy efficiency rating?

☐ Always
☐ Frequently
☐ Occasionally
☐ Rarely
☐ Never
☐ Don't Know ☐ Refuse

Q13. What is the primary heating source in your home as listed on your home insurance?
[Interviewer: check only one]

☐ Electric (Baseboard, furnace or boiler)
☐ Fuel Oil
☐ Propane
☐ Wood
☐ Other (specify): _____
☐ Don't Know ☐ Refuse

Q14. What additional heating sources exist in your home? [Interviewer: check all that apply]

☐ Electric (Baseboard, furnace or boiler)
☐ Fuel Oil
☐ Propane
☐ Wood
☐ Other (specify): _____
☐ Don't Know ☐ Refuse

Q15. If you heat with oil or propane, have you considered switching to electric heat?

☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q16. Please rank how the following five factors influence your home heating system selection. [Interviewer: please read all factors, then ask respondent to choose 1st, 2nd, etc. choice]

Factor	Ranking
a. Cost	
b. Comfort (such as dampness, perception of warmth, ease of controlling temperature)	
c. Safety (such as carbon monoxide, oil/gas tank placement)	
d. Environmental concerns (such as greenhouse gas emissions, fuel spills)	
e. Ease of maintenance	

Q17. If Yukon Energy is required to choose a fossil fuel for future back-up generation, which fuel do you prefer?

☐ Natural Gas ☐ Diesel Fuel ☐ Don't know ☐ Refuse

Q18. Do you have confidence in Yukon Energy to plan and develop sustainable energy sources to meet future needs?

☐ Yes ☐ No ☐ Don't know ☐ Refuse

Q19. You identify yourself as a:

- ☐ Male
- ☐ Female
- ☐ Other
- ☐ Prefer not to say

Q20. Is your age between:

- ☐ 18-29 years old
- ☐ 30-39 years old
- ☐ 40-49 years old
- ☐ 50-59 years old
- ☐ 60 years old or more
- ☐ Prefer not to say

Q21. What is your highest level of education?

- ☐ High School diploma or certificate
- ☐ GED (General Education Diploma)
- ☐ College/University Certificate/Diploma
- ☐ Trades or technical training/apprenticeship
- ☐ Trades or technical diploma/certificate
- ☐ Bachelor's degree
- ☐ Master's degree
- ☐ Doctorate
- ☐ Professional degree (medicine, law)
- ☐ None of the above
- ☐ Prefer not to say

Q22. What is your annual household income range before tax?

- ☐ Under $10,000
- ☐ $10,000 to less than $25,000
- ☐ $25,000 to less than $50,000
- ☐ $50,000 to less than $100,000
- ☐ $100,000 to less than $250,000
- ☐ $250,000 or more
- ☐ Prefer not to say

Q23. Do you identify yourself as an Aboriginal person (First Nations, Metis or Inuit)?

☐ Yes →Go to Q24 ☐ No →Go to Q25 ☐ Prefer not to say →Go to Q25

Q24. In which Aboriginal group do you associate?

- ☐ Carcross/Tagish First Nation
- ☐ Champagne/Aishihik First Nation
- ☐ Kluane First Nation
- ☐ Kwanlin Dun First Nation
- ☐ Liard First Nation
- ☐ Little Salmon Carmacks First Nation
- ☐ Na-cho Nyak Dun First Nation
- ☐ Ross River Dena First Nation
- ☐ Selkirk First Nation
- ☐ Ta'an Kwach'an First Nation
- ☐ Teslin Tlingit First Nation
- ☐ Tr'ondek Hwech'in First Nation
- ☐ Vuntut Gwitchin First Nation
- ☐ White River First Nation
- ☐ Non-Yukon First Nation
- ☐ Metis
- ☐ Inuit
- ☐ Prefer not to say

Q25. In which Yukon community do you live?

- ☐ Beaver Creek
- ☐ Burwash
- ☐ Carmacks
- ☐ Carcross
- ☐ Dawson City
- ☐ Destruction Bay
- ☐ Faro
- ☐ Haines Junction
- ☐ Keno
- ☐ Marsh Lake
- ☐ Mayo
- ☐ Old Crow
- ☐ Pelly Crossing
- ☐ Ross River
- ☐ Tagish
- ☐ Teslin
- ☐ Watson Lake
- ☐ Whitehorse
- ☐ Other (specify): _____
- ☐ I don't live in Yukon
- ☐ Prefer not to say

"Thank you for your time!"

Appendix 3.2. Communication Methods and Materials

Pre-Round	Timing	Goal	Notes
Meeting with Grand Chief of the Council of Yukon First Nations and several other Yukon First Nation Chiefs	Sep 2015	Engagement: to seek advice on engagement with FNs throughout the resource planning process.	• Yukon Energy received feedback that First Nations should be engaged as governments, and as potential business partners/investors, and as members of the Yukon public.
Information sheet	Sep 2015	Electricity literacy: to provide a summary of what a resource plan is and the steps that Yukon Energy expected to follow to complete the plan.	• This backgrounder was shared with Yukon First Nation governments and Development Corporations, along with stakeholders and members of the Yukon public.
Technical Advisory Committee meeting #1	Sep 2015	Engagement	• A summary of this meeting is posted on Yukon Energy's resource planning website.
Yukon-wide mailer #1	Oct 2015	Electricity literacy: to increase general understanding of utility issues.	• Mailer provided summaries of several "Electricity 101" information sheets, with links to the resource planning website where people could read full text. • Copies of mailer provided to First Nations as well as the Yukon general public.
Yukon News/l'Aurore boreale newspaper infomercials	Late 2015/early 2016	Electricity literacy: to increase general understanding of utility issues.	• Eight Electricity 101 information sheets were created both in English and French. • Each of the 8 sheets ran twice in the Yukon News and once in the French newspaper. • Sheets were provided to First Nations and electronic copies were posted on Yukon Energy's resource planning website.
RFP ads	Nov. 2015	Information: advising local contractors of employment opportunities and informing local First Nations of research that would be completed in their traditional territories.	• RFP ads were placed in both local newspapers and on Yukon Energy's website. • Copies of the ads were provided to First Nations on whose traditional territory the research would be carried out.
Media coverage	Fall 2015	Information	• Coverage by local radio, TV, and newspaper media regarding the resource planning process.

Round 1	Timing	Goal	Notes
Yukon-wide mailer #2	Jan. 2016	Information and electricity literacy	• Explanation of the resource planning process, how people can be involved, and a summary of the meaning of a load forecast. • Copies were provided to First Nations.
"News from the Future" worksheet/discussion paper	Feb. 2016	Engagement and electricity literacy	• Used with six classes of F. H. Collins High School students to introduce the idea of resource planning.
Technical Advisory Committee meeting #2	Feb. 2016	Engagement	• A summary of this meeting is posted on Yukon Energy's resource planning website.
Radio ads for public meetings	Feb. – Mar. 2016	Information and engagement	• Ads notifying Yukoners about the first round of public meetings.
Newspaper ads for public meetings	Feb. 2016	Information and engagement	• Placements in Yukon News, Whitehorse Star, and What's Up Yukon notifying Yukoners about first round of public meetings.
Posters	Feb. and early March 2016	Information and engagement	• Posted at various public locations in Dawson, Mayo, Haines Junction, Carcross, and Teslin notifying Yukoners about first round of public meetings.
E-invites	Feb. and early March 2016	Information and engagement	• Notification to Yukoners, including First Nations, about first round of public meetings.
Social media (Yukon Energy blog, Facebook, Twitter, and LinkedIn)	Feb. 2016	Information and engagement	• Notification to Yukoners about first round of public meetings.
Media coverage	Feb. – March 2016	Information	• Local media coverage (radio and newspaper) of first round of public meetings.
Resource Planning website	Late 2015 and throughout 2016	Information and engagement	• Regular updates on resource planning work, notification of public meetings, and two-way conversation with Yukoners sharing information, ideas and opinions.
Electricity 101 information sheets (both English and French)	Feb. 2016	Increase electricity literacy	• Shared at all public meetings and posted on the Resource Plan website.
Public meetings	Feb. 29 – Mar. 17, 2016	Information and engagement	• Meetings in downtown Whitehorse, Whitehorse campus of Yukon College, Haines Junction, Carcross, Teslin, Dawson City, and Mayo.

Round 1	Timing	Goal	Notes
PowerPoint	Feb. 29 – Mar. 17, 2016	Information and engagement	• PowerPoint presentation for public meetings. Presentation was recorded and posted on Yukon Energy's resource planning website and YouTube channel.
Values survey	May – June 2016	Gather information about what Yukoners value when considering effects of future electricity projects.	• One-third of Yukoners from throughout the territory selected for survey. • Survey results posted on the resource plan website and shared at public meetings.
Technical Advisory Committee meeting #3	Aug. 2016	Engagement	• A summary of this meeting is posted on Yukon Energy's resource planning website.

Round 2	Timing	Goal	Notes
Technical Advisory Committee meeting #4	Sept. 2016	Information and engagement	• Summary notes of the meeting are posted on Yukon Energy's resource planning website.
Maps	Nov. 2016	Information and engagement	• Maps were provided to Yukon First Nations showing potential energy projects by traditional territory.
Newspaper ads	Nov. 2016	Information and engagement	• Placements in Whitehorse Star and Yukon News notifying Yukoners about Round 2 public meetings.
Facebook and Google ads/boosted Facebook posts	Nov. 2016	Information and engagement	• Ads ran two weeks ahead of public meetings to notify Yukoners about Round 2 sessions.
Radio ads	Nov. 2016	Information and engagement	• Ads notifying Yukoners about Round 2 public meetings
Social media (Yukon Energy blog, Facebook, twitter, LinkedIn)	Nov. 2016	Information and engagement	• Notification of Round 2 public meetings
Posters	Nov. 2016	Information and engagement	• Posted at various public locations in Dawson, Mayo, Haines Junction, Carcross, and Teslin notifying Yukoners about Round 2 public meetings.
E-invites	Nov. 2016	Information and engagement	• Notification to Yukoners, including First Nations, about Round 2 public meetings.

Round 2	Timing	Goal	Notes
Information sheets/poster boards	Nov. – Dec. 2016	Information and engagement	• Fourteen information sheets and poster boards outlining each of the energy options we considered. • Sheets were available at all of the public meetings and were posted on the resource planning website.
Public meetings	Nov. 22 – Dec. 1, 2016	Information and engagement	• Meetings at Mount McIntyre in Whitehorse, in Dawson City, Mayo, Haines Junction, Carcross and Teslin
PowerPoint	Nov. 22 – Dec. 1, 2016	Information and engagement	• PowerPoint presentation for public meetings
Yukon-wide mailer #3	Dec. 2016	Information and engagement	• Summaries of all the energy options considered with link to the resource planning website for more information.
Resource Planning website	Late 2015 and throughout 2016	Information and engagement	• Regular updates on resource planning work, notification of public meetings, and two-way conversations with Yukoners sharing information, ideas and opinions.
Media coverage	Nov. 2016	Information	• Media coverage of second round of public engagement on resource plan.

Round 3	Timing	Goal	Notes
Technical Advisory Committee #5	Jan. 13, 2017	Information and engagement	• Summary of the meeting minutes was posted on Yukon Energy's resource planning website.
Newspaper ads	Jan. 2017	Information and engagement	• Ads ran in Yukon News and Whitehorse Star advising the public about the third round of public meetings.
Radio ads	Jan. 2017	Information and engagement	• Ads advising the public about the third round of public meetings.
Online ads	Jan. 2017	Information and engagement	• Facebook ads advising the public about the third round of public meetings.
Social media	Jan. 2017	Information and engagement	• Posts on Yukon Energy's Facebook, Twitter, and LinkedIn pages, advising the public about the third round of public meetings.

Round 3	Timing	Goal	Notes
Posters	Jan. 2017	Information and engagement	• Posted at various locations in Haines Junction, Carcross, Mayo, Dawson City, Teslin and Faro informing people about the third round of public meetings.
E-invites	Jan. 2017	Information and engagement	• Notification to Yukoners, including First Nations, about the third round of public meetings.
First Nation meetings	Jan. – Feb. 2017	Information and engagement	• Yukon Energy President and Vice-President met with several First Nations, including Carcross-Tagish First Nation, Kwanlin Dun First Nation, and Little Salmon/Carmacks First Nation.
NDP briefing	Feb. 16, 2017	Information	• Yukon Energy President and vice-President met with the NDP MLAs to provide a briefing on the resource planning process and proposed action plan.
Information sheet	Jan. – Feb. 2017	Information	• Summary sheet of presentation given at public meetings. It was provided to First Nations, given out at public meetings, and posted on Yukon Energy's resource planning website.
PowerPoint	Jan. – Feb. 2017	Information	• Presentation given at public and First Nation meetings.
Media coverage	Jan. – Feb. 2017	Information	• Media coverage (newspaper and radio) on third round of public engagement on the resource plan.

Draft Plan	Timing	Goal	Notes
Draft of 2016 Resource Plan	Late Feb. 2017	Information and engagement	• Draft posted on Yukon Energy's resource planning website.
E-mails	Late Feb. 2017	Information and engagement	• Yukoners who had indicated they wanted to be kept up to date on the resource planning process and who had provided Yukon Energy with their email address received notification that the draft plan was available for review.
Social media/website	Late Feb. 2017	Information and engagement	• Posts on Yukon Energy's Facebook, Twitter, and LinkedIn pages, along with the Corporation's website, inviting people to provide

Draft Plan	Timing	Goal	Notes
			comments on the draft resource plan.

Table A-1: Very Low Industrial Activity Scenario

Calendar Year	Energy Requirements							System Peak			
	Commercial Sales	Residential Sales	Industrial Sales	EV Sales	Total Sales	Losses	Total Generation Requirement	Non-Industrial Hourly Peak	EV Hourly Peak	Industrial Hourly Peak	System Hourly Peak
	(GWh)	(GWh)	(GWh)	(GWh)	(GWh)	(GWh)	(GWh)	(MW)	(MW)	(MW)	(MW)

Appendix 4.2
Yukon Macroeconomic Model
2016-2035

14 July 2016
Revised: 16 March 2017

Executive Summary

The Yukon Macroeconomic Model (MEM) is a tool for generating future economic and demographic indicators for the Yukon. The Model outputs are then a key input into Yukon Energy's (YEC) electricity demand forecasting model, which provides a long-term outlook of YEC's electricity demand needs. This demand forecast ultimately informs the YEC 2016 Resource Plan (RP), which will present desirable supply options for meeting future customer electricity requirements.

The MEM is the first step of several towards the successful issuance of the RP. The economic and demographic indicators produced by the MEM are a critical step in forecasting future supply requirements.

This appendix provides an overview of the MEM, which is used to generate forecasts of key economic variables such as Gross Domestic Product and population. The time period for the MEM is 20 years (2016 to 2035); which is consistent with the demand forecast period, and the mandated planning period of the 2016 YEC RP.

A number of historical economic and demographic variables are used as inputs to the MEM, including: economic output by industry, labour productivity, employment, wages and other income, population, consumption of goods and services, exchange rates, commodity prices, and capital investment.

Model runs were undertaken for 14 economic scenarios; these scenarios were developed to represent a range of Yukon economic activity over the planning period. The scenarios primarily consider a range of industrial activity, mining in particular, and in addition, a range of government spending levels. Sensitivity analysis with respect to future activity in Yukon's smaller economic sectors (such as tourism) were also modeled. The 14 scenarios cover a wide but plausible range of potential outcomes.

Values of the key economic variables with relevance to electricity consumption and therefore, future electricity demand, are presented in the Table 1. These are for the base economic case (Scenario 3). The minimum, maximum and base key economic variables from all 14 scenarios are presented in the body of this report in Table 2.

Table 1: Yukon Macroeconomic Model Outputs – Base Case

	Current (2015)	Year 2025	Year 2035
Population (000's)	37.4	41.2	41.1
Households (000's)	17.7	17.7	17.8
Employment (000's)	19.7	21.0	20.6
Real Dollar Disposable Income ($M)	1,351	1,638	1,802
Real Dollar Gross Domestic Product ($M)	2,226	2,682	2,789

The appendix concludes with a discussion of the results generated by the Yukon MEM. It also includes an explanation of the improvements resulting from the forecasting approach adopted, relative to efforts in YEC's previous resource plans.

C4SE Firm Profile

The Centre for Spatial Economics (C4SE) was formed in 2000 as a partnership between two consulting firms, Stokes Economic Consulting and Strategic Projections Inc. The intent of the C4SE partnership is to improve the quality of quantitative economic research in small Canadian jurisdictions available to public and private organizations. Over its first fifteen years of operations, C4SE has developed an extensive client base. Public sector clients include provincial finance departments in Alberta, British Columbia, New Brunswick, Newfoundland and Labrador, Ontario and Saskatchewan. C4SE has also developed macroeconomic models for BC Hydro. A complete client list can be found here: (http://www.c4se.com/clients.html).

Robert Fairholm Economic Consulting joined the C4SE partnership in 2003 to increase C4SE's capacity and scope of services. In addition to the staff of these corporations, the C4SE draws from a list of academics and research consultants on an as-needed basis.

Robert Fairholm, Partner at C4SE and President at Robert Fairholm Economic Consulting Inc., was responsible for preparing the economic forecasts for the Yukon economy used in the YEC RP. Fairholm holds an MA in Economics from the University of Toronto and a BA in Economics from Queen's University. He has over 20 years of experience in economic analyses, modelling and forecasting. Prior to joining the C_4SE, Fairholm was the Managing Editor of the International Bank Credit Analyst from 2001 to 2003, and provided a monthly forecast of interest rates, equity markets, commodity prices, economic trends and currency movements in the world's principal economies. From 1993 to 2001, Fairholm directed the Canadian forecasting operations of Standard & Poor's Data Resources Incorporated. He was responsible for all the Canadian macro, industrial and provincial forecasts and related services. The C4SE model runs were facilitated on behalf of YEC by staff from the Business and Economic Research Branch, Yukon Economic Development.

Yukon Macroeconomic Model Specifications

The multi-sector MEM used to inform YEC's long-term demand forecast was initially developed by C4SE for the Yukon Government in 2010. The MEM has been regularly maintained and updated by C4SE since. The Yukon MEM is similar to those developed by the C4SE for its forecasting for other provincial governments and agencies. These models are categorized as "fixed-price" general equilibrium models. They are made up of a series of mathematical equations which together describe the linkages and dependencies between sectors in an economy. As the equations are executed in parallel during runs, this type of model is also known as a simultaneous equation model.

Quantity adjustments rather than price adjustments clear markets in the short to medium term. Examples of quantity adjustments used in the model include changes in a) the utilization of capital b) the utilization of labour and c) changes in the movement of labour. A fixed price structure is used because firms are price takers in the small open economies for which the models are designed. An example of this reality is the price of mine output such as copper and gold. The mining output of the Yukon does not significantly influence the global price for metals.

A distinction is made in the MEM between industries that primarily export and sectors that primarily serve the local economy. Rest-of-world forces largely influence investment decisions by sectors that focus on exports; whether national or international. Assumptions with respect to export-driven investment are set exogenously. The investment decisions made by non-export driven sectors are driven largely by economic activity and demographics within the local economy.

Investment in industries that are primarily export oriented (mining) are set based on views regarding growth in the rest of the world and economic policies that influence the cost of investment and profitability. Investment is determined by the expected amount of capital that will be needed to achieve a target level of output. The target is determined by growth in demand for the particular industry's product, which depends on the growth in the other industries in the local economy and domestic demand along with capital costs.

Model Operation

The MEM operates on a year-by-year basis. It attempts to achieve an internally-consistent and stable solution for the first year of the forecast; once this achieved, it then increments to the next year.

The list of MEM input and output variables is provided below:

Yukon Macroeconomic Model Inputs:	**Yukon Macroeconomic Model Outputs:**
• Global economic indicators (historical and forecast real GDP, inflation and interest rates); • Historical government economic policies; • Historical production capacity by sector and capacity utilization rates; • Historical real economic output by industry; • Historical labour productivity; • Historical population; • Historical employment, wages and other income; • Historical net population in---migration; • Historical consumption of goods and services by individuals, companies and government; • Historical investment;	• Production capacity by sector and capacity utilization rates; • Real GDP and inflation; • Consumption of goods and services by individuals, companies and government; • Labour productivity; • Employment, wages and other income; • Population; • Net population in---migration; and, • Real economic output by industry.

• Exchange rates; • Commodity prices; • Mineral production; and, • Capital spending and employment associated with export-oriented projects.	

Economic Scenarios

Notwithstanding the challenges of economic forecasting in a small jurisdiction where economic output can be significantly altered by the opening or closing of a single mine, the C4SE Yukon MEM represents a robust attempt to forecast a reasonably wide range of economic activity in the Yukon over the forecast period.

A total of 14 economic scenarios were conceived for Yukon economic activity over the forecast period. The development of the economic scenarios was seeded via a planning session with two engineers from YEC, two economists from Yukon Economic Development and an independent economist from Vector Research. The choice of scenarios is intended to cover a wide but plausible range of possible economic activity in the Yukon.

The draft scenarios were considered by a panel of business and institutional leaders at a one day economic retreat hosted by YEC in Whitehorse on September 2015. The session was facilitated by Dr. Mark Jaccard of Simon Fraser University. Feedback received at the session was used to refine the economic scenarios which were then presented to the Technical Advisory Committee for inclusion into the RP. The scenarios were further refined on the basis of RP Technical Advisory Committee feedback and advice from the Yukon Minerals Advisory Board.

Historically, and currently, mining is the largest non-government entity in the Territory. Due to the relatively large electricity demand of a single typical mining customer, this sector is a key uncertainty and risk in the YEC RP. The Yukon economy is small; in 2015, the Gross Domestic Product of Yukon accounted for 0.13% of total Canadian Gross Domestic Product. Any Yukon mine of economic scale would have a significant influence on overall Yukon economic output, therefore, mining is a key factor for consideration in all of the 14 scenarios developed by YEC. This is not to infer that future mines were included in every scenario, but mining was a key consideration in the development in all of the scenarios.

Uncertainty in the YEC demand forecast is not just from direct electricity demand from a mine, but also due to the secondary economic spin-off activity of mining. The potential influence of mining on the demand for electricity would occur even if a mine is not served by YEC from the electricity transmission grid. All mining activity has an impact on overall economic activity in the Yukon, including overall employment, the need for commercial services, and ultimately government services. These secondary linkages then drive future demand for electricity.

Mining project parameters were informed by publically available information including company presentations, technical reports and news releases. Key assumptions incorporated into the scenarios include estimates of development costs, timing and length of the mine development phases (construction, operation and reclamation).

While designing the industrial activity scenarios, assumptions were made in relation to the future of commodity prices. The Very Low Industrial Activity scenario assumes that commodity prices (particularly refined mine products such as gold and copper) would remain at currently low levels, or follow a decreasing trend over the next 20 years. In contrast, the Very High Industrial Scenario assumes commodity prices will rebound from current levels and increase over subsequent years, thus creating a favorable investment environment for the advancement of mining projects. The following four projects were selected to serve as proxies for mining activity of the forecast period: Eagle Gold, Coffee Gold, Wellgreen Platinum, and Casino (gold and molybdenum). Selection of the four projects was based on the current placing of each project with respect to mine permitting, feasibility assessment and the environmental assessment process.

Mining and the public sectors combined dominate the Yukon economy; the influence of Yukon's smaller economic sectors (tourism, agriculture, forestry and fishing) on total territorial economic output is relatively smaller. To explore the effects of changes in economic activity in Yukon's smaller economic sectors on potential electricity demand, sensitivity analyses were carried out by doubling input variable ranges to test the effects.

Federal transfer payments to the Yukon Government have significant influence on the Yukon economy. In the 2014/15 fiscal year, transfers from the Federal Government accounted for 83% of total Yukon Government revenues. As 39% of total Yukon Gross Domestic Product was attributable to the public sector in the 2015 calendar year, changes in growth rates and levels of federal transfers to the Yukon will have material effects on overall economic activity in the Yukon. For this reason, sensitivities were undertaken to determine the economic effects of changes in Federal transfer payments.

Federal transfer payments to the Yukon Government grew steadily and significantly during the 2000 to 2015 period, increasing by an average of 6.5% per annum. In all of the constructed scenarios, Federal transfers are expected to increase until at least 2019, at which the scenarios branch. In some scenarios, such as Low Industrial Activity with tapering government spending, Base Case with tapering government spending, and Low Mining Activity with Minto Mine ending production in 2017 and sensitivity analysis of government spending, transfers are expected to be flat from 2020 to the end of forecast period. It was assumed that government spending was capped on a real per person basis. In the remaining scenarios, the transfer payments, and government spending consequently, are assumed to grow on the average at a real rate of 0.5% per year per capita.

A total of 14 scenarios were modelled and they are described in the following paragraphs.

1. Very Low Industrial Activity

- Production at the Minto Mine ends after 2017.
- No new mines over the forecast period.
- Government spending is assumed to continue to grow beyond 2019.

2. Low Industrial Activity

- Production at the Minto Mine continues to the end of current productive life in 2022.
- One new medium-sized mine is brought into production. The Eagle Gold project is used as the proxy mine. Eagle Gold development begins in 2019 followed by full production from 2021 to 2035 with production tapering off and the mine closing in 2036.
- Government spending is assumed to continue to grow beyond 2019.

3. Base Case (Medium Industrial Activity)

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- Government spending is assumed to continue to grow beyond 2019.

4. High Industrial Activity including a new Large Mine

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Three new medium-sized mines are brought into production. The Eagle Gold, Coffee and Wellgreen projects are used as medium proxy sized mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
    - Wellgreen development begins in 2020 followed by production from 2022 to 2046.
- One new large mine is brought into production. The Casino project is used a large proxy mine. Casino mine development begins in 2018 and mine production begins in 2019, with operations continuing until 2043.
- Government spending is assumed to continue to grow beyond 2019.

5. Low Industrial Activity with tapering government spending

- Production at the Minto Mine continues to the end of current productive life in 2022.
- One new medium-sized mine is brought into production. The Eagle Gold project is used as a proxy mine. Eagle Gold development begins in 2019 followed by production from 2021 to 2036 with production beginning to taper off in 2035.

- Government spending is assumed to continue to grow only until 2019 after which time government spending growth is flat, i.e., government spending levels remain constant from 2020 to end of the forecast period.

6. Base Case with tapering government spending

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines.
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036 with production beginning to taper off in 2035.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- Government spending is assumed to continue to grow only until 2019 after which time government spending growth is flat, i.e., government spending levels remain constant from 2020 to end of the forecast period.

7. Base Case with sensitivity analysis of smaller economic sectors (agriculture, forestry and fishing)

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- Government spending is assumed to continue to grow beyond 2019.
- Yukon's other economic sectors hold potential to influence economic output, though not at the same scale as the mining sector. Sensitivity analysis was undertaken to better understand the combined influence of the agriculture, forestry and fishing sectors on the MEM variables. This sensitivity analysis was executed by running the MEM with input variable ranges doubled compared to the base case to demonstrate the economic impacts.

8. Base Case with sensitivity analysis of natural gas projects

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- Government spending is assumed to continue to grow beyond 2019.
- Yukon's oil and gas sector holds potential to make a significant contribution to economic output. To understand the potential influence of this sector on the MEM variables, a sensitivity analysis was undertaken on one medium-sized natural gas project. Based on the limited data on gas projects available, a project with production estimated to last 15 years at a gas extraction

rate of 100 Mmcf/day was considered. The project related data were sourced from a feasibility study prepared by the Mines and Resources Oil & Gas Branch of the Yukon Government.

9. Base Case with later start of production for new Large Mine

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- One new large mine is brought into production, two years later than in Scenario 4. The Casino project is used a proxy large mine. Casino mine development begins in 2020 and mine production begins in 2021, continuing until 2045.
- Government spending is assumed to continue to grow beyond 2019.

10. Base Case with induced mining "bust and boom cycle"

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines. To illustrate to effects of a potential boom and bust cycle, the start of both projects is delayed to represent a bust period in the near term and both projects begin production at the same time to represent a boom period:
    - Eagle Gold development begins in 2028 followed by production from 2030 to 2041.
    - Coffee development begins in 2029 followed by production from 2030 to 2041.
- Government spending is assumed to continue to grow beyond 2019.

11. Base Case with advanced mine production timing

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines. The base case scenario is modified by bringing the two proxy mines into production two years earlier:
    - Eagle Gold development begins in 2017 followed by production from 2019 to 2034.
    - Coffee development begins in 2020 followed by production from 2021 to 2034.
- Government spending is assumed to continue to grow beyond 2019.

12. Low Mining Activity with Minto Mine ending production in 2017

- Production at the Minto Mine ends after 2017.
- One new medium-sized mine is brought into production. The Eagle Gold project is used as a proxy mine. Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
- Government spending is assumed to continue to grow beyond 2019.

13. Low Mining Activity with Minto Mine ending production in 2017 and sensitivity analysis of government spending

- Production at the Minto Mine ends after 2017.
- One new medium-sized mine is brought into production. The Eagle Gold project is used as a proxy mine with development starting in 2019, followed by production from 2021 to 2036.
- Government spending is assumed to continue to grow to 2019 after which time growth in government spending is frozen.

14. Base Case with sensitivity analysis of tourism

- Production at the Minto Mine continues to the end of current productive life in 2022.
- Two new medium-sized mines are brought into production. The Eagle Gold and Coffee projects are used as proxy mines:
    - Eagle Gold development begins in 2019 followed by production from 2021 to 2036.
    - Coffee development begins in 2022 followed by production from 2023 to 2036.
- Government spending is assumed to continue to grow beyond 2019.
- Yukon's smaller economic sectors hold potential to influence economic output, although not at the same scale as the mining sector. To understand the influence of these sectors on the model output, a sensitivity analysis was undertaken across the industries which comprise the tourism sector including retail trade, accommodation, food services and transportation. The rate of tourism growth was doubled compared to the base case.

Yukon Microeconomic Model Results

The C4SE model generates outputs for an extensive list of economic variables. Output ranges and average values for the key economic variables with relevance to electricity consumption and therefore, future electricity demand, are presented in Table 2 below. To illustrate the range of key economic variables which inform the demand forecast, minimum, maximum and base values drawn from all 14 scenarios are presented for two future dates. Note that demographic parameters are much less variable than the economic parameters. The latter are heavily impacted by mining assumptions.

Table 2: Yukon Macroeconomic Model Outputs – Including Scenario Results

	Current (2015)	Year 2025	Year 2035
Population Base Case (000's)	37.4	41.2	41.1
Highest Scenario		43.1	42.6
Lowest Scenario		40.0	38.5
Households Base Case (000's)	17.7	17.7	17.8
Highest Scenario		18.4	18.4
Lowest Scenario		17.2	16.8
Employment Base Case (000's)	19.7	21.0	20.6
Highest Scenario		21.9	21.6
Lowest Scenario		20.4	19.0
Real Dollar Disposable Income Base Case ($M)	1,351	1,638	1,802
Highest Scenario		1,781	1,912
Lowest Scenario		1,548	1,611
Real Dollar Gross Domestic Product Base Case ($M)	2,226	2,682	2,789
Highest Scenario		4,238	4,459
Lowest Scenario		2,407	2,480

Descriptive charts for key economic variables which inform the electricity demand forecast are presented in the following sections. To avoid potential confusion that can be caused by 14 sometimes overlapping lines presenting 14 scenarios, the charts show 5 major scenarios (Very Low Industrial Activity, Low Industrial Activity, Low Industrial Activity with Early Minto Closure, Medium Industrial Activity, and Very High Industrial Activity) and the range of the remaining scenarios as a shaded area. The 5 major scenarios are selected due to their higher probability of realization compared to that of the rest of the scenarios.

Forecast Yukon Gross Domestic Product

Figure 1 illustrates forecast of Yukon Gross Domestic Product (Real dollars) over the forecast period for the economic scenarios. Growth in real GDP fall within a relatively narrow band except for the High Mining Activity including a new Large Mine scenario (scenario 4) and the Base Case with later start of production for new Large Mine scenario (scenario 9).

Figure 1: GDP including Mining Forecast

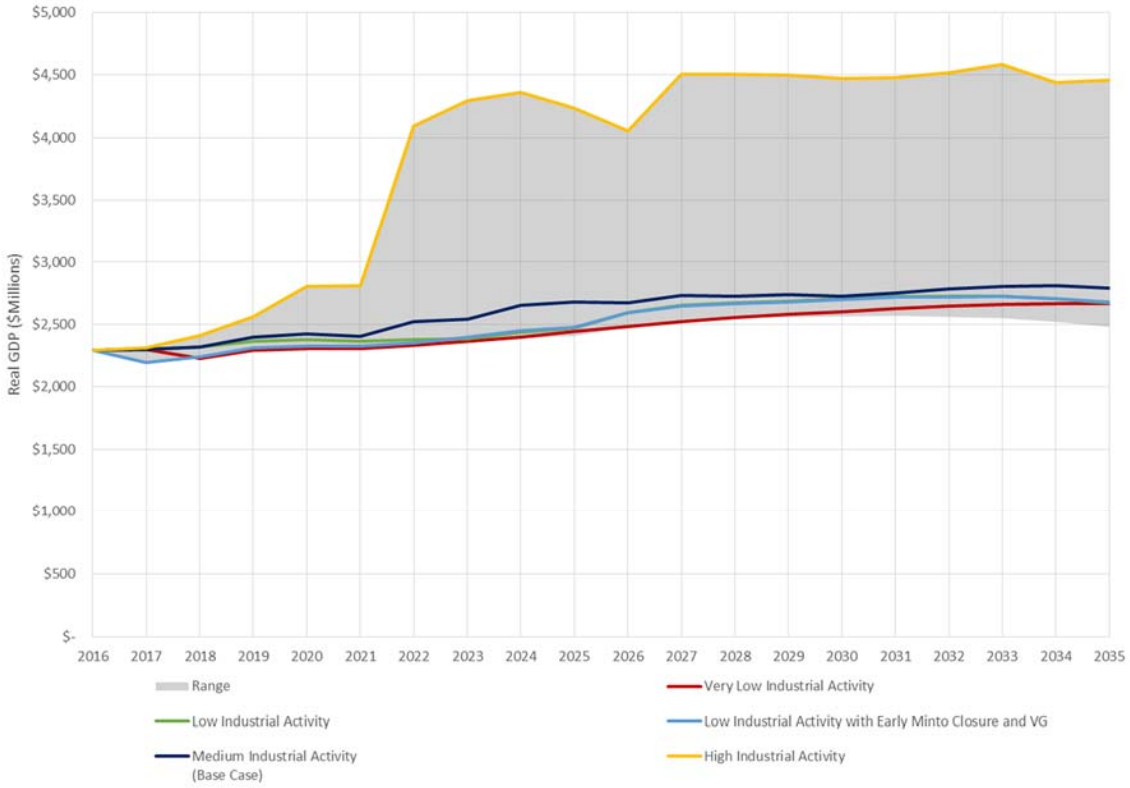

Figure 2 below illustrates a forecast of Yukon Gross Domestic Product (Real dollars) over the forecast period for the economic scenarios without the contribution of the mining industry. Growth in real GDP generally fall within a relatively narrow band except for the High Mining Activity including a new Large Mine scenario (scenario 4) and the Base Case with sensitivity on natural gas development (scenario 8).

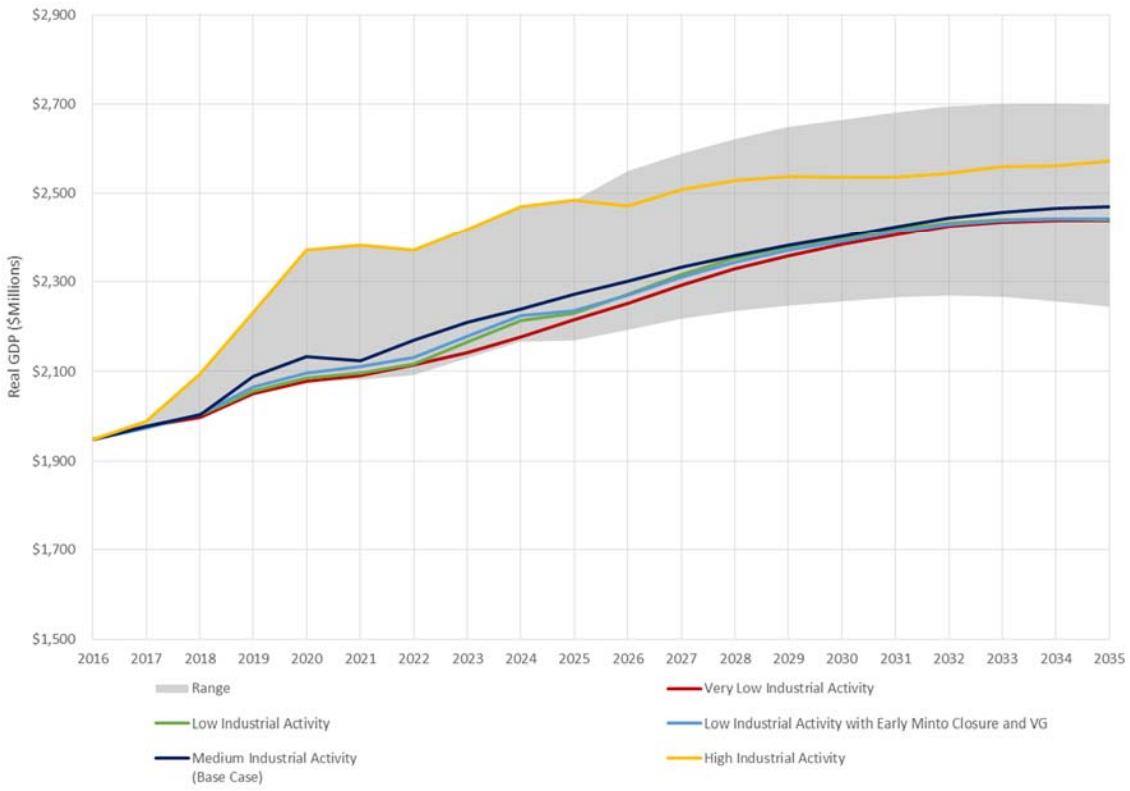
Figure 2: GDP excluding Mining Forecast

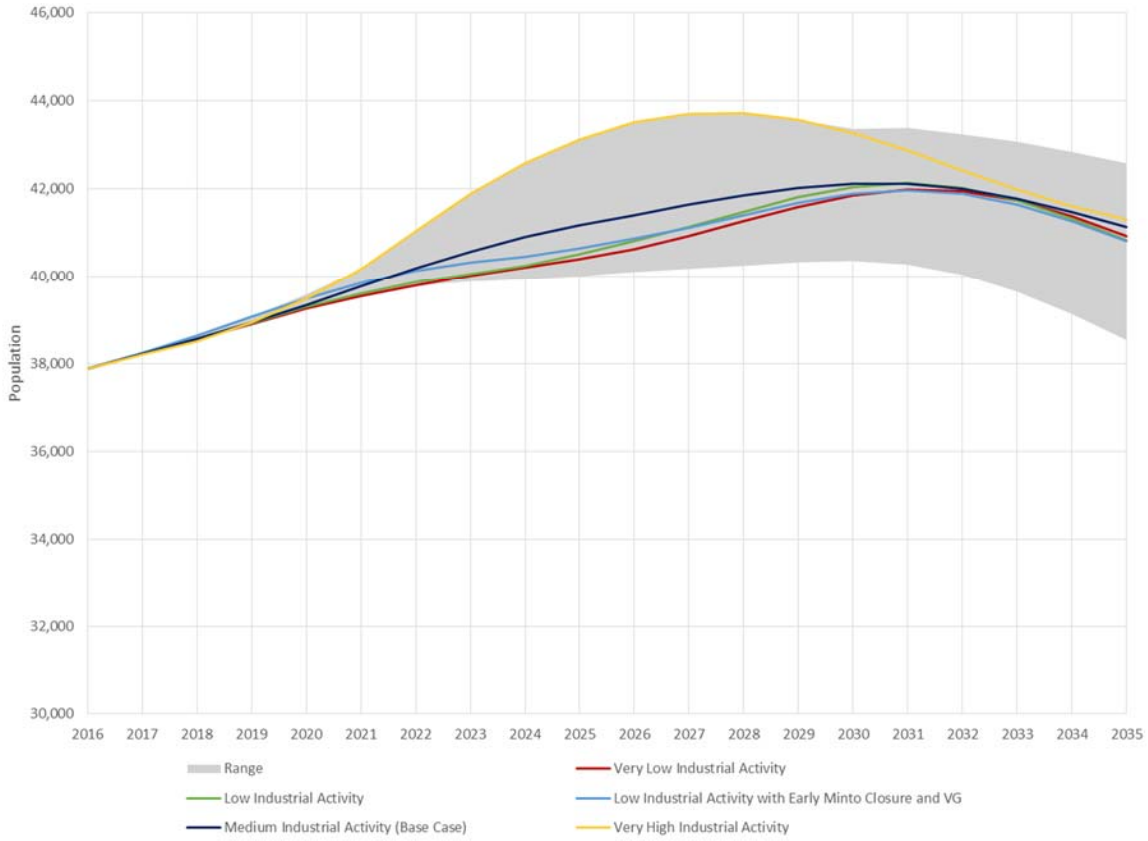


Forecast Yukon Population

Figure 3 below illustrates forecast of Yukon population over the forecast period for the economic scenarios. As Figure 3 shows, the population changes fall into a relatively narrow for all the scenarios. The direct connection between population growth and economic activity that is implicit in the YEC MEM by the slight decline in Yukon's population for the period after 2030. The MEM forecasts indicate an accelerating decline in the natural population growth rate, from 0.6% per annum currently to zero growth by 2030. After 2030, the difference between the number of deaths and births per year is expected to widen each year. The decline in the natural population growth rate will be compounded by an increasingly aging population. Whereas the 65+ age cohort represented only 11% of the total population in the Territory in 2015, by 2035 the 65+ age cohort is predicted to account for 23% of the population. This will translate into fewer people of working age. Further impacting Territory employment, the assumption is made that mineral production activities in the Yukon will become more automated, as a competitive measure. This will result in less operational employment opportunities in Yukon mines.

The small population of Yukon makes it a challenge to forecast long-term population. Nevertheless, changes in the Yukon population over the next 20 years will have a significant influence on YEC electricity demand, as residential and commercial sector electricity requirements tends to follow trends in population and housing starts.

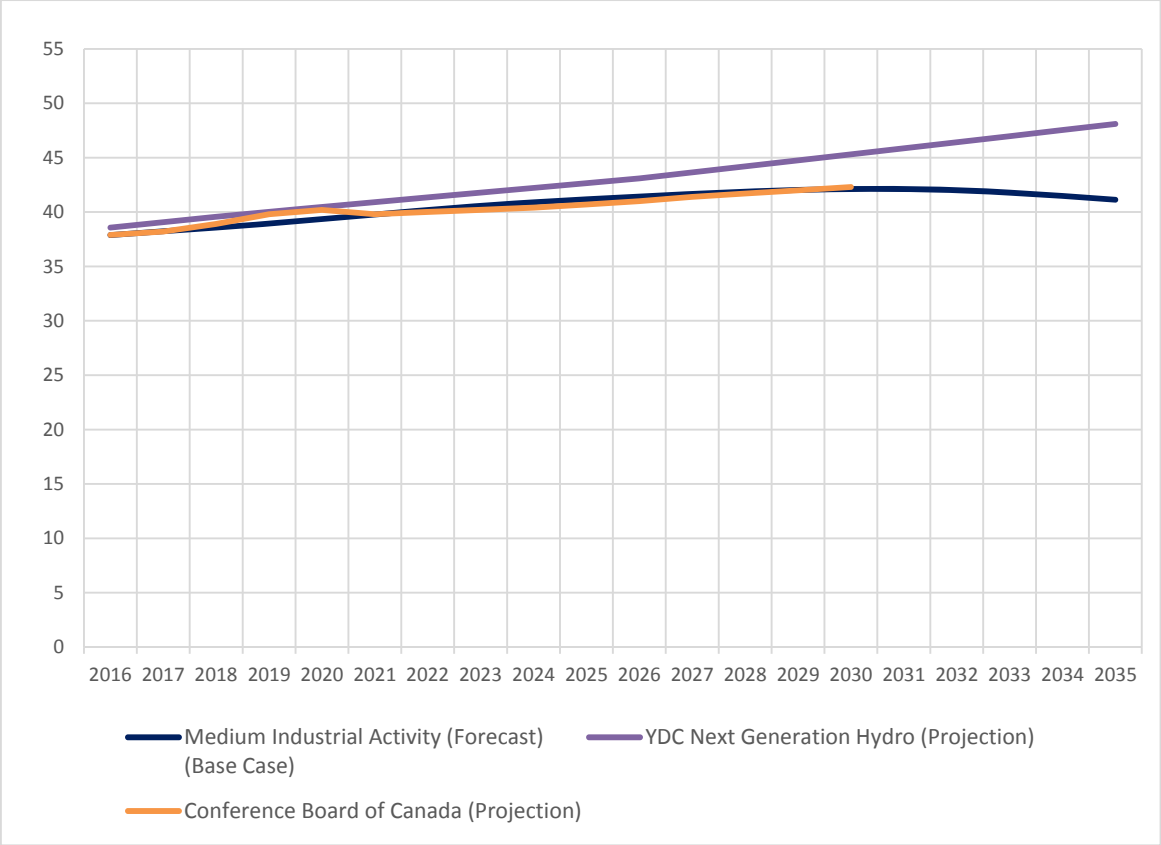
Figure 3. Population Forecast



The simplest approach to forecast the future is by extrapolation; this could include population projections. This approach implies that the past is the primary determinant of the future, and that recent trends will persist. Given inescapable demographic facts (i.e. the aging of the baby boomer generation), this approach will miss likely strategic outcomes, such as naturally declining employment levels or the need to import workers in the event of a domestic construction boom.

Forecasts of future population levels based on demographic trends (such as fertility and migration rates) are the basis of the C4SE and the Conference Board of Canada's population forecasts. As the fertility rate in Canada has been declining steadily for many years, and is expected to decline further, the forecast population growth in the Yukon is largely driven by assumptions regarding net in-migration. In contrast to the C4SE approach to long-term population forecasting, the Next Generation Hydro or previous forecasts done for YEC resource plans, were not directly informed by forecasts of economic activity. A comparison of recently developed population forecasts is illustrated in Figure 4.

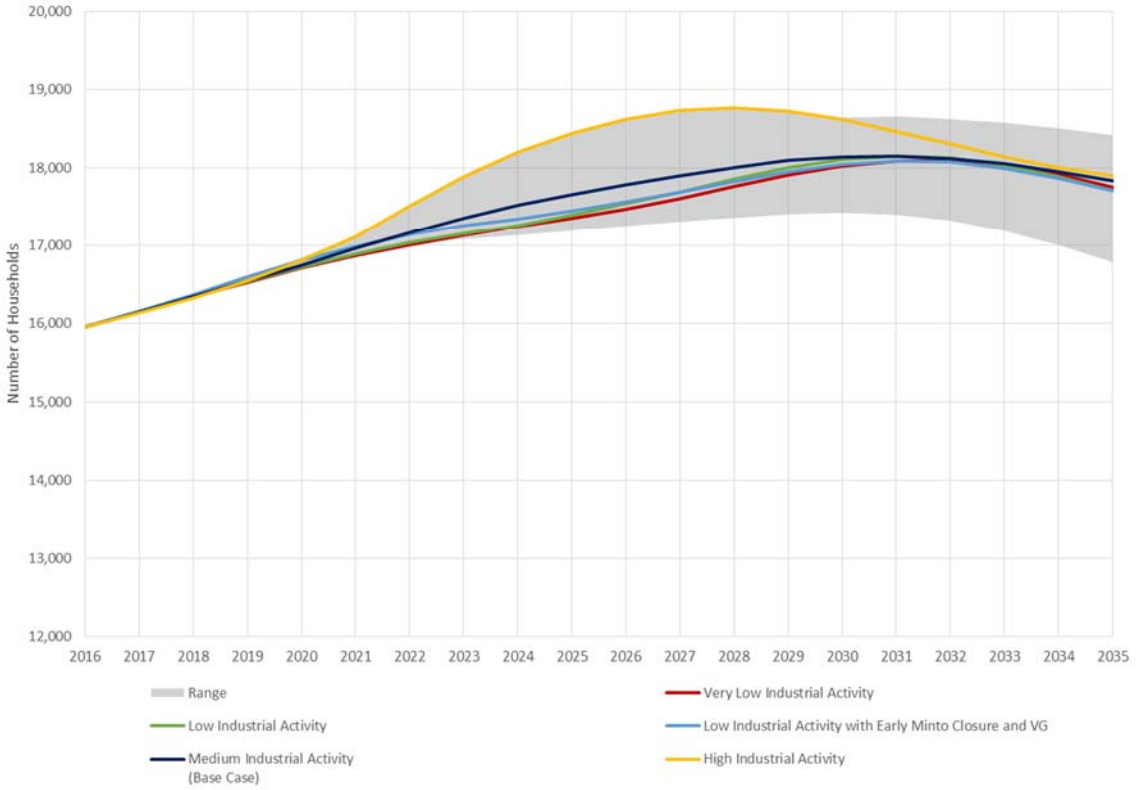
Figure 4. Projected and Forecast Yukon Population (in '000)



Forecast Number of Yukon Households

Figure 5 illustrates number of Yukon households forecast over the forecast period for the economic scenarios. As shown in Figure 5, growth in the number of households is forecast to be relatively steady over the forecast period. Consistent with the population forecast, the number of Yukon household peaks in the late 2020's before a gradual decline.

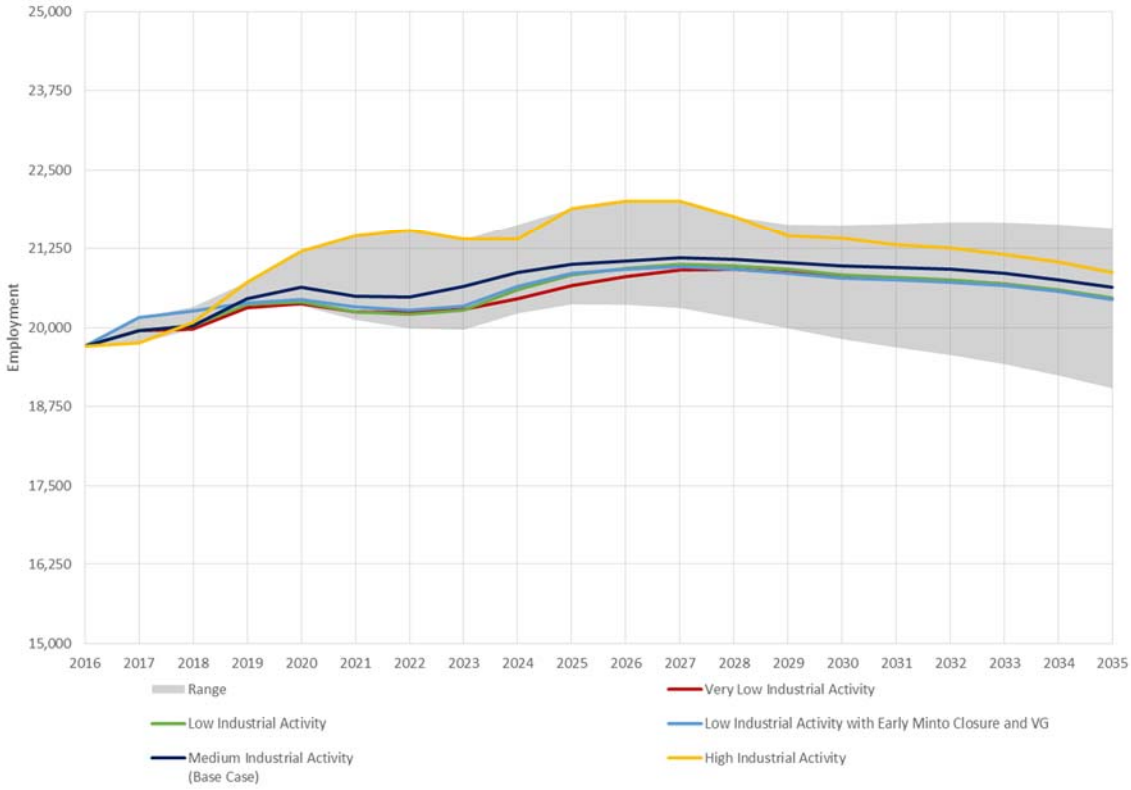
Figure 5. Number of Household Forecast



Forecast Yukon Employment

Figure 6 illustrates the forecast of total Yukon employment over the forecast period for the economic scenarios. The employment forecast is used to estimate commercial electricity demand over the forecast period, with the level of total employment directly related to electrical sales. As the level of total employment increases, electrical sales will also increase. Overall, total Yukon employment is forecast to grow until 2030 before beginning to decline slightly, a pattern consistent with the forecasts for population and the number of households as generated by the MEM.

Figure 6. Employment Forecast



Forecast Yukon Per Capita Disposable Income

Figure 7 illustrates the forecast of total Yukon employment over the forecast period for the economic scenarios. Yukon per capita disposable income (Real dollars) is used to forecast electrical sales to residential customers and is directly related to sales. As disposable income increases, residential electrical demand will correspondingly increase. As shown in Figure 7, the MEM results indicate a relatively narrow range of variations in per capita disposable income over the forecast period. In contrast to the forecasts for population, number of households and employment, per capita disposable income is expected to steadily increase under all scenarios through to the end of the forecast period in 2035.

Figure 7. Real Per Capita Disposable Income Forecast

YUKON ENERGY

1 Overview

Itron, Inc. (Itron) was contracted by the Yukon Energy Corporation (YEC) to develop a process for forecasting system energy and peaks using a bottom up class level forecasting approach. Itron's modeling approach incorporates the 2015 SAE (Statistically Adjusted End-Use) indices, as well as current economic data. This document outlines underlying data, the structure of the models, and the modeling process.

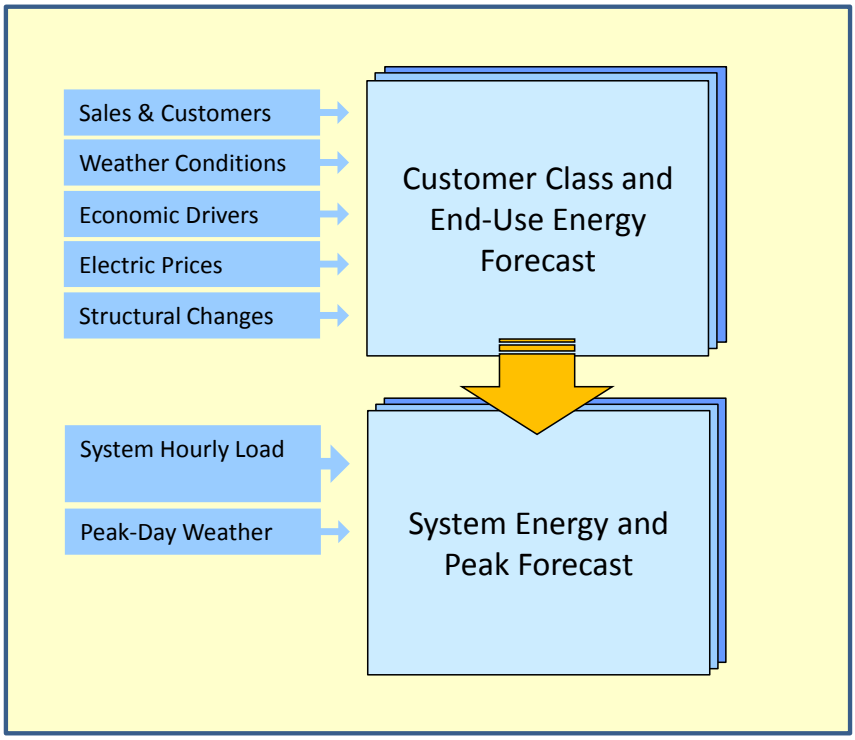
Itron constructed all forecasting and weather normalization models in MetrixND, Itron's statistical modeling application. MetrixND is ideally suited for this purpose as Itron designed and developed the software specifically to meet the needs of the utility industry. In this case, MetrixND generates monthly sales and peak demand. Further, MetrixND acts as the forecasting engine that supports hourly and sub-hourly processes for long-term planning, as well as real-time and day-ahead forecasting to support generation dispatch and load scheduling. Table 1-1 summarizes YEC energy and demand forecast (excluding industrial).

Table 1-1: Energy and Demand Forecast: Base Case

Year	Energy (MWh)		Peak (MW)	
2015	374,882		76.9	
2016	389,806	4.0%	82.2	6.9%
2017	393,583	1.0%	83.8	1.9%
2018	399,238	1.4%	85.9	2.5%
2019	406,423	1.8%	88.2	2.7%
2020	413,561	1.8%	90.8	2.9%
2021	418,684	1.2%	92.8	2.2%
2022	425,589	1.6%	95.2	2.6%
2023	432,219	1.6%	97.4	2.3%
2024	439,363	1.7%	99.8	2.4%
2025	443,536	0.9%	101.2	1.4%
2026	447,317	0.9%	102.5	1.3%
2027	451,336	0.9%	103.8	1.3%
2028	455,839	1.0%	105.2	1.4%
2029	457,568	0.4%	105.8	0.5%
2030	458,274	0.2%	106.1	0.3%
2031	457,059	-0.3%	105.8	-0.3%
2032	456,036	-0.2%	105.6	-0.2%
2033	452,276	-0.8%	104.6	-1.0%
2034	448,774	-0.8%	103.7	-0.8%
2035	444,998	-0.8%	102.8	-0.9%
2016-2025		1.4%		2.3%
2016-2035		0.7%		1.2%

The long-term energy and demand forecast is developed using a “build-up” approach. This approach entails first estimating class and end-use energy requirements and then using class and end-use sales projections to drive system peak demand. The forecast models capture not only economic activity and population projections, but also expected weather conditions, the impact of improving end-use efficiency and standards, and electricity prices. The forecast does include the impact of future conservation programs savings. Figure 1-1 shows the general approach.

Figure 1-1: Forecast Approach



In the long-term, both economic growth and structural changes drive sales and demand requirements. Structural changes are captured in the residential and commercial sales forecast models through SAE (Statistically Adjusted End-Use) specifications. The SAE model variables explicitly incorporate end-use saturation and efficiency projections, as well as changes in population, economic conditions, price, and weather. End-use efficiency projections include the expected impact of new end-use standards and naturally occurring efficiency gains. The industrial sales forecast is derived using a generalized econometric model that relates industrial sales to regional industrial GDP growth. The Street Light (ST) sales forecast is also derived using a generalized econometric model that relates ST sales to the residential customer forecast. Table 1-2 summarizes customer class sales forecast excluding industrial saels.

YUKON ENERGY

Itron

Table 1-2: Customer Class Sales Forecast: Base Case (MWh)

Year	Residential		Commercial		ST		SP		Total	
2015	155,443		173,005		291		14		328,754	
2016	162,786	4.7%	175,799	1.6%	291	0.2%	14	0.2%	338,890	3.1%
2017	165,192	1.5%	176,657	0.5%	292	0.2%	14	0.0%	342,154	1.0%

2028	203,768	1.4%	192,043	0.5%	297	0.1%	14	0.0%	396,122	1.0%
2029	204,709	0.5%	192,601	0.3%	298	0.1%	14	0.0%	397,621	0.4%
2030	205,508	0.4%	192,416	-0.1%	298	0.0%	14	0.0%	398,235	0.2%
2031	205,253	-0.1%	191,620	-0.4%	298	0.0%	14	0.0%	397,186	-0.3%
2032	205,298	0.0%	190,696	-0.5%	298	0.0%	14	0.0%	396,306	-0.2%
2033	203,568	-0.8%	189,165	-0.8%	298	-0.1%	14	0.0%	393,044	-0.8%
2034	202,212	-0.7%	187,484	-0.9%	297	-0.1%	14	0.0%	390,008	-0.8%
2035	200,789	-0.7%	185,631	-1.0%	297	-0.1%	14	0.0%	386,731	-0.8%
2016-2025		2.1%		0.8%		0.2%		0.0%		1.4%
2016-2035		1.1%		0.3%		0.1%		0.0%		0.7%

The strong growth in Residential sales is the result of increasing saturation of electric heat. Residential electric heat saturation grows from approximately 12% in 2015 to 21% by 2025 before flattening out at 23% by 2031. This saturation is driven by the assumption that 95% of all new residential customers will have electric heat. Residential average use increases 1.0% annually through 2025. Commercial sales are also driven by increases in electric heat saturation. Growth rates in all classes begin to decline in the out years, driven by significant declines in the population and GDP forecasts.

2 Forecast Data and Assumptions

2.1 Historical Class Sales and Energy Data

The process begins by estimating long-term monthly sales models at the revenue class level. Forecast models are estimated for residential, commercial, industrial, and street lighting revenue classes. Regression models are estimated using historical monthly billing data that includes sales, customers, and revenue. The residential and commercial models are estimated using monthly billed sales, customer and price data for the period January 2006 to September 2015. The industrial model is estimated using monthly data for the period January 2006 to September 2015. Street light models are estimated using monthly billed sales data from January 2006 to September 2015.

System monthly energy and monthly demand data are derived from historical hourly load data for the period January 1, 2006 to September 30, 2015 with estimated hourly loads for the Elsa and Minto mines removed.

Hourly Elsa mine loads are approximated subtracting the Elsa SCADA data hourly load from the system loads to obtain a monthly system demand modifier. The modifier is further reduced by 0.28 MW which approximates the non-Elsa mine load from hourly SCADA data based on the average of the SCADA data demand after the Elsa mine closed in August 2013.

Hourly Minto mine loads are approximated by subtracting the Minto mine loads from the system loads to obtain a monthly system demand modifier from January 2013 through September 2015. The demand modifier for data prior to January 2013 is estimated by applying the average ratio of the demand modifier to the Minto non-coincident billing peaks and applying the ratio to the January 2006 through December 2012 time period.

2.2 Weather Data

YEC provided daily historical minimum and maximum dry bulb temperature data for Whitehorse, Canada for the period January1, 1970 to September 30, 2015. These data are obtained from Environment Canada and used as the proxy weather station for the entire YEC service territory.

Using these data, a daily average temperature concept is calculated, as well as daily Heating Degree Day (HDD) and Cooling Degree Day (CDD) concepts for numerous breakpoints. As class sales data is measured on a billing month basis, models are estimated using billing-

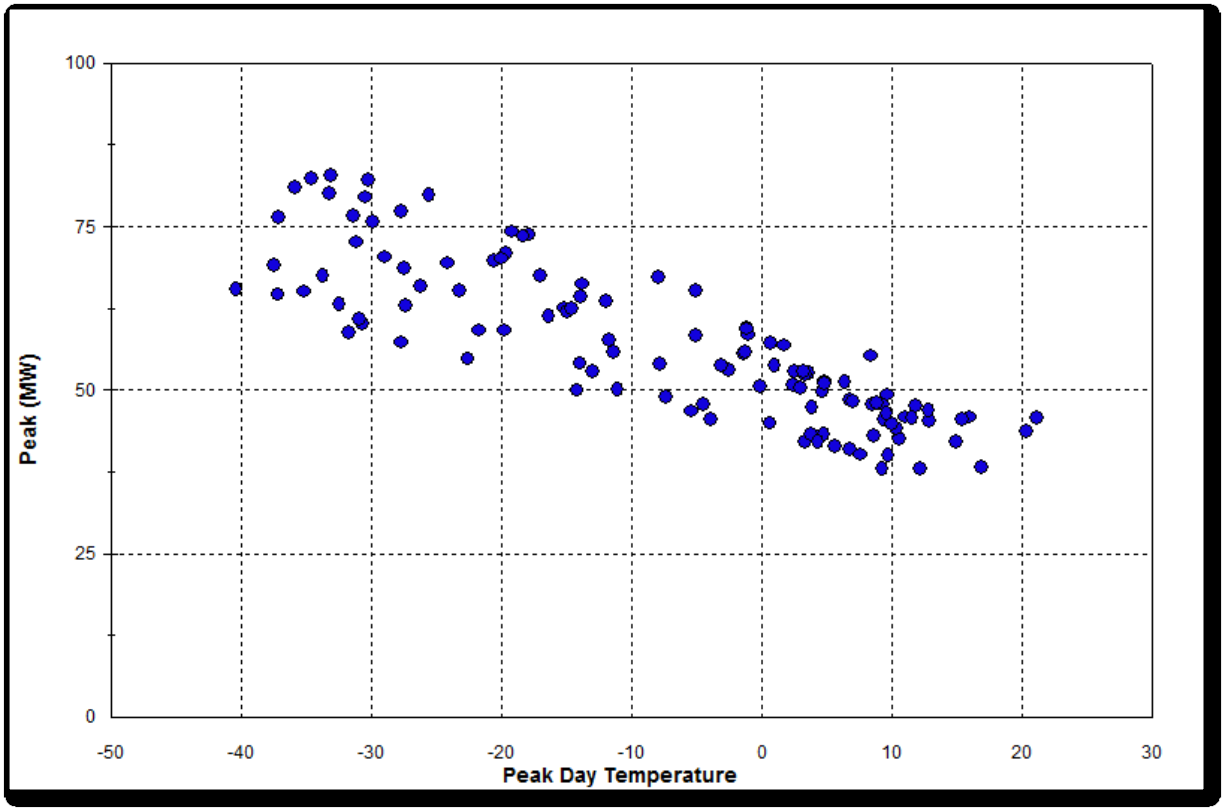
month or cycle-weighted HDD and CDD. These cycle-weighted HDD and CDD concepts are calculated using a meter read schedule, which sums the daily HDD and CDD concepts over the monthly billing cycles. Ultimately, our objective is to generate calendar-month sales and energy forecasts. To derive calendar month sales forecasts, simulation objects are used where billing month HDD and CDD in the estimated model are replaced with calendar month normal HDD and CDD and the number of billing days used in the estimated model is replaced with the number of calendar days.

Normal calendar and cycle-weighted degree days are calculated based on the 30-year period January 1, 1981 to December 31, 2010 using an average by date method.

Peak-Day Weather Variables

The peak forecast is generated from a monthly peak regression model. Peak-day HDD and CDD are derived from historical daily average weather data. Peak-day HDD and CDD are calculated by first finding the peak in each month (the maximum hourly demand), identifying the day, and finding the average temperature for that day. The average peak-day temperature is then used to construct peak-day HDD and CDD variables. The appropriate breakpoints for the HDD and CDD variables are determined by evaluating the relationship between monthly peak and the peak-day average temperature, shown in Figure 2-1.

Figure 2-1: Monthly Peak Demand vs. Temperature Relationship



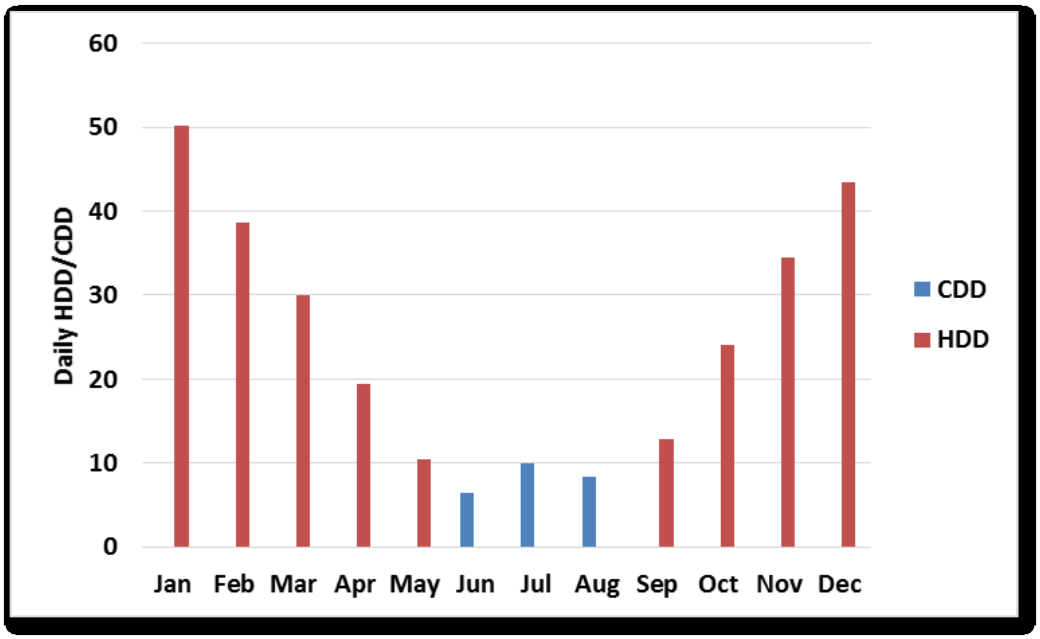
Monthly peak-day HDD and CDD are calculated for the estimation period – January 2006 to September 2015 based on these temperature relationships.

Normal peak-day CDD and HDD are calculated from monthly extreme temperature observations. This method is chosen because historic load data is not available prior to 2006; therefore peak day weather cannot be determined. For the months of June, July, and August the monthly maximum temperature is used, for all other months the monthly minimum is used. Normal peak-day HDD and CDD are calculated using 30 years of historical weather data (1981 to 2010). The calculation process entails using a *rank and average* approach as described below:

1. Find the lowest or highest temperature observation for a given month. This calculation occurs within the Loads.NDM.
2. *Rank* the monthly HDD and CDD in each year from the highest value to the lowest value.
3. *Average* across the annual rankings – average the highest HDD values in each year, average the second highest in each year, the third highest …., average the lowest HDD values in each year.

4. Assign the HDD and CDD values to specific months based on past weather patterns. The highest HDD is assigned to January and the highest CDD value is assigned to July. Figure 2-2 shows the calculated peak-day normal HDD and CDD

Figure 2-2: Peak-Day Normal HDD and CDD



2.3 Economic Data

Economic data was provided by YEC. These data are obtained from the Centre for Spatial Economics (C4SE) and include a base case and nine economic scenarios. The main differing factor among the scenarios is mining activity. The economic scenarios and their impact on the load and demand forecast will be covered in detail in the Forecast Scenarios section of this document.

The primary economic drivers in the residential model include income per capita, households, and population. Commercial sales are driven by commercial regional non-mining output, which represents territorial GDP without the contribution of the mining industry, and employment. The economic driver used in estimating the industrial sector model is mining output. Table 2-1 summarizes the primary economic drivers for the residential class.

YUKON ENERGY

Table 2-1: Residential Drivers: Base Case

Year	Population		HouseHolds		Per Capita Income	
2015	37.4		15.7		36.1	
2016	37.9	1.2%	16.0	1.5%	36.3	0.6%

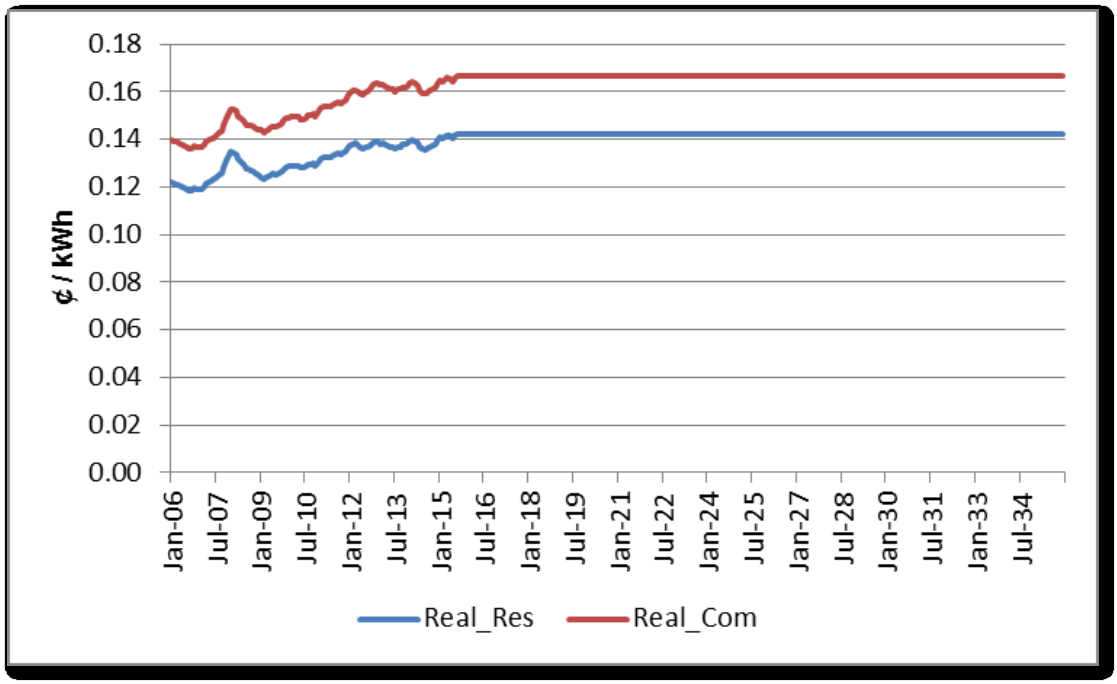
2.4 Price Data

Historical average real prices are derived from historical billing and revenue data. Prices impact the class sales through imposed price elasticities. The residential and commercial price elasticity is -0.10. Itron's 2006 Price Effects survey identifies the range of price elasticities from 0.0 to 0.35 for residential customers and 0.0 to 0.5 for commercial customers. The selection of the price elasticity is based on adjusting the elasticity in the model and determining the impact on overall model fit.

Though the elasticities are small, relatively strong price increases through 2015 have a measurable impact on near-term usage. Over the long-term, constant real prices are assumed rendering the impact of elasticity in the forecast as unimportant while leaving the forecast unbiased regarding unadopted price increases and decreases. Figure 2-3 shows price forecasts by class.

Figure 2-3: Historical and projected real electricity prices (cents per kWh)

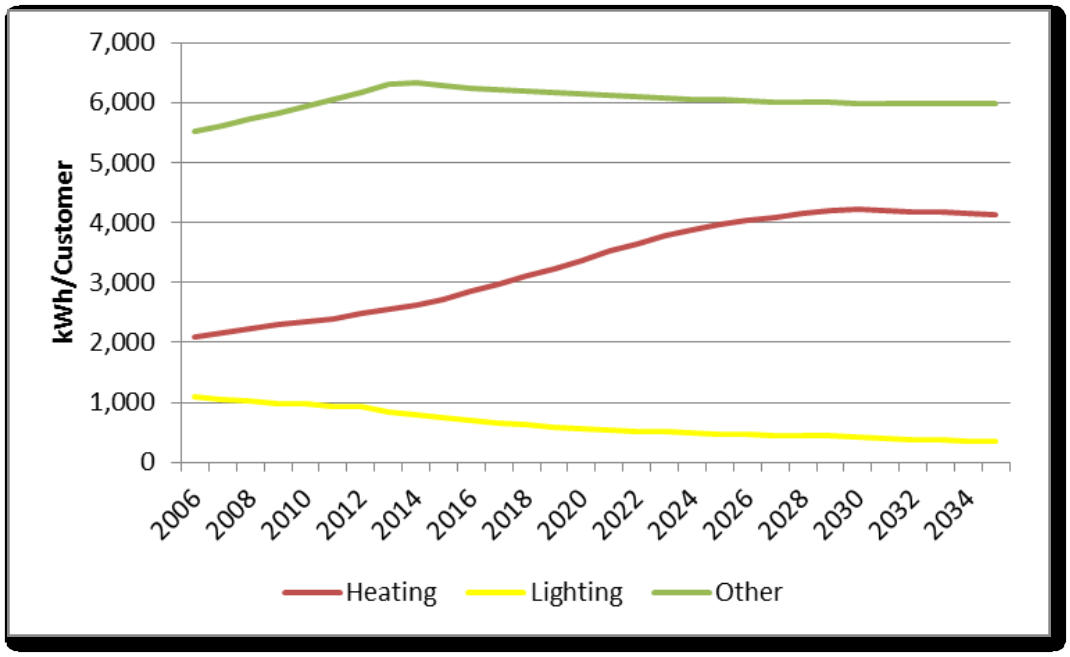


2.5 Appliance Saturation and Efficiency Trends

Over the long-term, changes in end-use efficiency and equipment stock impact energy and peak demand. These trends are explicitly captured in the forecast model variables. The residential sector incorporates saturation and efficiency trends for seventeen end-uses. The commercial sector captures end-use intensity projections for ten end-use classifications across ten building types. Residential end-use efficiency and commercial end-use efficiency are derived from the U.S. Energy Information Administration's (EIA) 2015 West North Central Census Division forecast. Historic and projected residential end-use saturations are based on a combination of data from Natural Resources Canada (NRCan),a 2011 potential study, *Yukon Conservation and Demand Management Potential Review* (CPR), and a 2016 CPR study. The residential electric heat saturation projection is calculated using the assumption that 95% of all new customers use electric heat as their primary heating source.

Residential sales forecast are derived as the product of monthly customer forecast and average use forecast. For the residential average use model, end-use intensity projections (use per household) are aggregated into three generalized end-uses; heating, lighting, and other use, no residential cooling is present in YEC's service territory, per the 2011 potential study. Figure 2-4 shows the resulting aggregated end-use intensity projections.

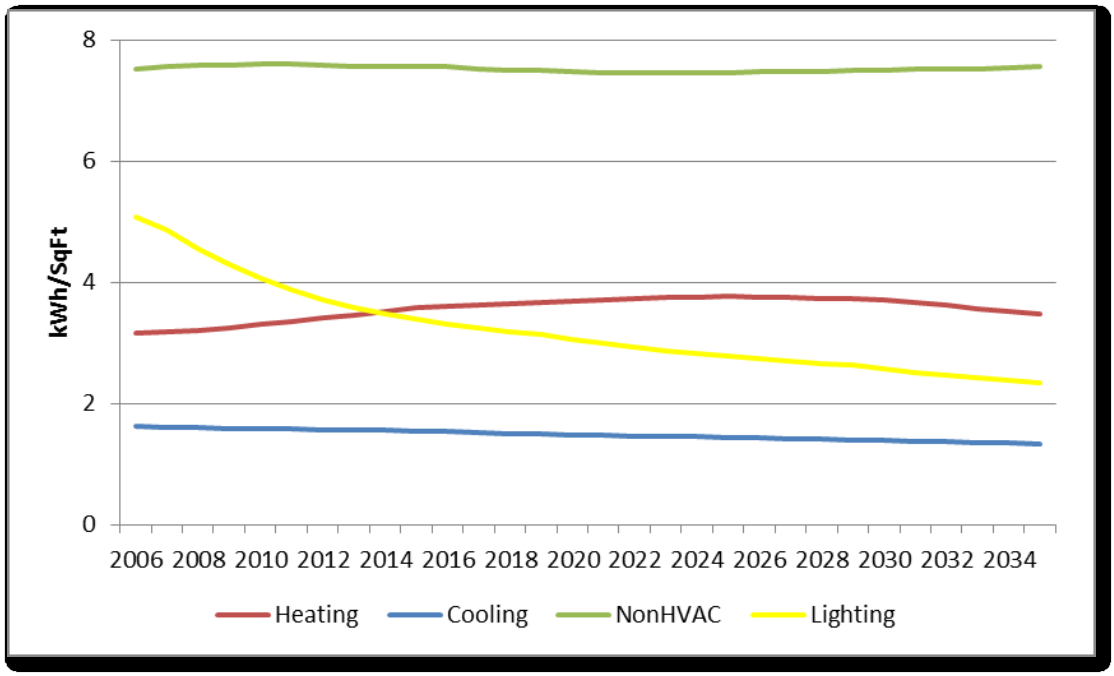
Figure 2-4: Residential End-Use Energy Indices [kWh per Customer]



The heating intensity increases 2.9% annually through the first 10 years of forecast period, driven by the assumption that 95% of all new customers will use electric heat. The 95% electric heat assumption is based on the Energy Solution Centre's work showing that 97% of new homes since 2013 use electric heat as their primary fuel source. After 2032, heating intensity begins to flatten out as the customer forecast declines driven by negative household growth projections. Non-weather sensitive use, "Other", which includes all appliances, plug loads, and water heating declines 0.4% through the first 10 years of the forecast, mainly driven by efficiency improvement in water heating and refrigeration, although this is partially offset by increases in plug loads. Lighting declines fairly steadily as the impact of the new lighting standards (that effectively eliminate traditional incandescent light bulbs) begin to take effect, intensity declines 2.4% through the first 10 years of forecast period.

For the commercial average use model, end-use intensity projections (use per square foot) are aggregated into four generalized end-uses; heating, cooling, lighting, and non-HVAC. It is important to point out that although a cooling intensity projection is developed there is no cooling variable in the commercial average use model; the variable was statistically insignificant. End-use consumption and commercial square footage data from the 2011 CPR was used to calibrate into base year end-use intensities. Projected end-use consumption figures from the 2016 CPR were then used as the basis for deriving intensity projections. Figure 2-5 shows commercial end-use energy intensity forecasts for the aggregated end-use categories.

Figure 2-5: Commercial End-Use Energy Intensity [kWh/SqFt]



Similar to the Residential intensity, Commercial heating intensity (use per square foot) is also increasing. The strong decline in historic and future lighting intensity is largely the result of improving lighting efficiency.

3 Forecast Methodology

3.1 Class Sales Forecast

Changes in economic conditions, prices, weather conditions, as well as appliance saturation and efficiency trends drive energy deliveries and demand through a set of monthly customer class sales forecast models. Monthly regression models are estimated for each of the following primary revenue classes:

- Residential
- Commercial
- Industrial
- Street Lights (ST)
- Space Lights (SP)

While Itron developed an Industrial model, YEC decided to remove the Industrial model (Appendix D) to manually manage the addition and subtraction of major industrial customers.

3.1.1 Residential Model

Residential average use and customers are modeled separately. The residential sales forecast is then generated as the product of the average use and customer forecasts.

The residential average use model is specified using an SAE model structure. The technique is fully described in Appendix B and has been adopted by 60 companies across North America.

While a traditional approach to forecasting sales is developing an econometric model that relates monthly sales to weather, seasonal variables, and economic conditions, the approach cannot explicitly capture changes in the underlying energy efficiency of end-uses. In contrast, end-use models capture energy efficiency changes, but are cumbersome and require costly databases that track technology changes over time. The SAE approach blends econometric models with end-use information based on studies conducted by the U.S. Energy Information Administration. The SAE model exploits the strengths of econometric and end-use models by using national-level end-use data and local economic drivers calibrated to utility specific sales to capture growth based on changes in end-use technology.

The SAE approach begins by defining average use as a function of the four primary end-uses -- heating (XHeat), other use (XOther), and lighting (XLight)

$$ResAvgUse_m = B_0 + (B_1 \times XHeat_m) + (B_2 \times XOther_m) + +(B_3 \times XLight_m) + e_m$$

The end-use variables incorporate both a variable that captures short-term utilization (Use) and a variable that captures changes in end-use efficiency and saturation trends (Index). The heating variable is calculated as:

$$XHeat = HeatUse \times HeatIndex$$

Where

$$HeatUse = f(HDD, Household\ Income, Household\ Size, Price)$$

$$HeatIndex = g(Heating\ Saturation, Efficiency, Shell\ Integrity, Square\ Footage)$$

XOther captures non-weather sensitive end-uses, not including lighting:

$$XOther = OtherUse \times OtherIndex$$

Where

$$OtherUse = f(Seasonal\ Use\ Pattern, Household\ Income, Household\ Size, Price, Days)$$

$$OtherIndex = g(Other\ Appliance\ Saturation\ and\ Efficiency\ Trends)$$

XLight captures lighting end-use,

$$XLight = OtherUse \times LightIndex$$

Where

$$OtherUse = f(Seasonal\ Use\ Pattern, Household\ Income, Household\ Size, Price)$$

$$LightIndex = g(Lighting\ Saturation\ and\ Efficiency)$$

The specific calculations of the end-use variables are presented in Appendix B. Figure 3-1 to Figure 3-3 show the constructed monthly end-use variables.

Figure 3-1: Residential XHeat: Base Case (kWh per month)

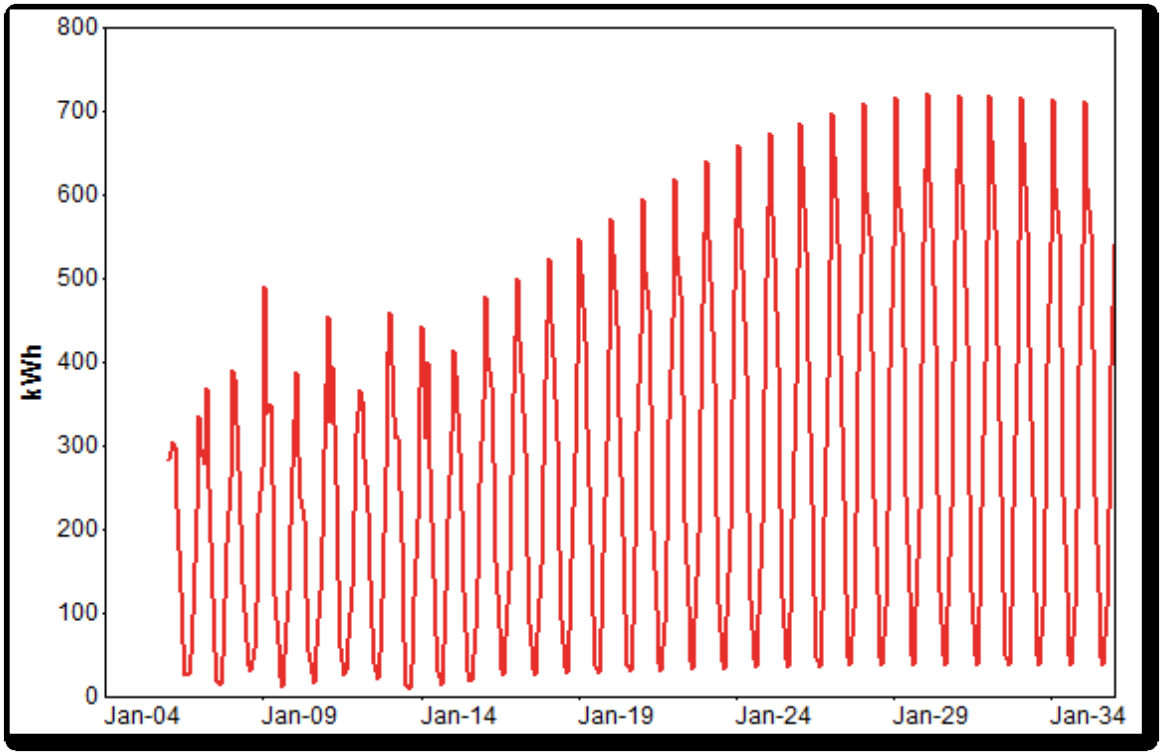


Figure 3-2: Residential XOther: Base Case (kWh per month)

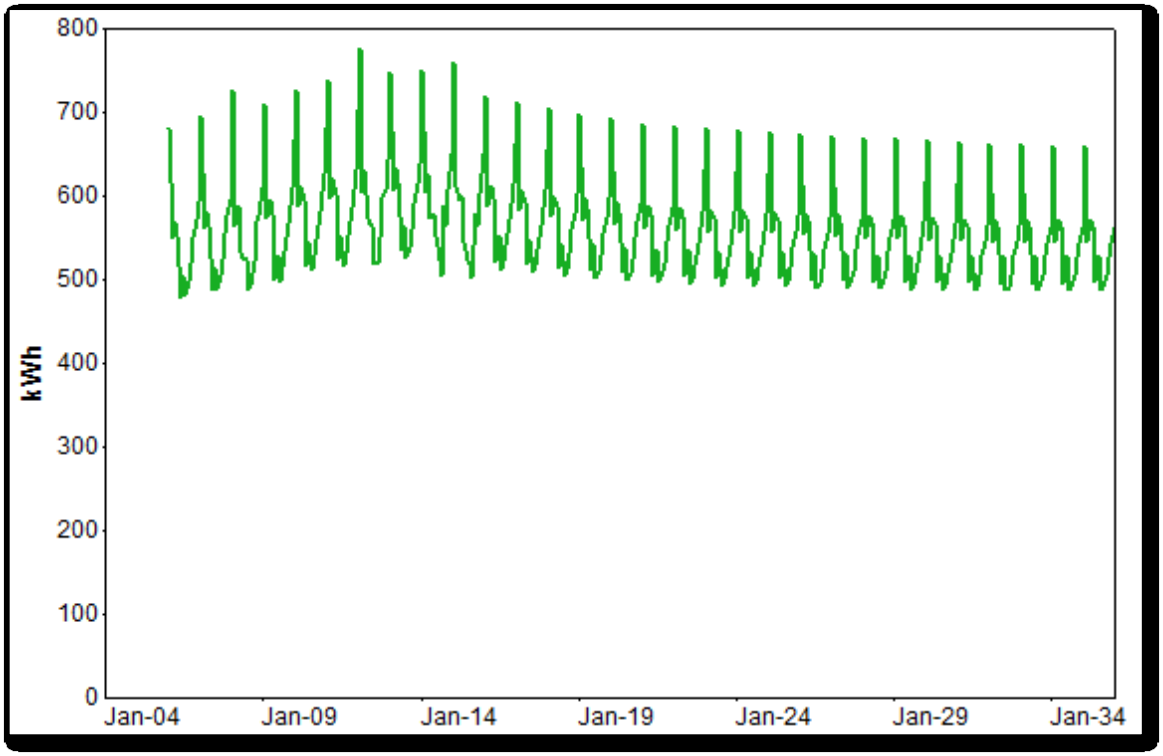

Figure 3-3: Residential XLight: Base Case (kWh per month)

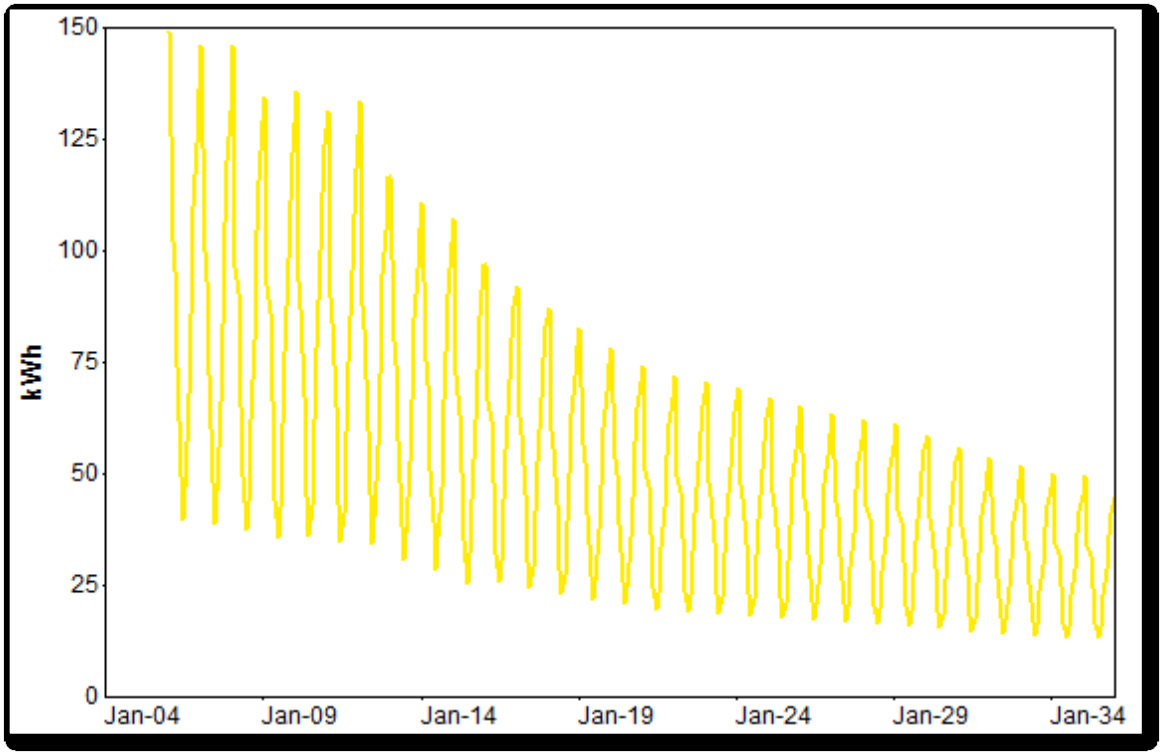
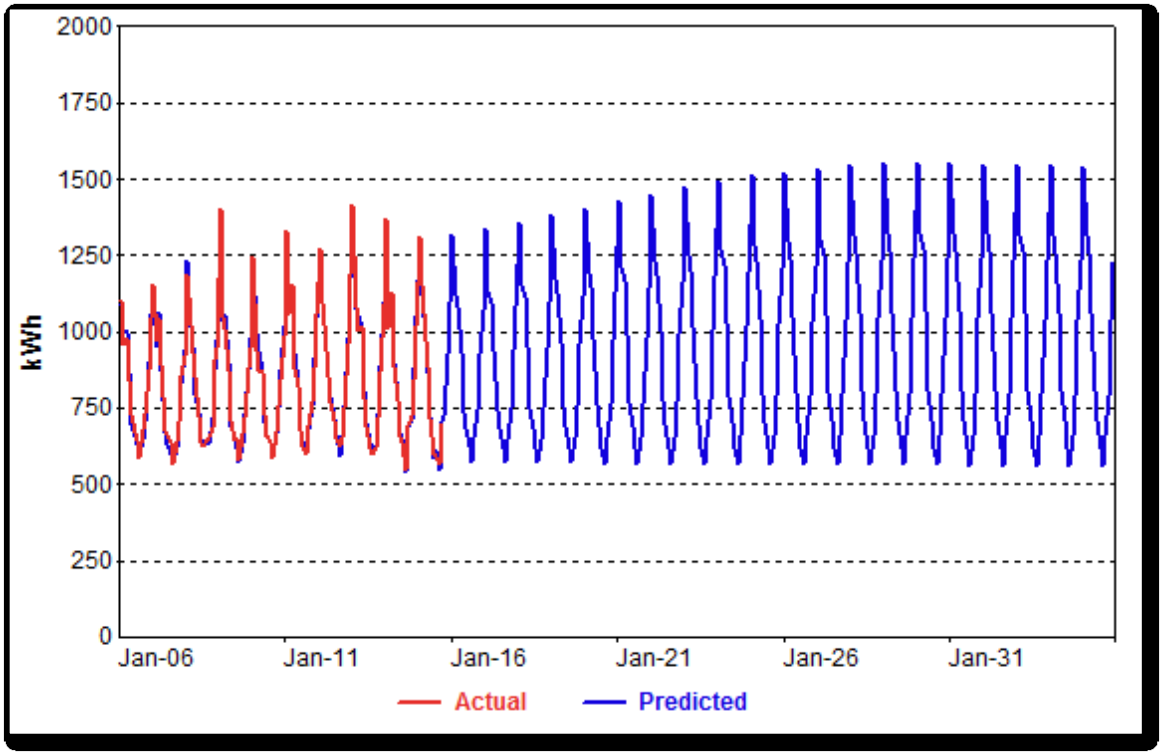


The average use model is estimated over the period January 2006 through September 2015. The model explains historical average use well with an Adjusted R^2 of 0.98 and in-sample Mean Absolute Percent Error (MAPE) of 2.28%. The model accuracy was tested by estimating the model through September 2014 and calculating out of sample model statistics for the 12 withheld observations. The out of sample MAPE of 2.45% confirms that accuracy and robustness of the model. Figure 3-4 shows actual and predicted average use.

Figure 3-4: Actual and Predicted Residential Average Use: Base Case (kWh)



Model coefficients and statistics are provided in Appendix A: Model Statistics.

Use per customer is increasing by 1.0% annually through 2025. This is due to the increase in the electric heat saturation, the result of the assumption that 95% of new customers will use electric heat. Average use begins to flatten in the later years as customer growth declines and eventually becomes negative.

Residential Customer Forecast

The residential customer forecast is based on a monthly regression model that relates the number of customers to household projections. There is a strong correlation, 0.99, between the number of customers and households - customer growth tracks household projections with customers averaging 1.1% annual growth through 2025.

With 1.0% increase in average use and 1.1% customer growth, total residential sales average 2.1% growth between 2016 and 2025. Table 3-1 summarizes the residential forecast.

Table 3-1: Residential Forecast: Base Case

Year	Sales (MWh)		Customers		Avg Use (kWh)	
2015	155,443		15,179		10,241

2034	202,212	-0.7%	17,226	-0.5%	11,739	-0.1%
2035	200,789	-0.7%	17,114	-0.7%	11,733	-0.1%
2016-2025		2.1%		1.1%		1.0%
2016-2035		1.1%		0.6%		0.5%

3.1.2 Commercial Model

Like the residential sector commercial average use and customers are modeled separately. The commercial sales forecast is then generated as the product of the average use and customer forecasts. The commercial SAE average use model is fully described in Appendix C and expresses monthly average use as a function of XHeat, XOther, and XLight. It is important to point out that an XCool variable was constructed and incorporated into the model at first but the variable was statistically insignificant and therefore removed. The end-use variables are constructed by interacting annual end-use intensity projections (EI) that capture end-use efficiency improvements, with non-mining GDP and employment ($ComVar_m$), real price ($Price_m$), and monthly HDD: Non-mining GDP still includes the associated economic impact of mining activities in the non-mining sectors.

$$XHeat_m = EI_{heat} \times Price_m^{-0.10} \times ComVar_m \times HDD_m$$
$$XOther_m = EI_{other} \times Price_m^{-0.10} \times ComVar_m \times Days_m$$
$$XLight_m = EI_{light} \times Price_m^{-0.10} \times ComVar_m \times Days_m$$

The coefficients on price are imposed short-term price elasticities. A monthly forecast sales model is then estimated as:

$$ComSales_m = B_0 + B_1 XHeat_m + B_2 XOther_m + B_3 XLight_m + e_m$$

Commercial Economic Driver

Output and employment are combined through a weighted economic variable where ComVar is defined as:

$$ComVar_m = (Employ_m^{0.25}) \times (Non - MiningOutput_m^{0.75})$$

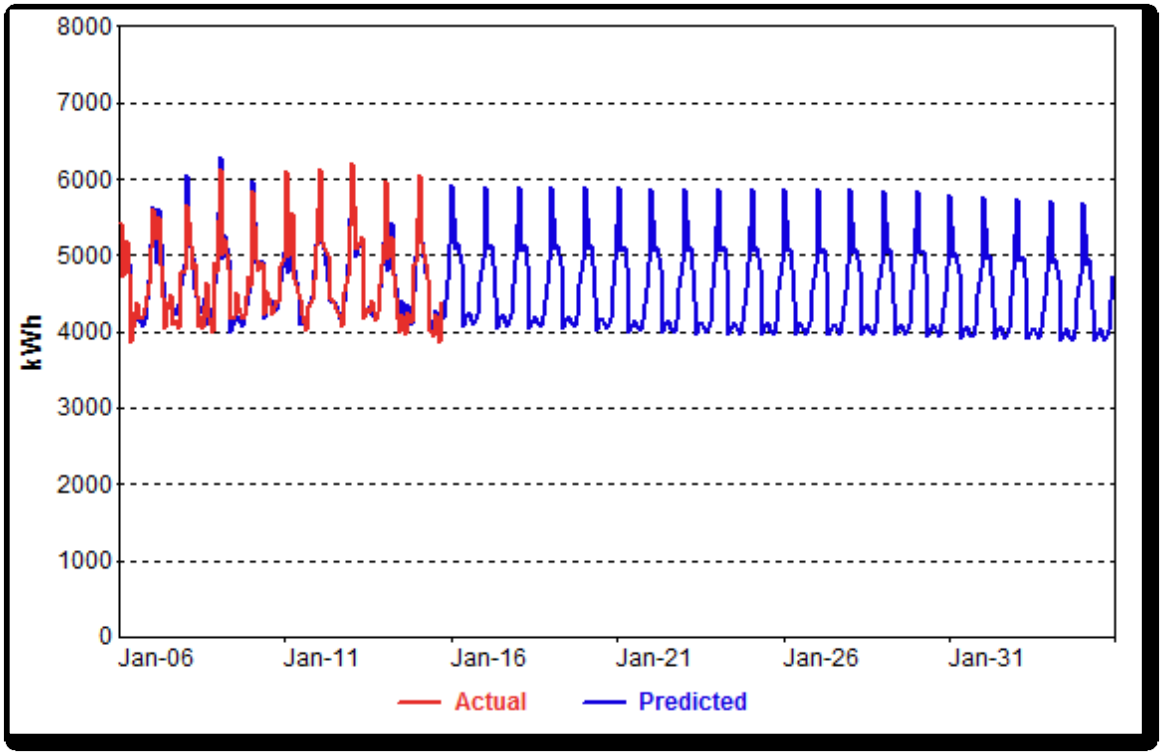
The ComVar uses a weight of 0.25 on employment and 0.75 on non-mining output. The weights were determined by evaluating the in-sample and out-of-sample model statistics for different sets of employment and output weights.

The resulting commercial average use model performs well with an Adjusted R^2 of 0.92 and an in-sample MAPE of 2.5%. The model accuracy was tested by estimating the model through September 2014 and calculating out of sample model statistics for the 12 withheld observations. The out of sample MAPE of 2.01% confirms that accuracy and robustness of the model Figure 3-5 shows actual and predicted monthly commercial average use.

Commercial Customer Forecast

The commercial customer forecast is based on a monthly regression model that relates the number of commercial customers to the residential customer forecast. There is a strong correlation, 0.96, between commercial and residential customers. With an implied elasticity of 0.92 on the residential customer variable commercial customer growth will be slightly less than residential. Commercial customer growth averages 1.0% through 2025.

Figure 3-5: Actual and Predicted Commercial Average Use: Base Case (kWh)



Model coefficients and statistics are provided in Appendix A: Model Statistics.

With 0.2% decrease in average use and 1.0% customer growth, total commercial sales growth average 0.8% between 2016 and 2025. The estimated model coefficients and model statistics are included in Appendix A: Model Statistics. Table 3-2 shows detailed commercial forecast.

Table 3-2: Commercial Forecast: Base Case

Year	Sales (MWh)		Customers		Avg Use (kWh)	
2015	173,005		3,105		55,719

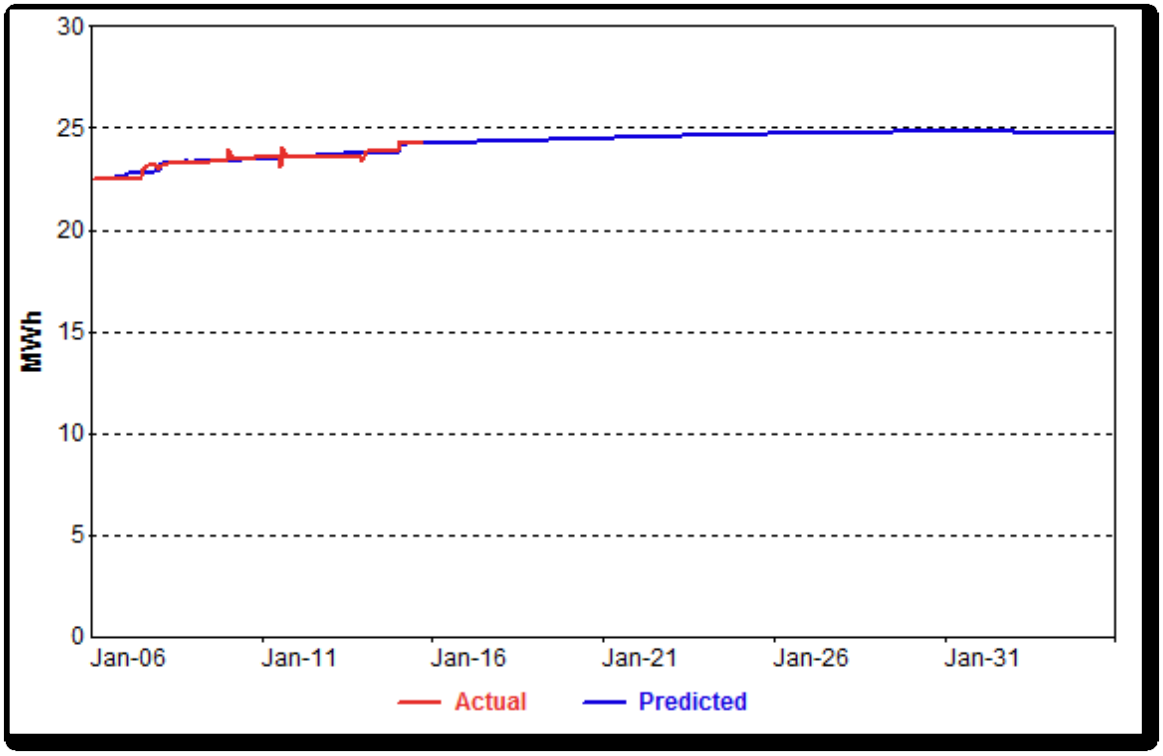
2016-2025		0.8%		1.0%		-0.2%
2016-2035		0.3%		0.5%		-0.3%

3.1.3 ST & SP Sales

The Street Light (ST) sales forecast is based on a generalized monthly regression model where ST sales are specified as a function of residential customers and year binaries. ST sales increase 0.2% annually through 2025, although the magnitude of sales in this class is insignificant in terms of its impact on total sales or system load. Figure 3-6 shows actual and predicted monthly ST sales.

Space Lights (SP) sales are fitted with a simple seasonal exponential smoothing model which holds the forecast constant.

Figure 3-6: Actual and Predicted ST Sales: Base Case (MWh)

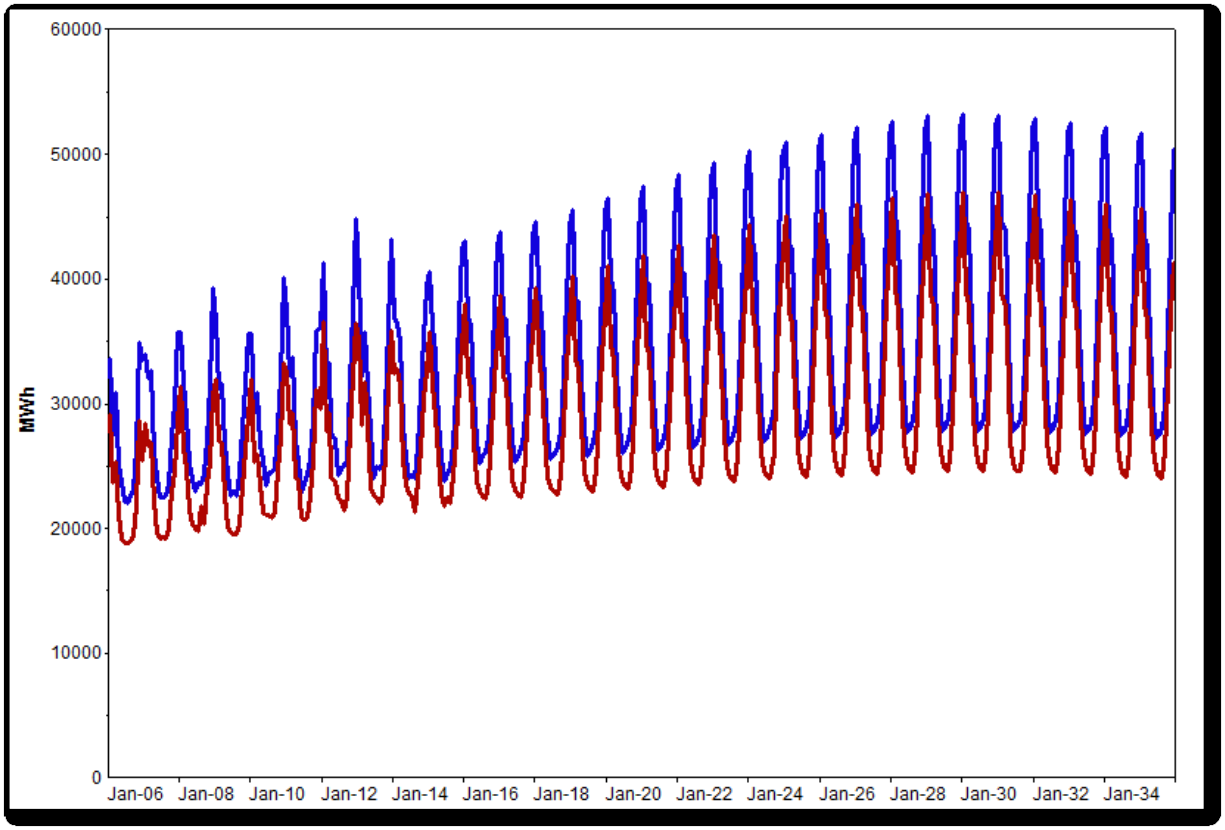


3.2 Energy and Peak Forecast

3.2.1 Energy Forecast

The YEC system energy forecast is derived directly from the sales forecast by applying a monthly energy adjustment factor to the monthly *calendarized* total sales forecast (excluding industrial). The energy adjustment factor includes line losses and any differences in timing between monthly sales estimates and delivered energy (*unaccounted for energy*). Monthly adjustment factors are calculated as the average monthly ratio of energy to sales. Figure 3-7 shows the resulting monthly **sales** and **energy** forecast.

Figure 3-7: Energy and Sales Forecast: Base Case (MWh)



3.2.2 Peak Forecast

The long-term system peak forecast is derived through a monthly peak linear regression model that relates monthly peak demand (excluding industrial) to heating, cooling, and base load requirements:

$$Peak_m = B_0 + B_1 HeatVar_m + B_2 CoolVar_m + B_3 BaseVar_m + e_m$$

The model variables ($HeatVar_m$, $CoolVar_m$, and $BaseVar_m$) incorporate changes in heating, cooling, and base-use energy requirements derived from the class sales forecast models as well as peak-day weather conditions.

Heating and Cooling Model Variables

Heating requirements are driven by customer growth, economic activity, changes in end-use saturation, and improving end-use efficiency. These factors are captured in the class sales forecast models. The composition of the models allows us to estimate historical and forecasted heating and cooling load requirement.

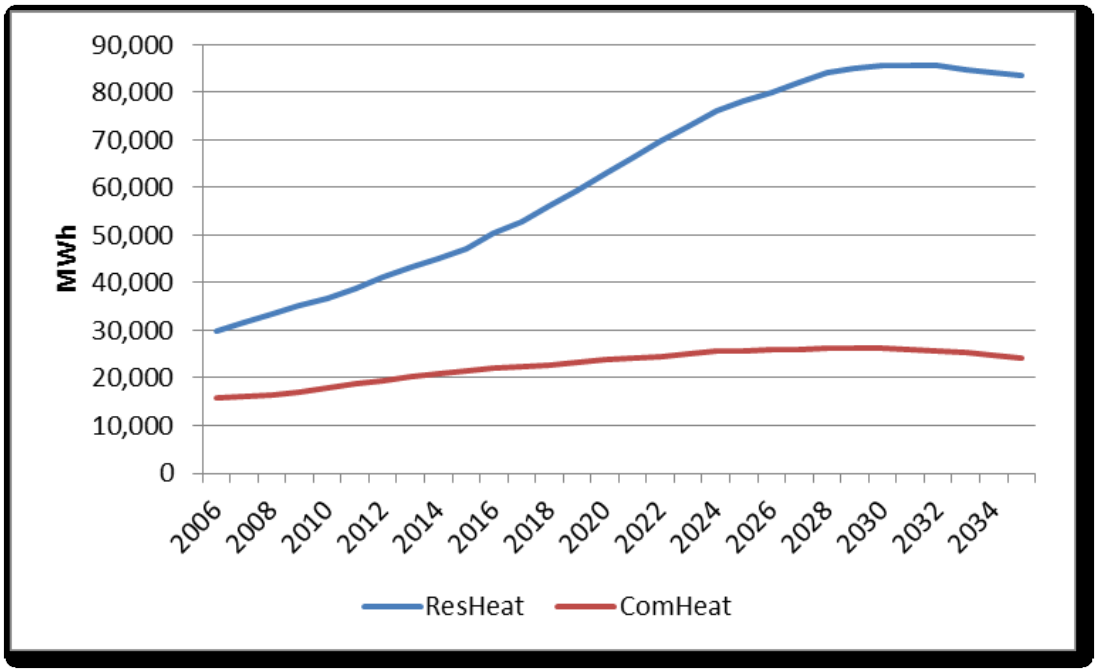
The estimated model coefficients for the heating (XHeat) combined with heating variable for normal weather conditions (*NrmXHeat*) gives us an estimate of the monthly heating load requirements. Heating requirements are calculated as:

$$HeatLoad_m = B_1 \times ResNrmXHeat_m + C_1 \times ComNrmXheat_m$$

B_1 and C_1 are the coefficients on *XHeat* in the residential and commercial models.

Figure 3-8 show resulting historical (weather normalized) and forecasted heating load requirements.

Figure 3-8: Annual Heating Load: Base Case (MWh)

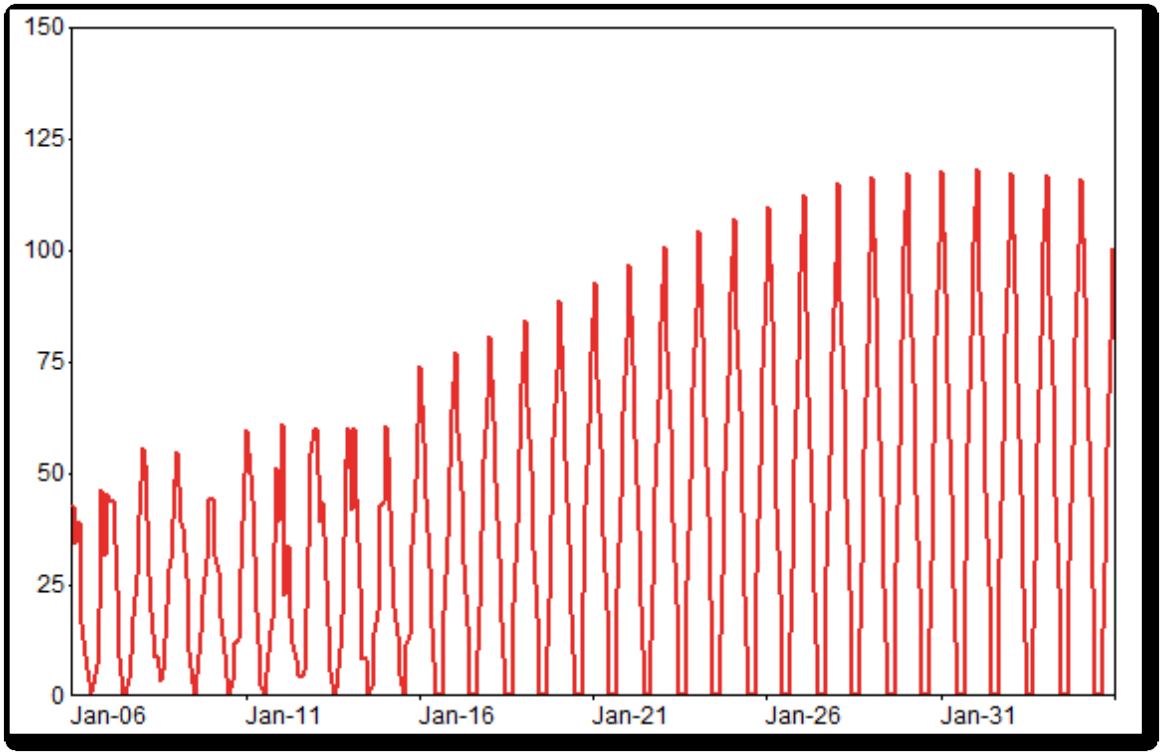


The impact of peak-day weather conditions is captured by interacting peak-day HDD with monthly heating load requirements indexed to a base year (2007). The peak model heating variable is calculated as:

$$HeatVar_m = HeatLoadIdx_m \times PkHDD_m$$

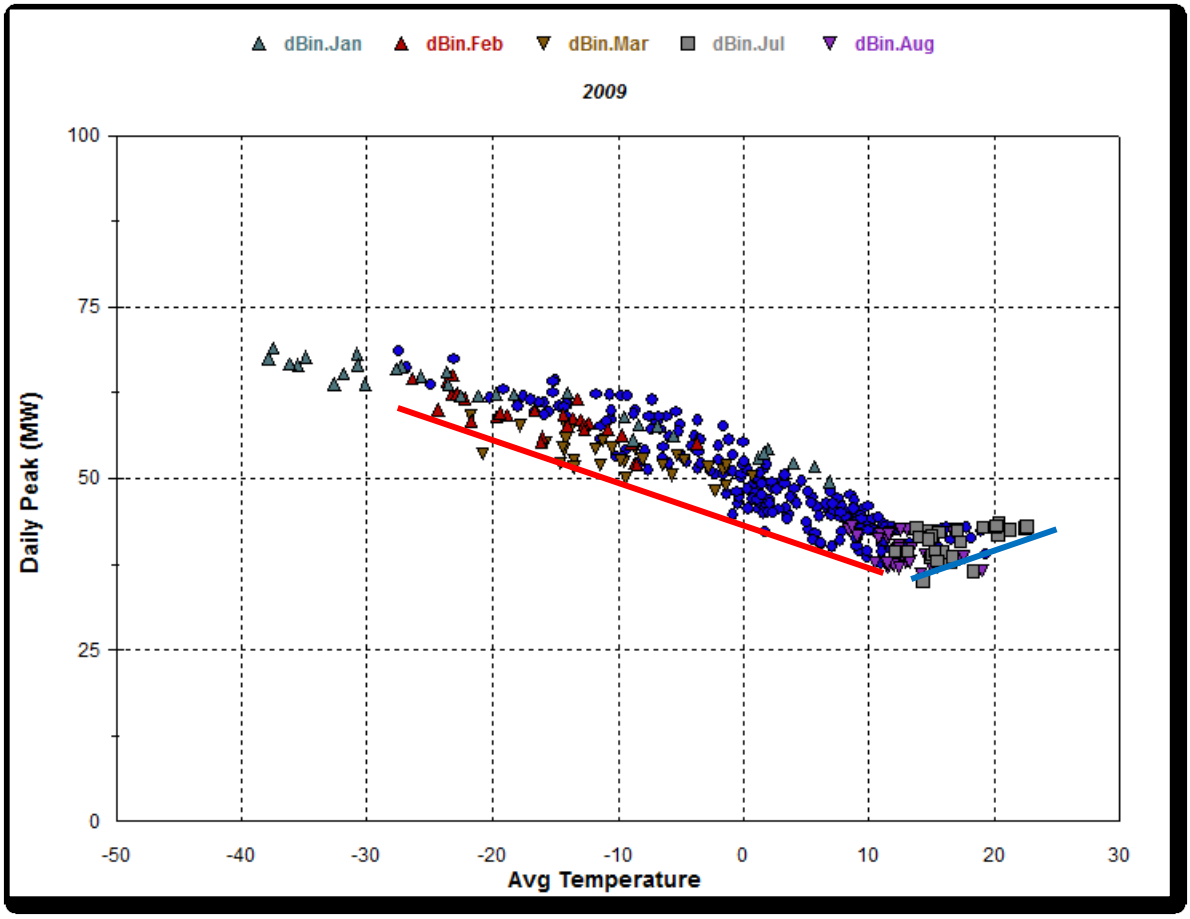
Figure 3-9 shows the resulting peak model heating variable.

Figure 3-9: Peak Model Heating Variable (Index): Base Case



The construction of the peak cooling variable takes on a different form as there is no cooling load associated with the class levels sales. Although there is no cooling variable in any of the class models, as they were statistically insignificant or the coefficients had the incorrect sign, it is likely that commercial cooling load does impact summer peaks. Figure 3-10 shows the relationship between daily peaks and average temperature in 2009. There is clearly a strong heating load that can be seen in the left-hand side of the scatter plot at temperatures below 10 degrees, but what is also evident is the cooling load on the right-hand side at temperatures above 13 degrees.

Figure 3-10: Daily Peaks Vs Temperature Relationship

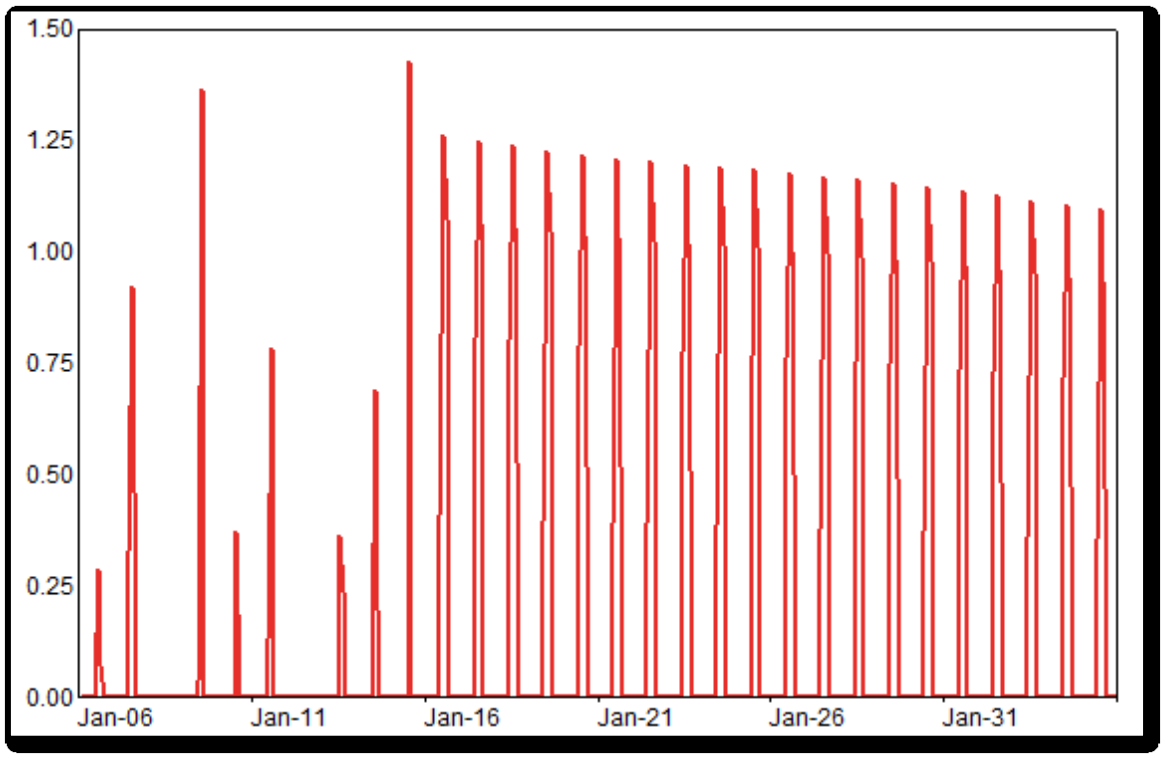


The peak cooling variable is constructed by interacting peak-day CDD with the commercial cooling intensity projections. When used in the peak model the cooling variable is marginally significant and does add additional load to the summer months. The peak model cooling variable is calculated as:

$$CoolVar_m = CommercialCoolingIntensity_y \times PkHDD_m$$

Figure 3-11 shows the resulting peak model cooling variable.

Figure 3-11: Peak Model Cooling Variable (Index): Base Case



Base Load Variable

The peak model base load variable ($BaseVar_m$) derived from the sales forecast models is an estimate of the non-weather sensitive load at the time of the monthly system peak demand. The base load variable is defined as:

$$BaseVar_m = ResOtherCP_m \times ComOtherCP_m + StLightingCP_m$$

Base load requirements are derived for each revenue class by subtracting out heating and cooling load requirements from total load requirements. Using the SAE modeling framework, class annual base load requirements are then allocated to end-uses at the time of monthly peak demand. For example, the residential water heating coincident peak load estimate is derived as:

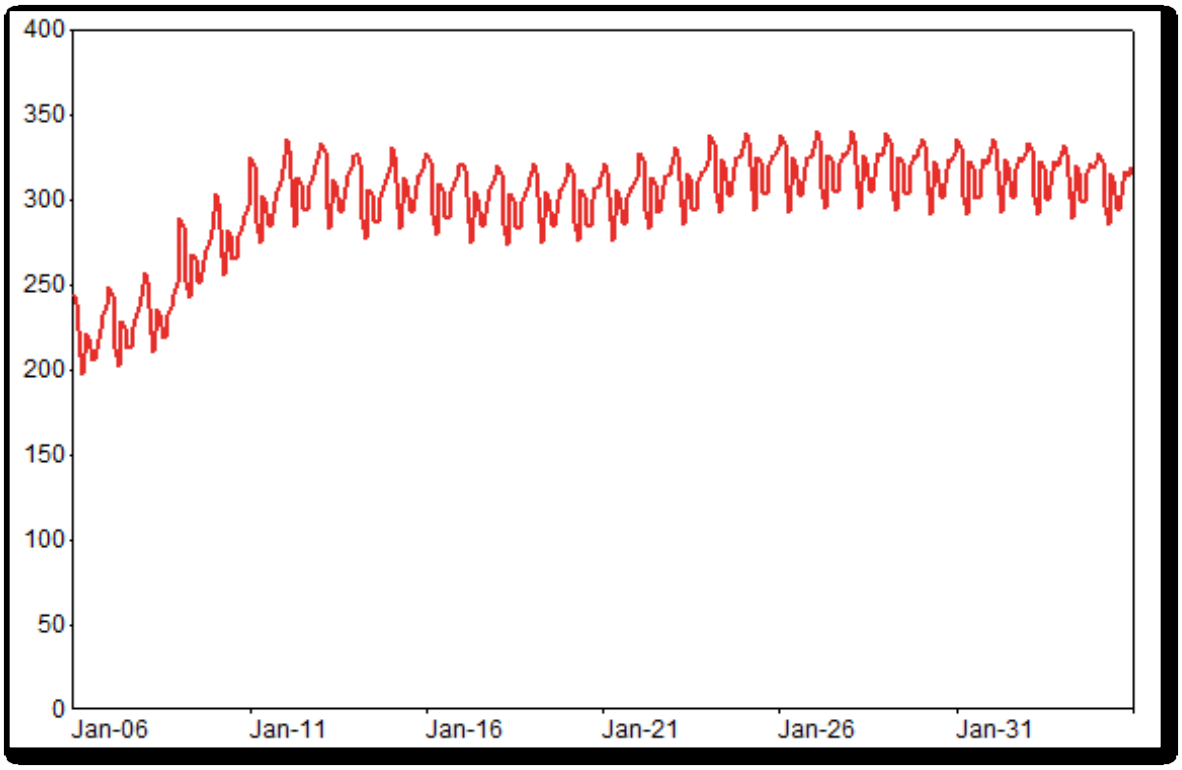
$$ResWaterCP_m = ResBaseLoad_m \times \left({ResWaterEI_a}/{ResBaseEI_a} \right) \times ResWaterFrac_m$$

Where

ResWaterEI = Annual water heating intensity (water use per household)
ResBaseEI = Annual base-use intensity (non-weather sensitive use per household)
ResWaterFrac = Monthly fraction of usage on at peak (estimates are based on Itron's hourly end-use load profile database)

End-use load estimates are aggregated by end-use and then revenue class resulting in the base load variable. Figure 3-12 shows the peak model base load variable.

Figure 3-12: Base Load Variable: Base Case



Model Results

The peak model is estimated over the period January 2006 to September 2015. The model explains monthly peak variation well with an adjusted R^2 of 0.97 and an in-sample MAPE of 2.36%. Figure 3-13 shows actual and predicted results. Model statistics and parameters are included in Appendix A: Model Statistics.

Figure 3-13: Peak Model: Base Case (MW)

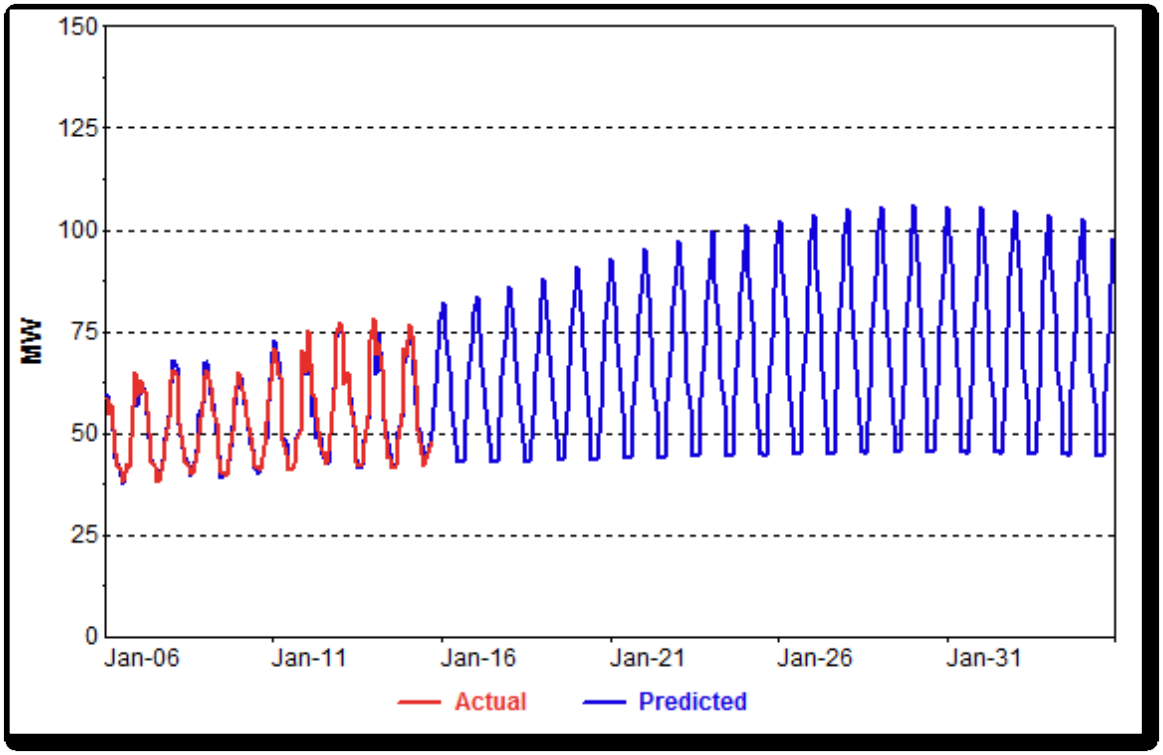


Table 3-3 shows the peak demand forecast (excluding industrial).

Table 3-3: Peak Demand Forecast: Base Case (MW)

Year	Peak (MW)	
2015	76.9	
2016	82.2	6.9%
2017	83.8	1.9%
2018	85.9	2.5%
2019	88.2	2.7%
2020	90.8	2.9%
2021	92.8	2.2%
2022	95.2	2.6%
2023	97.4	2.3%
2024	99.8	2.4%
2025	101.2	1.4%
2026	102.5	1.3%
2027	103.8	1.3%
2028	105.2	1.4%
2029	105.8	0.5%
2030	106.1	0.3%
2031	105.8	-0.3%
2032	105.6	-0.2%
2033	104.6	-1.0%
2034	103.7	-0.8%
2035	102.8	-0.9%
2016-2025		2.3%
2016-2035		1.2%

3.3 Solar Forecast

The forecast includes the impact of expected grid-connected solar generation. Currently there is very little grid-connected solar generation in the YEC service territory and it is not expected to grow to a point where it would significantly impact energy or peaks. Unlike many other parts of Canada and North America where solar is increasing in popularity due to decreases in system costs and utility incentives, which have made the systems economically viable, in Yukon the adaptation is not driven by economics or return on investment.

The solar generation forecast is derived by first forecasting the number of solar customers. Yukon provided 18 months of solar customer data, with a total of 16 grid-connected solar systems as of August 2015. A simple linear trend was imposed to predict the number of solar customers for the next 16 months, reaching 31 solar customers by December 2016. Starting in January 2017 the annual growth rate of solar capacity from the EIA's 2015 Annual Energy Outlook forecast is used to grow the solar customer forecast. Table 3-4 shows the resulting solar customer forecast.

An installed solar capacity forecast is then derived as the product of the solar customer forecast and the assumed average system size of 3.1 kW based on YEC's short-term expectations on size.

Using an 8760 hourly solar load shape for Whitehorse, provided by the National Renewable Energy Laboratory's PV Watt Calculator, monthly specific load factors are calculated. The month specific load factors are applied to the monthly capacity forecast to calculate the MWh solar generation forecast, shown in Table 3-4.

Table 3-4: Solar Forecast

Year	Solar Customers	Solar Capacity (kW)	Generation (MWh)
2015	15	48	45.3
2016	26	82	81.2
2017	32	98	99.2
2018	32	100	101.4
2019	33	103	104.3
2020	35	108	109.2
2021	37	114	115.4
2022	39	122	122.9
2023	42	130	131.4
2024	45	140	141.1
2025	48	150	151.4
2026	52	162	162.7
2027	56	173	174.5
2028	60	185	186.9
2029	64	197	198.7
2030	68	210	211.2
2031	72	222	224.1
2032	76	235	237.4
2033	80	248	250.0
2034	84	261	263.1
2035	88	274	276.6

4 Forecast Scenarios

In addition to the baseline economic forecast YEC provided 9 additional economic scenarios based on changing assumption regarding mining output and government transfer payments. These scenarios are used to generation alternative energy and load forecasts. Figure 4-1 defines the economic scenarios.

Figure 4-1: Economic Scenarios

Scenario Number	Definition
1	Very Low Mining Activity
2	Low Mining Activity
3	**Base Case (Medium Mining Activity)**
4	High Mining Activity + Large Mine
5	Low Mining Activity Scenario with sensitivity on government spending
6	"Base case" scenario with sensitivity on government spending
7a	"Base case" scenario with positive shock to Agriculture, Forestry and Logging industries
7b	"Base case" scenario with increased growth in Accommodations, Transportation and Warehousing, to account for tourism growth
9	"Base case" with sensitivity on large mine (later start of production)
10	Sensitivity on Boom and Bust Cycles in the Mining Industry

Figure 4-2 through Figure 4-6 compare the differences in the economic scenarios for the primary economic drivers of the sales models.

Figure 4-2: Real GRP

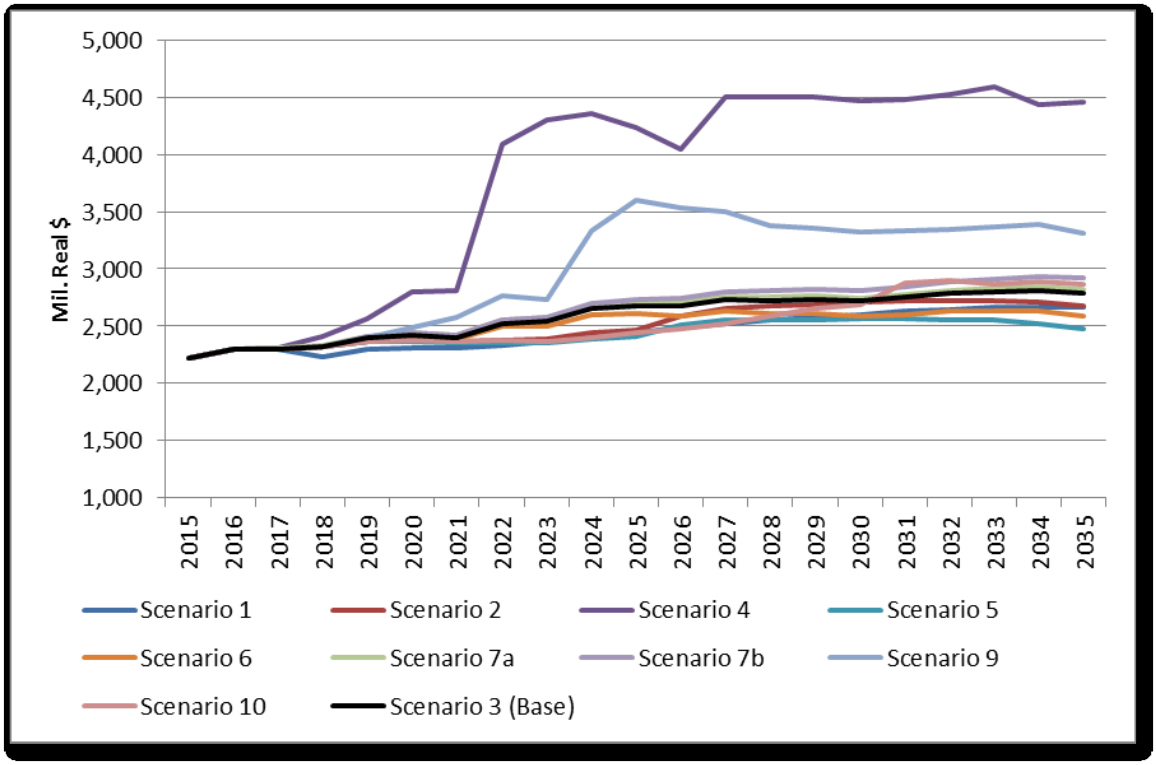

Figure 4-3: Real Mining GRP

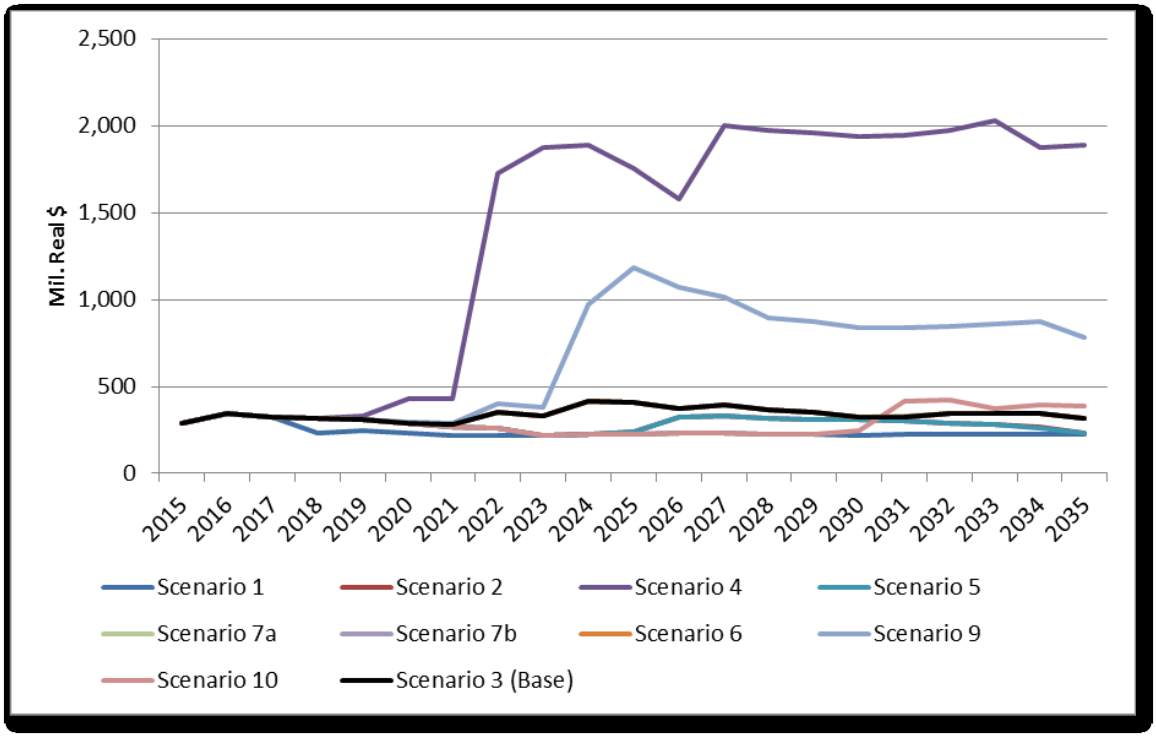

Figure 4-4: Real Income Per Capita

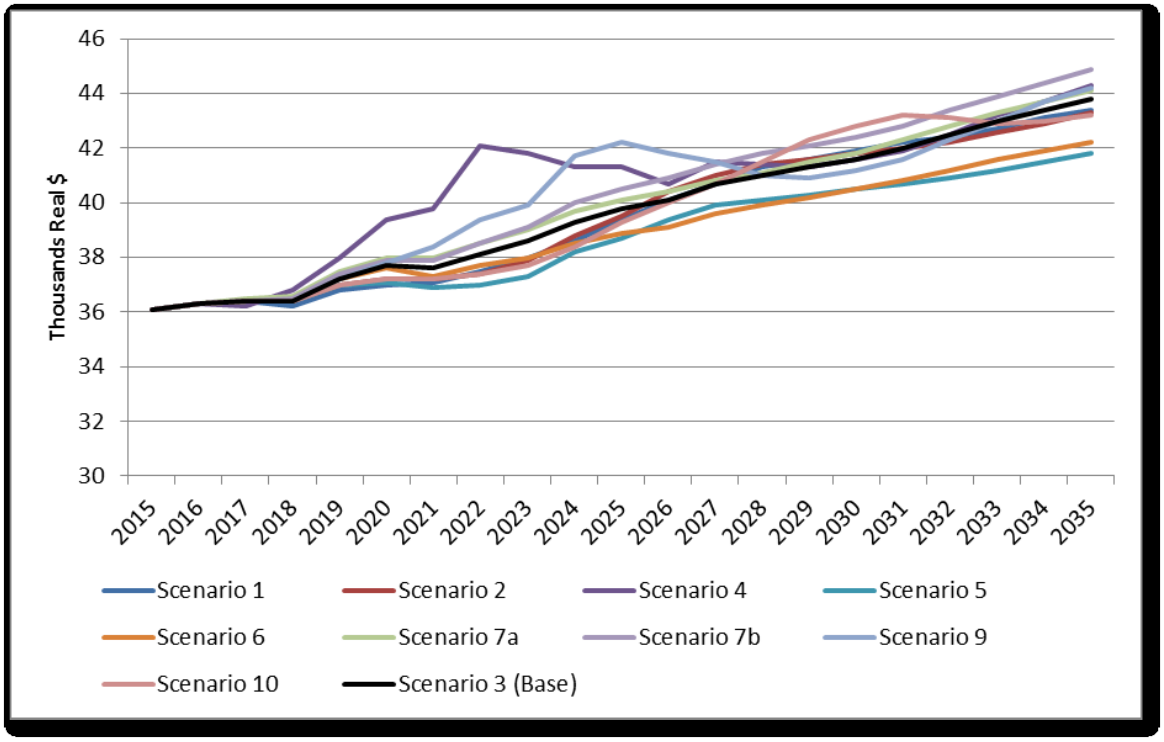

Figure 4-5: Households

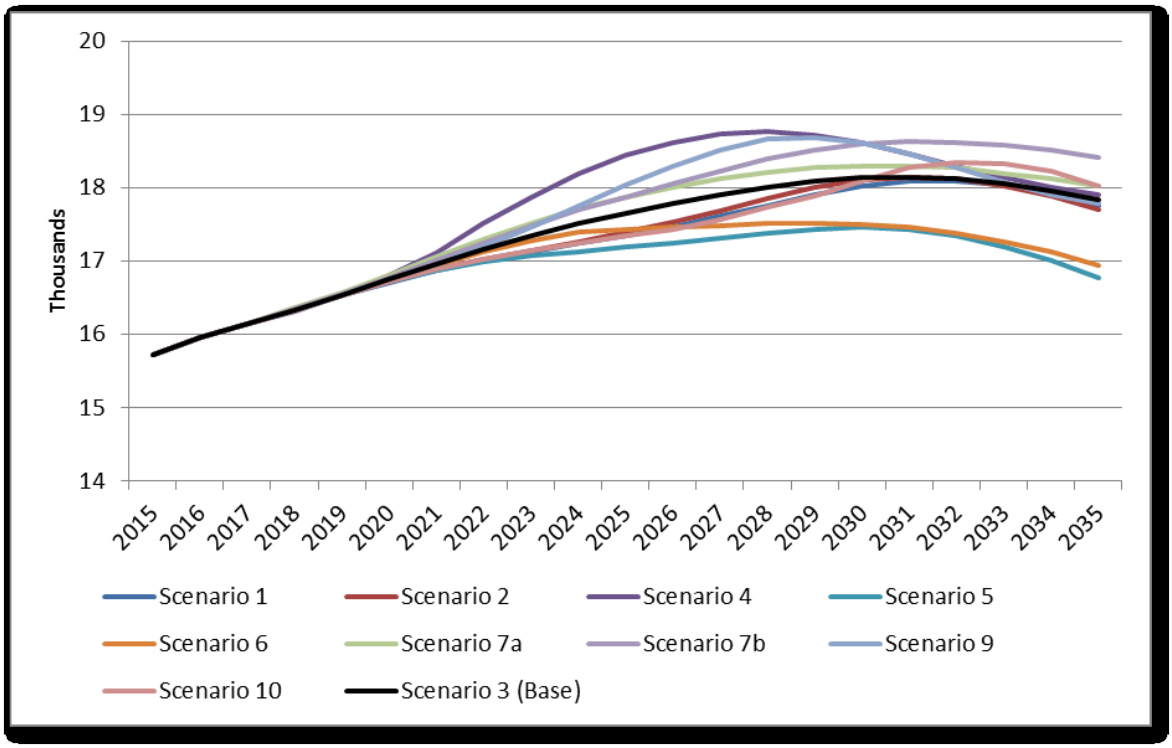

Figure 4-6: Employment

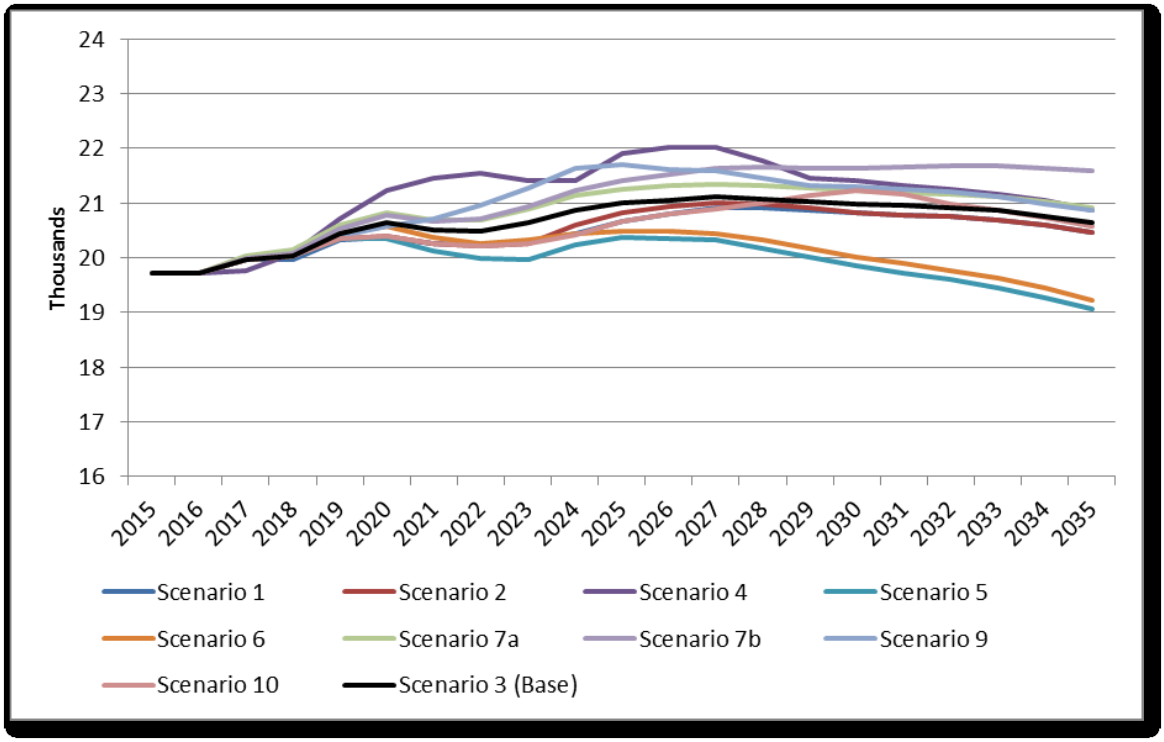

Using the same model specifications and estimation periods these alternative economic drivers are used to estimate class average use, customer, and total sales models, which are used to derive the total energy and peak forecast. Table 4-1 and Table 4-2 summarize the energy and peak forecasts (excluding industrial) under the different economic scenarios.

6 Appendix B: Residential SAE Modeling Framework

The traditional approach to forecasting monthly sales for a customer class is to develop an econometric model that relates monthly sales to weather, seasonal variables, and economic conditions. From a forecasting perspective, econometric models are well suited to identify historical trends and to project these trends into the future. In contrast, the strength of the end-use modeling approach is the ability to identify the end-use factors that are drive energy use. By incorporating end-use structure into an econometric model, the statistically adjusted end-use (SAE) modeling framework exploits the strengths of both approaches.

There are several advantages to this approach.

- The equipment efficiency and saturation trends, dwelling square footage, and thermal shell integrity changes embodied in the long-run end-use forecasts are introduced explicitly into the short-term monthly sales forecast. This provides a strong bridge between the two forecasts.
- By explicitly introducing trends in equipment saturations, equipment efficiency, dwelling square footage, and thermal integrity levels, it is easier to explain changes in usage levels and changes in weather-sensitivity over time.
- Data for short-term models are often not sufficiently robust to support estimation of a full set of price, economic, and demographic effects. By bundling these factors with equipment-oriented drivers, a rich set of elasticities can be incorporated into the final model.

This section describes the SAE approach, the associated supporting SAE spreadsheets, and the *MetrixND* project files that are used in the implementation. The source for the the SAE spreadsheets is the 2013 Annual Energy Outlook (AEO) database provided by the Energy Information Administration (EIA).

6.1 Statistically Adjusted End-Use Modeling Framework

The statistically adjusted end-use modeling framework begins by defining energy use ($USE_{y,m}$) in year (y) and month (m) as the sum of energy used by heating equipment ($Heat_{y,m}$), cooling equipment ($Cool_{y,m}$), and other equipment ($Other_{y,m}$). Formally,

$$\mathrm{USE}_{y,m} = \mathrm{Heat}_{y,m} + \mathrm{Cool}_{y,m} + \mathrm{Other}_{y,m} \qquad (1)$$

Although monthly sales are measured for individual customers, the end-use components are not. Substituting estimates for the end-use elements gives the following econometric equation.

$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + \varepsilon_m \quad (2)$$

$XHeat_m$, $XCool_m$, and $XOther_m$ are explanatory variables constructed from end-use information, dwelling data, weather data, and market data. As will be shown below, the equations used to construct these X-variables are simplified end-use models, and the X-variables are the estimated usage levels for each of the major end uses based on these models. The estimated model can then be thought of as a statistically adjusted end-use model, where the estimated slopes are the adjustment factors.

6.1.1 Constructing XHeat

As represented in the SAE spreadsheets, energy use by space heating systems depends on the following types of variables.

- Heating degree days
- Heating equipment saturation levels
- Heating equipment operating efficiencies
- Average number of days in the billing cycle for each month
- Thermal integrity and footage of homes
- Average household size, household income, and energy prices

The heating variable is represented as the product of an annual equipment index and a monthly usage multiplier. That is,

$$XHeat_{y,m} = HeatIndex_{y,m} \times HeatUse_{y,m} \quad (3)$$

Where:

- $XHeat_{y,m}$ is estimated heating energy use in year (y) and month (m)
- $HeatIndex_{y,m}$ is the monthly index of heating equipment
- $HeatUse_{y,m}$ is the monthly usage multiplier

The heating equipment index is defined as a weighted average across equipment types of equipment saturation levels normalized by operating efficiency levels. Given a set of fixed weights, the index will change over time with changes in equipment saturations (*Sat*), operating efficiencies (*Eff*), building structural index (*StructuralIndex*), and energy prices. Formally, the equipment index is defined as:

$$HeatIndex_y = StructuralIndex_y \times \sum_{Type} Weight^{Type} \times \frac{\left(Sat_y^{Type} \Big/ Eff_y^{Type} \right)}{\left(Sat_{05}^{Type} \Big/ Eff_{05}^{Type} \right)} \quad (4)$$

The *StructuralIndex* is constructed by combining the EIA's building shell efficiency index trends with surface area estimates, and then it is indexed to the 2005 value:

$$StructuralIndex_y = \frac{BuildingShellEfficiencyIndex_y \times SurfaceArea_y}{BuildingShellEfficiencyIndex_{05} \times SurfaceArea_{05}} \quad (5)$$

The *StructuralIndex* is defined on the *StructuralVars* tab of the SAE spreadsheets. Surface area is derived to account for roof and wall area of a standard dwelling based on the regional average square footage data obtained from EIA. The relationship between the square footage and surface area is constructed assuming an aspect ratio of 0.75 and an average of 25% two-story and 75% single-story. Given these assumptions, the approximate linear relationship for surface area is:

$$SurfaceArea_y = 892 + 1.44 \times Footage_y \quad (6)$$

In Equation 4, 2005 is used as a base year for normalizing the index. As a result, the ratio on the right is equal to 1.0 in 2005. In other years, it will be greater than 1.0 if equipment saturation levels are above their 2005 level. This will be counteracted by higher efficiency levels, which will drive the index downward. The weights are defined as follows.

$$Weight^{Type} = \frac{Energy_{05}^{Type}}{HH_{05}} \times HeatShare_{05}^{Type} \quad (7)$$

In the SAE spreadsheets, these weights are referred to as *Intensities* and are defined on the *EIAData* tab. With these weights, the *HeatIndex* value in 2005 will be equal to estimated annual heating intensity per household in that year. Variations from this value in other years will be proportional to saturation and efficiency variations around their base values.

For electric heating equipment, the SAE spreadsheets contain two equipment types: electric resistance furnaces/room units and electric space heating heat pumps. Examples of weights for these two equipment types for the U.S. are given in Table 6-1.

Table 6-1: Electric Space Heating Equipment Weights

Equipment Type	Weight (kWh)
Electric Resistance Furnace/Room units	505
Electric Space Heating Heat Pump	190

Data for the equipment saturation and efficiency trends are presented on the *Shares* and *Efficiencies* tabs of the SAE spreadsheets. The efficiency for electric space heating heat pumps are given in terms of Heating Seasonal Performance Factor [BTU/Wh], and the efficiencies for electric furnaces and room units are estimated as 100%, which is equivalent to 3.41 BTU/Wh.

Price Impacts. In the 2007 version of the SAE models, the Heat Index has been extended to account for the long-run impact of electric and natural gas prices. Since the Heat Index represents changes in the stock of space heating equipment, the price impacts are modeled to play themselves out over a ten year horizon. To introduce price effects, the Heat Index as defined by Equation 4 above is multiplied by a 10 year moving average of electric and gas prices. The level of the price impact is guided by the long-term price elasticities. Formally,

$$HeatIndex_y = StructuralIndex_y \times \sum_{Type} Weight^{Type} \times \frac{\left(Sat_y^{Type} \Big/ Eff_y^{Type} \right)}{\left(Sat_{05}^{Type} \Big/ Eff_{05}^{Type} \right)} \times$$

$$\left(TenYearMovingAverageElectric\ \mathrm{Price}_{y,m}\right)^{\phi} \times \left(TenYearMovingAverageGas\ \mathrm{Price}_{y,m}\right)^{\gamma} \quad (8)$$

Since the trends in the Structural index (the equipment saturations and efficiency levels) are provided exogenously by the EIA, the price impacts are introduced in a multiplicative form. As a result, the long-run change in the Heat Index represents a combination of adjustments to the structural integrity of new homes, saturations in equipment and efficiency levels relative to what was contained in the base EIA long-term forecast.

Heating system usage levels are impacted on a monthly basis by several factors, including weather, household size, income levels, prices, and billing days. The estimates for space heating equipment usage levels are computed as follows:

$$HeatUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5}\right) \times \left(\frac{WgtHDD_{y,m}}{HDD_{05}}\right) \times \left(\frac{HHSize_{y}}{HHSize_{05}}\right)^{0.25} \times \left(\frac{Income_{y}}{Income_{05}}\right)^{0.20} \times \left(\frac{Elec\,Price_{y,m}}{Elec\,Price_{05,7}}\right)^{\lambda} \times \left(\frac{Gas\,Price_{y,m}}{Gas\,Price_{05,7}}\right)^{\kappa} \quad (9)$$

Where:

- *BDays* is the number of billing days in year (*y*) and month (*m*), these values are normalized by 30.5 which is the average number of billing days
- *WgtHDD* is the weighted number of heating degree days in year (*y*) and month (*m*). This is constructed as the weighted sum of the current month's HDD and the prior month's HDD. The weights are 75% on the current month and 25% on the prior month.
- *HDD* is the annual heating degree days for 2005
- *HHSize* is average household size in a year (*y*)
- *Income* is average real income per household in year (*y*)
- *ElecPrice* is the average real price of electricity in month (*m*) and year (*y*)
- *GasPrice* is the average real price of natural gas in month (*m*) and year (*y*)

By construction, the $HeatUse_{y,m}$ variable has an annual sum that is close to 1.0 in the base year (2005). The first two terms, which involve billing days and heating degree days, serve to allocate annual values to months of the year. The remaining terms average to 1.0 in the base year. In other years, the values will reflect changes in the economic drivers, as transformed through the end-use elasticity parameters. The price impacts captured by the Usage equation represent short-term price response.

6.1.2 Constructing XCool

The explanatory variable for cooling loads is constructed in a similar manner. The amount of energy used by cooling systems depends on the following types of variables.

- Cooling degree days
- Cooling equipment saturation levels
- Cooling equipment operating efficiencies
- Average number of days in the billing cycle for each month
- Thermal integrity and footage of homes
- Average household size, household income, and energy prices

The cooling variable is represented as the product of an equipment-based index and monthly usage multiplier. That is,

$$XCool_{y,m} = CoolIndex_{y} \times CoolUse_{y,m} \tag{10}$$

Where

- $XCool_{y,m}$ is estimated cooling energy use in year (y) and month (m)
- $CoolIndex_{y}$ is an index of cooling equipment
- $CoolUse_{y,m}$ is the monthly usage multiplier

As with heating, the cooling equipment index is defined as a weighted average across equipment types of equipment saturation levels normalized by operating efficiency levels. Formally, the cooling equipment index is defined as:

$$CoolIndex_{y} = StructuralIndex_{y} \times \sum_{Type} Weight^{Type} \times \frac{\left(Sat_{y}^{Type} \Big/ Eff_{y}^{Type} \right)}{\left(Sat_{05}^{Type} \Big/ Eff_{05}^{Type} \right)} \tag{11}$$

Data values in 2005 are used as a base year for normalizing the index, and the ratio on the right is equal to 1.0 in 2005. In other years, it will be greater than 1.0 if equipment saturation levels are above their 2005 level. This will be counteracted by higher efficiency levels, which will drive the index downward. The weights are defined as follows.

$$Weight^{Type} = \frac{Energy_{05}^{Type}}{HH_{05}} \times CoolShare_{05}^{Type} \tag{12}$$

In the SAE spreadsheets, these weights are referred to as *Intensities* and are defined on the *EIAData* tab. With these weights, the *CoolIndex* value in 2005 will be equal to estimated annual cooling intensity per household in that year. Variations from this value in other years will be proportional to saturation and efficiency variations around their base values.

For cooling equipment, the SAE spreadsheets contain three equipment types: central air conditioning, space cooling heat pump, and room air conditioning. Examples of weights for these three equipment types for the U.S. are given in Table 6-2.

Table 6-2: Space Cooling Equipment Weights

Equipment Type	Weight (kWh)
Central Air Conditioning	1,661
Space Cooling Heat Pump	369
Room Air Conditioning	315

The equipment saturation and efficiency trends data are presented on the *Shares* and *Efficiencies* tabs of the SAE spreadsheets. The efficiency for space cooling heat pumps and central air conditioning (A/C) units are given in terms of Seasonal Energy Efficiency Ratio [BTU/Wh], and room A/C units efficiencies are given in terms of Energy Efficiency Ratio [BTU/Wh].

Price Impacts. In the 2007 SAE models, the Cool Index has been extended to account for changes in electric and natural gas prices. Since the Cool Index represents changes in the stock of space heating equipment, it is anticipated that the impact of prices will be long-term in nature. The Cool Index as defined Equation 11 above is then multiplied by a 10 year moving average of electric and gas prices. The level of the price impact is guided by the long-term price elasticities. Formally,

$$CoolIndex_y = StructuralIndex_y \times \sum_{Type} Weight^{Type} \times \frac{\left(Sat_y^{Type} \Big/ Eff_y^{Type} \right)}{\left(Sat_{05}^{Type} \Big/ Eff_{05}^{Type} \right)} \times \left(TenYearMovingAverageElectric\ \mathrm{Price}_{y,m} \right)^{\phi} \times \left(TenYearMovingAverageGas\ \mathrm{Price}_{y,m} \right)^{\gamma} \quad (13)$$

Since the trends in the Structural index, equipment saturations and efficiency levels are provided exogenously by the EIA, price impacts are introduced in a multiplicative form. The long-run change in the Cool Index represents a combination of adjustments to the structural integrity of new homes, saturations in equipment and efficiency levels. Without a detailed end-use model, it is not possible to isolate the price impact on any one of these concepts.

Cooling system usage levels are impacted on a monthly basis by several factors, including weather, household size, income levels, and prices. The estimates of cooling equipment usage levels are computed as follows:

$$CoolUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5}\right) \times \left(\frac{WgtCDD_{y,m}}{CDD_{05}}\right) \times \left(\frac{HHSize_{y}}{HHSize_{05}}\right)^{0.25} \times \left(\frac{Income_{y}}{Income_{05}}\right)^{0.20} \times \left(\frac{Elec\ Price_{y,m}}{Elec\ Price_{05}}\right)^{\lambda} \times \left(\frac{Gas\ Price_{y,m}}{Gas\ Price_{05}}\right)^{\kappa} \quad (14)$$

Where:

- *WgtCDD* is the weighted number of cooling degree days in year (*y*) and month (*m*). This is constructed as the weighted sum of the current month's CDD and the prior month's CDD. The weights are 75% on the current month and 25% on the prior month.
- *CDD* is the annual cooling degree days for 2005.

By construction, the *CoolUse* variable has an annual sum that is close to 1.0 in the base year (2005). The first two terms, which involve billing days and cooling degree days, serve to allocate annual values to months of the year. The remaining terms average to 1.0 in the base year. In other years, the values will change to reflect changes in the economic driver changes.

6.1.3 Constructing XOther

Monthly estimates of non-weather sensitive sales can be derived in a similar fashion to space heating and cooling. Based on end-use concepts, other sales are driven by:

- Appliance and equipment saturation levels
- Appliance efficiency levels
- Average number of days in the billing cycle for each month
- Average household size, real income, and real prices

The explanatory variable for other uses is defined as follows:

$$XOther_{y,m} = OtherEqpIndex_{y,m} \times OtherUse_{y,m} \quad (15)$$

The first term on the right hand side of this expression ($OtherEqpIndex_y$) embodies information about appliance saturation and efficiency levels and monthly usage multipliers.

The second term (*OtherUse*) captures the impact of changes in prices, income, household size, and number of billing-days on appliance utilization.

End-use indices are constructed in the SAE models. A separate end-use index is constructed for each end-use equipment type using the following function form.

$$ApplianceIndex_{y,m} = Weight^{Type} \times \frac{\left(Sat_{y}^{Type} \Big/ \frac{1}{UEC_{y}^{Type}} \right)}{\left(Sat_{05}^{Type} \Big/ \frac{1}{UEC_{05}^{Type}} \right)} \times MoMult_{m}^{Type} \times \left(TenYearMovingAverageElectric\ \mathrm{Price}\right)^{\lambda} \times \left(TenYearMovingAverageGas\,\mathrm{Price}\right)^{\kappa} \quad (16)$$

Where:

- *Weight* is the weight for each appliance type
- *Sat* represents the fraction of households, who own an appliance type
- $MoMult_m$ is a monthly multiplier for the appliance type in month (m)
- *Eff* is the average operating efficiency the appliance
- *UEC* is the unit energy consumption for appliances

This index combines information about trends in saturation levels and efficiency levels for the main appliance categories with monthly multipliers for lighting, water heating, and refrigeration.

The appliance saturation and efficiency trends data are presented on the *Shares* and *Efficiencies* tabs of the SAE spreadsheets.

Further monthly variation is introduced by multiplying by usage factors that cut across all end uses, constructed as follows:

$$ApplianceUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5} \right) \times \left(\frac{HHSize_{y}}{HHSize_{05}} \right)^{0.46} \times \left(\frac{Income_{y}}{Income_{05}} \right)^{0.10} \times \left(\frac{Elec\,\mathrm{Price}_{y,m}}{Elec\,\mathrm{Price}_{05}} \right)^{\phi} \times \left(\frac{Gas\,\mathrm{Price}_{y,m}}{Gas\,\mathrm{Price}_{05}} \right)^{\lambda} \quad (17)$$

The index for other uses is derived then by summing across the appliances:

$$OtherEqpIndex_{y,m} = \sum_{k} ApplianceIndex_{y,m} \times ApplianceUse_{y,m} \quad (18)$$

7 Appendix C: Commercial Statistically Adjusted End-Use Model

The traditional approach to forecasting monthly sales for a customer class is to develop an econometric model that relates monthly sales to weather, seasonal variables, and economic conditions. From a forecasting perspective, the strength of econometric models is that they are well suited to identifying historical trends and to projecting these trends into the future. In contrast, the strength of the end-use modeling approach is the ability to identify the end-use factors that are driving energy use. By incorporating end-use structure into an econometric model, the statistically adjusted end-use (SAE) modeling framework exploits the strengths of both approaches.

There are several advantages to this approach.

- The equipment efficiency trends and saturation changes embodied in the long-run end-use forecasts are introduced explicitly into the short-term monthly sales forecast. This provides a strong bridge between the two forecasts.
- By explicitly introducing trends in equipment saturations and equipment efficiency levels, it is easier to explain changes in usage levels and changes in weather-sensitivity over time.
- Data for short-term models are often not sufficiently robust to support estimation of a full set of price, economic, and demographic effects. By bundling these factors with equipment-oriented drivers, a rich set of elasticities can be built into the final model.

This document describes this approach, the associated supporting Commercial SAE spreadsheets, and *MetrixND* project files that are used in the implementation. The source for the commercial SAE spreadsheets is the 2010 Annual Energy Outlook (AEO) database provided by the Energy Information Administration (EIA).

7.1 Commercial Statistically Adjusted End-Use Model Framework

The commercial statistically adjusted end-use model framework begins by defining energy use ($USE_{y,m}$) in year (y) and month (m) as the sum of energy used by heating equipment ($Heat_{y,m}$), cooling equipment ($Cool_{y,m}$) and other equipment ($Other_{y,m}$). Formally,

$$\mathrm{USE}_{y,m} = \mathrm{Heat}_{y,m} + \mathrm{Cool}_{y,m} + \mathrm{Other}_{y,m} \qquad (1)$$

Although monthly sales are measured for individual customers, the end-use components are not. Substituting estimates for the end-use elements gives the following econometric equation.

$$USE_m = a + b_1 \times XHeat_m + b_2 \times XCool_m + b_3 \times XOther_m + \varepsilon_m \quad (2)$$

Here, $XHeat_m$, $XCool_m$, and $XOther_m$ are explanatory variables constructed from end-use information, weather data, and market data. As will be shown below, the equations used to construct these X-variables are simplified end-use models, and the X-variables are the estimated usage levels for each of the major end uses based on these models. The estimated model can then be thought of as a statistically adjusted end-use model, where the estimated slopes are the adjustment factors.

7.1.1 Constructing XHeat

As represented in the Commercial SAE spreadsheets, energy use by space heating systems depends on the following types of variables.

- Heating degree days,
- Heating equipment saturation levels,
- Heating equipment operating efficiencies,
- Average number of days in the billing cycle for each month, and
- Commercial output and energy price.

The heating variable is represented as the product of an annual equipment index and a monthly usage multiplier. That is,

$$XHeat_{y,m} = HeatIndex_y \times HeatUse_{y,m} \quad (3)$$

where, $XHeat_{y,m}$ is estimated heating energy use in year (y) and month (m),
$HeatIndex_y$ is the annual index of heating equipment, and
$HeatUse_{y,m}$ is the monthly usage multiplier.

The heating equipment index is composed of electric space heating equipment saturation levels normalized by operating efficiency levels. The index will change over time with changes in heating equipment saturations (*HeatShare*) and operating efficiencies (*Eff*). Formally, the equipment index is defined as:

$$HeatIndex_y = HeatSales_{04} \times \frac{\left(HeatShare_y / Eff_y \right)}{\left(HeatShare_{04} / Eff_{04} \right)} \quad (4)$$

In this expression, 2004 is used as a base year for normalizing the index. The ratio on the right is equal to 1.0 in 2004. In other years, it will be greater than one if equipment saturation levels are above their 2004 level. This will be counteracted by higher efficiency levels, which will drive the index downward. Base year space heating sales are defined as follows.

$$HeatSales_{04} = \left(\frac{kWh}{Sqft} \right)_{Heating} \times \left(\frac{CommercialSales_{04}}{\sum_e kWh / Sqft_e} \right) \quad (5)$$

Here, base-year sales for space heating is the product of the average space heating intensity value and the ratio of total commercial sales in the base year over the sum of the end-use intensity values. In the Commercial SAE Spreadsheets, the space heating sales value is defined on the *BaseYrInput* tab. The resulting $HeatIndex_y$ value in 2004 will be equal to the estimated annual heating sales in that year. Variations from this value in other years will be proportional to saturation and efficiency variations around their base values.

Heating system usage levels are impacted on a monthly basis by several factors, including weather, commercial level economic activity, prices and billing days. Using the COMMEND default elasticity parameters, the estimates for space heating equipment usage levels are computed as follows:

$$HeatUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5} \right) \times \left(\frac{WgtHDD_{y,m}}{HDD_{04}} \right) \times \left(\frac{Output_y}{Output_{04}} \right)^{0.20} \times \left(\frac{Price_{y,m}}{Price_{04}} \right)^{-0.18} \quad (6)$$

where, *BDays* is the number of billing days in year (y) and month (m), these values are normalized by 30.5 which is the average number of billing days
WgtHDD is the weighted number of heating degree days in year (y) and month (m). This is constructed as the weighted sum of the current month's HDD and the prior month's HDD. The weights are 75% on the current month and 25% on the prior month.
HDD is the annual heating degree days for 2004,
Output is a real commercial output driver in year (y),

Price is the average real price of electricity in month (m) and year (y),

By construction, the $HeatUse_{y,m}$ variable has an annual sum that is close to one in the base year (2004). The first two terms, which involve billing days and heating degree days, serve to allocate annual values to months of the year. The remaining terms average to one in the base year. In other years, the values will reflect changes in commercial output and prices, as transformed through the end-use elasticity parameters. For example, if the real price of electricity goes up 10% relative to the base year value, the price term will contribute a multiplier of about .98 (computed as 1.10 to the -0.18 power).

7.1.2 Constructing XCool

The explanatory variable for cooling loads is constructed in a similar manner. The amount of energy used by cooling systems depends on the following types of variables.

- Cooling degree days,
- Cooling equipment saturation levels,
- Cooling equipment operating efficiencies,
- Average number of days in the billing cycle for each month, and
- Commercial output and energy price.

The cooling variable is represented as the product of an equipment-based index and monthly usage multiplier. That is,

$$\mathrm{XCool}_{y,m} = \mathrm{CoolIndex}_{y} \times \mathrm{CoolUse}_{y,m} \qquad (7)$$

where, $XCool_{y,m}$ is estimated cooling energy use in year (y) and month (m),
$CoolIndex_y$ is an index of cooling equipment, and
$CoolUse_{y,m}$ is the monthly usage multiplier.

As with heating, the cooling equipment index depends on equipment saturation levels (*CoolShare*) normalized by operating efficiency levels (*Eff*). Formally, the cooling equipment index is defined as:

$$CoolIndex_{y} = CoolSales_{04} \times \frac{\left(CoolShare_{y} / Eff_{y} \right)}{\left(CoolShare_{04} / Eff_{04} \right)} \qquad (8)$$

Data values in 2004 are used as a base year for normalizing the index, and the ratio on the right is equal to 1.0 in 2004. In other years, it will be greater than one if equipment saturation levels are above their 2004 level. This will be counteracted by higher efficiency levels, which will drive the index downward. Estimates of base year cooling sales are defined as follows.

$$CoolSales_{04} = \left(\frac{kWh}{Sqft}\right)_{Cooling} \times \left(\frac{CommercialSales_{04}}{\sum_{e} kWh/Sqft_{e}}\right) \quad (9)$$

Here, base-year sales for space cooling is the product of the average space cooling intensity value and the ratio of total commercial sales in the base year over the sum of the end-use intensity values. In the Commercial SAE Spreadsheets, the space cooling sales value is defined on the *BaseYrInput* tab. The resulting *CoolIndex* value in 2004 will be equal to the estimated annual cooling sales in that year. Variations from this value in other years will be proportional to saturation and efficiency variations around their base values.

Cooling system usage levels are impacted on a monthly basis by several factors, including weather, economic activity levels and prices. Using the COMMEND default parameters, the estimates of cooling equipment usage levels are computed as follows:

$$CoolUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5}\right) \times \left(\frac{WgtCDD_{y,m}}{CDD_{04}}\right) \times \left(\frac{Output_{y}}{Output_{04}}\right)^{0.20} \times \left(\frac{Price_{y,m}}{Price_{04}}\right)^{-0.18} \quad (10)$$

where, *WgtCDD* is the weighted number of cooling degree days in year (y) and month (m). This is constructed as the weighted sum of the current month's CDD and the prior month's CDD. The weights are 75% on the current month and 25% on the prior month.
CDD is the annual cooling degree days for 2004.

By construction, the *CoolUse* variable has an annual sum that is close to one in the base year (2004). The first two terms, which involve billing days and cooling degree days, serve to allocate annual values to months of the year. The remaining terms average to one in the base year. In other years, the values will change to reflect changes in commercial output and prices.

7.1.3 Constructing XOther

Monthly estimates of non-weather sensitive sales can be derived in a similar fashion to space heating and cooling. Based on end-use concepts, other sales are driven by:

- Equipment saturation levels,
- Equipment efficiency levels,
- Average number of days in the billing cycle for each month, and
- Real commercial output and real prices.

The explanatory variable for other uses is defined as follows:

$$\mathrm{XOther}_{y,m} = \mathrm{OtherIndex}_{y,m} \times \mathrm{OtherUse}_{y,m} \tag{11}$$

The second term on the right hand side of this expression embodies information about equipment saturation levels and efficiency levels. The equipment index for other uses is defined as follows:

$$OtherIndex_{y,m} = \sum_{Type} Weight_{04}^{Type} \times \left(\frac{Share_{y}^{Type} \Big/ Eff_{y}^{Type}}{Share_{04}^{Type} \Big/ Eff_{04}^{Type}} \right) \tag{12}$$

where, *Weight* is the weight for each equipment type,
Share represents the fraction of floor stock with an equipment type, and
Eff is the average operating efficiency.

This index combines information about trends in saturation levels and efficiency levels for the main equipment categories. The weights are defined as follows.

$$Weight_{04}^{Type} = \left(\frac{kWh}{Sqft} \right)_{Type} \times \left(\frac{CommercialSales_{04}}{\sum_{e} kWh \Big/ Sqft_{e}} \right) \tag{13}$$

Further monthly variation is introduced by multiplying by usage factors that cut across all end uses, constructed as follows:

$$OtherUse_{y,m} = \left(\frac{BDays_{y,m}}{30.5}\right) \times \left(\frac{Output_{y}}{Output_{04}}\right)^{0.20} \times \left(\frac{Price_{y.m}}{Price_{04}}\right)^{-0.18} \quad (14)$$

In this expression, the elasticities on output and real price are computed from the COMMEND default values.

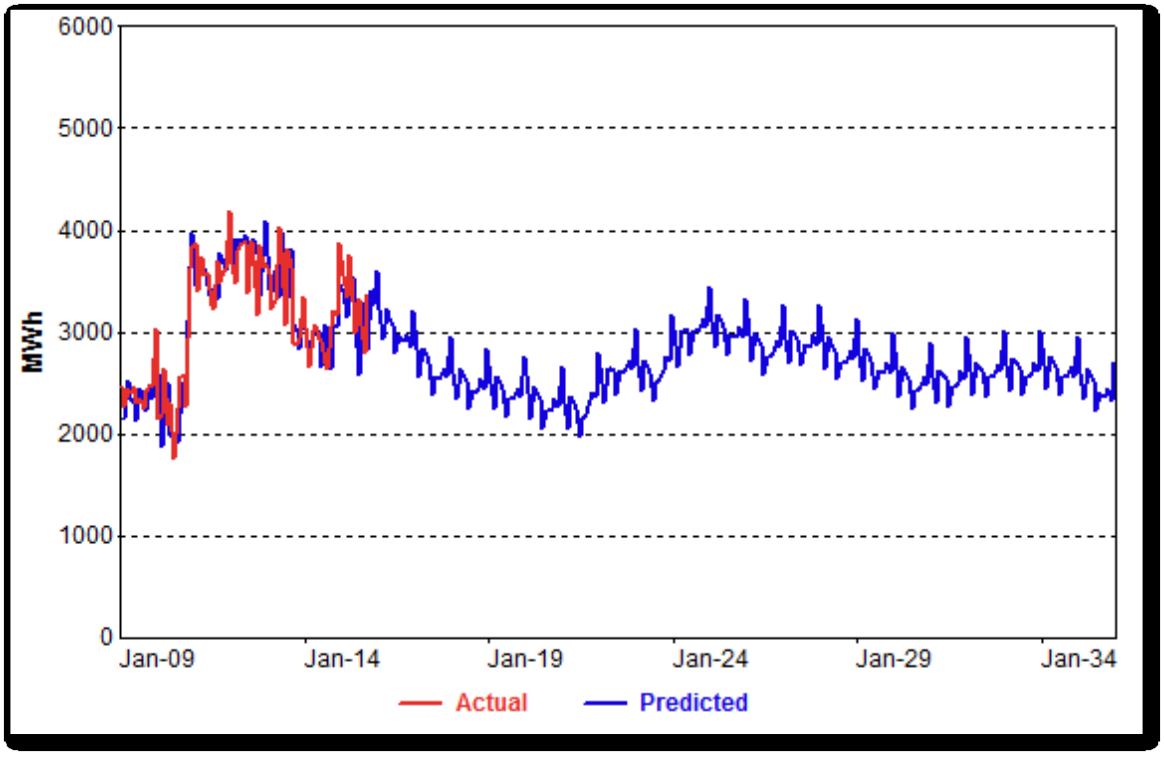
8 Appendix D: Industrial Model

While Itron developed the Industrial model, this model is not used in the final forecast. YEC chose to remove the model results in favor of manually adjusting the forecast based on large industrial customer changes. This Appendix documents the model developed by Itron.

The industrial sales forecast is based on a generalized monthly regression model where industrial sales are specified as a function of mining output and monthly binaries to capture seasonal load variation and shifts in the data.

The final model's Adjusted R^2 is 0.73 with in-sample MAPE of 7.09%. The relatively low Adjusted R^2 and high MAPE are due to the "noisy" nature of industrial monthly billing data. Actual and predicted monthly industrial sales are depicted in Figure 8-1. Model specification and statistics are shown in Table 8-2 and Table 8-3.

Figure 8-1: Actual and Predicted Industrial Sales: Base Case (MWh)



Given the volatility of mining output, industrial sales growth will vary; sales are projected to decrease through 2021 before increasing through the 2022-25 period. Table 8-1 shows the industrial forecast

Table 8-1: Industrial Sales Forecast

Year	Sales (MWh)	
2015	39,782	
2016	36,236	-8.9%
2017	31,919	-11.9%

1.1 Introduction

The industrial load forecast includes all customers in the industrial rate class. At this time, the only large industrial customers in the territory are mines. All other industries of the territorial economy (e.g., agriculture, construction and forestry) are captured in the commercial forecast.

The industrial load and peak demand forecast considers the electricity requirements for mines connected to the grid. Historically, the alternative for industrial customers was to operate and meet power requirements with on-site thermal generation from imported fossil fuels (e.g., diesel). Recently, mining companies have relied on other resource options such as liquefied natural gas (e.g., Stornoway's Renard diamond mine), wind (e.g., Glencore's Raglan mine and Rio Tinto's Diavik mine) or solar photovoltaic (e.g., Sandfire Resources' DeGrussa Copper-Gold Mine) to meet industrial projects energy requirements.

1.2 Background

The Yukon Territory economy is sensitive to fluctuation in commodity prices which impacts the global mineral resource industry. From 2012 to 2014, the contribution of the Mining and Oil and Gas Extraction industry to the territorial GDP has averaged just over 21%.

Prior to the Faro Mine closure in 1988, industrial power requirement amounted to 43% of the energy and 30% of the total demand on the system (Whitehorse-Aishihik-Faro and Mayo-Dawson grids; 1996/97 Cost of Service Study).

The years following the closure at Faro saw substantial capacity and energy surplus hydro generation when compared to the load. The connection of new industrial customers (i.e., Minto mine and the Bellekeno silver mine) to the grid in 2008 and 2010 eroded the surplus. During the same period, commercial and residential electricity requirements have increased significantly. Recent residential and commercial developments increased pressure on existing generating assets due to the high penetration of electrical heating (over 90% for both commercial and residential classes).

In 2013, the Bellekeno silver mine ceased operations, decreasing industrial demand by about 32%. In 2016, Capstone Mining announced it would cease operations at Minto mine in the near future unless commodity prices would increase.

Since 2011, several projects such as Wellgreen (Wellgreen Platinum Corp.), Eagle Gold (Victoria Gold Corp.), and the Coffee Gold Project (Goldcorp, formerly Kaminak Gold Corp.), have continued exploration activities, feasibility work or sought permitting.

1.3 Source of Information

The industrial load and peak demand forecast uses data from proxy mines to estimate electricity needs from mines connected to the grid. Information used to generate the industrial peak and load forecast includes:

- information provided on specific projects in operation or planning phase via direct communication with mining companies

- historical demand and sales data
- information included in past YEC regulatory applications
- information from YEC 2011 Resource Plan

In many instances, the information is preliminary and will be subject to changes as the mining companies advance the engineering and definition of their respective project. To that effect, Yukon Energy will adjust the energy and peak demand forecast should material change occur in the future.

1.4 Industrial Projects Requirements

Due to the significant cost of the transmission lines required to connect some industrial projects to the Yukon Power System (YPS), only a subset projects closer to the grid were considered to be connected to the grid for the industrial load and peak demand forecast. The projects retained were as follow:

- Potential Industrial Developments
    - Victoria Gold Eagle Gold Project
    - Copper North's Carmacks Copper Project
    - Golder Predator's Brewery Creek Project
- Existing Industrial Developments
    - Capstone Mining's Minto mine
    - Alexco Resources' Bellekeno mine

It should be noted that the availability of details relating to the various phases of an industrial project is not consistent amongst projects. A project like Victoria Gold's Eagle Gold project has more information on energy and peak demand requirements through all phases of its project life than a project such Golder Predator's Brewery Creek Project.

Unless specified, Yukon Energy assumed the entirety of the energy and peak demand requirements would have to be met using the utility's assets and thus, did not include any contribution by generating assets located at the project site.

It is generally recognized that load profile of industrial projects across the calendar year is constant; therefore, not as sensitive to fluctuations in weather conditions as non-industrial loads are. Unless otherwise stated within the information available, monthly industrial energy and peak demand requirements were assumed constant throughout the year.

The following subsections present the energy and peak demand requirements at the point of delivery (i.e., exempt of losses) assumed for each of the industrial projects. The forecast of the total energy and peak demand requirements, including the losses, is presented in the last section of this report. The losses include transmission and distribution line losses, transformer losses and station service loads. A review of actual sales and generation data indicates overall losses on the Yukon Power System for the

2012-2015 period is 8.8%. This represents an increase of 0.1% from the 8.7% reported in the 2012 GRA[1] and LNG Part III application[2].

1.4.1 Potential Industrial Developments

This section describes power requirements for potential industrial developments that have gone through permitting or are going through the environmental and socio-economic review.

1.4.1.1 Eagle Gold Project

The property is located 45 km from the grid and 45 km north of the Town of Mayo. The project has all the necessary permits to move the project forward to construction and later, production. The project can be divided between the following four stages with associated duration:

- Construction: 1.5 years
- Production: 10 years
- Post-Production
    - Rinsing: 2 years after end of production
- Closure: 3 years after end of rinsing

Power requirement during the construction phase is estimated at less than 1 GWh/month. For the purposes of the industrial load forecast, 1 GWh/month or 12 GWh/year is assumed (Table B-1). Assuming an 85% load factor, the anticipated peak demand at the site is 1.6 MW (Table B-1).

During the production phase, Victoria Gold is also looking at implementing a summer and winter schedule whereby peak demand would decreased between the months of December until the mid-March (Table B-1). The load would then ramp up for the reminder of the year.

Energy requirement during the rinsing and closer phases are similar and estimated at 4 GWh/month or 48 GWh/year (Table B-1). Assuming a load factor of 85%, peak demand, net of losses, is estimated at 6.5 MW (Table B-1).

[1] Yukon Energy Corporation, 2012. 2012/2013 General Rate Application, application submitted to the Yukon Utilities Board, April 2012.
[2] Yukon Energy Corporation, 2013. *Application for an Energy Project Certificate and an Energy Operation Certificate Regarding the Proposed Whitehorse Diesel-Natural Gas Conversion Project*, application submitted to the Yukon Utilities Board, December 2013.

Table B-1: Eagle Gold Project Power Requirements over Project Life

Phase	Duration	Peak Demand	Load Factor	Annual Energy Requirement
	(Years)	(MW)	(%)	(GWh)
Construction	1.5	1.6	85%	12.0
Production	10	18.2 (Summer)	85%	114.8
		8.0 (Winter)	85%	
Post-Production	2	6.5	85%	48.0
Closure	3	6.5	85%	48.0

Notes:

- *Numbers rounded to nearest digit after the decimal point*
- *Excludes losses*
- *Does not assume any on-site generation*
- *Summer season extends from the start of December to mid-March*
- *Winter season is defined as Mid-March to end of November*
- *Victoria Gold Corporation is updating its feasibility study in 2016*
- *Numbers presented in the table are subject to changes in the future*
- *Includes 10% contingency*

1.4.2 Carmacks Copper Project

The property is located 12 km from grid and 38 km northwest of Carmacks. The forecast peak demand during the production phase is estimated at 14 MW (Table B-2). Connection of the project to the Yukon Power System is expected to occur during the construction phase. Before the interconnection to the YPS is completed, Copper North would rely on on-site thermal power to meet immediate needs. Once connected, the energy need is expected to last for about 8 months at 0.2 GWh/month or 1.6 GWh for the entire period (Table B-2). Peak demand during construction is expected to be 0.5 MW (Table B-2).

Total anticipated energy requirement during production phase is estimated at 6 GWh/month or 72 GWh/year (Table B-2). Mine life included in the YESAB project proposal is 7 years but current resources indicate mine life could be extended to 10+ years. For the 20-year energy and peak demand forecast, the mine life was assumed to be 10 years (Table B-2).

Energy and peak demand requirements during reclamation and closure are estimated at 200 MWh/month or 2.4 GWh/year and 0.5 MW, respectively, for a duration of 2 years after end of production. The project needs to complete the YESAB review process before moving forward.

Table B-2: Carmacks Copper Project Power Requirements over Project Life

Phase	Duration	Peak Demand	Load Factor	Annual Energy Requirement
	(Years)	(MW)	(%)	(GWh)
Construction	0.75	0.5	60%	1.6
Production	10	14	60%	72.0
Post-Production	N/A	N/A	N/A	N/A
Closure	2	0.5	60%	2.4

Notes:

- *Numbers rounded to nearest digit after the decimal point*
- *Excludes losses*
- *Initial construction loads met with onsite thermal generation*
- *Does not assume any more contribution from on-site generation*
- *Load assumed constant throughout the year*
- *Preliminary data for reclamation and closure period, may be subject to change in the future*

1.4.3 Brewery Creek Project

The property is located 55 km southeast of Dawson City and 27 km from the 69 kV Mayo-Dawson transmission line. At this time, there is limited information available that would suggest this is a firm load for resource planning purposes (i.e., no recent regulatory filings or publically available information defining potential load requirements).

Energy and peak demand information from the 2014 Preliminary Economic Assessment[3] were considered for the industrial load forecast. Power requirement during construction are expected to be met with the existing on-site thermal assets.

During the production phases, winter peak demand is expected to reach 1.8 MW for a 9-year production period (Table B-3). Energy requirements are estimated at 23.5 GWh/year (Table B-3)broken down as follow:

- 5 GWh/year or 1.1 GWh/month during the winder period
- 18.6 GWh/year or 2.4 GWh/month during the operating period

The information on closure and reclamation suggest Golden Predator will implement a passive solution that will not result in material power requirement over a 15-year period. As such, neither energy nor peak demand requirements were considered in the industrial forecast for this project.

[3] EBA, A Tetra Tech Company, 2014. 2012 Preliminary Economic Assessment for the Brewery Creek Property Yukon Territory, Canada National Instrument 43-101 Technical Report, report submitted to Golden Predator Exploration Ltd. November 2014.

Table B-3: Brewery Creek Project Power Requirements over Project Life

Phase	Duration	Peak Demand	Load Factor	Annual Energy Requirement
	(Years)	(MW)	(%)	(GWh)
Construction	1	N/A	N/A	N/A
Production	9	1.8 (Winter)	32%	23.5
		3.9 (Operating)	54%	
Post-Production	N/A	N/A	N/A	N/A
Closure	N/A	N/A	N/A	N/A

Notes:

- *Numbers rounded to nearest digit after the decimal point*
- *Excludes losses*
- *Power requirements during construction assumed to be provided by on-site thermal generation*
- *Operating season defined as start of March until late October*
- *Winter season is defined as late October to end of February*
- *Does not assume any more contribution from on-site generation*
- *Load assumed constant throughout the year*
- *No major loads expected during closure period*
- *Includes 19% contingency*

1.4.4 Existing Industrial Developments

This section describes power requirements for existing industrial developments. Of the two properties, only the Minto mine is still operating. Alexco's Bellekeno mine was considered as a potential project should commodity prices increase in the near-future.

1.4.4.1 Minto Mine

The Minto Mine is located 27 km west of Minto Landing. The Copper-Gold mine started production in 2007. In 2008, the mine was connected to the newly built spur line between the mine site and Minto Landing as part of the Phase 1 of the Carmacks-Stewart Transmission Line project.

Historical data indicate the mine has an operating winter peak load of 6 MW (assuming a power factor of 0.95). Actual annual energy requirements have averaged 36.7 GWh for the 2014-2015 period. Pursuant to the power purchase agreement (PPA) between Yukon energy and Capstone Mining Corporation (formerly Minto Exploration Ltd.), the company could elect to increase its annual energy requirements to 42 GWh/year at a peak load of 6 MW (assuming power factor of 0.95). The maximum energy and peak demand requirements outlined in the PPA were used for the purposes of estimating the industrial electrical requirements (Table B-4). The mine is assumed to operate until mid-2022[4].

[4] Minto Explorations Ltd., 2012. *Minto Phase VI Preliminary Feasibility Study Technical Report Minto Mine Yukon, Canada*, report prepared by Minto Explorations Ltd., December 2012.

Table B-4: Minto Project Power Requirements over Project Life

Phase	Duration	Peak Demand	Load Factor	Annual Energy Requirement
	(Years)	(MW)	(%)	(GWh)
Construction	N/A	N/A	N/A	N/A
Production	6.5	6.0	80%	42.0
Post-Production	N/A	N/A	N/A	N/A
Closure	N/A	N/A	N/A	N/A

Notes:

- *Numbers rounded to nearest digit after the decimal point*
- *Excludes losses*
- *Does not assume any more contribution from on-site generation*
- *Load assumed constant throughout the year*
- *Last year of production period is expected to last 6 months*

1.4.4.2 Bellekeno mine

Alexco's Bellekeno mine is located in the Keno region. Alexco is also operating a mill in the Keno region and plans to develop other silver deposits in the vicinity to use this mill in the near-term. The project started production in 2010 and operated until its temporary closure in 2013. The mine life was initially estimated to be 10 years. Based on the duration of historical mining activities, it is estimated that the projects has a remaining life of 7 years (Table B-5).

Table B-5: Bellekeno Project Power Requirements over Project Life

Phase	Duration	Peak Demand	Load Factor	Annual Energy Requirement
	(Years)	(MW)	(%)	(GWh)
Construction	N/A	N/A	N/A	N/A
Production	3	3.5	65%	20.0
	4	2.6	66%	15.0
Post-Production	N/A	N/A	N/A	N/A
Closure	N/A	N/A	N/A	N/A

Notes:

- *Numbers rounded to nearest digit after the decimal point*
- *Excludes losses*
- *Load assumed constant throughout the year*

Actual energy sales averaged 12 GWh/year for the 2011-2012 period. Peak load is estimated at about 3.5 MW based on actual demand data. At the time of the closure, information provided by Alexco suggested the project had three additional years of production with an energy requirement of 20 GWh/year and peak load of 3.5 MW. This period would be followed by four years of production with a lower energy requirement estimated at 15 GWh/year and peak load of 2.6 MW. The remaining life of the Bellekeno mine was assumed for the purposes of estimating the industrial electrical requirements (Table B-5).

1.5 Industrial Activity Scenarios

Four major scenarios and a set of sensitivity scenarios were defined on the basis of the intensity of industrial activity. The following subsections describe the assumptions relating to the timing and life of the existing and planned industrial projects. Industrial projects assumed to connect to the Yukon Power System are also presented below.

1.5.1 Very Low Industrial Activity

The Very Low Industrial Activity scenario assumes the following:

- Minto Mine remains the only mine connected to the grid with mine closure at the end of 2017.

For the purposes of estimating energy and peak demand requirements over the planning period (2016-2035), no new mines are assumed to connect to the grid.

1.5.2 Low Industrial Activity

The Low Industrial Activity scenario assumes the following:

- Minto Mine remains the only mine connected to the grid with mine closure in mid-2022.

For the purposes of estimating energy and peak demand requirements over the planning period (2016-2035), no new mines are assumed to connect to the grid.

1.5.3 Medium Industrial Activity

The Medium Industrial Activity (Base Case) scenario assumes the following:

- Minto Mine remains in operation and connected until mine closure at the end of 2022.
- Eagle Gold (Victoria Gold) connects to the grid with construction starting in 2019, production starting in mid-2020 and mine closure activities starting in 2030.

1.5.4 High Industrial Activity

For the High Industrial Activity scenario, the following was assumed:

- Minto Mine remains in operation and connected until closure in 2022
- Alexco Mine coming back online in 2020 until 2026
- Three medium mine connecting to the Yukon Power System as follow:
    - Victoria Gold's Eagle Gold from 2017 to 2034
    - Copper North's Carmacks Copper from 2020 until the end of 2031

- Golden Predator's Brewery Creek from 2020 until the end of 2030

1.5.5 Sensitivity Scenarios

A total of 11 sensitivity scenarios were defined to quantify the impact of climate change, other industries and sectors of the Yukon economy. These scenarios focus on variations on mining starts and impacts on the territorial economy. The sensitivity scenarios considered the following:

- Impact of mining boom and bust cycle
- Early and late mining starts
- Potential oil and gas development
- Changes in government spending as a proxy to variations in federal transfer payments
- Increase in activity of Yukon's smaller economic sectors including tourism, forestry, agriculture, and fishery.

For each of the sensitivity scenario, timing of the project start was consistent with the econometric scenario description presented in the appendix on Yukon Macroeconomic Model 2016-2035 (Appendix B). For instance, under the impact of Boom and Bust cycle scenario (Scenario 10), construction of the Eagle Gold project is assumed to start in 2028 as opposed to 2019 for the Base Case (Scenario 3)

Because the sensitivity scenarios are variations on the four major industrial activity scenarios, only energy and peak demand data for those four scenarios are discussed and presented in this document. Detailed numerical data on industrial energy and peak demand requirements for the sensitivity scenarios can be found in the Energy and Peak Demand Forecast Data 2016-2035 appendix (Appendix A).

1.6 Industrial Energy and Peak Demand Forecast

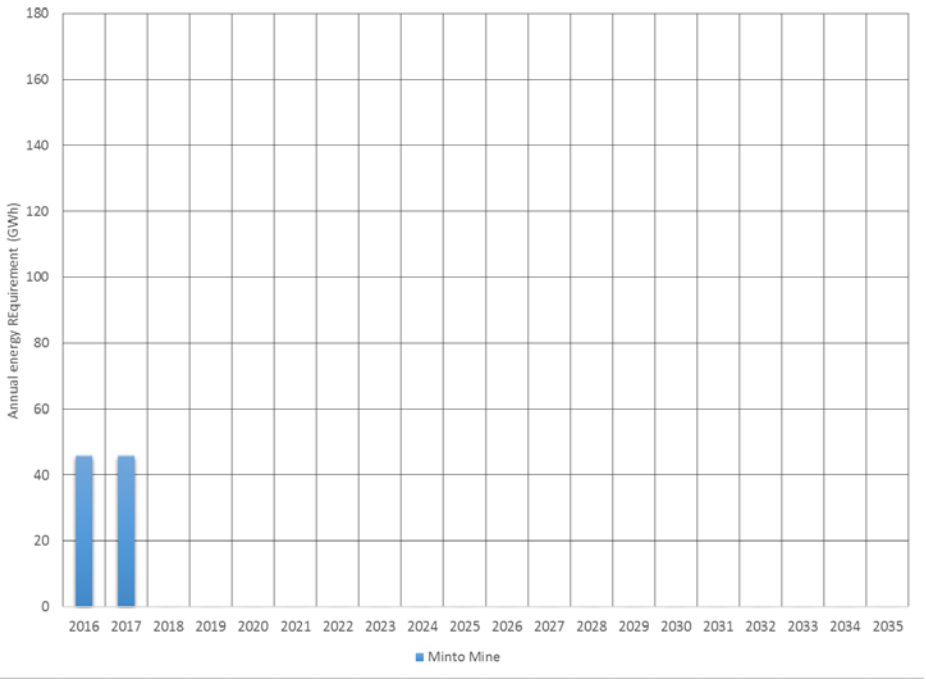
The industrial energy and peak demand forecast considered the same mines and timing described in the appendix on Yukon Macroeconomic Model 2016 – 2035 (Appendix B). Only the forecast for the four major scenarios are presented below. Results for the sensitivity scenarios are effectively variations of the four major scenarios. Industrial forecasts for all scenarios are included in Appendix A. All the forecast values presented in this section are inclusive of losses end represent the energy and peak demand YEC needs to meet at the generating stations.

1.6.1 Industrial Energy Forecast

The Very Low Industrial Activity shows a constant energy requirement for 2016 and 2017 at 45.7 GWh/yr (Figure 1). After 2017, Minto mine is assumed closed for the remaining of the forecast period (Figure 1). No other industrial projects are assumed for this scenario

The Low Industrial Activity shows a constant energy requirement between 2016 and 2021 at 45.7 GWh/yr (Figure 2). In 2022, Minto mine is expected to operate for 6 months and therefore, decrease its energy requirement by half (Figure 2). After 2022, this scenario assumes one industrial project would start operation but would not connect to the Yukon Power System.

Figure 1: Very Low Industrial Activity Energy Forecast



Similar the Low Industrial Activity scenario, the Medium Industrial Activity (Base Case) scenario assumes the Minto mine is in operation through mid-2022 (Figure 3). A peak energy requirement of 170.6 GWh/year is estimated to occur in 2021 and is due to the first full year of production at Eagle Gold and the last full production year at Minto mine (Figure 3). Energy requirements decrease over the following two years as a result of the Minto mine closure and level off at 124.9 GWh/year for the 2023-2029 period (Figure 3). Starting in 2030, energy requirements materially decrease due to the end of the production period at Eagle Gold and the start of the post-production and closure activities until 2035 (Figure 3).

Figure 2: Low Industrial Activity Energy Forecast

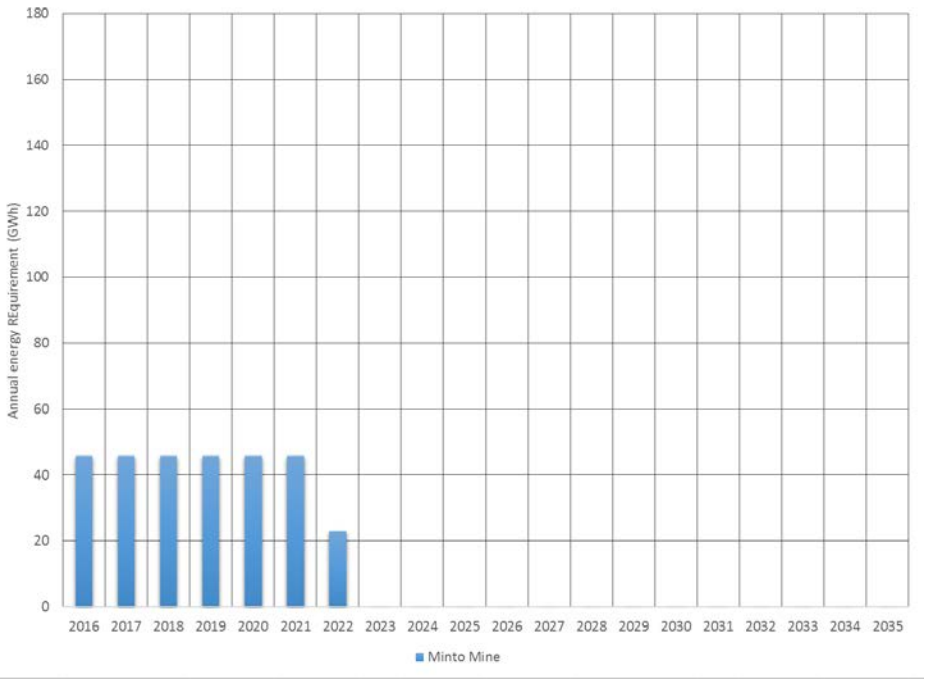


Figure 3: Medium Industrial Activity (Base Case) Energy Forecast

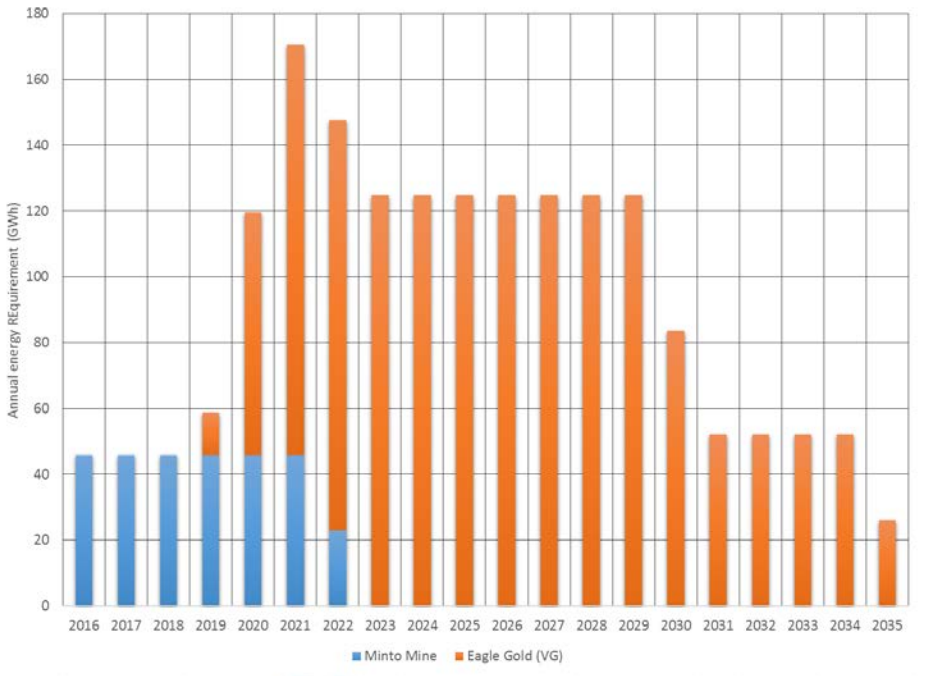
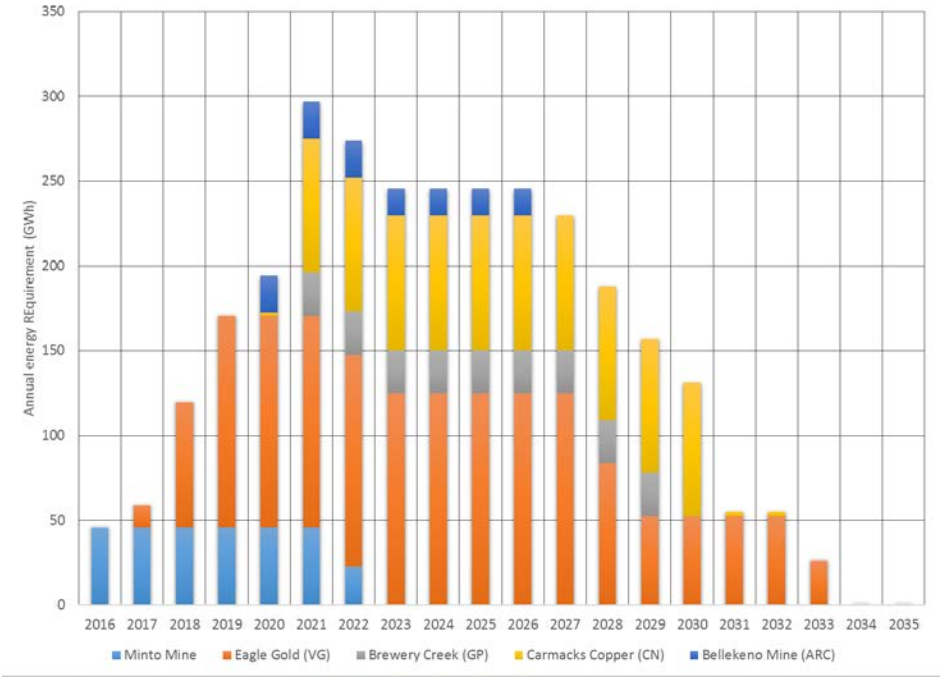


For the High Industrial Activity, Minto mine is still assumed to operate at 45.7 GWh/year until 2022 where its energy requirement decreases to 22.8 GWh (Figure 4). Industrial energy requirements start ramping up in 2019 to culminate at 296.9 GWh/year in 2022 (Figure 4). The material increase is in part

due to the start of construction and later, production at the Eagle Gold property (Figure 4). Compounding the effect of the Eagle Gold project is the start of construction and production activities at the Carmacks Copper, Brewery Creek and Bellekeno mine in 2020. Subsequent to 2021, energy requirements decrease by 22.9 GWh and 28.3 GWh for 2022 and 2023, respectively. This reduction is due to the closures of the Minto mine. Beyond 2023, industrial energy needs remains constant at 245.7 GWh/year until 2026. After 2026, the Bellekeno mine is assumed to shut down. Forecast energy requirement begins to ramp down in 2027 until 2030. Several factors explain this decrease, notably the transition from production to post-production and closure at Eagle Gold project and the expected closure of the Brewery Creek project. From 2031 to 2033, energy requirements are intended to support closure activities at Carmacks Copper and Eagle Gold projects. The industrial energy forecast decrease to 0 GWh/year for the last two years of the forecast period.

Figure 4: High Industrial Activity Energy Forecast



1.6.2 Industrial Peak Demand Forecast

The contribution of the industrial projects to the overall system peak for the Very Low Industrial Activity and Low Industrial Activity scenarios are closely related to the production activities at the Minto mine. A contribution to the peak of 6.5 MW is expected until 2017 and 2022 for Very Low Industrial Activity (Figure 5) and Low Industrial Activity (Figure 6) scenarios, respectively. Subsequent to the Minto mine closure, the industrial demand contributing to the overall system peak is expected to drop off to 0 MW.

Figure 5: Very Low Industrial Activity Peak Demand Forecast

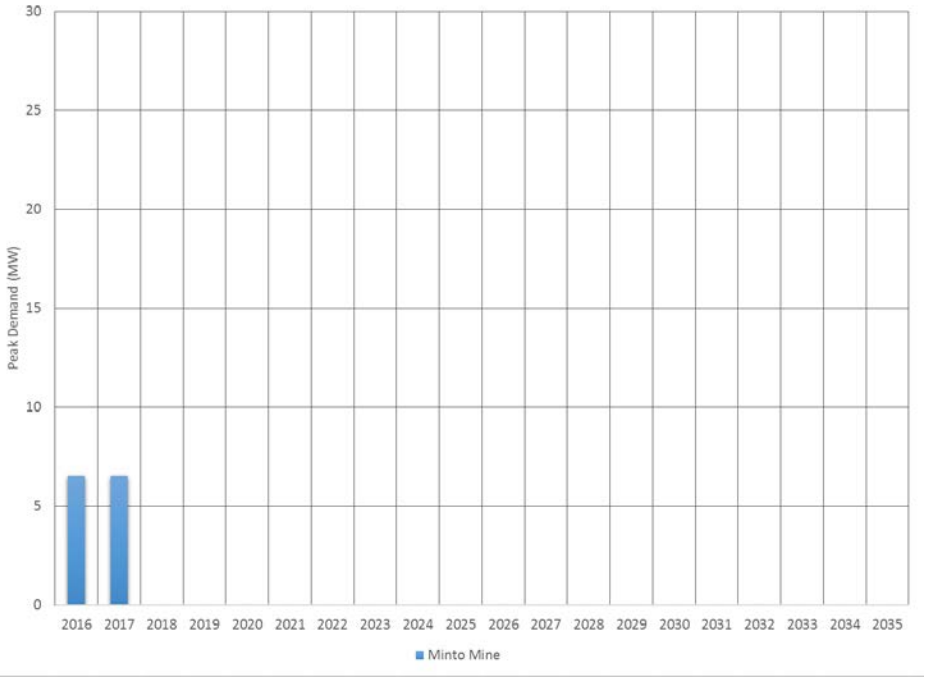


Figure 6: Low Industrial Activity Peak Demand Forecast

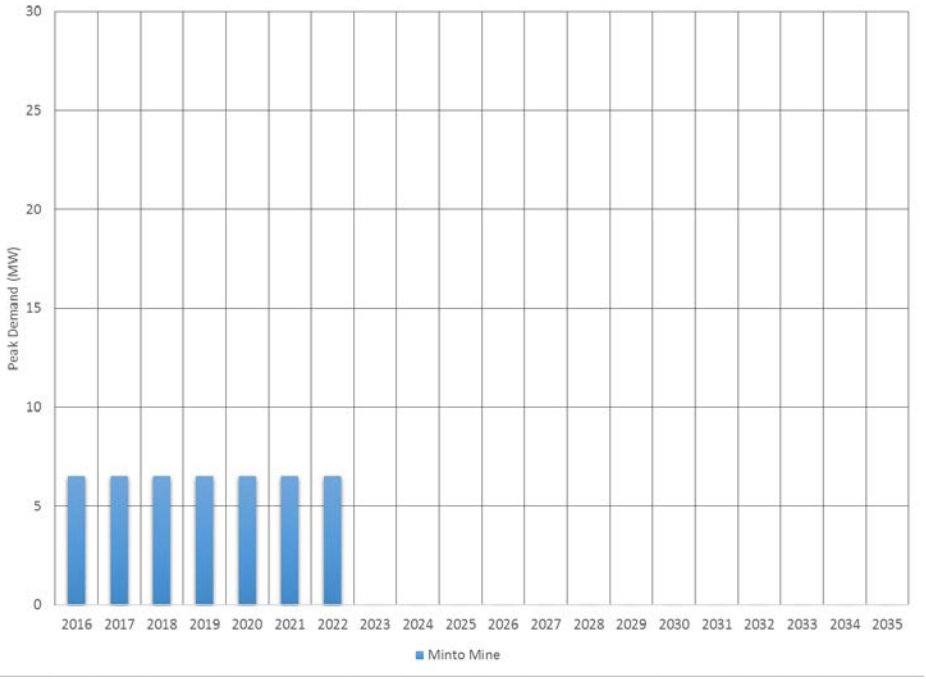
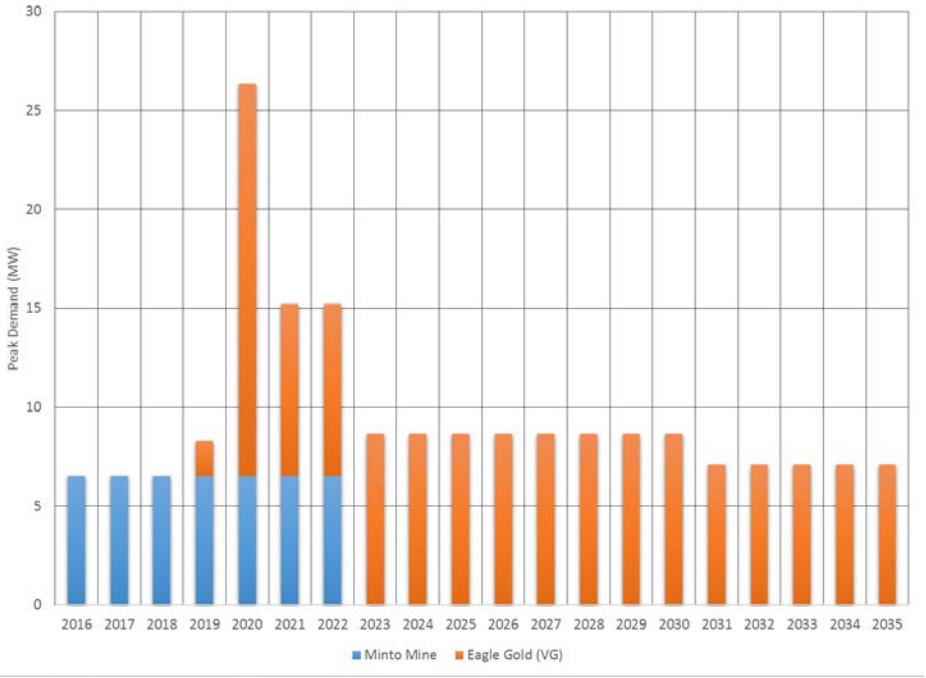


The forecast peak demand for the Medium Industrial Activity scenario shows an increase of 26.4 MW as the connected mine, Victoria Gold's Eagle Gold project, starts its production phase in 2020 (Figure 7). For the remainder of its operation phase, the contribution of the Eagle Gold project to the peak demand is estimated at approximately 8.7 MW (Figure 7); this corresponds to the peak demand during the

winter period (November to January). Summer peak demand (February to October) for the project at the point of delivery is just over 19.8 MW. Although greater than the winter peak demand, the summer peak demand is non-coincident to the non-industrial peak demand forecasted to occur in January of each forecasted year. Only one year (2020) shows a contribution of the project of 19.8 MW to the system peak demand attributable to the transition from construction to production.

Figure 7: Medium Industrial Activity (Base Case) Peak Demand Forecast



For the High Industrial Activity scenario, the contribution to the overall system peak of the industrial peak demand is estimated to reach 36.2 MW in 2021 (Figure 8).

Prior to 2021, industrial peak demand is expected to contribute 26.3 MW to the system peak in 2018 (Figure 8). This elevated demand is associated with the transition between construction phase and the production phase at the Eagle Gold project. This is similar to what is expected in 2020 under the Base Case scenario (Figure 7).

After 2021, peak demand is expected to gradually decrease until 2030 where it is expected to reach 22.3 MW. After 2030, the peak industrial demand decreases to 7.7 MW and stay relatively constant until 2034 where it drops to zero (Figure 8). The drop occurring in 2031 is associated with the end of the production period and start of the closure activities at the Eagle Gold Project and end of production at Golden Predator's Brewery Creek project (Figure 8).

Executive Summary

The deployment of plug-in electric vehicles has the potential to reduce petroleum consumption and greenhouse gas emissions dramatically, and increase energy independence through the utilization of locally produced energy. However, the success of long-term transportation electrification will depend in part on the near-term deployment of vehicles and charging infrastructure. Yukon Energy stands to play a significant role in the transition towards higher rates of plug-in electric vehicle adoption and the deployment of charging infrastructure. The objective of this report is to provide Yukon Energy Corporation and partners an assessment of the technical feasibility of plug-in electric vehicles (PEVs) in the Yukon Territory and their potential opportunities and impact to the current grid. The goal of this project is to determine to what extent an active engagement in PEV and charging station deployment is a wise investment in the Yukon. Additionally this project determines the potential long-term associated impacts or opportunities for electrical sales and peak and base loads.

ICF's investigation of the potential for electric vehicles in the Yukon Territory is focused on 1) a review of cold weather impacts on plug-in electric vehicles and charging infrastructure, 2) a market assessment for the Yukon Territory, including vehicle forecasts, and associated greenhouse gas impacts of electric vehicle deployment, and 3) a grid impact assessment regarding the amount of energy that Yukon will need in the future, and the potential stress on some distribution assets. ICF's key findings are summarized here:

- ICF's literature review indicates that residents in the Yukon Territory will have difficulty maintaining normal functionality of electric vehicles during the coldest months of the year; however, electric vehicles, particularly plug-in hybrid electric vehicles (PHEVs), are still a viable transportation option. The main hurdle for electric vehicle adoption in the Yukon Territory will be vehicle performance in below freezing temperatures. The range of an electric vehicles can be more than halved in below freezing temperatures, requiring double the electricity to charge these vehicles for daily use (or relying more significantly on plug-in hybridization). Notably, even a halving of the range of many PHEVs on the market today will keep the electric range of the vehicle within the scope of the average Yukon commute. One factor bolstering the potential for electric vehicles in the Yukon Territory is the ubiquitous availability of vehicle charging at homes and business, which is tied to the availability of plug-in engine block heaters.
- ICF developed three electric vehicle penetration scenarios–low, medium, and high–with varying assumptions regarding the growth in total vehicle sales, electric vehicles sales, vehicle offerings (e.g., light trucks), vehicle pricing, and fuel pricing. Generally, ICF finds that there is low to modest potential for electric vehicle adoption in the Yukon Territory, with percent of new sales ranging from 2.6–11.7% by 2035. Limited electric vehicle offerings, notably limited availability of plug-in electric light-duty trucks, is a major hindrance to electric vehicle adoption in the Yukon Territory. About 60% of new vehicle registrations in the Yukon Territory are light-duty trucks; if this pattern of vehicle ownership persists over time, then it will be challenging for the Yukon Territory to increase electric vehicle adoption moving forward.

- On-road gasoline and on-road diesel use accounts for about 50 percent of total Yukon greenhouse gas emissions. Even at low adoption levels, electric vehicles can have a substantive impact on greenhouse gas emissions. ICF estimates that PEVs could reduce greenhouse emissions by about 120–410 MT by 2025 and 650–2,800 MT by 2035. For the sake of comparison, the Government of Yukon reports a total of 638,000 MT of GHG emissions in the territory.
- The forecasted levels of electric vehicles will have only minor grid impacts in the Yukon. ICF's grid impact assessment is based on assumptions regarding vehicle charging levels, vehicle energy consumption, and the rate schedules that consumers might use. ICF assessed the impacts of electric vehicle adoption on peak load assuming that vehicles (PHEVs and battery electric vehicles) charge on a time-of-use (TOU) rate at Level 1 (110 V) or Level 2 (220 V), or on a standard household rate (i.e., non TOU[1]). We find that the maximum peak demand occurs at Level 2 charging on a TOU rate, with a range of 0.1–1.4 MW and 0.6–9.4 MW in 2025 and 2035, respectively, across the three electric vehicle adoption scenarios (low, medium, and high). ICF notes that the peak demand has the same values as peak energy values, simply with units of MWh–our current understanding of how electric vehicles charge does not allow us to make estimates at less than one hour intervals. As a result, we simply assume that the demand (MW) is constant over a one-hour period (yielding energy demand in units of MWh).
- ICF also assessed the potential for impacts on Yukon Energy's distribution assets, by reviewing the potential increased load on Yukon Energy feeders. We looked at the Haines Junction and Dawson 2 feeders, which distribute about 1.8% and 1.3% of the electricity that Yukon generates. Using a fair share assumption (i.e., that electric vehicles are adopted proportionally to electricity consumption), and considering the load associated with the high electric vehicle deployment scenario in 2035 (when there are nearly 1,900 PEVs assumed to be on the road in the Yukon), ICF finds that the additional load from PEVs may have an impact on Yukon's distribution assets assuming that no upgrades occur over the study time period. This is particularly true in the winter months when charging demands are likely to increase.
- ICF also considered the potential for electric vehicle clustering. This is important because more than 75% of the Yukon Territory population is located in Whitehorse. However, most of the distribution assets in Whitehorse are owned and operated by ATCO. In other words, the only way that clustering would have an impact on Yukon Energy's assets is if electric vehicle deployment were concentrated outside of Whitehorse and consistently charged at higher-than-expected levels, which ICF believes is unlikely. ICF and Yukon Energy did reach out to ATCO regarding this study, and were informed that breakers are not the weak points in their distribution system; rather they highlighted that there are a variety of issues associated with managing load and assets in the downtown core (of Whitehorse), with a focus on a planned 25 kv conversion project. ATCO noted that ICF's forecasts for increased load from electric vehicle adoption would change ATCO's annual load increase from about 2.2% per year to 2.24% per year and 2.39% per year in the low and high cases, respectively. ATCO has agreed that the

[1] ICF does not assume an explicit blend of Level 1 and Level 2 charging for the non TOU rate; rather the rate is reflective of the time that vehicles would charge. The power draw associated with this rate implies that it is about a 50-50 blend of Level 1 and Level 2 charging.

magnitude of this potential load increase should be included in their incremental load growth forecasts moving forward.

- Finally, despite the modest potential for electric vehicles in the Yukon, Yukon Energy has the opportunity to establish a leadership position in the market with only minor investment. More specifically, targeted outreach and education to consumers in the near-term future, as interest for electric vehicles increases over the next several years, will be critical. Furthermore, strategic partnerships and engagement with other stakeholders, including ATCO, automobile manufacturers, and local automobile dealerships, can help establish a leadership position in the market. ICF is not seeking to over-state the potential in the Yukon for electric vehicles, but low-investment engagement such as keeping updated on market developments and consumer interest over the next several years could have significant implications in the mid- to long-term future for resource planning.

1 Introduction

The deployment of plug-in electric vehicles (PEVs) has the potential to reduce petroleum consumption and greenhouse gas (GHG) emissions dramatically, and increase energy independence through the utilization of locally produced energy. However, the success of long-term transportation electrification will depend in part on the near-term deployment of vehicles and charging infrastructure. The transition towards higher rates of PEV adoption and the corresponding charging infrastructure requires a broad range of stakeholders to prepare and plan for deployment. Yukon Energy is understandably keen on engaging in this space given the opportunity; however, there are challenges and obstacles, namely the impacts of cold weather on electric vehicle operation that must be considered.

Objective

The objective of this report is to provide Yukon Energy Corporation and partners an assessment of the technical feasibility of PEVs in the Yukon and their potential opportunities and impact to the current grid. The goal of this project is to determine to what extent an active engagement in PEV deployment is a wise investment in the Yukon, and to determine what the associated impacts or opportunities might be in the long term for electrical sales and peak and base loads.

Background on Plug-in Electric Vehicles and Charging Infrastructure

Vehicles

Electricity is used as transportation fuel in three types of vehicles: hybrid electric vehicles (HEV), which are powered by both an internal combustion engine (ICE) and an electric motor; plug-in hybrid electric vehicles (PHEV), which have an ICE and larger battery packs than HEVs and are designed to plug into the electrical grid to charge the vehicle; and battery electric vehicles (BEV), which plug into the electrical grid and are then powered solely by energy from the battery. In the context of this report, vehicles that use electricity from the grid are referred to as plug-in electric vehicles (PEV), a term that includes both PHEVs and BEVs.

The battery technology used in PEVs has been in development for over a decade; however, limitations on stability, energy capacity, energy storage capacity, and the cost of producing the battery have been barriers to widespread deployment in vehicles. Despite the latest advances in rechargeable battery technology, most recently using lithium-ion technology, the energy densities of batteries are still about two orders of magnitude less when compared to common liquid fuels used in ICEs. Prior to 2012, PEVs were limited to niche markets, introduced in demonstration programs, converted by aftermarket companies, or legacy PEVs from the deployment in the 1990s. More recently, the number of vehicle offerings is steadily increasing. For instance, both the Nissan LEAF (a BEV) and the Chevrolet Volt (a PHEV) have been available since early 2011; today, there are more than twenty (20) PEV offerings in the marketplace. However, these vehicles are not available everywhere.

Most PHEVs are designed to provide an all-electric driving range of 16 to 65 km. However, when the battery state of charge falls to a predetermined limit, the system automatically switches to the ICE.

Battery-related costs tend to be lower for PHEVs as compared to BEVs because of the smaller battery size, but this is partially offset by the additional expense of outfitting a vehicle with two powertrains (electric and ICE). PHEVs can have two types of drivetrain architectures, characterized as series or parallel configurations. The series PHEV is designed for electric motor propulsion only, with the ICE acting as a backup generator. Currently, the only series PHEV on the market is the Chevrolet Volt. The parallel PHEV is based on a conventional HEV architecture and has two powertrains, one with the electric motor and one with the ICE. The parallel PHEV is equipped with additional battery capacity and a higher power electric system to extend the electric motor propulsion system range. Parallel PHEV models based on aftermarket conversions of the Prius have been available in the past, but in the near future most original equipment manufacturers (OEM) models are expected to produce parallel PHEVs as well.

BEVs operate solely on an electric powertrain and therefore are equipped with more batteries to extend the operating range. This is a very simple architecture where the battery drives the electric motor to propel the vehicle. This simplified architecture may make BEVs less expensive than the comparable PHEVs in some cases, but given the greater need for electricity, BEVs also typically have a heavier reliance on infrastructure with faster charging times.

PEV Charging

Electric vehicle charging infrastructure (often referred to as electric vehicle supply equipment, EVSE) is typically differentiated by the maximum amount of power provided to a PEV battery. Two primary types of EVSE provide either alternating current (AC) or direct current (DC) electricity to PEVs. Current SAE standards are as follows:

- **Level 1 AC** – These chargers use standard 120 volt (V), single phase service with a three prong electrical outlet at 15-20 amperage (A). Local codes may apply to limit cord and plug connection length. Level 1 charging outlets should have ground fault interrupters installed and a 15 A minimum branch circuit protection. Level 1 charging requires no new electrical service for a building operating on an existing circuit. The main drawback of Level 1 charging is the time required to recharge the PEV. At 15 A and 85% electrical transfer efficiency, the power delivered is 1.4 kW.[2] This leads to longer charging times (ranging from about 4–20 hours, depending on the size of the battery).
- **Level 2 AC** – These chargers are used specifically for PEV charging and are rated at less than or equal to 240 V AC, and less than or equal to 80 A. Level 2 EVSE requires additional grounding, personal protection system features, a no-load make/break interlock connection, and a safety breakaway for the cable and connector. If 240 V service is not already installed at the charging site, a new service drop will be required from the utility. With a 40 A, 240 V service power can be delivered at 7.5 kW which shortens charging time considerably for PEV. These chargers use a standard SAE approved J1772 connector
- **Level 1 & 2 DC** – Level 1 & 2 DC chargers, also known as DC fast chargers, provide power much faster than the AC counterparts. However, DC fast chargers are more expensive to build and operate

[2] For the sake of comparison, most engine block heaters use between 0.4-1.5 kW of power.

due to the equipment and electrical upgrades necessary to operate them. Thus, they are less common than Level 2 AC chargers, and will not likely be used for residential applications. Few PEVs are currently equipped with compatible hardware for DC charging, but certain models such as the Nissan LEAF, Mitsubishi iMiEV, Kia Soul, BMW i3, Volkswagen eGolf, and Tesla do come with "fast charging" as an option. SAE approved (in 2013) the DC charging standard for the Level 1 and 2 DC coupler and connector as part of the J1772 standard.[3] The central component of the standard is the Combo Connector, which maintains the functionality of the previous J1772 connector and introduces two new pins that provide the option of charging via DC. DC charging typically requires a dedicated circuit of 20–100 A, with a 480 V service connection. Power is typically delivered in the range of 50–150 kW.

Charging Times

One of the common questions asked about PEVs is: How long do they take to charge? The simple answer is: It depends. One of the key aspects to understand about PEVs is the battery pack: The battery capacity is the amount of electrical charge a battery can store. Maximum capacity can only be reached; however, under optimal discharge conditions that account for the magnitude of the current, the allowable terminal voltage of the battery, and other external conditions such as temperature. PEV manufacturers have optimized battery packs to provide maximum capacity through devices such as battery thermal management systems. Thermal management systems maintain a constant temperature around the battery pack to prevent potential impacts from extreme hot or cold temperatures.

In addition to temperature, vehicle charging time is heavily dependent on the current type (AC or DC), electric potential difference (V), current (A), maximum power (kW), and the on-board charging capabilities of the vehicle. The most important determination of charging time is generally the charging capabilities of the vehicle. For example, the Chevy Volt and original Nissan LEAF both included a 3.3 kW on-board charger; Nissan has since upgraded to 6.6 kW on-board chargers. The Tesla charging system has a capacity of 10 to 20 kW. Battery capacities vary amongst vehicles, therefore electric vehicle range also varies.

The times needed to replenish a battery halfway and fully for the Toyota Prius Plug-in, Chevy Volt, and Nissan LEAF are shown in Table 1 below. Charging times on Level 1 infrastructure are primarily suitable for small battery vehicles, such as the Volt, which require over 7 hours to fully charge. Estimated charge times using DC fast charging for the Prius Plug-in, Volt and LEAF are included.[4] For DC fast charging, calculations assume the battery is charged to only 80% and the remaining 20% is completed by charging at a slower rate. If left connected at high power, the time to fully charge the battery will increase above an hour due to the nature of direct DC fast charging. Furthermore, some industry observers have voiced

[3] EVs get boost from new SAE standard for dc fast charging, SAE Vehicle Engineering Online. Available online at: http://www.sae.org/mags/sve/11484/

[4] ICF notes that neither the Prius Plug-in nor Chevrolet Volt is equipped with the appropriate charging couplers to charge using a DC fast charger; these values are shown for illustrative purposes only.

concerns about the effects of fast charging on battery life due to potential over-heating and over-voltage; however, Nissan reports that proper cooling and voltage can allay these effects.[5]

Table 1. Estimated charging times using various EVSE (hours:minutes)

Charger Type	Charge	Vehicle		
		Prius	Volt	LEAF
		4.4 kWh (3.5 kWh usable)	16 kWh (12.8 kWh) useable)	24 kWh (21.6 kWh useable)
Level 1 1.4 kW	Half	1:34	3:42	7:42
	Full	3:08	7:25	15:25
Level 2 7.5 kW	Half	0:40	1:34	3:16
	Full	1:20	3:09	6:32
DC Fast 50 kW	Half	0:02	0:06	0:12
	Full	0:05	0:47	1:39
DC Fast 150 kW	Half	0:01	0:02	0:04
	Full	0:02	0:41	1:25

Structure of Report

The remainder of this report includes the following:

- Section 2 provides an overview of how cold weather impacts PEV performance and charging.
- Section 3 includes ICF's market assessment, with a focus on the potential for PEV adoption in the Yukon Territory, as well as our low, medium, and high forecasts for the region out to 2035.
- Section 4 reviews the potential grid impacts of the PEV deployment scenarios, with a focus on Yukon Energy distribution assets.
- Section 5 concludes with recommendations.

2 Electric Vehicle and Charging Impacts in Cold Weather

Plug-in electric vehicles currently make up less than 1% of vehicle sales in Canada, with only seven models currently available.[6] As a reminder, this report uses the term PEV to include BEVs and plug-in PHEVs. A recent survey in Canada however has shown that there is a demand for PHEVs, with more than

[5] Mark Perry, Nissan, EVS26, May 6-9, 2012. Los Angeles, CA.

[6] Axsen, J., S. Goldberg, J. Bailey, G. Kamiya, B. Langman, J. Cairns, M. Wolinetz, and A. Miele (2015). Electrifying Vehicles: Insights from the Canadian Plug-in Electric Vehicle Study. Simon Fraser University, Vancouver, Canada. http://rem-main.rem.sfu.ca/papers/jaxsen/Electrifying_Vehicles_(FINAL)_V2.8_(July10).pdf, (last accessed July 23, 2015)

a third of participants wanting to buy a PEV, mostly PHEVs.[7] In the Yukon Territory however, cold weather performance will be a critical issue to the viability of PEVs.

Limited studies are available for PEVs in the coldest regions of the world, but it is clear that cold temperatures primarily impact the time it takes to use all of the battery energy or recharge a PEV battery. This report outlines specific issues related to impacts on vehicle range, including the impact of auxiliary power consumption and reduced efficiency from cold weather conditions on battery life. Additionally, this report outlines the impact on charging infrastructure (namely, EVSE) to transfer electricity to the vehicle in cold weather conditions.[8]

Cold Weather Impacts on Vehicle Range

Two things happen when a vehicle system is cold: 1) it will lead to an increase in auxiliary power consumption as drivers increase energy demand to heat the passenger cabin and to operate the defogger, and 2) vehicle components will become less efficient from increases in internal friction as an engine or battery gets colder. The greatest impact on range in cold weather usually comes from auxiliary loads, such as cabin heaters and fans and component heaters (i.e., battery heaters). Conventional vehicles use waste heat to help warm the cabin, but because all-electric vehicles do not generate sufficient waste heat, an electric heater must be used. Cabin heating therefore reduces the battery charge and potential range of a PEV. For some PEVs, a pre-heating setting is available to allow the battery and cabin heaters to run while still plugged in, preventing any initial loss in range to heat the vehicle. PHEVs are able to heat the cabin from engine rather than battery thereby minimizing battery efficiency loses at the expense of gasoline. However, like other gasoline engines, these PHEVs will need engine block heater to operate properly in extremely cold climates.

A cold battery also reduces regenerative braking which is used by most PEVs to increase driving range. Vehicles are typically outfitted with an electric heater to warm up the battery, which can draw as much as 6 kW of electricity. Some vehicle manufacturers are beginning to offer more efficient heaters and researchers are looking at methods to improve the insulation and special window coatings to reduce heating demand, but it is unlikely these solutions will be available in the near-term future.

Based on findings of the AAA Automotive Research Center, PEV battery range on a limited number of sample vehicles was reduced by nearly 60% at -7°C (20°F), largely due to the vehicles auxiliary loads.[9] Another report by researchers at Carnegie Mellon University found similar results, which increased the emissions associated with PEVs because of the additional electricity requirements.[10] This may be less of an issue for Yukon Energy customers where 99.6% of power generation in 2014 was from clean

[7] Ibid.

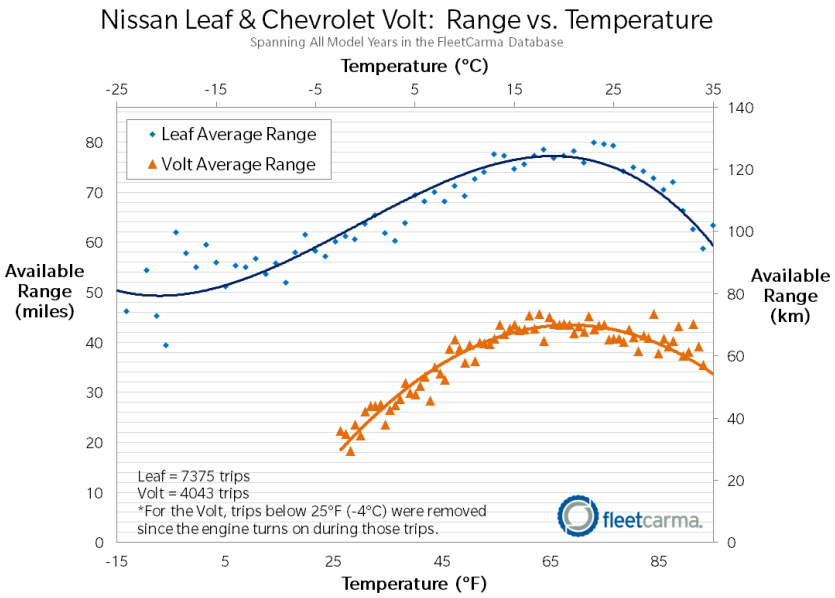
[8] ICF notes that we did not consider the power requirements associated with pre-heating the interior of the vehicle, as we assume that this load is comparable to the load of an engine block heater for conventional vehicles using an internal combustion engine.

9 AAA Automotive Research Center, 2014, http://newsroom.aaa.com/2014/03/extreme-temperatures-affect-electric-vehicle-driving-range-aaa-says/.

[10] Yuksel, T. and Michalek, J., 2015, Effects of Regional Temperature on Electric Vehicle Efficiency, Range, and Emissions in the United States, http://pubs.acs.org/doi/pdf/10.1021/es505621s.

hydropower, unless backup power is required from Yukon's fleet of diesel or natural gas generators (which is discussed in more detail in Section 3). FleetCarma, a vehicle monitoring service for major auto manufacturers, aggregated data from Chevrolet Volt and Nissan Leaf drivers to assess the range impact at temperatures between -25°C (-15°F) and 35°C (100°F).[11]

Figure 1. Electric Vehicle Range vs Temperature



Source: *FleetCarma*

Based on over 11,000 logged trips, driving range was reduced by about half in colder temperatures. At extreme cold temperatures, PHEVs automatically switch back to operating on the internal combustion engine, as noted in the graph that Volts switched to the engine at -4°C. Vehicle range was reduced by driver habits, such as using seat heaters to reduce the need for cabin heat.

PEVs require good battery thermal management to operate in the coldest months. Allowing the battery to be plugged in continuously to Level 1 chargers may help keep the battery warm and will be critical to normal function.[12] PEVs can be adapted to winter road conditions as the battery cells create a lower center of gravity to help vehicles gain traction.

Fleet Case Studies

Calstart: Calstart studied electric trucks in Chicago, with testimony from three fleets and input from custom electric vehicle suppliers: AMP Electric Vehicles, Motiv Power Systems, and Smith Electric

[11] FleetCarma, 2013, 'Electric Vehicle Range for the Nissan Leaf and Chevrolet Volt in Cold Weather,' http://www.fleetcarma.com/nissan-leaf-chevrolet-volt-cold-weather-range-loss-electric-vehicle/. The Chevrolet Volt turns on the gasoline engine intermittently at temperatures below 25°F (-4°C), so trips with ambient temperatures below that threshold were excluded.

[12] Arctic Energy Alliance, 2013, 2013 Electric Vehicle Update http://www.aea.nt.ca/files/download/5500e4297ef91bf,

Vehicles.[13] The average minimum temperature for the study was -21°C, going as low as -27°C, with -12°C the observed threshold that fleets began to notice a difference in vehicle operations. Lithium ion battery vehicles were observed to have a loss of 10-20% charge at temperatures between -10 to 0°C, and a loss of up to 40% charge at temperatures below -20°C. Cabin heating was found to be an additional drain on battery life, lowering the charge another 20-40%. Overall it was found that these specific electric trucks with a 130 km range were reduced to a range of 32 km on days with temperatures below -10°C.

Hydro Québec: Hydro Québec collected data on 30 Mitsubishi i-MiEV BEVs in both Europe and near Montreal for 3 years from 2010–2013.[14] Twenty-seven companies and organizations took part in the initiative, which involved 31 users for a total of 650 vehicle-months and 740,000 km driven. A compact four-seater, the i-MiEV has a range of 120 km, with a 16 kWh lithium-ion battery. It takes about six hours to charge at Level 2 (240 V) or 12 to 21 hours at Level 1 (120 V). Every car in the project was equipped with on-board instruments to register energy consumption (charging pattern) and the effect of temperature on charging and users' charging habits. An observed loss of range of 13 km when temperatures were between 0°C and 10°C due to heating the interior of the vehicle. The range of the BEV used depends heavily on the ambient temperature and loss of range increased to 40% in below freezing conditions. Car heating has more of an effect (13 km less when the temperature is between 10°C and 20°C) than air-conditioning (5 km less when the temperature is above 20°C).

Manitoba Hydro: Manitoba Hydro added Hymotion lithium ion battery packs to 10 existing Toyota Prius Hybrids in 2008, allowing the vehicles to plug-in to charge, converting the traditional hybrid vehicles to PHEVs[15] Manitoba Hydro then monitored the vehicle for 3 years in the Winnipeg area. Driving 233,000 km over the course of the study, noting on average an additional 10% savings to fuel economy over the traditional Prius. Electricity use in the winter was not closely monitored, however vehicles were noted to have a significant range drop and required some modifications to the vehicles to enhance performance. The original 12V Prius batteries had to be replaced with newer and more efficient 12V battery and then were trickle charged whenever the vehicles were plugged in. Tests were run with engine blankets and electric in-car warmers, which both proved effective at reducing range issues associated with heating the interior.

Manitoba Hydro, in collaboration with the Province of Manitoba, Mitsubishi Heavy Industries, New Flyer Industries, Winnipeg Transit and Red River College, operate an all-electric bus on a daily, 20 km route[16]. The route runs a loop from the Winnipeg Richardson International Airport where it charges whiles waiting at the stop. Chargers are roof mounted and replace two operational hours of charge in approximately 10 minutes. The electric bus was originally a demonstration project used as a shuttle for

Manitoba Hydro beginning in March 2014[17], and was so successful that the airport route was added in November 2014. Manitoba Transit has installed additional chargers in their fleet yard in anticipation of future electric vehicle additions.

Province of Manitoba: The Province of Manitoba signed an MOU with Mitsubishi in 2011 to test two Mitsubishi i-MiEV BEVs for two years[18]. Winter testing included driving in temperatures as low as -29°C, the lowest (public) recorded driving temperature of an electric vehicle within Manitoba. Tests included driving vehicles to battery depletion in temperatures ranging from -15°C to -29°C, where it was discovered that all interior heating had to be redirected to the defogger to maintain an unfrozen windshield. When operating in these negative temperatures, the average ranges of the iMiEVs was discovered to drop to 40-50 km, less than half of the average range of 110-120 km.

Lessons Learned from Vehicle Testing

Electric vehicle manufacturers have been unable to share externally many of their cold weather testing results. This is due in a large part to the current research and development happening to improve cold weather vehicle operations and increase vehicle efficiencies. Current research for many manufacturers revolves around thermal management systems, specifically whether air-cooled or liquid-cooled batteries can produce the best performance in weather extremes. Improvements for alternative heating packages are being explored as well, such as Tesla's "cold weather package" which provides additional seat warmers, windshield fluid heaters, and modified intake grills.

Kia added new heating technologies to the 2015 all-electric Kia Soul, including a new heat pump, air intake controller, driver-side only heating options, and technology to pre-heat the vehicle while charging[19]. Kia tested these PEVs in the Arctic Circle, successfully operating the Soul in -40°C temperatures, including letting the PEVs become cold soaked by sitting in sub-zero temperatures for over 8 hours.

Battery testing is a major component to ongoing research and development of electric vehicles, as this is a constantly evolving technology. New battery materials and configurations are being tested, in efforts to find a longer-lasting battery that can handle cold weather and still be affordable.

Arctic Energy Alliance: The Arctic Energy Alliance began testing a Chevrolet Volt in January 2015.[20] Housed primarily in Yellowknife, the PHEV is being used throughout the Northwest Territories. To date, the electric range has been more than sufficient to accommodate the Yellowknife daily commute of 6.3 km, however while the average summer range has been approximately 67 km, the winter range was

[17] Manitoba Hydro, Electric Vehicles, https://www.hydro.mb.ca/environment/electric_vehicles.shtml (last accessed August 12, 2015)

[20] Arctic Energy Alliance, 2015, Electric Vehicle, http://aea.nt.ca/research/electric-vehicle

only 35 km.[21] This information is not entirely accurate for temperatures at or below -10°C, for at this temperature the internal combustion engine automatically turns on.

Arctic Energy Alliance has also noted a handful of traditional hybrid vehicles (non-plugins) in the Northwest Territories. A Hay River resident will soon have what they believe is the first Tesla in the Territory.

Home conversions: The first PEVs deployed in the Yukon Territory were conversions, as opposed to vehicles that come directly from the manufacturer[22]. The Government of Yukon has sponsored a course at Yukon College and at a local high school to convert vehicles to run off electricity. Currently there are at least three home-conversions in the Dawson area, and at least two in Whitehorse. Home conversions however do not have many of the auxiliary heating options that factory ready PEVs have, so typically are not able to be driven during the winter months.

Quantum Machine Works: In March 2014, Quantum Machine Works of Whitehorse purchased a Ford Focus PEV for the company use[23]. Purchased from a dealership in Vancouver, the PEV has worked great for the company in temperatures as low as -28°C. While the average warm weather vehicle range has been 100 km, in the winter the range drops to approximately 60 km. The PEV typically used for short trips by several employees, and is constantly connected to a charger when not in use. Quantum has had several other companies ask about the vehicle and has offered to loan it out for test drives.

Cold Weather Impacts on Vehicle Charging Time

Most electric vehicle chargers manufactured for residential and commercial use are suitable for outdoor use, although some perform better in extreme cold weather conditions. The operation of all equipment can be impacted when covered in snow or ice, particularly the charging cable, which could be encased if lying on the ground or coiled. If equipment must be outside, retractable charging cables or protecting the equipment with some form of shelter is preferable. Further, when siting charging equipment outside, considerations should be made for snow plow operations. Installing bollards, curbs, or wheel stops could help minimize equipment damage. Sub-surface heating of the charging space is another option, including hydronic (small tubes under the pavement circulating heated water and anti-freeze) and electric radiant (low-voltage mats under the pavement heated by electricity) heating.[24]

Chargers, also known as electric vehicle supply equipment, are available in a variety of charging levels. As noted previously, chargers are currently divided into Level 1, Level 2 and DC Fast Charging categories.[25]

Table 2. Electric Vehicle Supply Equipment Categories

	Level 1 Charging	Level 2 Charging	DC Fast Charging
Electrical Circuit	120V AC	208V or 240V AC	480V AC
Equipment Needed	None- Standard Outlet used for Block Heaters	Home or public charging equipment	Designated DC Fast chargers and charge receptacles on vehicles.
Charging Rate (Kilometres Per Charging Hour) [26]	3-8 km	16-32 km	80-113 km in 20 minutes

In addition to the physical impacts of extreme cold weather, some types of electric vehicle chargers have difficulty transferring electricity to the vehicle. As discussed below, case studies and lessons learned from charging equipment manufacturers may mitigate potential impacts.

Charging Case Studies

Hydro-Quebec: Between 2010 and 2013, Hydro-Quebec operated an electric vehicle pilot project to understand a number of issues, including how the ambient temperature impacted PEV charging.[27] The initiative included nine Level 1 workplace chargers, 47 Level 2 chargers (27 residential and 20 workplace), and one DC fast charger. The researchers found that the Level 2 charging time was not affected by the ambient temperature and was the same year-round. However, researchers noted the DC fast charger took considerably longer than the standard 30 minutes to charge a vehicle to 80% capacity in colder conditions. The extended charge length is related to the battery pack's internal resistance (in addition to temperature, calculated based on battery size, chemical properties, age, and discharge current), which will be higher during extreme cold conditions.[28] Numerous batteries are being tested and developed to determine which batteries are best for PEVs and PHEVs for the life of the vehicle.

Airport Cooperative Research Program (ACRP): According to researchers contracted by ACRP, PEV charging stations are not typically affected by extreme cold. Researchers advised that cold weather airports consider installing Level 1 charging stations in long-term facilities so that batteries could charge slowly and be kept warm, replacing any parasitic loss that would occur while the batteries are not in use.[29]

North Sea Region Electric Mobility Network: Researchers in Gothenburg, Sweden evaluated a pilot project with CHAdeMO fast chargers located around the city.[30] In an environment that frequently reaches extreme low temperatures, users reported a variety of charging impacts. If the battery

temperature was less than 10°C (50°F), it was difficult to charge beyond 20% capacity with the fast charger. Further, the charging cables felt 'like a pipe' in cold temperatures and there was often a problem returning the plug to the base after charging. Finally, the display was difficult to read in cold weather. These charging issues apply only to the fast chargers used in this study.

Engine Block Heater Outlets as Electric Vehicle Chargers

Helping to offset the loss of charge from cold weather is the widespread availability of Level 1 charging in the Yukon. Engine block heaters require similar electricity load and connections as Level 1 PEV charging (including a weatherized 120V outlet); ICF reviewed several block heater specifications available from retailers online and found a power draw in the range of 0.4-1.5 kW. As these connections are pre-existing across businesses and home in the Yukon, Level 1 charging is possible for almost all drivers.

Awareness of using these outlets as PEV chargers however is not widespread. Current PEV drivers in the Yukon indicated that they utilize these outlets daily, however never would have considered them for PEV use before they researched PEV charging.[31,32] Business owners currently offer these outlets as a necessity in winter, not expecting to have the same electricity demand the remainder of the year, so year round usage may require corporate policy changes.

Lessons learned from EVSE Manufacturer Testing

Certain types of DC fast charging equipment are unable to function properly in extreme cold. For example, Eaton DC fast charger screens were switched out to prevent fade-out in cold weather and some ChargePoint networking capabilities have reportedly gone down in extreme cold weather and need to be rebooted.[33] Some DC fast charger manufacturers, such as AeroVironment, have created a cold weather package option that testing has shown can accommodate temperatures as low as -30°C (-22°F).[34]

Summary of Findings

ICF's literature review indicates that residents in the Yukon Territory will have difficulty maintaining normal functionality of electric vehicles during the coldest months of the year; however, electric vehicles, particularly PHEVs, are still a viable transportation option. The hurdle for market penetration will be that the PEV range in below freezing temperatures will be less than half of the average vehicle range. This may require more electricity to charge these vehicles, consumers making sure that there vehicle has sufficient range (including the battery and a combustion engine, as with the PHEV), or behavioral change. For daily use in cold winter months, however, the reduced electric vehicle range may still be within the scope of the average Yukon commute, an average of 15 minutes for the

Whitehorse area and 15.7 minutes for the entire Yukon Territory (based on 2011 Census data)[35] or 4.1 km for Whitehorse and 3.9 km for the entire Yukon Territory (based on the 2006 Census data).[36] Dealerships in Yukon are not currently selling PEVs, requiring vehicles to be ordered online or from southern provinces. Training is needed for Yukon dealerships and mechanics on how to service these vehicles.

Unique to the Yukon market however is the vast abundance of Level 1 charging at homes and businesses, due to the readily available charging for engine block heaters. Awareness campaigns to educate the public and businesses that these can be used as chargers may increase the demand for electric vehicles. The Government of Yukon has indicated that they could easily promote electric vehicle charging, particularly as this additional electricity demand in warmer months would help even out the demand cycle.

Like conventional vehicles, precautions will need to be taken to allow the vehicles to start and function normally, including keeping the vehicles in garages and using good battery thermal management systems. Allowing the battery to remain plugged in to even a Level 1 charger will keep the battery warm and will be critical to normal function.[37] Further, drivers may want to consider alternative options to increase the cabin temperature, such as the use of seat heaters. By pre-starting these vehicles while attached to a charger, drivers can allow the vehicle cabin to warm and the windshield to defog before operating the vehicle on a reduced range; ICF estimates that this pre-heating will have the same or similar energy consumption as engine block heaters currently in use.

Additional precautions will also need to be exercised when installing and maintaining charging infrastructure, including public and workplace chargers that may be exposed to the elements.

3 Plug-in Electric Vehicle Market Assessment

Plug-in Electric Vehicle Forecasting in Yukon Territory

Consumers' willingness to pay for new technology, as well as the extent to which they value their convenience will play a large role in PEV deployment. Consumer surveys in the US indicate the manufacturer's suggested retail price (MSRP) of a PEV is a critical factor, with nearly 70% of survey respondents claiming it is the most important factor in deciding their purchase.[38] Furthermore, consumers expect PEVs to be cost-competitive with similar internal combustion engine (ICE) vehicle models, with a majority desiring a sticker price under $30,000.[39] While consumers do acknowledge the higher cost of PEVs and are willing to pay more, the price differential between a PEV and a conventional vehicle or even an HEV remains too high to induce larger volumes of vehicle sales.

Consumers' expectations regarding price, range, and charging time are in many cases not met by PEVs available today.[40] These barriers make converting potential consumers into actual purchasers a significant challenge. As discussed previously, vehicle price is the primary barrier to widespread PEV adoption in the near-term. Even with incentives, the initial costs of PEVs generally remain higher than HEVs and ICE vehicles.

To develop forecasts for Yukon Territory, ICF considered the parameters identified in the table below. The subsequent subsections discuss these parameters in more detail. ICF notes that we typically rely on hybrid electric vehicle (HEV) ownership data as a good indicator of the potential for PEV adoption. The premise of the relationship between HEV ownership and PEV adoption is that households that value non-economic benefits are more likely to purchase PEVs, and HEV owners show a willingness to pay to reduce gasoline use that goes beyond the economic benefits of using an HEV. While we were able to obtain vehicle registration counts from the Government of Yukon, they did not include HEV registration data. Despite this limitation in our forecasts, the parameters in the table below do provide good indicators for PEV adoption.

Table 3. Parameters Influencing PEV Adoption

Parameter	Description
Income	Studies have found that consumers of electric vehicles typically earn more than the average household
Commuting Patterns	Drivers consider many factors when purchasing vehicles; their daily work commuting is a significant factor. Interestingly, Yukon residents on average have a significantly shorter commuting distance than other parts of Canada
Access to Charging	Households that own their property are more likely to adopt a PEV than those who rent, according to market research by various analysts. Further, access to charging at workplaces can be a significant driver for growth.
Vehicles & Fuel Pricing	Vehicle population, population and economic growth, and vehicle turnover provide boundary conditions for the volume of and the rate at which PEVs can be deployed. Whereas fuel prices (gasoline and diesel) can impact consumer decision-making,

Income and Demographics

Key takeaways for Yukon Territory:

- The annual median income is relatively high compared to other provinces
- A large proportion of Yukon residents are within the age range of typical PEV consumers

Studies have found that consumers of electric vehicles typically earn more than the average household, with current PEV owners in Canada earning an annual income greater than $90,000.[41,42,43,44] Yukon residents may demonstrate greater rates of PEV adoption compared to other regions due to their higher than average median income. For the past five years, for instance, the annual median family income for a Yukon family is relatively high compared to other provinces and territories in Canada, with a median income of $95,360 per family in 2013, the third highest in the country (see Figure 2).

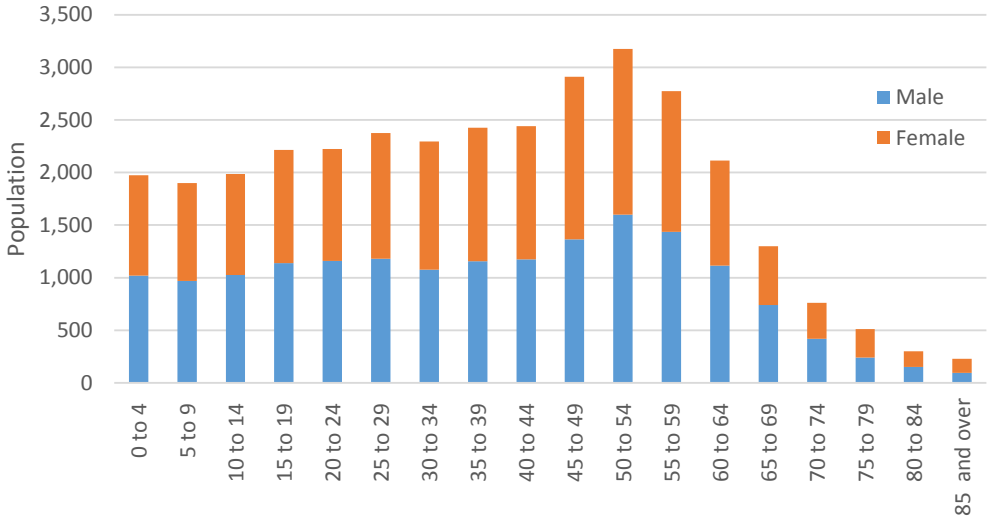
Source: StatsCanada

The previously referenced studies also found the majority of PEV consumers to be between the ages of between 35 and 54, with an average age of 46 years old. The demographics of Yukon residents support increased PEV adoption potential due to the high number of residents within the age category of PEV consumers[45], as shown in Figure 3.

[45] Statistics Canada, (2011). Focus on Geography Series, 2011 Census. Available at: http://www12.statcan.gc.ca/census-recensement/2011/as-sa/fogs-spg/Facts-pr-eng.cfm?Lang=Eng&GC=60.

Figure 3. Yukon - Population by five-year age groups and sex.



Source: 2011 Census Data, StatsCanada

Population and Commuting Patterns

Key takeaways for Yukon Territory:

- The majority of residents live in urban areas
- There are a significant number of daily commuters
- Commuter trip length is less than the range of PEVs in cold climates

Several factors related to commuting patterns of residents result in the potential for increased adoption rates of PEVs in the Yukon. While the population density overall is very low, at 0.1 persons per square kilometre, the majority of residents in the Yukon live in metropolitan or agglomeration areas (CMA/CA) (77%; 26,028 persons), with 69% of the population within the capital city of Whitehorse itself.[46] Of these residents, there are a significant number of daily commuters, with 75% of Whitehorse residents driving a vehicle to work (see Table 4).

[46] Statistics Canada (2011). Focus on Geography Series, 2011 Census. Available at: http://www12.statcan.gc.ca/census-recensement/2011/as-sa/fogs-spg/Facts-pr-eng.cfm?Lang=Eng&GC=60.

Table 4. Yukon mode of transportation to work

Commute Mode	Percent
Car, truck, van as driver	75%
Car, truck, van as passenger	8%
Public transit	5%
Walk to work	7%
Bicycle	3%
Other (motorcycles, taxi, etc.)	2%
Source: Government of Yukon (2011 Canadian Census)	

As discussed previously in Section 2, the Yukon's cold climate impacts charging abilities and driving range of PEVs, reducing the range of PEVs up to approximately 60%. Considering this reduced driving range, the average commuter trip length is still comparable to the expected PEV range. For instance, a survey conducted by the City of Whitehorse in 2000 indicated that most commuters drive less than 10 km one-way to work (Table 5).[47] The City of Whitehorse's Transportation Demand Management Plan Employee Survey,[48] which surveyed 207 employees from Yukon Government, Yukon Energy and City of Whitehorse, validates the 2000 report numbers referenced above. Compared to Canadians, Yukon residents on average have a significantly shorter commuting distance, with a median distance of 3.9 km for Yukon residents versus 7.6 km for Canadians (Figure 4).

[47] Public Service Commission, City of Whitehorse (2000). "How Do You Get to Work" A Transportation Survey of Whitehorse Area Employees: Technical Report. Available at: http://www.whitehorse.ca/home/showdocument?id=1602.

[48] Whitehorse Transportation Demand Management Plan, City of Whitehorse, YT, March 2015. Available online at http://www.whitehorse.ca/home/showdocument?id=4250

Taking into consideration the fact that many people (43%) use their vehicle at lunch time, increasing the daily range requirements, the daily commute of most residents remains below the typical range of PEVs in cold climates.

Table 5. Home to Work Commuting in Whitehorse, 2002

Responses to transport survey question: "Approximately how many kilometres is it from your home directly to work (one-way)?"		
Distance	No. of Responses	Percent of Responses
< 5 km	639	29.5%
5–10 km	618	28.5%
10–25 km	672	31.0%
> 25 km	239	11.1%
Total	**2,168**	**100%**

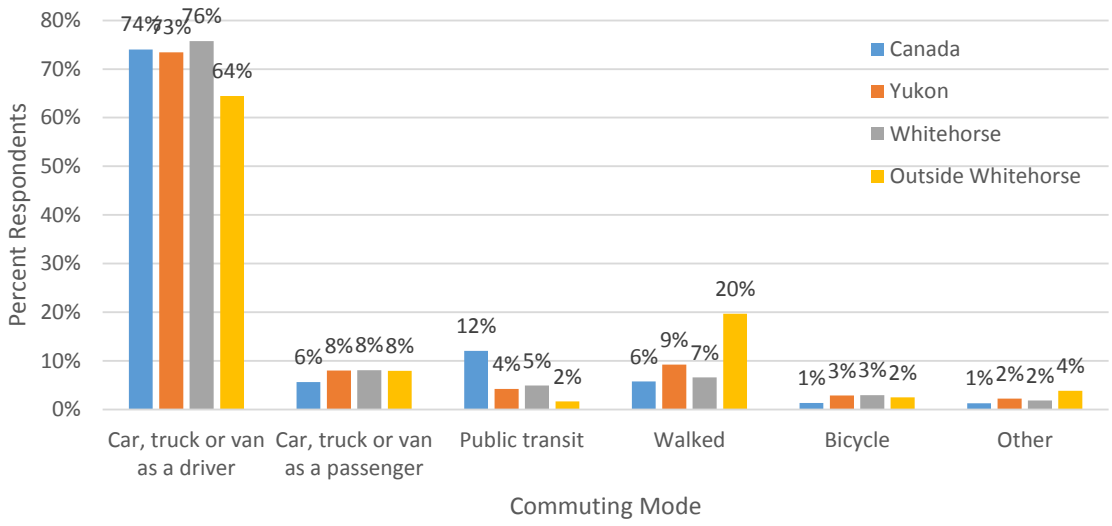
Figure 4. Commuting Modes in Canada, Yukon, Whitehorse, and Outside Whitehorse



Source: 2011 Canadian Census

Access to Charging Stations

Key takeaway for Yukon Territory:

- Access to suitable areas for home charging
- Access to suitable charging infrastructure at work

As colder temperatures increase the time needed to charge PEV batteries, access to charging infrastructure is an important factor to consider. The majority of Yukon residents live in houses[49] (75.9%) versus apartments (23.9%) (compared to 65.8% and 34.3% of Canadians, respectively).[50] These dwelling types are more likely to have access to a garage, providing an area protected from the elements, thereby reducing the charging time required.

Access to suitable charging infrastructure is also available to residents at work. According to the City of Whitehorse survey[51], 72.3% of commuters have plug-ins available at work parking areas and for those that do not have access to plug-ins, 20.1% already start their car periodically throughout the day. The remaining portion either do not bring their vehicles to work on very cold days, have a command start or have access to parking in a heated garage.

Vehicles and Fuel Prices

Key takeaways for Yukon Territory:

- Vehicle registration in the Yukon is steadily increasing annually; however, vehicle purchasing patterns indicate a preference for light-duty trucks, for which there are few PEV offerings today.
- Gas and diesel prices are on average higher in Yukon Territory (although prices in Whitehorse are sometimes comparable to lower mainland prices), resulting in higher fuel cost savings with the purchase of a PEV.

Increased forecast adoption of electric vehicles can also be supported by evidence of increasing vehicle registration in the Yukon, as electric vehicles are a portion of these increasing registrations. Vehicle registration in the territory has steadily increased annually at an average rate of 3% since 2001 (see Figure 5).[52] Most vehicles registered are classified as *vehicles up to 4.5 tonnes* (passenger vehicles and light-duty trucks).

[49] Houses include single-detached houses, semi-detached houses and row houses. Apartments include apartment buildings, duplexes and other movable dwellings.

[50] Statistics Canada (2011). Focus on Geography Series, 2011 Census. Available at: http://www12.statcan.gc.ca/census-recensement/2011/as-sa/fogs-spg/Facts-pr-eng.cfm?Lang=Eng&GC=60.

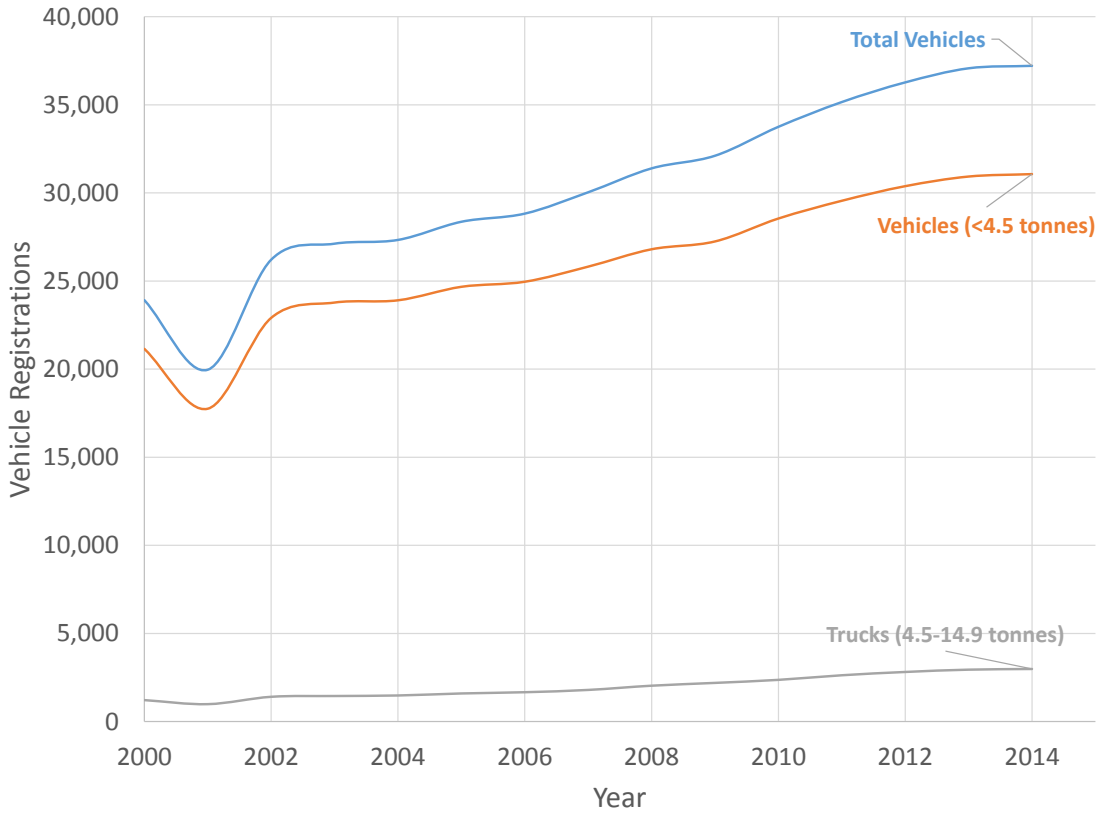
Figure 5. Vehicles registered in the Yukon, 2000–2014[53]



Source: Statistics Canada (2015)

Gasoline and diesel prices also play a significant role in adoption rates of electric vehicles.[54] Conventional fuel prices are high in the Yukon, with the price of diesel and gasoline steadily increasing from 1999–2012 (Figure 6).[55] The higher fuel cost savings for PEV consumers in the Yukon results in increased adoption potential within the territory.

PEV Forecasts for Yukon Territory

ICF estimates about 3,000 vehicles sold in Yukon Territory in 2014; showing average increase of about 5-6% (year-over-year) for the last 7 years.[56] Data from the Motor Vehicles Section of the Government of Yukon indicate that about 39% of registered light-duty vehicles since 2009 are passenger cars.[57] Statistics Canada only reports data for "British Columbia and the Territories", and does not report new vehicle sales for the Yukon Territory; however, the aggregated data for British Columbia and the Territories indicate that over the same time period for which we have total vehicle registration data (2009-2014), 41% of new light-duty vehicle sales were passenger cars. Further, for comparative purposes, we note that the country-wide average is about 43% of new light-duty vehicle purchases are passenger cars and 57% are light trucks. This vehicle split limits the potential of PEVs in the near-term future because there are limited offerings available today in the cross-over segments and light trucks.

[56] Based on ICF analysis of vehicle sales, registered vehicle data, and population (via Statistics Canada).

[57] Vehicle registration data also includes heavy-duty trucks, buses, and other vehicles; however, for the purposes of this analysis, we only considered vehicles less than 4,500 kg.

To estimate sales growth moving forward, ICF used a combination of forecasted demand for vehicle kilometres traveled, population growth, and economic growth. ICF assumes a year-over-year increase in new vehicle sales of 1.0% for 2015-2035. [58] For vehicle-kilometres traveled (VKT), ICF reviewed the most recently available data from the Canadian Vehicle Survey, which reports average VKT growth for all of Canada at 2.5% for the period from 2000-2009.[59] However, in Canada's Energy Future 2013, the National Energy Board reports an assumed growth of 1.0% in VKT. ICF notes that VKT is a good proxy for forecasting, and more reliable than fuel consumption, for instance, because it is largely unaffected by vehicle efficiency/fuel economy.

Growth rates for electric vehicles are derived from hybrid electric vehicle adoption in multiple jurisdictions, modified for local factors such as income and demographics, and commuting patterns. Generally we forecast exponential growth in the first 5-9 years of electric vehicle adoption, with that growth tailing off into a linear function by year 10. That linear growth is not a constant over time; rather, it increases with vehicle price reductions in the years 10-15, and decreases thereafter.

ICF developed three penetration scenarios out to 2035:

- **Low**: Assumed low levels of PHEVs deployed in light-duty passenger vehicles; no penetration in light-duty trucks. PEVs represent about 3% of new passenger car sales in 2025 in this scenario, increasing to 6.7% of new passenger car sales in 2035. ICF opted not to include light-duty trucks because there is significant uncertainty around automobile manufacturers' willingness to transition their electrification plans to their light trucks. Generally, ICF assumes that OEMs will meet fuel economy and GHG standards by focusing on a combination of fuel efficiency improvements and electrification for conventional light-duty passenger cars; whereas, OEMs will focus almost exclusively on fuel efficiency improvements (e.g., via light weighting and powertrain improvements) for light-duty trucks.[60]
- **Medium**: Assumed modest levels of PHEVs deployed in passenger vehicles with low levels of adoption in light-duty trucks. PEVs represent about 7% of new passenger car sales in 2025 and 18% in 2035. PEVs represent about 2.7% of new light truck sales in 2025 and 6.7% in 2035.
- **High**: Assumed more aggressive levels of PHEVs deployed in passenger vehicles; some penetration in light-duty trucks. In this scenario, ICF assumes that OEMs take a more aggressive approach towards meeting existing regulations via the deployment of plug-in hybrid and battery electric trucks. PEVs represent about 7.8% of new passenger car sales and 5.5% of new light-truck sales in 2025, increasing to 23.2% and 13.4% in 2035.

[58] ICF notes that the variations in our forecasts are all linked to the same VKT and sales growth forecasts, which are linked to other forecasts of population and economic growth. This growth is held constant across each EV deployment scenario developed; the variation arises from parameters such as vehicle availability and vehicle pricing.

[59] Natural Resources Canada, Canadian Vehicle Survey, 2009. Available online at http://oee.nrcan.gc.ca/publications/statistics/cvs09/pdf/cvs09.pdf

[60] The U.S. Energy Information Administration's Reference Case in the Annual Energy Outlook 2015, for instance, forecasts an average ratio of nearly 60-to-1 for electrified powertrains (including PHEVs and BEVs) in cars versus trucks through 2040. Over the same time period, the fuel efficiency of light trucks is forecasted to improve at a comparable rate to passenger vehicles.

ICF assumed a 50-50 split of PHEVs between the PHEV32 and PHEV64 vehicle categories in each deployment scenario. Figure 7 below show the cumulative PEVs in each scenario and Table 6 below includes the total number of EV passenger cars and light-trucks deployed in each scenario, as well as the share of electric vehicles of the total on-road vehicle fleet in the Yukon from 2015–2035.

Figure 7. PEV Forecasts for Yukon Territory in Low, Medium, and High Scenarios, 2015-2035

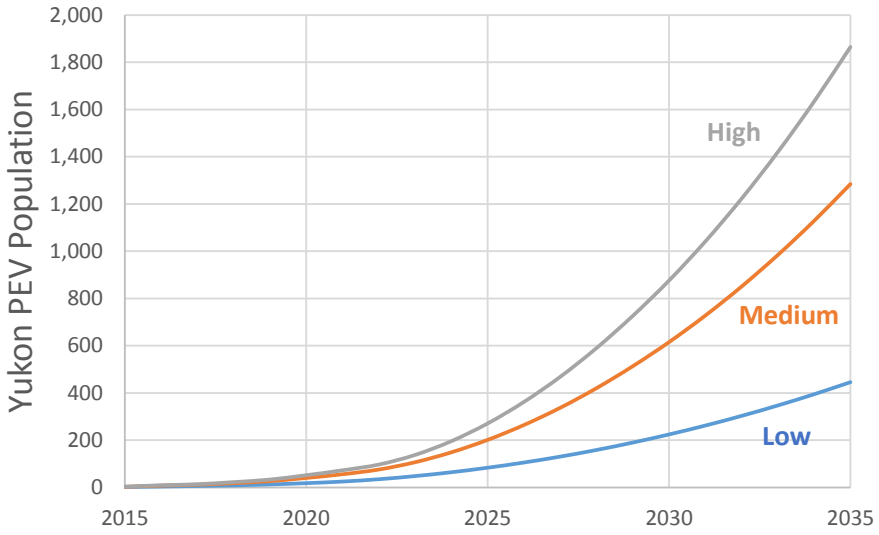

Table 6. PEV Deployment in Yukon Territory (Percent of Total On-Road Vehicles)

Deployment Scenario	Vehicle Type	2015	2020	2025	2030	2035
Low	Passenger Cars	2	18	83	224	445
	%Total Vehicles	0.0%	0.0%	0.2%	0.5%	1.1%
Medium	Passenger Cars	2	34	175	544	1,144
	Light Trucks	1	6	26	71	140
	%Total Vehicles	0.0%	0.1%	0.5%	1.5%	3.0%
High	Passenger Cars	1	33	183	640	1,397
	Light Trucks	2	19	87	235	467
	%Total Vehicles	0.0%	0.1%	0.7%	2.1%	4.4%
	Total Vehicles	37,736	38,556	39,602	40,833	42,214

Greenhouse Gas Impacts of Plug-in Electric Vehicles

PEV have zero tailpipe GHG emissions; however, there are upstream emissions attributable to electricity generation that must be accounted for to conduct a proper GHG reduction analysis. In the case of the Yukon Territory, even the upstream emission factors are small because such a large share of the generation profile comes from renewable resources, predominately hydropower. The emission factors

for transportation fuels are reported on a lifecycle or well-to-wheels basis and are reported as grams of carbon dioxide equivalents per unit of energy (g CO_2eq/MJ) – also referred to as carbon intensity. ICF used emission factors from GHGenius, as shown in Table 7 below.

Table 7. GHG Emissions for Electricity and Gasoline

Fuel	Carbon intensity (gCO_2eq/MJ)
Electricity*	8.24 g/MJ
Gasoline	87.29 g/MJ
*Assumes 3% of power generated is from diesel generators	

The GHG emission reductions are reported as the difference between a light-duty internal combustion engine vehicle using gasoline and a PEV using electricity (and gasoline for PHEVs). The carbon intensity of electricity reported in the table above does not account for the fact that electricity used to power a motor is more energy efficient than gasoline. As a result, one must apply a factor referred to as the energy economy ratio (EER). For electricity, the value is 3.4; in other words, after accounting for the EER of electric vehicles, the effective carbon intensity of electricity is 2.42 gCO_2eq/MJ.

GHG Emission Reductions

The equations below shows how the various parameters outlined previously are combined into calculations to yield the GHG emission reductions attributable to vehicles using gasoline and electricity, or a combination thereof.

$$GHG_{gasoline} = PEVs * \left(\frac{VMT}{mpg}\right) * \delta_{gasoline} * CI_{gasoline},$$

where $\delta_{gasoline}$ is the energy density of gasoline, 34.69 MJ/L, and $CI_{gasoline}$ is the carbon intensity of gasoline.

$$GHG_{PHEV} = PHEVs * \left[\left(\frac{(1-eVMT)}{mpg}\right) * \delta_{gasoline} * \frac{CI_{gasoline}}{EER_{Fuel}} + \frac{eVMT}{mpg} * \delta_{gasoline} * CI_{electricity}/ EER_{electricity}\right]$$

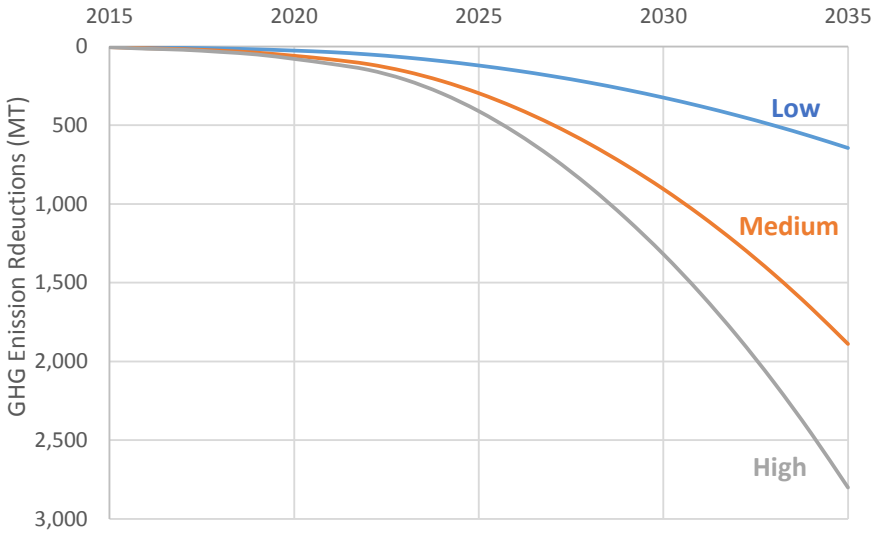
$$GHG_{BEV} = BEVs * \left(\frac{VMT}{mpg}\right) * \delta_{gasoline} * CI_{electricity}/EER_{electricity}$$

$$GHG\ Emission\ Reductions = \Delta\left(GHG_{gasoline}, GHG_{PHEV} + GHG_{BEV}\right), \text{ where}$$

$$PEVs = PHEVs + BEVs.$$

Figure 8 below shows annual reductions as metric tons for each of the PEV deployment scenarios developed previously.

Figure 8. GHG Emission Reductions from PEV Forecasts



ICF estimates that PEVs could reduce GHG emissions by about 120–410 MT by 2025 and 650–2,800 MT by 2035. For the sake of reference, the Yukon Transportation Sector GHG emissions report[61] on-road diesel and on-road gasoline accounted for 274,000 MT CO2e in 2012, representing about 50% of total GHG emissions for the Yukon Territory (638,000 MT CO2e). These GHG reduction estimates account for the cold weather performance of plug-in electric vehicles and assume that the range of PHEVs is halved in the winter months (e.g., from 64 km to 32 km) and that there is twice as much electricity consumed in battery electric vehicles–in other words, we do not assume that drivers travel fewer kilometres, rather that they need to charge their vehicles more. Table 8 below shows the estimated emissions performance of conventional vehicles running on gasoline compared to PHEVs and BEVs in standard operating (or summer) conditions and in cold weather (or winter). The values are shown for new vehicles purchased in the year indicated, and do not represent the fleet average vehicle performance.

[61] Yukon Greenhouse Gas Emissions: The transportation sector, Updated Report 2015. Available online at http://www.env.gov.yk.ca/publications-maps/documents/Yukon_Transportation_Sector_GHG_Emissions_Final_Updated_Report_March_2015.pdf

Table 8. GHG Emissions Rates (gCO2e/km) for various vehicle types and different operating conditions

Conditions	Year	Conventional ICE		PHEV32		PHEV64		BEV	
		Car	Light Truck	Car	Light Truck	Car	Light Truck	Car	Light Truck
Standard Operation / Summer	2015	218	277	118	161	19	35	6	9
	2020	166	239	91	139	16	28	6	9
	2025	127	182	70	107	13	22	6	9
	2030	127	182	70	107	13	22	6	9
	2035	127	182	70	107	13	22	6	9
Cold Weather Operation / Winter	2015	240-273	305-346	186-211	243-275	130-147	139-157	13	18
	2020	183-208	263-299	143-162	210-238	100-113	106-121	13	18
	2025	140-159	200-227	110-125	161-182	77-87	82-93	13	18
	2030	140-159	200-227	110-125	161-182	77-87	82-93	13	18
	2035	140-159	200-228	110-125	161-182	77-87	82-93	13	18

The emissions rates for cold weather are reported as a range to account for impacts to both conventional vehicles and electric vehicles. For instance, the Natural Resources Canada reports a 12–28% increase in fuel consumption (per US EPA estimates) in urban commutes, increased highway fuel consumption as a result of increased aerodynamic resistance, increased resistance from poor road conditions, and the energy density of winter gasoline formulations.[62] For illustrative purposes, we use an estimated increase in emissions linked to increased fuel consumption of 10–25% for conventional vehicles. The GHG emission rates for PHEVs are linked to the share of kilometres traveled using electricity or gasoline, and the range of estimates for cold weather operation reflects the range of estimates for when the vehicle is operating using its combustion engine. ICF also notes that the emission rates plateau in improvement in 2025 and are constant thereafter, reflecting Environment Canada's regulations related to vehicular GHG emissions, proposed in 2012 and adopted in 2014.[63]

4 Grid Impacts of PEVs

One of the key concerns about PEVs is the potential impact to the electric grid. If vehicle charging occurs coincident with peak demands, increased loads will drive a need for new investment in generation, transmission and distribution capacity. If charging can be managed to occur primarily in off-peak periods, much of the load will potentially be served with existing infrastructure such that impacts on the electric grid will be significantly reduced and there will be a potential for significant grid benefits, such as deferred or avoided investments in generation, transmission, and distribution capacity. Furthermore, PEVs have the potential to help level load and support higher penetration of renewable generation on the grid by using the vehicles' batteries for storage.

In the following subsections, ICF outlines our approach to analyzing the potential grid impacts of PEVs in the Yukon Territory, namely by reviewing the potential energy consumption of PEVs and the corresponding load profiles of those vehicles.

Energy Consumption and Loadshapes of PEVs

Given that there is not a profile of PEV energy consumption in the Yukon Territory, ICF relied on energy consumption profiles developed elsewhere. In a recent report for the California Electric Transportation Coalition, ICF developed energy consumption profiles shown in the table below.

[62] Natural Resources Canada, Learn the facts: Cold weather effects on fuel efficiency, Available online at http://www.nrcan.gc.ca/energy/efficiency/transportation/cars-light-trucks/buying/16748.

[63] Regulations Amending the Passenger Automobile and Light Truck Greenhouse Gas Emission Regulations (SOR/2014-207)

Table 9. Energy Consumption of Plug-in Electric Vehicles

Vehicle Type (battery size)	Vehicle Kilometres Traveled		eVKT		Energy Consumption (kWh)	
	Daily	Annual	Daily	Annual	Daily	Annual
PHEV16 (4 kWh)	66	24,090	16	5,840	3.5	1,278
PHEV32 (8 kWh)			32	11,680	7.0	2,555
PHEV64 (16 kWh)			49	17,885	10.7	3,909
BEV (24-80 kWh)	48	17,370	48	17,374	10.3	3,770

These data are developed largely based on information from the EV Project.[64] The plug-in hybrid electric vehicles (PHEVs) are distinguished by their so-called all electric range or the estimated distance that each vehicle can travel using only battery power. These are listed as PHEV16, PHEV32, and PHEV64, capable of traveling an estimated 16, 32, and 64 km using only battery power before engaging the internal combustion engine.

ICF developed the values in the table above for PHEVs assuming that they would drive similar distances as the Chevrolet Volt (a PHEV64) and that they will exceed their all-electric range. For the purposes of this analysis, we excluded the consideration of PHEV16s, with the underlying assumption that the negative impacts on vehicle range would preclude them from deployment in the Yukon Territory. ICF held these values constant over time, considering the following: On one hand, battery technology will likely improve by 2035 to enable PEVs to travel longer distances. On the other hand, the lifetime of batteries for use in automotive applications is not well understood today. ICF recognizes that the constant VKT for PEVs is a simplifying assumption; however, given the uncertainty regarding battery technology today and into the future, we recommend a conservative simplifying assumption whereby VKT is held constant over the course of the analysis.

The all-electric range of these vehicles is likely to be reduced significantly in the winter months in the Yukon. Based on the research outlined previously in Section 2, ICF assumed a 50% reduction in the range of plug-in electric vehicles. We did not however, include any additional load during winter months for pre-heating the vehicle. Based on our research, pre-heating for plug-in electric vehicles would be the same or similar to the demand generated by engine block pre-heaters. ICF developed the daily energy consumption profiles shown in the table below for the Yukon Territory in summer (April to September) and winter (October to March) months.

[64] See for instance, The EV Project, Q2 2013 Quarterly Report

Table 10. Estimated Daily PEV Energy Consumption (in units of kWh) in the Yukon for Summer and Winter[65]

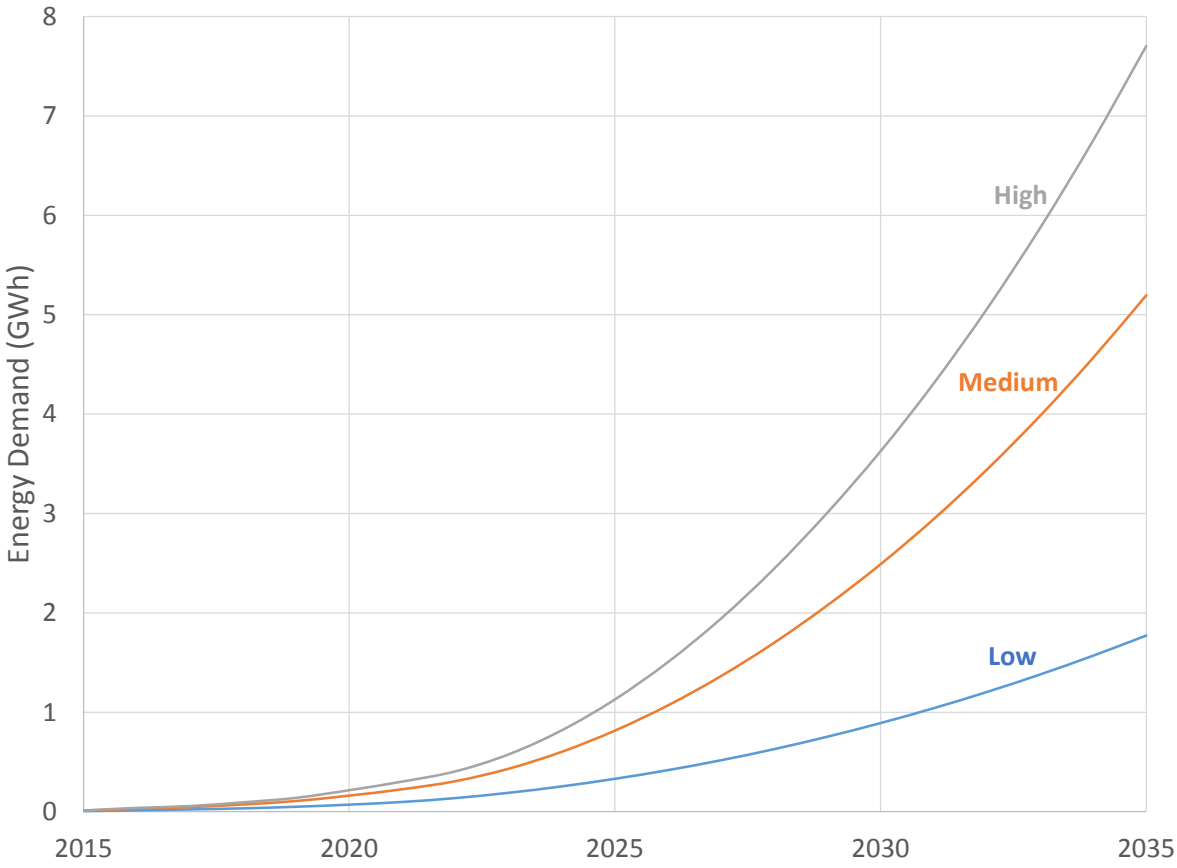
PEV Type	Passenger Car		Light Truck	
	Summer (Apr–Sept)	Winter (Oct–Mar)	Summer (Apr–Sept)	Winter (Oct–Mar)
PHEV32	7.0	7.0	10.0	10.0
PHEV64	10.7	14.0	15.3	15.3
BEV	10.3	20.6	14.8	29.5

We assume that passenger car and light truck PHEV32s deplete the full range of their battery in both summer and winter months; and in the winter months, they simply consume more gasoline to account for the additional reduced range using the battery. We assume that passenger car PHEV64s will consume the additional 24% of energy that the battery is capable of delivering in winter months. In the case of light truck PHEV64s, we assume that they consume the entirety of their battery power in both winter and summer months. For BEVs, we assumed that the vehicle would use its full range based on estimated battery sizing.

The figure below shows the forecasted energy demand (in MWh) of EVs in the low, medium, and high deployment scenarios.

[65] These values do not include line losses.

Figure 9. Forecasted Energy Demand (GWh) for EV Deployment Scenarios



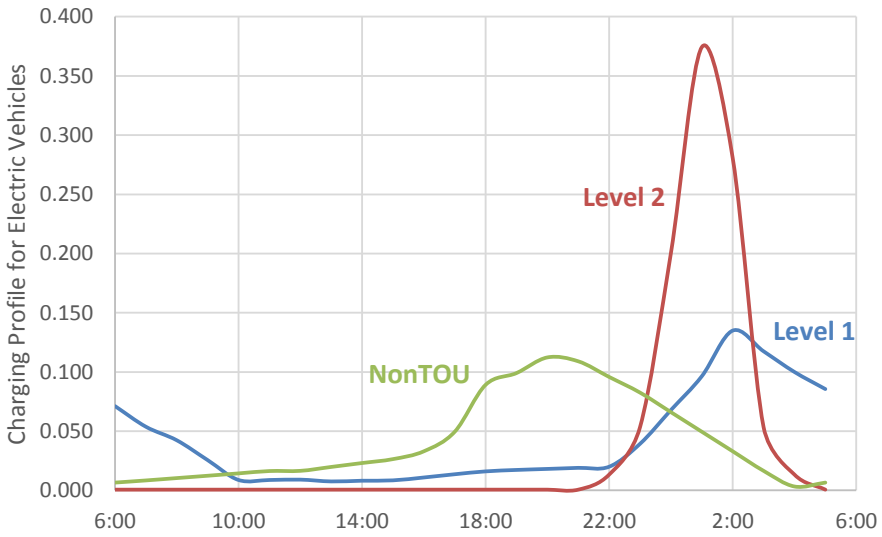
ICF also developed loadshapes for various charging scenarios, considering various charging levels and rate profiles. ICF considered both Level 1 and Level 2 charging; as noted previously, Level 1 charging is at 110 V and peaks around 1.4 kW. Level 2 charging is at 240 V and peaks around 7.5 kW. Note that many electric vehicles available today, particularly PHEVs, are power-limited by the on-board charger. For instance, the charging hardware on the Toyota Prius Plug-in and Ford Energi series of vehicles limit the charging rate to 3.3 kW. Nissan, on the other hand, quickly changed over to providing consumers with a 6.6 kW on-board charging rate within two generations of the LEAF. Given the long-term outlook of the illustrative analysis shown here, we assume a peak power demand of 7.5 kW at Level 2 charging.

For both Level 1 and Level 2 charging, we assume that there are time-of-use rates in place that incentivize charging at certain times of day. Ultimately, the structure of the TOU rate is up to the utility or load-serving entity. For the purposes of this analysis, we simply assumed that charging would be pushed off-peak.

The following bullets describe briefly the various charging scenarios considered, including charging level and rate assumptions:

- **L1 residential charging, TOU rate**: Level 1 charging at home is a proxy for charging of PHEVs with smaller batteries, like the PHEV16 or PHEV32. The normalized profile is based on a similar start time as L2 charging; however, it is stretched out over a longer period.
- **L2 residential charging, TOU rate**: Level 2 charging at home is a proxy for BEV or PHEV64 charging.
- **Residential charging, Non-TOU rate**: Residential charging in the non-TOU case is a modified version of what is reported in the EV Project for Nashville, Tennessee in the US–a region without a TOU rate.[66]

Figure 10. Daily Loadshapes for Electric Vehicles in Various Charging Scenarios



Note that the area under the curve of the daily load profiles shown in the figure above is normalized to 1.0. The daily charging profile has been normalized to 1.0 for illustrative purposes. In other words, the integrated area under the curve is equal to 1.0; and that value is adjusted in the analysis depending on the vehicle type and battery size. We did not modify the daily loadshapes over the analysis period; the loadshapes shown in the figure above were held constant over time.

ICF combined the energy consumption, load profiles, and PEV deployment scenarios to develop multiple load scenarios for analysis.

Feeder Impacts for Yukon Energy

The tables below include the peak demand (in units of MW) for summer (Table 11; April 1 to September 30) and winter months (October 1 to March 31), for each of the PEV deployment scenarios, and each charging scenario. The numbers shown are for weekday charging, with the note that weekend charging has lower demand.

[66] ICF does not assume an explicit blend of Level 1 and Level 2 charging for the non TOU rate; rather the rate is reflective of the time that vehicles would charge. The power draw associated with this rate implies that it is about a 50-50 blend of Level 1 and Level 2 charging.

ICF notes that peak energy values (in MWh) are not shown, but that they are equivalent to peak demand, simply in different units (MW). The reason these values are equivalent is that our current understanding of how vehicles charge does not allow us to make estimates at less than one hour intervals. As a result, we simply assume that the demand (MW) is constant over a one-hour period (yielding energy demand in units of MWh). In other words, the peak demand values listed in the tables below also represent our best estimate of peak load (in MWh). We effectively assume that charging events are staggered to some extent over each hour interval. In order for these values to not be representative of peak demand, one would have to assume that a large percentage of electric vehicles initiated charging events simultaneously (on the minute scale, not hourly scale).

Table 11. Peak Demand (in MW) during Summer (Apr 1–Sept 30), by Year for PEV Deployment Scenarios

Charging Scenario	Summer Peak Demand, Weekday, by Year (MW)				
	2015	2020	2025	2030	2035
Low PEV Deployment Scenario					
Level 1 TOU	0.0	0.0	0.1	0.3	0.6
Level 2 TOU	0.0	0.1	0.3	0.8	1.7
NonTOU	0.0	0.0	0.1	0.3	0.5
Medium PEV Deployment Scenario					
Level 1 TOU	0.0	0.1	0.3	0.8	1.7
Level 2 TOU	0.0	0.1	0.8	2.3	4.8
NonTOU	0.0	0.0	0.2	0.7	1.5
High PEV Deployment Scenario					
Level 1 TOU	0.0	0.1	0.3	1.1	2.4
Level 2 TOU	0.0	0.2	1.0	3.3	7.0
NonTOU	0.0	0.1	0.3	1.0	2.1

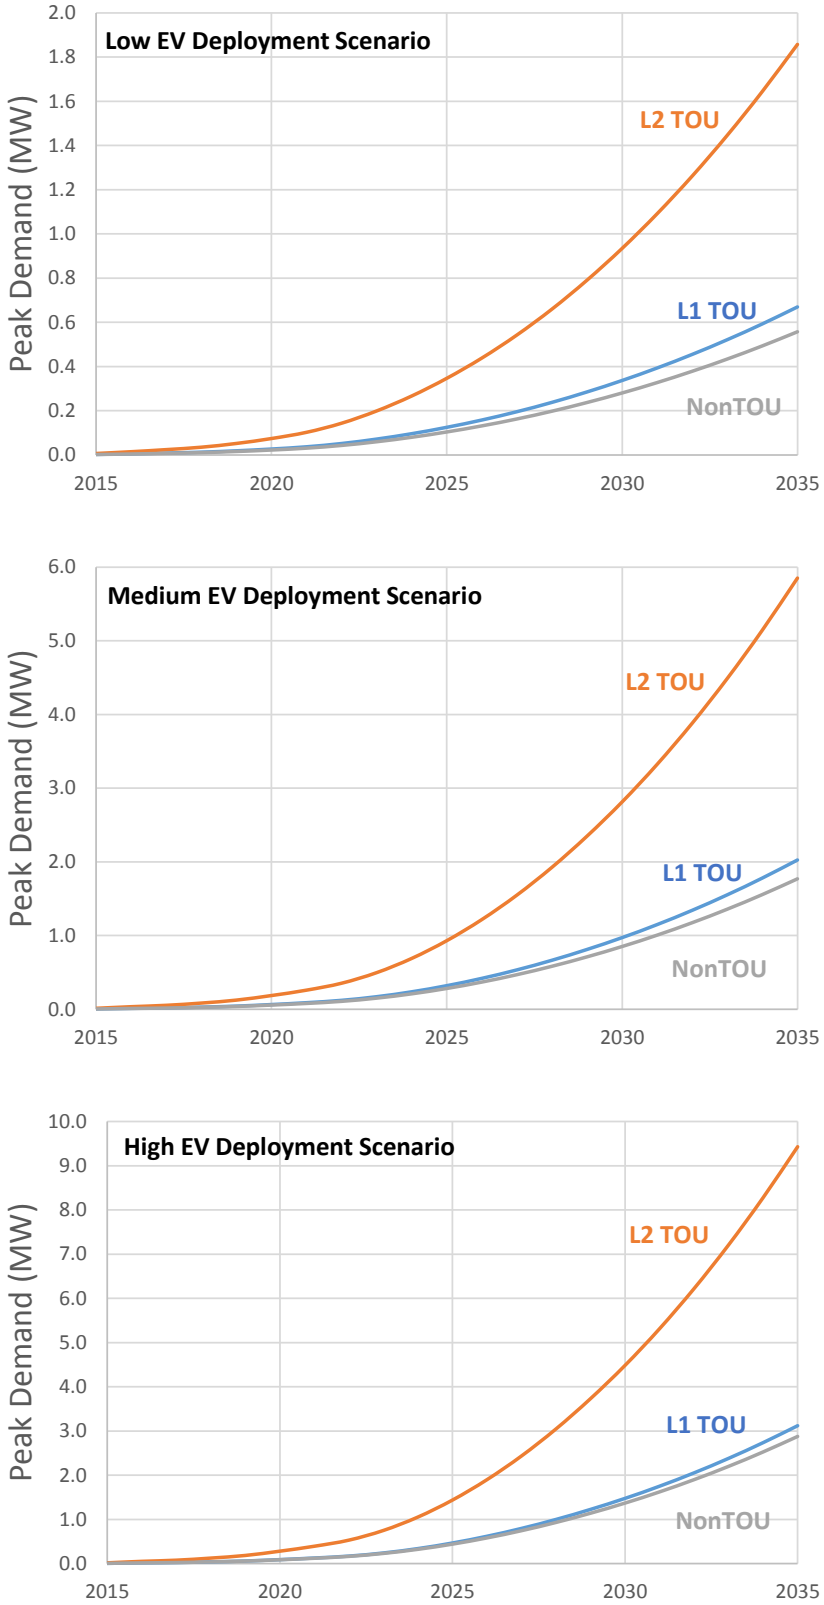
Table 12. Peak Demand (in MW) during Winter (Oct 1–Mar 31), by Year for PEV Deployment Scenarios

Charging Scenario	Winter Peak Demand, Weekday, by Year (MW)				
	2015	2020	2025	2030	2035
Low PEV Deployment Scenario					
Level 1 TOU	0.0	0.0	0.1	0.3	0.7
Level 2 TOU	0.0	0.1	0.3	0.9	1.9
NonTOU	0.0	0.0	0.1	0.3	0.6
Medium PEV Deployment Scenario					
Level 1 TOU	0.0	0.1	0.3	1.0	2.0
Level 2 TOU	0.0	0.2	0.9	2.8	5.9
NonTOU	0.0	0.1	0.3	0.9	1.8
High PEV Deployment Scenario					
Level 1 TOU	0.0	0.1	0.5	1.5	3.1
Level 2 TOU	0.0	0.3	1.4	4.5	9.4
NonTOU	0.0	0.1	0.4	1.4	2.9

The L2 TOU scenario has the highest peak (in MW) for each deployment scenario because of the way the load profile is developed (see Figure 10). The L2 TOU load profile assumes that drivers are provided with a price signal or incentive to encourage shifting at "off-peak" periods (i.e., at night). Similarly, the rate at which power is drawn during a charging event is higher. As a result the peak demand is predictably higher than the other charging scenarios. Also note that the values shown are for weekday peak demand, and that weekend peak demand is not shown simply because the values are consistently lower than for weekday charging events. ICF notes that the actual peak demand for the Yukon Territory is likely to be a mix of the various charging scenarios, with any near-term deployment likely to resemble the non-TOU charging scenario, simply because there is not an electric vehicle specific TOU rate.

The graphs in Figure 11 below show the peak demand (in MW) for the low, medium, and high EV deployment scenarios under different charging assumptions (L1, L2, and non-TOU).

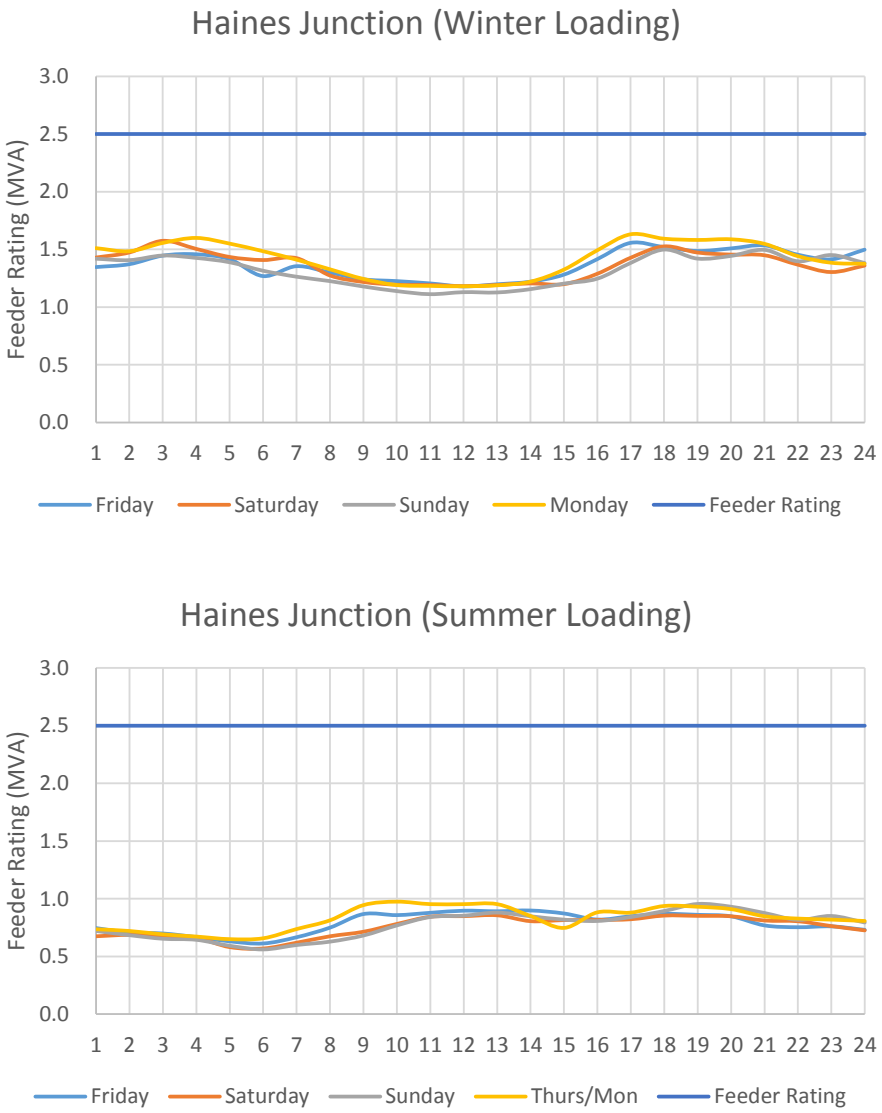
Figure 11. Forecasted Pea k Demand (MW) for EV Deployment in Different Charging Scenarios



Yukon Energy provided maximum ratings for several assets owned by Yukon Energy. For illustrative purposes, ICF selected two feeders to conduct our feeder impact analysis, focusing on feeders that are most likely to be overloaded based on data provided:

- The Haines Junction feeder (see figure below) is considered relatively high loading and is rated at 2.5 MW with a peak load of 1.6 MW (in the winter months).

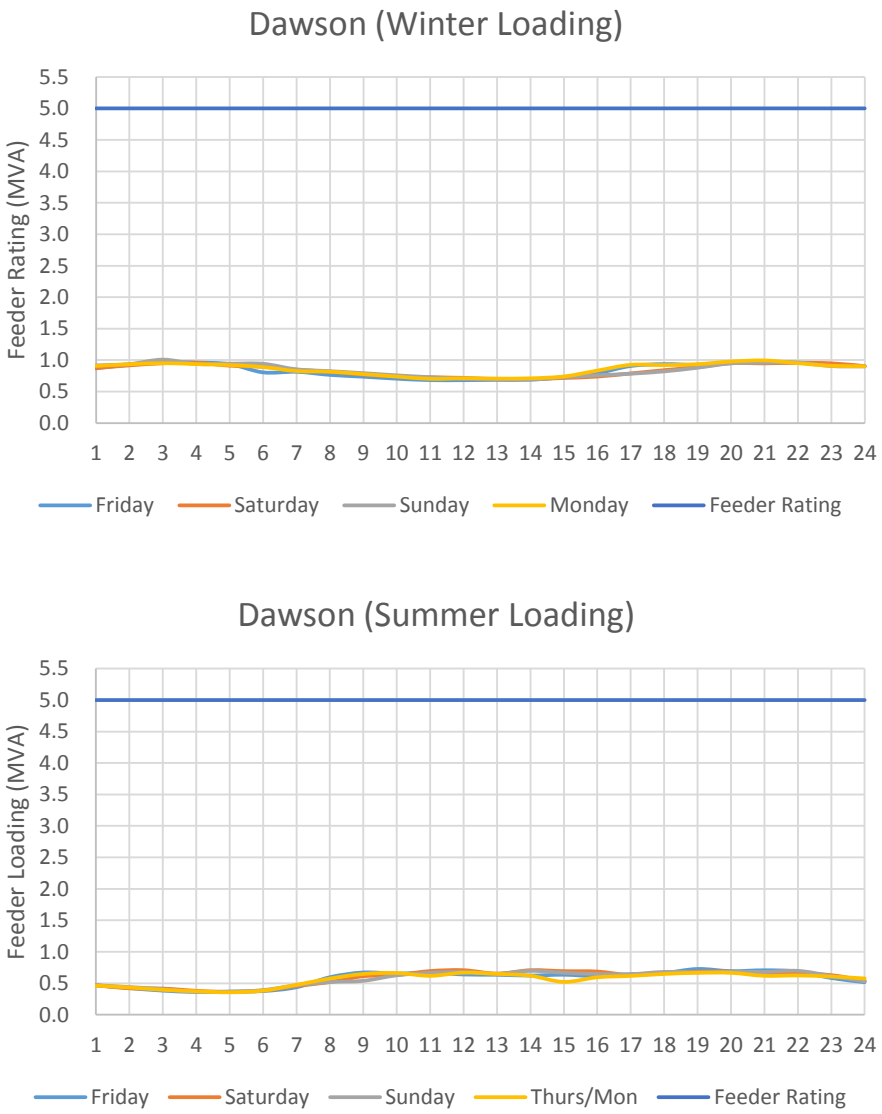
Figure 12. Winter and Summer Loadings on the Haines Junction Feeder



*Note: The summer "Monday" profile is a combination of half of Thursday and half of Monday

- The Dawson 2 feeder (see figure below) is low loading and is rated at 5.0 MW with a peak load of about 1.0 MW (also in the winter months).

Figure 13. Winter and Summer Loadings on the Dawson Feeder



*Note: The summer "Monday" profile is a combination of half of Thursday and half of Monday

One of the factors that our forecasts lacks is geographic distribution of PEVs. In other work, we have simply assumed that PEVs will be deployed in regions similar to the way that HEVs have been purchased. These data usually comes via vehicle registrations; however, as noted previously, we did not have this information available.

We present two ways to consider PEV adoption in Yukon Energy's territory:

- We assume that PEVs will be charged in a similar pattern in which electricity is currently distributed in Yukon Energy's service territory. This is a "fair-share" assumption i.e., that PEVs will be distributed across feeders according to their share of the distribution load.

- We assume that PEVs are clustered on certain feeders to determine the potential impacts.

ICF was provided distributed load on all Yukon Energy feeders and four ATCO feeders from 2013-2015 (year to date). Based on these data sets, the Haines Junction and Dawson 2 feeders distribute about 1.8% and 1.3% of the electricity. If we do a fair share distribution of the load associated with the high PEV deployment scenario in 2035 (when vehicle penetration is at its highest and there are nearly 1,900 PEVs assumed to be on the road), then this yields the equivalent of 34 and 24 PEVs on the Haines Junction and Dawson 2 circuits, representing a peak daily demand of about 0.23–0.99 MW and 0.17–0.71 MW, respectively, in the winter months.[67] Given the rating on both of these circuits and the current load, the additional load from PEVs may have an impact on Yukon's distribution assets in the winter months, depending on a) vehicle clustering, b) the timing of vehicle charging, and c) the types of electric vehicles) charging at the same time.

In the second part of the analysis, ICF considered the potential for PEV clustering. With more than 75% of the Yukon Territory population located in Whitehorse, it is unlikely that Yukon Energy's distribution assets will experience any severe clustering of PEVs. However, for the purposes of this analysis, we calculated the maximum number of PEVs that could charge on both the Haines Junction and Dawson 2 feeders before the assets would become stressed and trigger an upgrade. We performed this calculation using the three different charging profiles (L1-TOU, L2-TOU, and NonTOU) and for PHEVs and BEVs. Table 13 below highlights the maximum number of vehicles that can charge on each of the distribution assets before triggering an upgrade.

Table 13. Electric Vehicle Deployment and Stressed Assets

Feeder	Charging Profile	Maximum No. of Vehicles	
		PHEV	BEV
Haines Junction	L1-TOU	672	235
	L2-TOU	221	118
	NonTOU	822	398
Dawson 2	L1-TOU	2,827	1,035
	L2-TOU	974	522
	NonTOU	3,437	1,662
*ICF notes that we did not have a rating for ATCO feeders, and could not conduct the same analysis for Whitehorse			

The population of PEVs in the year 2035 for the three scenarios ranges from about 500–1,900. As the table above shows, you would need significant PEV clustering, representing 12–50% of the PEVs forecasted to be on the road charging at the same time on the Haines Junction feeder at Level 2 to trigger an upgrade.

[67] The daily load is presented as a range, with the minimum representing a passenger car PHEV32 (7 kWh/day) and the maximum representing a light-truck BEV (29.5 kWh/day).

Based on our analysis, it is unlikely that PEV charging will trigger upgrades to Yukon Energy's distribution assets, and will have minimal grid impacts absent more rapid adoption of PEVs than expected. That said, there are several variables that can change which would modify our conclusion:

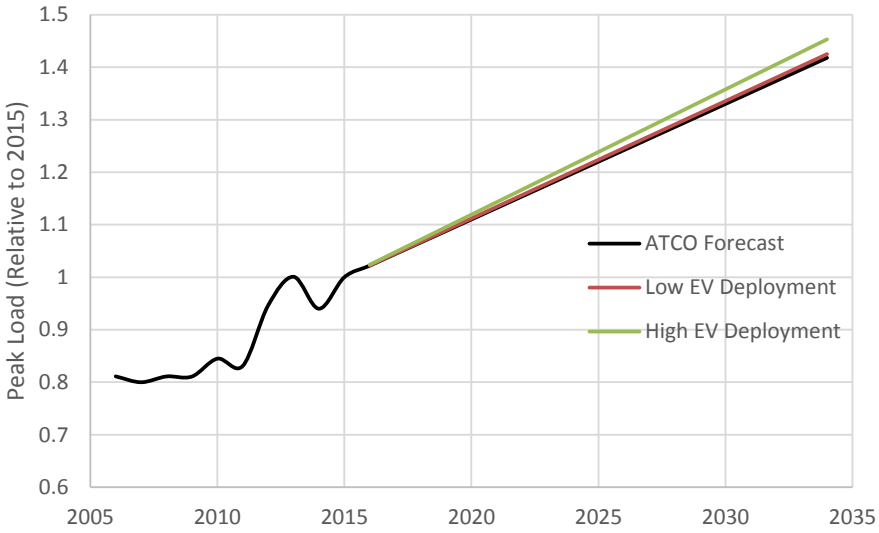
- Technological improvements to PEVs will likely yield larger batteries in the future, thereby increasing the daily load from PEV charging.
- Charging behavior can change depending on factors such as price signals (e.g., via utility intervention) and charging availability.
- Consumer purchasing preference could change over time, yielding a shift from light truck purchasing to passenger cars. One of the limiting factors for PEV deployment in our analysis is the assumed new truck sales as a percentage of new vehicle sales. If this changes over time, and the percentage of light duty passenger cars increases accordingly, then the electrification potential will increase accordingly.
- Policy changes could shift consumer purchasing as well. Incentives could induce a more significant deployment of PEVs in the near- to mid-term future. Furthermore, regulations that require reduced GHG emissions, perhaps with a focus on the transportation sector, can act as a strong incentive for electrification.

Impact on ATCO Assets

The feeders considered in the impact analysis in the previous subsection are a long distance from the City of Whitehorse, where 75% of the Yukon Territory's population resides and where ICF anticipates most electric vehicles will be deployed. Haines Junction, for instance, is a 90-minute drive from the City of Whitehorse and has a population under 1,000, whereas Dawson City is 6 hours north, does not have paved roads in the city, and has a population of 2,000. The distribution assets for the City of Whitehorse are primarily controlled by ATCO Electric, thereby limiting our ability to assess analytically the impact to their assets. ICF and Yukon Energy reached out to ATCO to help characterize the potential impacts on their system. The following information is a summary provided by ATCO and edited by ICF.

When contacted regarding the study, ATCO engineers noted that breakers are not the weak points in their distribution system; rather they highlighted that there are a variety of issues associated with managing load and assets in the downtown core, with a focus on a 25kv conversion project. ATCO expressed some reservations about modeling the increased load from the deployment of EVs and attributing the additional upgrades to EVs. For the sake of reference, ATCO noted that the low and high deployment scenarios would increase their load from about 2.2% per year to 2.24% per year and 2.39% per year, respectively. The figure below shows the forecasted peak load on ATCO's S150 and S170 feeders in Whitehorse (black line), with the impact of the electric vehicles in the low (red line) and high (green line) EV deployment scenarios. ATCO has agreed that the magnitude of this potential load and peak demand increases should be included in their incremental load growth forecasts. However, they also concluded that while it does not alleviate any existing loading issues, it further supports foreseeable upgrades that have already been identified as high priorities.

Figure 14. Peak Load Impact of EV Deployment on ATCO's Assets (S150 and S170)



5 Conclusions and Recommendations

ICF's finds modest potential for electric vehicles in the Yukon, with comparably modest GHG reduction potential. In a high forecasted electric vehicle deployment scenario at high charging, ICF's analysis indicates that it is conceivable that Yukon's distribution assets are stressed in the long-term future (e.g., around 2030–2035) absent any upgrades. However, this stress is dependent on a higher level of charging (Level 2 vs Level 1) and can be mitigated by shifting charging throughout the day (e.g., via workplace charging). Given the ubiquitous presence of engine block-heaters, it seems more likely to ICF that Level 1 charging will be more common than Level 2 charging at residences and workplaces.

The market potential for electric vehicles is constrained to some extent because of the cold weather in the Yukon, especially in the coldest months of the year. Most notably, vehicles may lose more than 50% of their advertised electric-powered range in cold weather. There are also near-term limitations on the electric vehicle market in the Yukon, namely the lack of dealerships selling electric vehicles and the limited vehicle offerings available more broadly to consumers. For instance, more than 60 percent of new vehicles sales are light trucks in the Yukon, likely because of weather and driving conditions, and other factors (e.g., consumer preference). As of 2015, electric vehicle manufacturers do not offer many models that can compete in this class.

Despite the limitations, electric vehicles, particularly PHEVs, are still a viable transportation option in the Yukon. Despite the potential loss of electric range, PHEVs also have the ability to run on petrol. Even after losing a portion of electric range due to cold weather, many electric vehicles will still provide sufficient range within the scope of the average Yukon commute. Furthermore, ICF may be under-estimating the potential for technological change and improvements in battery technology, thereby mitigating some of the concerns about diminished range.

The prevalence of engine block heaters also gives the potential electric vehicle market a boost in Yukon. These block heaters are effectively an ubiquitous electric vehicle charging network, currently available at homes and businesses. Public education and outreach could help new vehicle buyers understand the potential for vehicle electrification, and how the existing infrastructure can support that potential.

ICF generally recommends utility engagement in the electric vehicle market that keeps the utility slightly ahead of consumer preference and interest. There are a handful of electric vehicles in the Yukon, and interest is likely to improve moving forward. In that regard, Yukon Energy has an opportunity to support the deployment of electric vehicles through education and outreach to interested consumers, particularly in the role of trusted advisor that is common for a utility. ICF also recommends a more substantive engagement with ATCO, given their role as utility provider to the majority of residents in Whitehorse, where ICF anticipates the most significant electric vehicle deployment. To date, ATCO is justifiably focused on more pressing issues impacting their assets; however, moving forward, Yukon can work with ATCO to incorporate electric vehicle deployment into mid- and long-term resource planning. Outside of working with ATCO, Yukon Energy has an opportunity to maintain engagement with consumers and other stakeholders (e.g., automobile manufacturers and dealership) in the electric vehicle market space in the Yukon, thereby establishing a leadership position.

May 3, 2016

Executive Summary

Home heating represents a significant potential growth market for Yukon Energy and the electrification of heating also offers a means to significantly reduce greenhouse gas emissions in the Yukon. The number of homes in Yukon using electric heat is also a significant factor in how much electricity Yukon Energy needs to generate, particularly during peak periods.

To help understand the home heating market, Yukon Energy, with support from the Yukon Government Energy Branch, completed this study to analyze the business case for home owners to switch heating systems from fossil fuels to electric heat. This report also looks at the non-economic drivers that may affect the choice of home heating system and importance of economics as compared to other drivers. Finally, the report quantifies the reduction in GHG emissions from the switch to electric heat.

To complete the analysis for this report, the energy use of an archetype Yukon home was modelled at four thermal enclosure (insulation) levels which correspond to significant changes in insulation and air sealing practices. The energy model results were used to calculate the total fuel load for each level of insulation and heating system, which in turn were used to calculate annual fuel costs and GHG emissions. The upfront costs of completing the retrofit, maintaining and insuring each system, as well as the annual fuel costs were analyzed to understand the business case for a Yukon homeowner to retrofit their home with electric heat. Other non-economic drivers such as GHG emissions, safety and ease of maintenance are also discussed.

The economic analysis indicates that, at current prices, a retrofit from a functional oil or propane furnace to electric heating would increase homeowners' annual fuel costs with the exception of heat pumps. These increased fuel costs are partially offset by a small reduction in maintenance costs. Comprehensive home insurance costs were found to be relatively uniform across home heating types. The retrofit to a cold climate heat pump offers fuel savings and the payback period may be acceptable for some home owners.

The results of this cost analysis indicate that at current fuel pricing, there is no business case for home owners to switch from fossil fuel heat to electric heat for economic reasons. Consequently, it is not expected that many existing oil or propane heated homes will switch to electric heat in the near future as a cost saving measure.

1 Introduction

Home heating represents a significant potential growth market for Yukon Energy and the electrification of heating also offers a means to significantly reduce greenhouse gas emissions in the Yukon. The number of homes in Yukon using electric heat is also a significant factor in how much electricity Yukon Energy needs to generate, particularly during peak periods.

To help understand the home heating market, Yukon Energy, with support from the Yukon Government Energy Branch, completed this study in analyze the business case for home owners switching heating fuels from fossil fuels to electric heat. Most existing homes in the Yukon are heated primarily with oil or propane. However, analysis of the energy labelling requirements in the City of Whitehorse and energy assessment data show that the majority of newly constructed homes are heated electrically. This report also looks at the non-economic drivers that may affect the choice of home heating system and importance of economics as compared to other drivers. Finally, the report quantifies the reduction in GHG emissions from the switch to electric heat.

2 Methodology

2.1 Home Energy Use

The energy use of an archetype Yukon home was modelled at four thermal enclosure (insulation) levels. The enclosure levels selected corresponded to significant changes in insulation and air sealing practices, and included:

- Older Home (pre-1980s) – 2x4 walls (R11), uninsulated slab, ceiling (R40), 7 air changes per hour (ACH) (@50Pa)
- Newer Home (1980s and newer) – 2x6 walls (R21), 2ft perimeter slab insulation (R5), ceiling (R40), 5 ACH (@50Pa)
- Energy Efficient Home (Whitehorse Green Building Standard) – 2x6 walls (R28), whole slab (R10), ceiling (R60), 1.5 ACH (@50Pa)
- Super-Insulated Home – Double stud wall (R60), whole slab (R10), ceiling (R80), 1.5 ACH (@50Pa)

It is not expected that there are a large number of super-insulated homes currently heated with fossil fuels. However, this insulation level was modelled to evaluate the effects of increased insulation values as well as to allow the model to be used for a follow-up economic analysis on increasing thermal envelope performance. The layout for the archetype home can be found in Appendix A. Energy use modelling of the archetype home was completed using BEOpt, a free modelling software package developed by the National Renewable Energy Laboratory of the US Department of Energy's Office of Energy Efficiency. This software was chosen for its ease of use and availability to anyone wanting to recreate the model and adapt it to their requirements. The BEOpt model estimated the total energy needs of the home, reported by end-use including heating. These results were used to calculate total

fuel loads for each insulation level and heating system, which in turn was used to calculate annual fuel cost and GHG emissions.

2.2 Heating System Retrofit Costs

Cost estimates for both the labor and materials to remove an existing oil or propane furnace and replace it with an electrical heating system in the archetype house were obtained from local contractors and previous reports[1]. The study examined switching from both oil and propane forced air furnaces to the following range of electric heating systems:

- electric baseboard
- electric forced air furnace
- cold climate heat pump with electric back-up
- electro-thermal storage with forced air circulation

In each case an assumption was made that the home was upgraded from a 100 amp to 200 amp service to meet the additional load from the electrical heating system, but would not require an upgrade to the neighborhood transformer. For the electric forced air systems, it was assumed that no upgrades were needed to the ducting and for the electric baseboard installation it was assumed that the ducting was left in the home.

2.3 Heating System Operating Costs

2.3.1 Fuel Costs

The amount of energy required to maintain the archetype home at 19 °C was estimated using the BEOpt model. This was used to calculate the quantities of oil, propane or electricity to heat the archetype home, which was then used to calculate the associated fuel costs. The price of electricity was based on the 2015 electrical rates including rate riders[2], and an assumption was made that the cost of heating is incremental to the existing base electrical use of the home. The costs of heating with oil and propane were calculated using Yukon Government posted prices for furnace oil and propane (500 gallon tank) delivered to a residence of Whitehorse on December 9, 2015. The efficiency of the oil furnace was assumed to be a 90% and the efficiency of the propane furnace was assumed to be 95%. These efficiencies are a conservative assumption and more fuel would be used for less efficient furnaces.

In order to understand how future potential carbon pricing might impact the costs of fossil fuels and thereby impact the business case for conversion to electrical heating, a carbon tax of $30 and $100/tonne of CO_2 equivalent (CO_2e) was included in the operating costs of the fossil fuel heating systems as a scenario.

[1] *Draft Shifting Demand: Yukon Home Heating Trends,* Yukon Government Energy Branch, November 17, 2015, Yukon Housing Website, Energy Efficient Heating http://www.housing.yk.ca/eeh.html accessed December 2015
[2] Riders R and J at a net increase of 18.21% and Riders E and F for a net decrease of $0.0124/kWh

2.3.2 Maintenance Costs

The costs of maintaining a home heating system can change depending on the type heating system. Both oil and propane furnaces as well as heat pumps require annual maintenance, while electrical heating systems do not. All forced air systems require the home owner to check and change filters periodically. Estimated annual maintenance costs of each heating system were obtained from local contractors and previous reports.

2.3.3 Insurance Costs

Home insurance costs may depend on the type of heating system in the home and annual insurance costs for each system were obtained from local insurance agents. Some insurance companies require oil tanks to be replaced periodically. The cost for tank replacement was not considered in this study.

2.4 Business Case

The costs of completing the retrofit, annual fuel costs as well as maintenance and insurance costs of each system were analyzed to understand whether Yukon homeowners have an economic business case to retrofit their fossil fuel based heating system with electric heating. In cases where the annual operating costs of electric heating systems are lower than the corresponding operating costs of fossil-fuel based heating systems, the simple payback period on the upfront costs of the electric heating system was estimated.

In cases where the annual operating costs of electric heating systems are higher than the corresponding operating costs of fossil-fuel based heating systems at current fuel prices, the break-even fossil fuel prices required to provide homeowners with a 5 year simple payback on the retrofit investment were also calculated for each electrical heating option.

2.5 Non-Financial Considerations

Currently 24% of the GHG emissions in the Yukon are a result of space heating with oil or propane[3]. Electricity produced on the Yukon Integrated Grid is generated by over 99% renewable (hydro and wind) with only a small amount generated from burning diesel or natural gas. Home owners may choose to switch to electric heat in order to reduce the GHG emissions from their homes. A home in the Yukon that is serviced by an isolated diesel grid (e.g. Watson Lake) may only be heated electrically if written permission is obtained from their service provider as per the Yukon Utilities Board Terms of Reference. The GHG emissions for electricity supplied from an isolated diesel grid would be higher that calculated in this report due to the fact that all electricity is generated by diesel instead of majority hydro. This report assumes that the archetype home is in Whitehorse.

Other non-economic drivers such as safety and ease of maintenance are also documented, based on comments from homeowners shared by contractors.

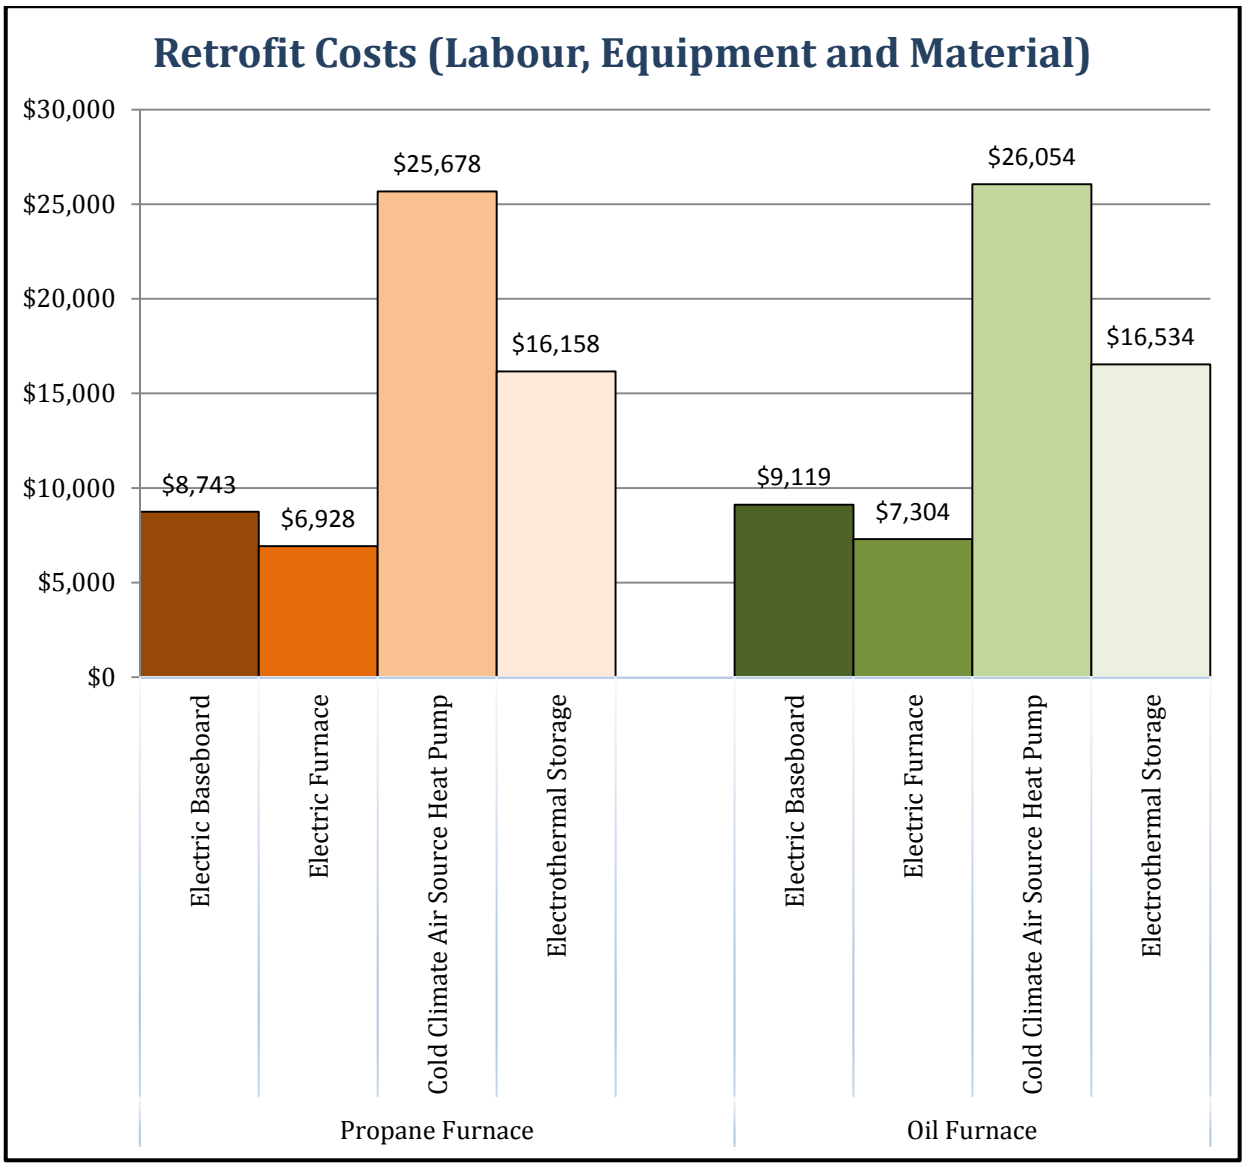
[3] *Yukon Greenhouse Gas Emissions: The Transportation Sector, Updated Report 2015*, prepared by Malcolm Taggart in association with Forest Pearson for the Yukon Government Climate Change Secretariat, March 23, 2015. Calculations assuming year is 2012.

3 Results

3.1 Retrofit Costs

A summary of the total labor, equipment and material costs involved in retrofitting existing fuel oil and propane based heating systems to electrical heating is presented in Figure 1 below.

Figure 1: Retrofit Costs (Labour, Equipment and Material)



In general, the retrofit costs in the case of an oil furnace are slightly higher than in the case of a propane furnace due to the additional time required to remove the oil tank. The retrofit costs of the air source heat pumps and electrothermal storage are both higher due to the higher costs of the heating units

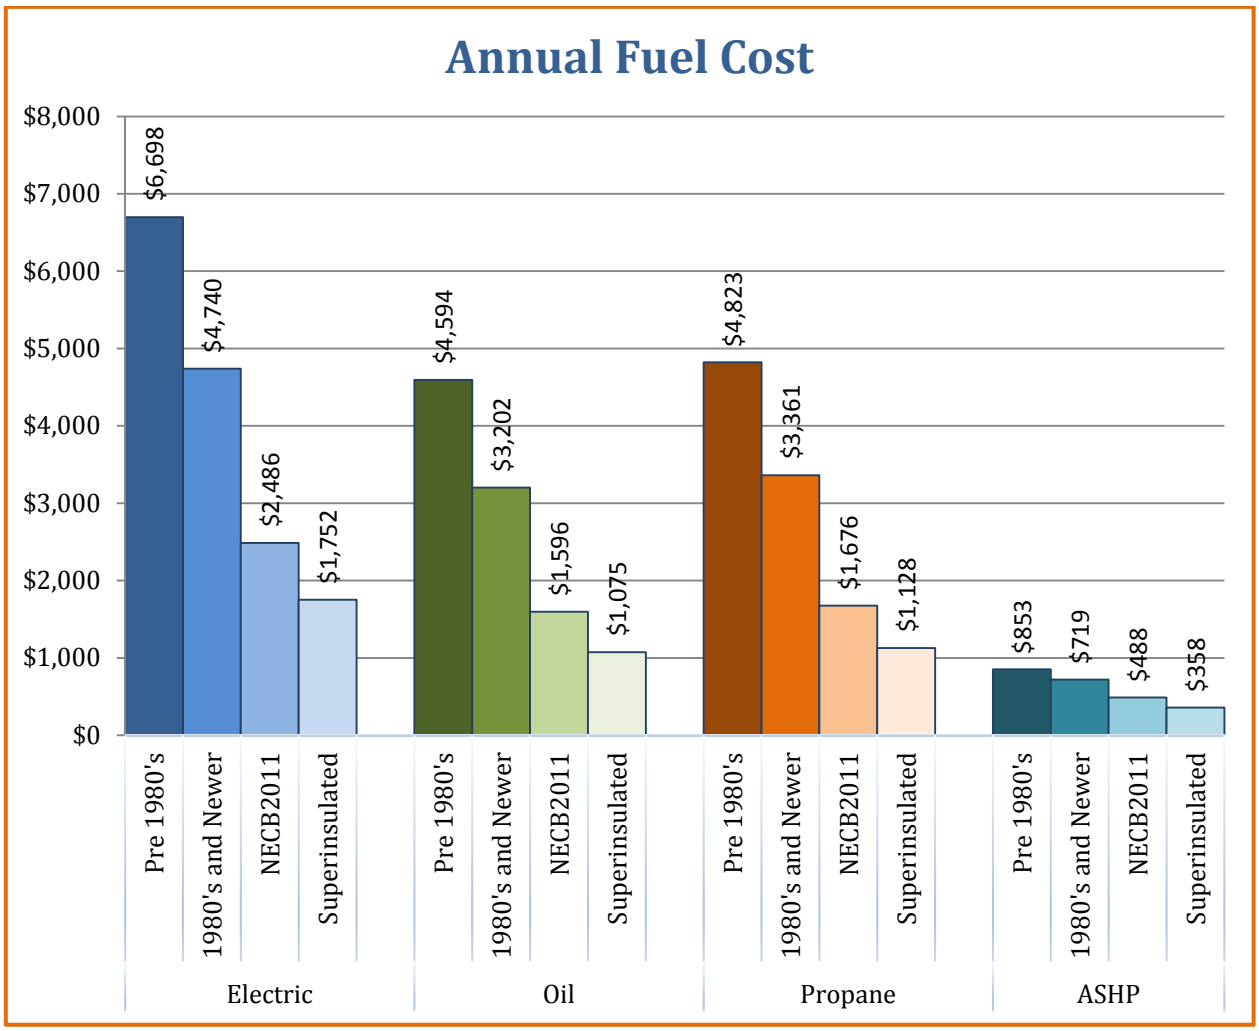
(equipment) when compared to baseboard heaters or an electric furnace. The costs of an electrical service upgrade is included for all of the retrofit options.

3.2 Operating Costs

3.2.1 Cost of Fuels

The annual fuel costs for each heating system and building enclosure level are summarized in Figure 2 below.

Figure 2: Annual Fuel Cost



The data in illustrates the significantly higher heating requirements and heating costs of an older home when compared to a modern home. The older homes require nearly three times as much heat as homes built to meet the current code, and the four times more than a super-insulated home. The data also shows that the annual fuel costs for the electric baseboards, electric furnaces and electrothermal heating systems are higher than the corresponding fuel costs for the propane and oil heating systems.

This result is consistent for all building envelope types. The exception is the cold climate air source heat pump (ASHP), which offers lowest annual fuel costs of all heating types. These heat pumps use a refrigerant system involving a compressor and a condenser to bring heat from the outdoors into the home. Cold climate heat pumps can function down to an outdoor air temperature of around -25°C before it is more efficient to switch to an electric resistance heat back-up. Heat pumps use much less electricity than conventional resistance electric heaters.

3.2.2 Maintenance and Insurance Cost

Estimated annual maintenance and insurance costs for each heating system are provided in Table 1 below.

Table 1: Annual Heating System Maintenance and Insurance Cost

	Annual Maintenance	Annual Insurance
Oil Furnace	$220	$1,424
Propane Furnace	$158	$1,424
Electric Baseboard	$0	$1,395
Electric Furnace	$0	$1,424
Electrothermal Storage	$0	$1,424
Cold Climate Heat Pump	$250	$1,424

Oil and propane furnaces have burners that require annual inspection and maintenance, while electric systems do not require the same level of annual maintenance. All forced air systems require a small amount of work by the owner to check and replace air filters as required. The cost of filters, and the time to check the filters, were not considered. Heat pumps required an annual maintenance by a specially trained professional.

The estimates received for insurance on the archetype home did not show a significant cost difference between a home with an oil or propane heating system and a home with an electric heating system. One insurance provider did offer a discount for electric baseboard heat.

The total annual operating cost for each system, including fuel, maintenance and insurance is shown in Table 2 below. The data show that the total operating costs of the electric baseboards, electric furnaces and electrothermal heating systems are higher than the fossil fuel heating systems for all enclosure levels. Cold climate air source heat pumps offer the lowers annual operating costs of all heating systems.

Table 2: Total Annual Operating Costs by Heating System

	Annual Operating Cost			
Heating System	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Oil Furnace	$5,983	$4,669	$3,153	$2,660
Propane Furnace	$5,864	$4,566	$3,070	$2,583
Electric Baseboard	$8,082	$6,032	$3,666	$2,903
Electric Furnace	$8,111	$6,061	$3,695	$2,932
Electrothermal Storage	$8,111	$6,061	$3,695	$2,932
Cold Climate Air Source Heat Pump	$2,887	$2,469	$2,072	$1,939

3.3 Economic Modeling Results

3.3.1 Annual Operating Costs

The change in annual operating costs, including cost of fuel, maintenance and insurance, of each retrofit scenario, are presented in Table 3 below.

Table 3: Change in Total Annual Costs

	Change in Annual Fuel, Maintenance & Insurance Cost from Oil Furnace			
Heating System	**Pre 1980s**	**1980s and Newer**	**NECB 2011**	**Super-Insulated**
Electric Baseboard	$2,099	$1,363	$514	$243
Electric Furnace	$2,128	$1,392	$543	$272
Electrothermal Storage	$2,128	$1,392	$543	$272
Cold Climate Heat Pump	-$3,097	-$2,199	-$1,081	-$720
Heating System	**Change in Annual Fuel, Maintenance & Insurance Cost from Propane Furnace**			
Electric Baseboard	$2,219	$1,465	$597	$319
Electric Furnace	$2,248	$1,494	$626	$348
Electrothermal Storage	$2,248	$1,494	$626	$348
Cold Climate Heat Pump	-$2,977	-$2,097	-$998	-$644

The results shown in indicate that a retrofit from a functional oil or propane furnace to an electric baseboard, electric furnace or electro-thermal storage system would result in an increase in annual operating costs at current fuel prices.

A retrofit to a cold climate air source heat pump would deliver savings to the homeowner from reduced annual operating costs. The simple payback period for the investment in a retrofit to a cold climate air source heat pump is presented in Table 4 below.

Table 4: Simple Payback of Cold Climate Air Source Heat Pump Retrofit

	Simple Payback of Cold Climate Air Source Heat Pump Retrofit - Years			
Heating System	**Pre 1980s**	**1980s and Newer**	**NECB 2011**	**Super-Insulated**
Furnace Oil	8.4	11.8	24.1	36.2
Propane	8.6	12.2	25.7	39.9

The data in Table 4 show that the operating costs savings from heat pumps may offer an acceptable payback period for some homeowners of just over 8 years for older building envelopes. However, the payback period becomes progressively longer and less acceptable for newer building envelopes with lower overall heating requirements. It should also be noted that heat pumps are a relatively rare in the Yukon and thus far the market uptake has been modest.

3.3.2 Break-Even Fuel Pricing

Five years is generally considered a reasonable payback period for homeowners to invest in home upgrades which deliver savings in operating costs. The break-even fuel prices that would deliver a 5 year payback on retrofits from an oil or propane furnace to electric systems are presented in Tables 5 and 6. These fuel prices were calculated to help understand the price points at which home owners may start

to switch heating systems for as a cost saving measures. It should be noted that current oil and propane prices are $1.005/L and $0.713/L respectively, and the pricing of these fuels peaked at $1.36 and $1.18 in November 2011 and February 2014 respectively.

The data in Tables 5 and 6 illustrate that fossil fuel prices need to reach levels significantly higher than recent peak pricing in order for electric baseboard, electric furnace or electro-thermal storage system to deliver an economic payback in a reasonable timeframe (5 years).

Table 5: Oil Pricing for a 5 Year Retrofit Payback

	Oil prices required for 5 year retrofit payback			
	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Electric Baseboard	$1.81	$1.96	$2.44	$2.91
Electric Furnace	$1.73	$1.84	$2.21	$2.57
Electrothermal Storage	$2.14	$2.42	$3.37	$4.30

Table 6: Propane Pricing for a 5 Year Retrofit Payback

	Propane prices required for 5 year retrofit payback			
	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Electric Baseboard	$1.25	$1.34	$1.66	$1.97
Electric Furnace	$1.20	$1.28	$1.53	$1.77
Electrothermal Storage	$1.48	$1.68	$2.33	$2.97

3.3.3 Impact of Carbon Pricing

Home heating is a large emitter of greenhouse gases in the Yukon. Table 7 below shows the annual CO2e emissions for the study home at each insulation level.

Table 7: Annual CO2e Emissions

	Annual GHG Emissions (CO2e) by Home Insulation Level			
Heating System	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Furnace Oil	11.88	8.29	4.13	2.78
Propane	9.67	6.74	3.36	2.26

The addition of a carbon tax on oil or propane would increase the cost of these fuels, thus improving the business case for a retrofit to electric heating. To understand the impacts a future carbon tax could have on the business case of retrofits, a carbon tax of $30 and $100/tonne of CO^2e was applied to the annual operating costs of oil and propane heating systems. The incremental annual carbon tax costs at both prices are shown in Table 8 below.

Table 8: Annual Carbon Tax

	Annual Carbon Tax at $30/ Tonne			
Heating System	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Furnace Oil	$356	$249	$124	$83
Propane	$290	$202	$101	$68
	Annual Carbon Tax at $100/ Tonne			
Furnace Oil	$1,188	$829	$413	$278
Propane	$967	$674	$336	$226

Figures 3 and 4 below show the annual fuel costs for each heating system and insulation level, with carbon taxes applied at $30 and $100/tonne of CO_2e. This data show that even with a carbon tax as high as $100, electricity is still a more expensive heating fuel choice than oil or propane.

Figure 3: Annual Fuel Costs with $30/tonne Carbon Tax

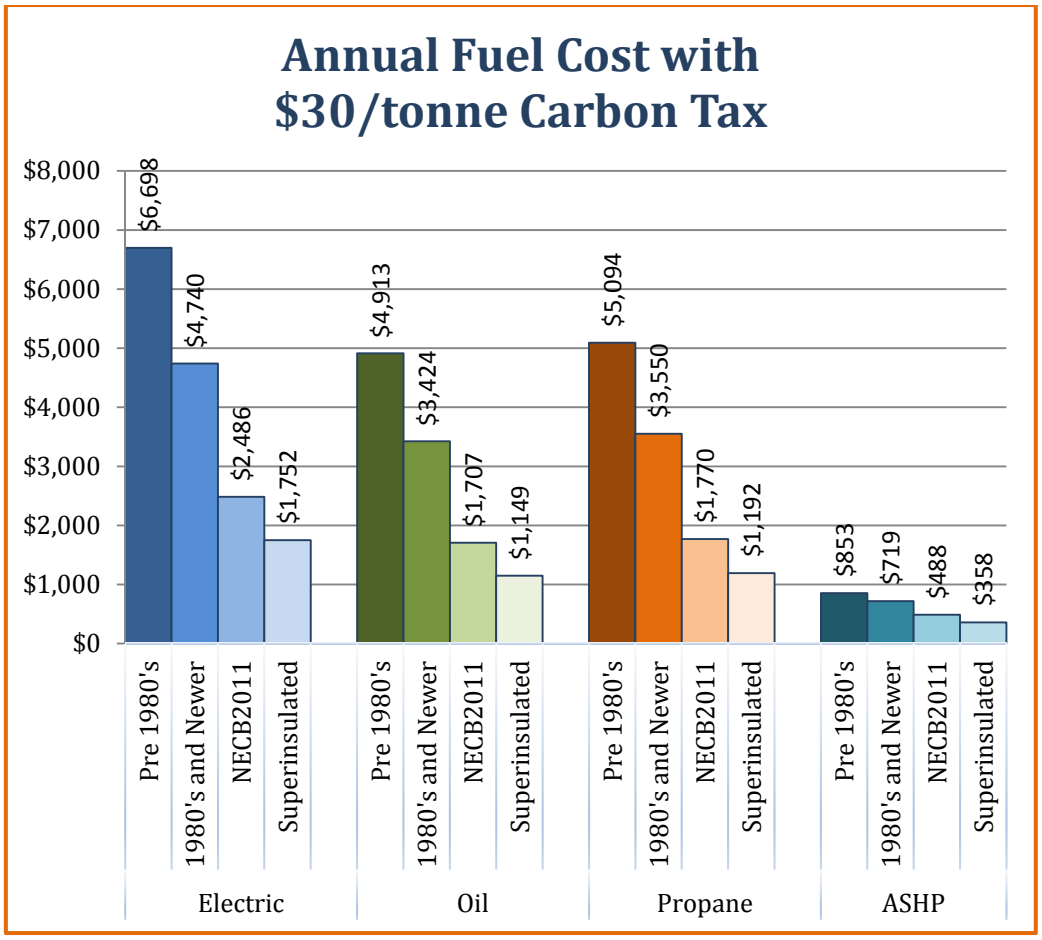


Figure 4: Annual Fuel Costs with $100/tonne Carbon Tax

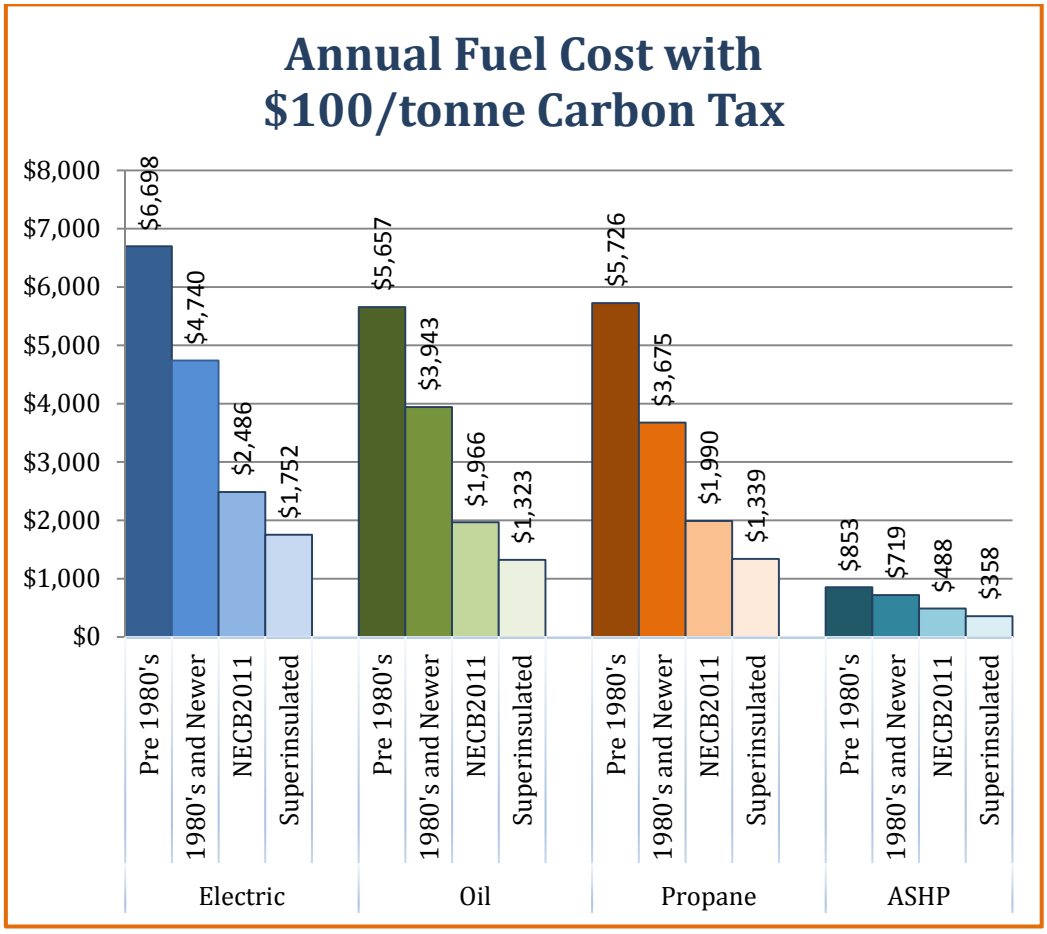

The payback period for the Cold Climate Air Source Heat Pump with the $30 and $100/tonne of CO_2e carbon tax applied can be seen in Tables 10 and 11 below. The data in Tables 9 and 10 show that the inclusion of a carbon tax reduces the payback period of cold climate air source heat pumps to 6-8 years for older building envelopes. However, the payback period remains long for newer building envelopes with lower overall heating requirements.

Table 9: Simple Payback for a Cold Climate Air Source Heat Pump with $30/tonne Carbon Tax

Simple Payback of Cold Climate Air Source Heat Pump Retrofit - $30/tonne carbon tax				
Heating System	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Furnace Oil	7.5	10.6	21.6	32.4
Propane	8.0	11.3	23.7	36.6

Table 10: Simple Payback for a Cold Climate Air Source Heat Pump with $100/tonne Carbon Tax

Simple Payback of Cold Climate Air Source Heat Pump Retrofit - $100/tonne carbon tax				
Heating System	Pre 1980s	1980s and Newer	NECB 2011	Super-Insulated
Furnace Oil	6.1	8.6	17.4	26.1
Propane	6.6	9.4	19.5	29.9

A carbon tax would also affect the break-even fossil fuel prices which would deliver a 5 year payback on a retrofit to electrically heated systems. Appendix B show the prices that oil and propane would have to reach to give a five year retrofit payback with a $30 and $100/tonne of CO_2e carbon tax applied.

It was found that for a $30/tonne tax, oil prices would need to be between $1.74/L and $4.22/L while propane would need to cost between $1.21/L and $2.92/L to achieve a five year payback on a heating system retrofit. At a $100/tonne tax, oil prices would need to be between $1.55/L to $4.04/L and propane prices between $1.11/L and $2.83/L for a five year payback on a heating system retrofit.

3.4 Non-Financial Considerations

3.4.1 Greenhouse Gas (GHG) Emissions

As shown in Table 7, the electrification of a home heating system from oil or propane could reduce the GHG emissions. Given the growing concern about climate change, some homeowners may choose to change their heating system in order to reduce their personal GHG emissions footprints.

3.4.2 Other

When choosing a heating system for a home, homeowners may take other considerations into account in addition to cost and GHG emissions. These non-economic considerations were noted from discussions with contractors and homeowners. These considerations include:

- Safety: Burning fossil fuels could result in carbon monoxide being released into the home, which is dangerous and potentially fatal.
- Environmental Liability: The cost of remediating a hydrocarbon spill from an oil tank can be very high and a liability that homeowners and insurance companies are becoming less comfortable assuming.
- Commercial Convenience: The convenience offered by a monthly electrical bill instead of large fuel bills after a fill-up is attractive to many homeowners.
- Maintenance: Not having to remember to arrange an annual furnace service is also a convenience offered by electric heating systems.

4 Conclusions and Next Steps

The results of this study indicate that with current fuel and electricity pricing, home owners are unlikely to switch from fossil fuel heat to electric heat for economic reasons. The payback for a retrofit to a cold climate heat pump in an older home may be acceptable to some homeowners. The introduction of a carbon tax, even as high as $100/tonne CO_2e would not change the business case for home heating retrofits, also with the exception of bringing the payback period for Air Source Heat Pumps retrofits in older home to six years. Research from the Oak Ridge National Laboratory[4] shows that consumers

[4] D Greene. How Consumers Value Fuel Economy: A Literature Review, EPA-420-R-10-008, March 2010. Available online: http://www3epa.gov/otaq/climate/regulations/420r10008.pdf

heavily discount future fuel savings in comparison to upfront cost due to the high uncertainty of fuel prices.

Additional areas of study to build on the findings of this report could be:

- A survey to confirm the primary drivers of homeowners' choice of home heating system.
- Further analysis to assess the impact of secondary biomass heating on the net heating needs of a home, and resulting changes to the economics of electric retrofits.
- Economics of the retrofit for a homeowner interested in installing solar panels and participating in the governments microgeneration program
- Further investigation into the insurance costs for home heated by different heating options. For example, requirements to replace oil tanks periodically were not addressed in the insurance estimates received.
- Confirmation of the retrofit costs by sourcing quotations for additional contractors, as well as homeowners themselves increasing the number of pricing quotations, either directly or from homeowners that have actually completed a heating system retrofit, would be helpful to refine the cost estimates used in the study.

Yukon Energy KV-16 August 2016 Inspection

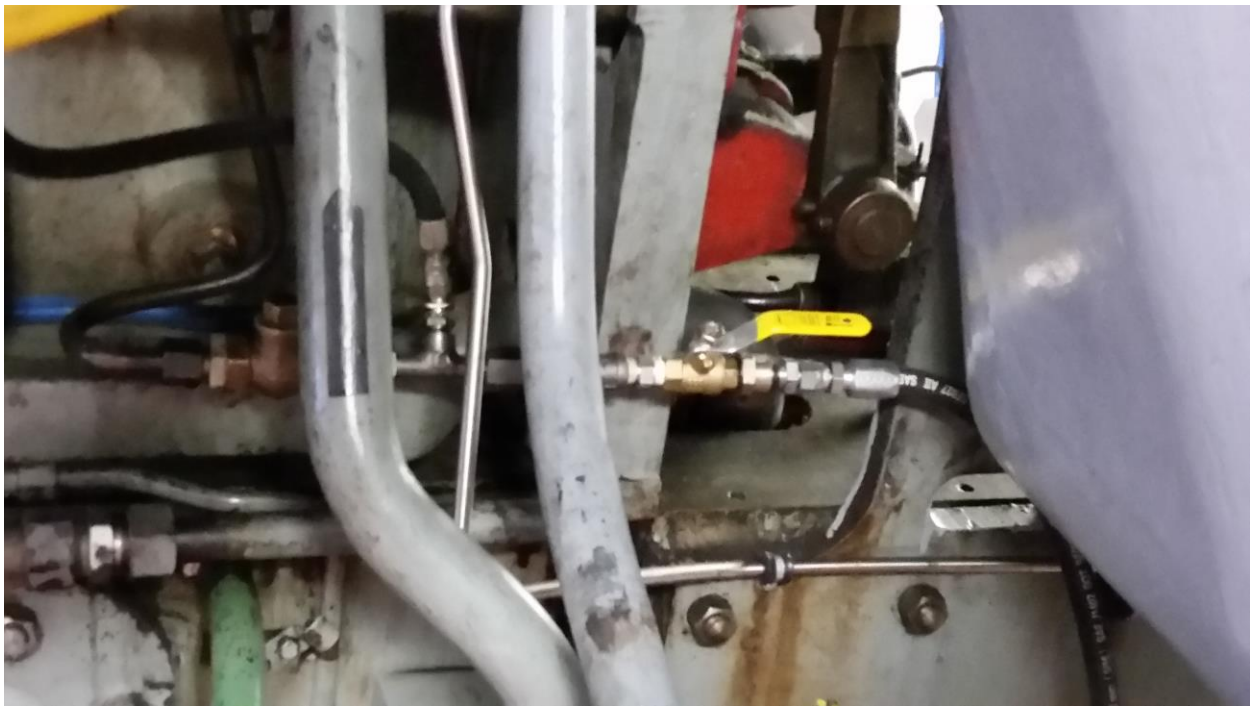
Overview

Inspections were completed on WD3 and FD1.
Since the BC Hydro report of 2004, the two engines have been overhauled. Although in better condition, the engines still do not meet Yukon Energy's criteria for emergency standby and peaking. These engines are intended to run for longer periods of time at base load operation; not the present mode of operation. Testing the engines for one hour a month causes more wear and tear, thus requiring more maintenance than a continuous running engine.

These engines are over 45 years old and do not meet today's environmental emission standards. In the future, this may cost Yukon Energy a major capital investment to upgrade the exhaust system to meet today's standards.

WD3 KV-16
S/N 6444-1
Engine Hours
Last Major Overhaul Completed: Sept 2008
Last Overhaul Hours 39040

Engine Test
The lubricating rocker pressure regulator was removed from WD2 to replace the manual valve that was installed at the last overhaul. This valve was found to be defective and the manual valve was reinstalled. (This regulator valve could not be sourced by MAN at the last overhaul.)



The engine did not start at first attempt; some fuel pumps were sticking.
All fuel pumps and linkage were oiled and racks freed.
All three engine air tank valves were opened to make one system (Operations say this is a common problem on starting).
Engine was started and ran on line up to 3.7 MW for one hour.

Engine started to overheat, jacket water cooling system was up to 200° F.
No alarm came on; **needs to checked**.
Aftercooler outlet temperature should be between 110° and 120° F with a maximum temperature of 125° F.
'A' bank was up to 150° F and the alarm came on.
'B' bank was running at 138° F with no alarm.

Concerns
The secondary cooling system uses untreated river water and the engine pipe work and valves look original and could be over 45 years old.

The overheating problem could also be restrictions in the pipe work due to 45 years of scale build up. The scale could also be blocking the plate type heat exchangers. Cleaning and inspections of the plate heat exchangers is a one to two-week job with parts.

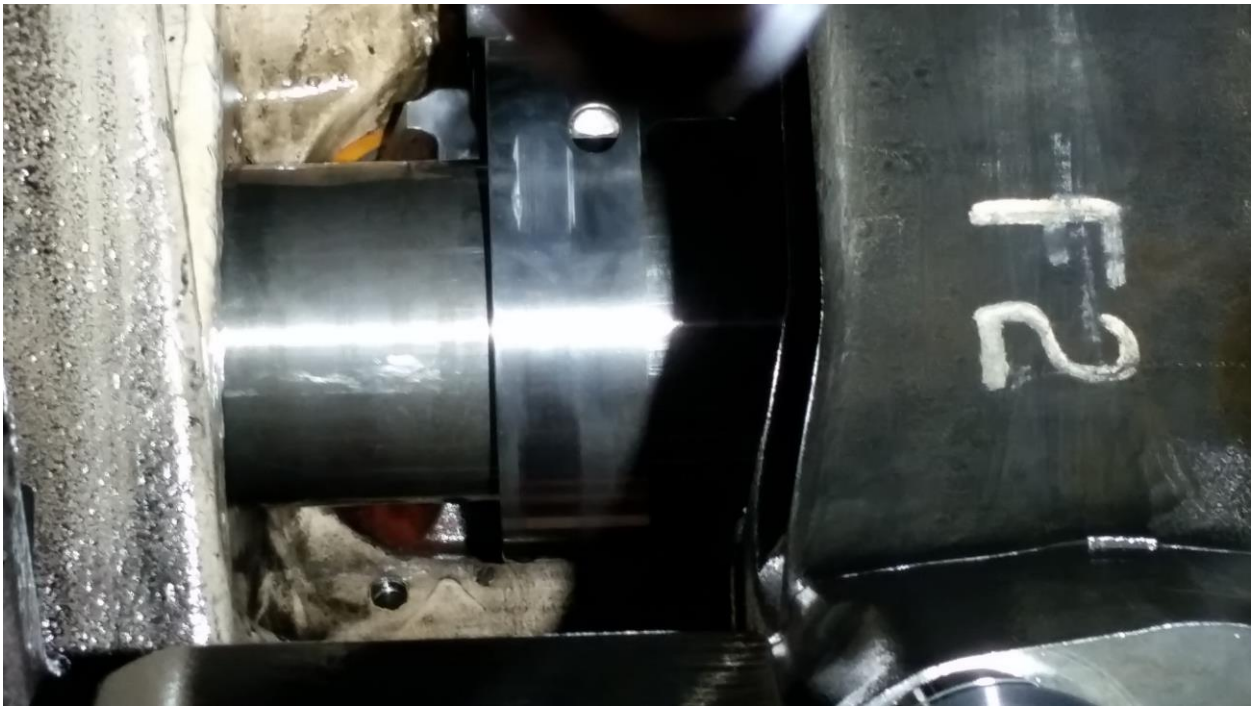
The raw water pump may not be operating properly. There is also a possibility of a closed valve in the system due to WD1 and WD2 taken out of service.

There are only two pumps installed for cooling of engines, which are fed from the hydro plant. After the unit was taken off line, the operator switched over to the other pump.
The pump taken out of service should be checked to make sure it is operational.

The engine jacket water and valve cage cooling system ran on river water from installation until the last overhaul in 2006 when the engine cooling system was changed to anti-freeze.
Some erosion of both the block and liner lands was observed at the last overhaul due to the river water. The liner lands were filled with plastic steel.

Engine Internal Inspection
A visual inspection completed on the outside of the engine.
Doors 2, 4, 6 and 8 removed from 'A' bank side
Doors 1, 3, 5 and 7 removed from 'B' bank side.

Visual signs of B6 exhaust cam (K22448) picking up. B6 crankcase door was removed.
Unable to inspect further due to type of clearance on the unit.
Recommend removal of cam door for more detailed inspection. If the cam needs to be replaced, this job could take up to a month after the parts are sourced.



Bottom of cylinder liners that could be seen are showing signs of polishing.
The piston oil return still has the spay type return plugs installed.
The extent of the polishing is not known and can be caused by the short runs or the liners not properly honed at the time of the last overhaul.

If a piston needs to be removed, it could take anywhere from a week to a month after the parts are sourced depending on what is found.

Operations noted that the gear train is extremely noisy in the winter months, which could be caused by engine foundation movement. The original grout that is installed is prone to crumbling due to the type used at the time of installation.

Replacing the grout requires the complete strip down of the engine and removal of the generator to jack up the bed plate; this would run into millions of dollars and the engine out of service for a year or more and that's if all the parts can be sourced.

Recommend that crankshaft deflections be taken in beginning of spring, the middle of summer, fall, and the middle of winter to see if there is crankshaft and bedplate movement. Inter-gear clearances should be checked at the same time.
This job is about one week.

If a failure occurs of any the gears or inter-gear brackets, the engine will be out of commission for an extremely long time until the parts are made.

There was no overhaul report submitted to Yukon Energy from DEAS, so there is no record of tolerances (liners, piston grove clearances, gear backlash). This could have a major impact on future parts requirements, down time, and costs.

This engine has been down rated due to the generator having one coil isolated.
Max load is 4.5 MW. Estimated cost to repair the generator is $1 to 1.5 million with a down time of over six months.

Faro

Plant is kept in a clean and orderly manner.

FD1 KV-16
S/N 6451-1
Engine Hours: 247.5 on the hour meter
Last Major Overhaul Completed: Oct 2009
Hours at last Overhaul: 22277

Engine Internal Inspection

A visual inspection completed on the outside of the engine.
Doors 2 and 8 removed from 'A' bank side.
Doors 3 and 7 removed from 'B' bank side.

Engine inside was clean.
Liners that could be seen still had the cross hatch.

Engine Test

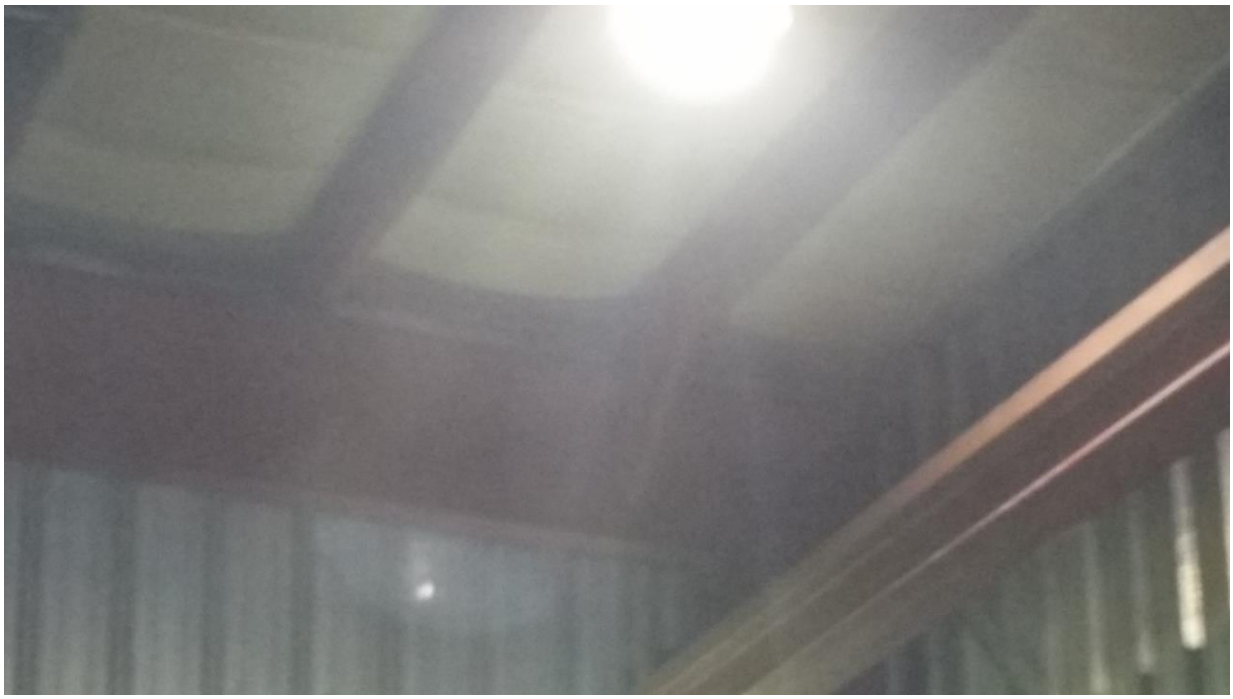
Engine remote started from Whitehorse and started first time.
Engine was loaded to 2 MW

Large amount of oil is getting into the exhaust system due to the wrong Fairchild Valves install. MAN supplied these valves, and were installed at the last overhaul.
The lubricating rocker pressure regulator was replaced with a manual valve at the last overhaul (this regulator valve could not be sourced at the last overhaul). With the engine being in auto start, the valve is left open causing oil to enter the cylinder liners through the valves.

Engine Concerns
Mechanical emergency over-speed and low lube oil pressure trip shutdown blocked with a wedge. It was found that the unit trips off when running.
This could have a catastrophic failure if there is a governor failure.

Misalignment of the tripping lever mechanism is caused by movement of the cylinder block.
The mechanical overspeed trip and low lube pressure is now not operational and is relying on the electrical shut downs
Realignment of the tripping mechanism is needed; this could take up to a month to correct.

Heavy exhaust smoke fills the plant from oil in the exhaust pipes when starting the engine requiring operator evacuation.
Large amounts of smoke from the stacks drifts over the town on start up.



Recommendation
The cylinder head rocker lubrication valve should be closed when the engine is not running, requiring someone to be at site when starting the engine.
Fairchild valves for valve guide lubrication need changing to the correct ones. (WD2 valves checked for use on FD1, but they are also the wrong ones.)

Next Maintenance PM
Valves need resetting, exhaust has some blown gaskets need replacing, water manifold pipe needs the supports fixing,

Engine Common Failures
Jacket water leaks from the liner "O" rings. This is a minimum two-week job with the parts
Valve cage cooling water leaks. This is up to a week with parts

Catastrophic failures
Inter-gear brackets cracking, if this is not found will destroy the gear chain and possibly the engine. The problem is these brackets are no longer made and would be a special order or find a second hand one. (engine could be out of service could be over a year).

A failure to the piston crown will have the engine out of service for a long period, it could take more than a year to source parts to repair or it could destroy the engine beyond repair.

Conclusions
Mirrlees no longer exists as an engine manufacturer and is owned by MAN Diesel.
MAN, never informed Yukon Energy of the closure of the Ontario office or any procedure for purchasing parts.

These engines are over 45 years of age and Mirrlees-experienced service engineers are not stationed in Canada. This will have a higher cost to provide service engineers in the future.

Stocking of parts are no longer in Canada and delivery of parts in a timely manner and cost are a major concern.

Brown Boveri VTR turbo chargers for these engines are no longer made and no parts are stored in Canada. The only suppler I could find on line was aftermarket parts in Europe.

NTPC in Yellowknife had to salvage parts from Yukon Energy to finish their overhaul.
Exhaust valve cages loaned to NTPC in Yellowknife took over three years to replace.

The use of aftermarket parts is not recommended, Yukon Energy tried this already and cost a lot of money for parts that did not meet Mirrlees specifications.

We tried to phone the Ontario service office for a time estimate for delivery of parts, only to find the office was closed
This is the contact information we were given for MAN was from NTPC:

Due to the age of the units, FD1 and WD3 are considered to be “end of life” and would require major work and operating methods to extend life. Even if this work is carried out equipment obsolescence will result in difficulty of obtaining parts at reasonable cost. The loss or OEM technical support compromises the life extension of these units. A major failure would result in an extended outage on the unit, and a cost prohibitive repair. YEC should replace the units.

Generation Adequacy Evaluation of the Yukon Energy Corporation Power System Incorporating Major Power Delivery Constraints

Prepared By

Rajesh Karki, Ph.D., P.Eng.

February 23, 2017

EXECUTIVE SUMMARY

This report presents adequacy evaluation studies of the Yukon Energy Corporation (YEC) electric power system considering major capacity delivery constraints. The results of the studies carried out to develop a suitable reliability model for the existing YEC system are presented. The developed model was integrated in a software tool named YESREL which is a modified version of WAFSREL [1]. A number of case studies were also conducted using the YESREL program.

The Whitehorse, Aishihik and Faro (WAF) sub-systems were the major components of the YEC system in 2005, when a study [2] was carried out to recommend a reliability criterion of LOLE = 2 hours/year for capacity planning. The 2005 study showed that the capacity constraint imposed by the line L171, that interconnects the Aishihik hydro plant, had significant impact on the overall adequacy of the WAF system, and was therefore incorporated in the reliability model. A reliability software WAFSREL [1] then developed included this model in reliability evaluation of the WAF system. Another reliability study [3] was carried out in 2011 after the Mayo and Dawson (MD) sub-systems were integrated to the WAF system. The study recommended that the WAFREL software that was developed for the WAF system should be upgraded in response to the system changes in the WAF-MD system.

This report consists of 5 sections. Section 1 provides introduction to the work in this project. Section 2 presents the generation and load data of the WAF-MD system. The total system capacity of 131.21 MW was considered for the WAF-MD system. The total effective winter capacity was reduced to 109.61 MW as the Whitehorse and Mayo hydro plants during the winter season are limited to 24.5 MW and 9.0 MW respectively due to seasonal hydrological constraints. Generating unit forced outage rate of 1%, 4% and 15% were used respectively for the hydro, diesel and natural gas units in the evaluation. Section 2 also presents results of basic generation adequacy evaluation of the WAF-MD system, in which the transmission lines are not considered. This approach is taken in LOLE evaluation of many large power systems, and LOLE of 0.1 days/year is often used as a capacity planning criterion. Using this criterion, the WAF-MD system can carry a peak load of

94.36 MW. An LOLE of 0.1 days/year was found be equivalent to LOLE of 0.5 hours/year for the WAF-MD system without considering transmission constraints. It should be noted that that the Aishihik hydro capacity limitation due to the line L171 was considered in the WAF system reliability criterion of LOLE = 2 hours/year.

The impact on the YEC adequacy of the major transmission line outages is analyzed and presented in Section 3. The studies show that the line L171 (connecting Ashihik) has the largest impact on the LOLE and LOEE results. The parallel lines L172 and the distribution lines connecting Takhini and Whitehorse also showed notable impact on the system indices. The lines L176, L174+L173 and L170 connect the Mayo hydro generation to the bulk system load at Whitehorse, and the impact of these lines increases with their proximity to Whitehorse area load. However, the lines L177 (connecting Dawson) and Line L178 (connecting Faro) have very little impact on the system indices, and therefore, need not be considered in the generation adequacy model of the system.

Five different generation adequacy models were developed for the WAF-MD system and presented in Section 4, based on the analyses of the results obtained in the Section 3 studies. The five generation adequacy models are arranged in the report in the order such that the amount of input data requirements and evaluation complexity increases from Models 1 to 5 in the list. In this order, the models also deviate further away from a basic generation capacity adequacy model or HLI (Hierarchical Level I) model towards a composite generation and transmission adequacy or HLII (Hierarchical Level II) model. LOLE evaluation was also done using a sixth model, the HLII model, and compared with the previous 5 different adequacy models. A comparative analyses of the results from the 6 different adequacy models suggest that the “Hydro Plants Interconnection Model” is a suitable generation adequacy model for the YEC system since it is relatively simple and provides reasonable results. This adequacy model was therefore incorporated in the program YESREL.

Section 5 presents results from selected case studies of potential future scenarios. The results show that the existing WAF-MD system can carry a peak load of 82.8 MW at the LOLE criterion of 2 hours/year. Including the mobile diesel units and YECL generation, the system can up to 91.4 MW of peak load. This would have reduced to 84.3 MW if the YEC had not installed the distribution

line to add redundancy to the line L172. As the system peak load is around 83 MW, the YEC/YECL system has adequate capacity to meet the short term load growth. This scenario will change in 2021 as two YEC diesel units (FD1 and WD3) retire. This will cause a capacity deficit as the YEC/YECL will only be able to carry a peak of 81.8 MW. If 25 MW capacity assistance can be provided through the Skagway line, the YEC/YECL system will be able to carry a peak load of 109.9 MW. When all the YEC diesel units retire in 2026, the YEC/YECL system will only be able to carry a peak load of 56.3 MW. Twining the line L171 will raise the peak load carrying capability to 71.2 MW. A firm purchase of 25 MW through the Skagway line will enable the system to carry a peak load of 85.3 MW. Additional generation capacity installation will be required to meet the LOLE criterion of 2 hours/year in the year 2026. Representative data taken from the CEA Equipment Reliability Information System have been used to supplement the data provided by YEC. It should be noted that the study results are highly dependent on the generating unit and transmission line failure and repair parameters used in the analyses.

1. INTRODUCTION

This report presents the results of generation system adequacy evaluation studies of the Yukon Energy Corporation (YEC) electric system considering the major power delivery constraints in order to assist with the update of their 20-Year Resource Plan. The University of Saskatchewan conducted a reliability evaluation of the Whitehorse-Ashihik-Faro (WAF) electric power system in 2005 [1], and developed a software tool named WAFSREL [2] that incorporates the generation adequacy model developed in the 2005 study. There have since been significant changes to the topology and the configuration of the YEC system. The northern Mayo-Dawson (MD) system was interconnected to the southern WAF system through the Carmacks-Stewart transmission line. The University of Saskatchewan conducted a reliability evaluation of the extended Whitehorse-Ashihik-Faro-Mayo-Dawson (WAF-MD) electric power system in 2011 [3], and indicated that the WAFSREL program required relevant modification to incorporate the changes in the YEC electric power system. There have been further changes to generation capacity at various locations in the WAF and MD systems. This report also includes investigative studies to determine an appropriate generation adequacy evaluation model of the YEC electric power system to incorporate in the modified software tool.

Probabilistic reliability evaluation techniques [4] will be used in the overall project to carry out a number of case studies, and analyze the results to recommend an appropriate generation adequacy model for the YEC system under the changed scenario. The basic elements in a capacity adequacy review are the installed generating capacity and the system load. The YEC system load is dominated by the Whitehorse area load. Transmission lines are not generally considered in the generation capacity adequacy evaluation. Specific transmission facility that connects the power system to a remotely located large generation plant with insignificant local load are however typically considered in generation adequacy study. This approach will also be considered in the study to consider the ability of the remote generation at Aishihik, Faro, Mayo and Dawson to deliver their capacity to the Whitehorse load through the respective transmission lines. The impacts of major transmission line constraints in delivering the system generation capacity to the Whitehorse area were assessed in the study.

The project was carried out in five tasks. The first task was to carry out a basic generating capacity adequacy assessment of the YEC system considering the existing generation and load data. The transmission constraints to deliver the power to the system load were not considered in this task. The work in this task provides a base case to conduct comparative studies done in the next task to evaluate the impact of transmission lines. The second task was to evaluate the YEC system using a conditional probabilistic approach to assess the impact of the forced outages of major transmission lines on the generating capacity adequacy. The results of Task 2 studies were analyzed to quantitatively compare the impacts on the system adequacy of the individual transmission lines in order to assess their significance in the development of the system capacity adequacy model. The third task is to incorporate the constraints of all major transmission lines in the generating capacity adequacy evaluation of the YEC system, and determine an appropriate generation adequacy model for the YEC system. A number of case studies will be carried out in Task 4 using the transmission line constrained generating capacity adequacy model developed in Task 3. The final task is to develop a graphical user interface software tool that incorporates the transmission line constrained generating capacity adequacy model developed in Task 3.

A wide range of indices have been developed to quantify the reliability of electric power systems. These indices are described in detail in [4]. The basic concepts used to obtain the results provided in this report are also discussed and illustrated in [4]. The Loss of Load Expectation (LOLE), the Loss of Energy Expectation (LOEE), and the Peak Load Carrying Capability (PLCC) are the most commonly used indices in generating capacity reliability evaluation. The LOLE is the expected number of days or hours in the specified period when the load exceeds the available generating capacity. It is the most widely used index. The LOEE is the expected energy not served as a result of system generating capacity inadequacy. The PLCC is the peak load that the power system can carry while meeting the adequacy criterion. A LOLE of 2 hours/year is the accepted criterion adopted by YEC for generation planning.

2. BASIC ADEQUACY EVALUATION

This section presents a description of the relevant data, evaluation models and results obtained from a basic generating capacity adequacy assessment of the current YEC system using the conceptual reliability model [4] shown in Figure 2.1.

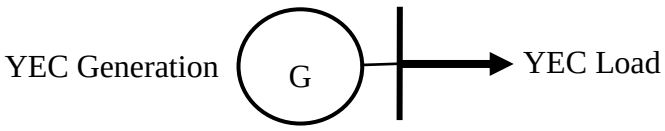

Figure 2.1: Basic Generation Adequacy Evaluation Model

The objective of the basic generation adequacy evaluation is to assess if an electric power system has sufficient generation facilities to meet the projected system demand within acceptable risk. This study does not consider the ability of the transmission system to deliver the power to the system load. A system generation model is created in the form of a discrete probability distribution by combining all the generating units in the system. A system load model is developed from the annual load profile of the entire power system. The line losses are included in the system load. The generation model and the load model are convolved to obtain quantitative risk indices. The loss of load expectation (LOLE) and the loss of energy expectation (LOEE) are the two important generation adequacy indices that will be used to quantify the level of system reliability. The peak load carrying capability (PLCC) of the generating system at the LOLE criterion of 2 hours per year will also be evaluated in the study. The results obtained from this study will be used to benchmark and compare the results obtained from the studies in the subsequent tasks.

2.1 System Generation Data

The YEC system generation data used in the study is shown in Table 2.1. The maximum continuous rating (MCR), generation type, location of the generation plants, and the total plant capacity are shown in the table.

Table 2.1: YEC System Generation Data

Location	Unit Type	Unit ID	MCR (MW)	Plant Capacity (MW)	
				Summer	Winter
Whitehorse	Hydro	WH1	5.8	38.0	24.5
		WH2	5.8		
		WH3	8.4		
		WH4	20		
	Diesel	WD3	4.5	15.0	15.0
		WD4	2.5		
		WD5	2.5		
		WD6	2.5		
		WD7	3.0		
	Natural Gas	WG1	4.4	8.8	8.8
		WG2	4.4		
Aishihik	Hydro	AH1	15	37.0	37.0
		AH2	15		
		AH3	7		
Faro	Diesel	FD1	4.0	6.8	6.8
		FD7	2.8		
Mayo	Hydro	MH1	2.55	11.6	9.0
		MH2	2.55		
		MBH1	5.0		
		MBH2	5.0		
	Diesel	FD2	0.85	2.55	2.55
		FD3	0.85		
		FD4	0.85		
Dawson	Diesel	DD1	0.72	5.96	5.96
		DD2	0.92		
		DD3	0.92		
		FD5	1.0		
		DD5	1.4		
		FD6	1.0		

The total MCR in the above table is 131.21 MW. The total effective summer and winter capacities are 125.71 MW and 109.61 MW respectively. The winter season was considered to consist of the months from November to March, with the remaining months grouped into the summer category. The effective capacity of the Whitehorse and Mayo hydro plants during the winter season is limited to 24.5 MW and 9.0 MW respectively due to seasonal hydrological constraints. The effective capacity of the Whitehorse and Mayo hydro plants during the summer season is limited to 38.0 MW and 11.6 MW respectively due to water spilling requirements.

Table 2.2 shows an analysis of the forced outage rate (FOR) [4] data provided by YEC on all of their generating units. The generating units have been classified into 4 groups based on their types and sizes in the analysis. A five-year average FOR is calculated for each classification using the YEC data.

The FOR is the expected probability that the generating unit will not be available for service due to random failure, and is calculated using Equation 2.1 [5]. The utilization forced outage probability (UFOP) [4] is the appropriate parameter to represent the unavailability of a peaking unit that is only operated during the peak hours of the day. The UFOP is calculated using Equation 2.2 [5].

$$\text{FOR} = \frac{\text{FO} + \text{FEMO} + \text{FEPO}}{\text{FO} + \text{FEMO} + \text{FEPO} + \text{O} + \text{O(FD)} + \text{O(SD)}} \text{ x } 100 \qquad (2.1)$$

$$\text{UFOP} = \frac{\text{f(FO} + \text{FEMO} + \text{FEPO)}}{\text{f(FO} + \text{FEMO} + \text{FEPO)} + \text{O} + \text{O(FD)} + \text{O(SD)}} \text{ x } 100 \qquad (2.2)$$

Where f = demand factor $= \dfrac{\frac{1}{r} + \frac{1}{T}}{\frac{1}{r} + \frac{1}{T} + \frac{1}{D}}$,

and the durations,

FO = forced outage
FEMO = forced extension of maintenance outage

FEPO = forced extension of planned outage
O = operating
O(FD) = operating under a forced derating
O(SD) = operating under a scheduled derating
r = average repair time of the unit
D = average in-service time per occasion of demand
T = average reserve shutdown time between periods of need

Table 2.2: Analysis of YEC Generating Unit FOR Data

Unit ID	MCR (MW)	2015	2014	2013	2012	2011	Average

Table 2.3 shows the relevant FOR and UFOP data from the CEA-ERIS 2014 Generation Equipment Status Annual Report [5].

Table 2.3: CEA-2014 Generation Forced Outage Data [5]

Size & Operating Factor	Hydro Unit, FOR	Combustion Turbine, UFOP
Small units	9.70% (5-23 MW, 607.5 uy)	47.14% (10-24 MW, 12.8 uy)
All sizes	5.03%, (2290.8 uy)	15.31%, (165.2 uy)
Op. Factor below 10%	95.92%	19.95%, (106.9 uy)
Op. Factor 11-20%	64.49%	16.29%, (5.0 uy)
Op. Factor 21-30%	24.69%	8.44%, (24.4 uy)
Op. Factor 61-70%	1.23% (37.2 uy)	
Op. Factor 71-80%	2.08% (65.2 uy)	
Op. Factor 81-90%	1.40%, (669.8 uy)	
Op. Factor above 90%	0.61%, (366.5 uy)	

Note: uy = units years

The YEC generation system includes hydraulic units, diesel engine units and natural gas combustion turbine units. The CEA report does not include diesel engine units. The YEC data for the diesel unit FOR was obtained from a population of 38 units years of data, and are used in the study. A review of YEC data and CEA data shown Tables 2.2 and 3.3 indicate that the YEC hydro unit FOR data are within the range of the CEA data for hydro units with high operating factors. As most YEC hydro units have high operating factors, the average of the actual YEC data is used in this study. There is very little YEC data on the forced outage of natural gas units. The CEA data for small combustion turbine units is skewed by the full outage of 3 units reported in the year 2014. The CEA UFOP data considering all operating factors and sizes of combustion turbine units calculated from a sample of 165.2 unit years are, therefore, used as representative data for natural gas combustion turbine in this study. Table 2.4 shows the generating unit FOR data used in the 2011 YEC report [3], the average FOR data obtained from actual YEC data collection, and the

FOR data used in the current reliability study. The FOR data used in this study are shown in the last column of Table 2.4.

Table 2.4: FOR Data for YEC Generating Units

Generating Unit	FOR (%)		
	2011 Study Data [3]	YEC Actual Data	Data for this study
Hydro	3.0	0.9	1.0
Diesel	10.0	3.7	4.0
Natural Gas	N/A	0.6	15.0

2.2 System Load Data

Historical data on the total chronological hourly generation to meet the system load for the past five years were provided by YEC, and is shown in Figure 2.2.

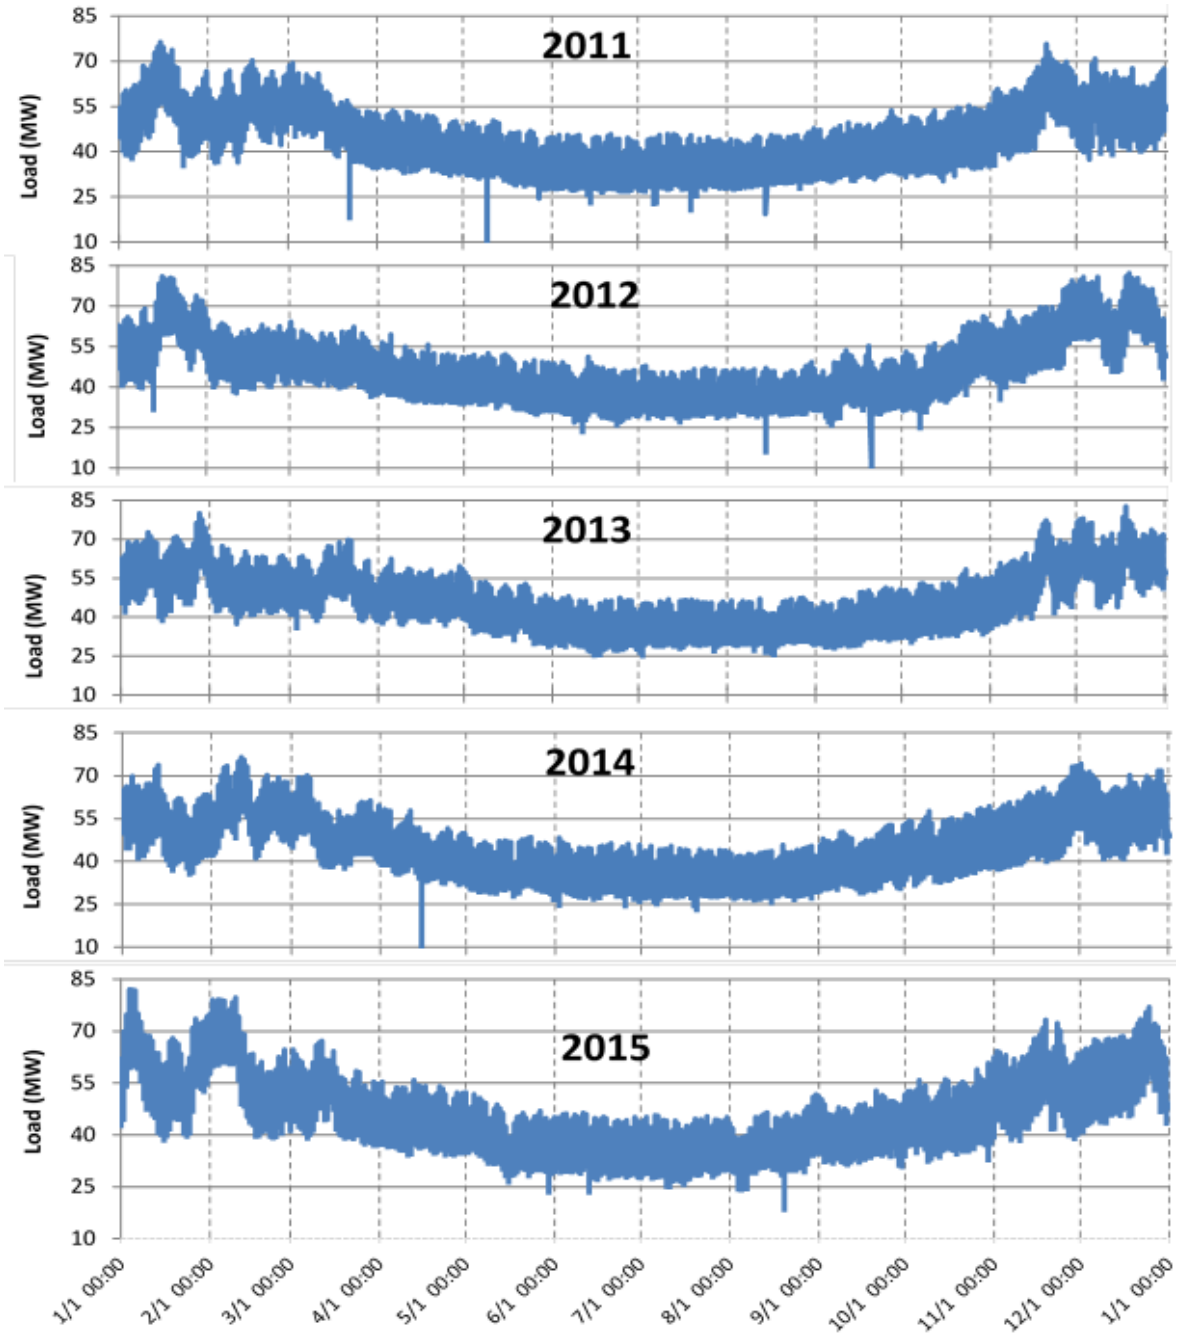

Figure 2.2: YEC Hourly Generation Data, 2011 – 2015

The sudden drops in generation in Figure 2.2 likely indicate data associated with loss of load events, and are therefore replaced by interpolated data. Figure 2.3 shows the modified chronological load data for the past 5 years.

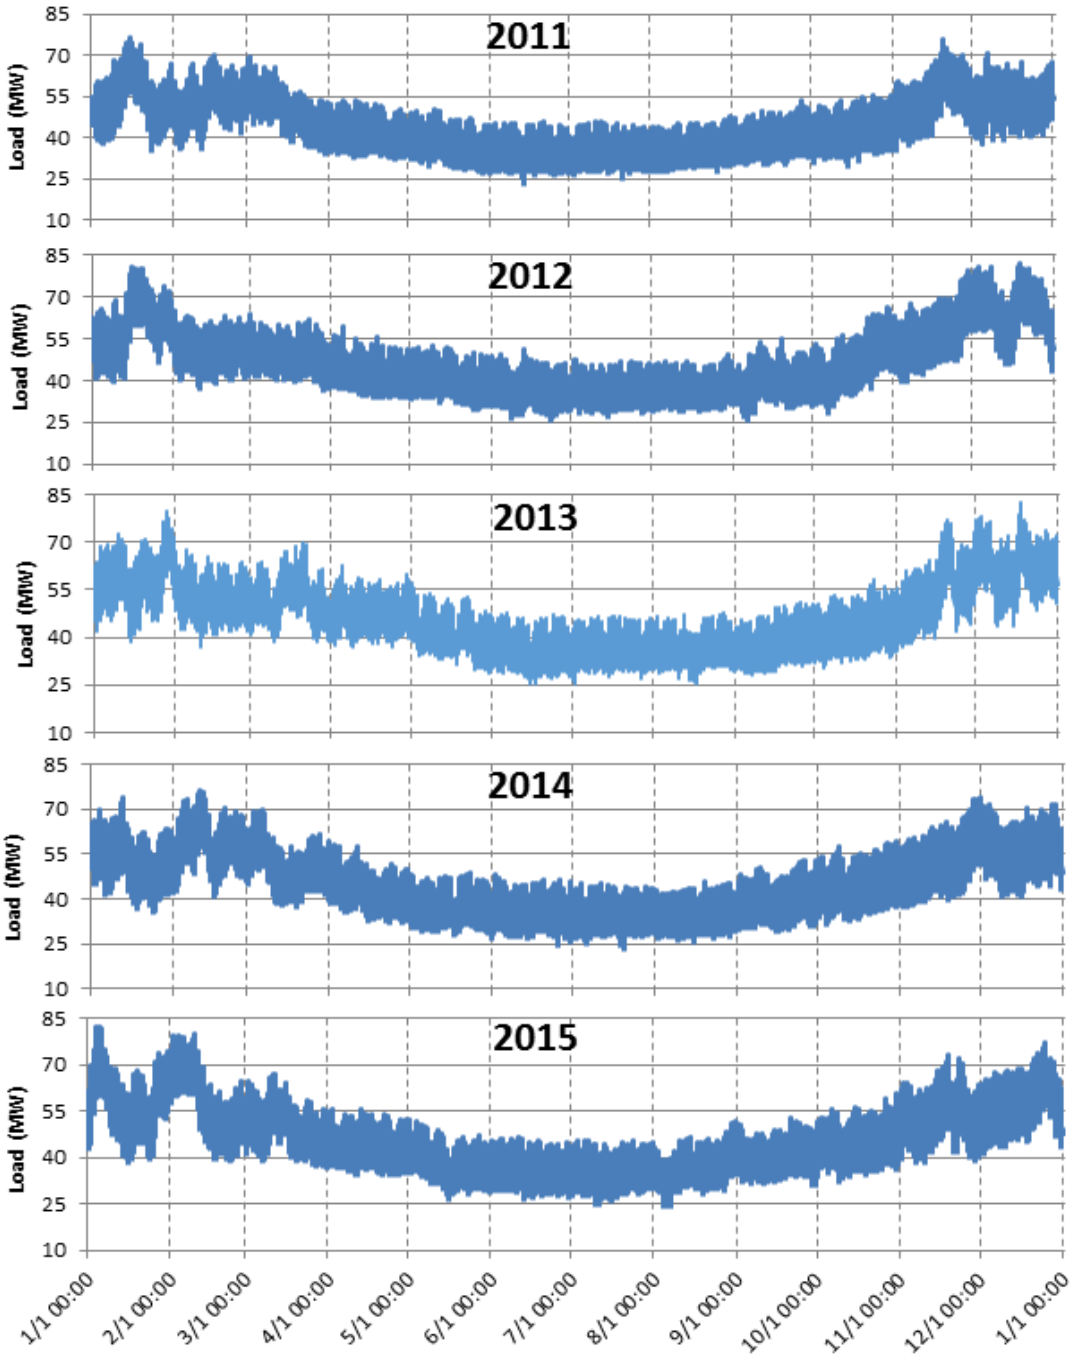

Figure 2.3. YEC Hourly Load Data for 2011-2015

The chronological load data were sorted in the decreasing order and expressed in per unit of the corresponding peak loads of the year to create the annual load duration curve (LDC) for each year. Data for the extra day in the leap year were not considered in the load model. Table 2.5 shows the annual peak load and the load factor for each year. Figure 2.4 shows the annual LDC for the 5 years. The average LDC was obtained by averaging the 5 LDC load points expressed in per unit of their respective peak loads that are arranged in the decreasing order. The average LDC can be used as a representative load model in reliability studies for system planning. The average LDC is also shown in the figure.

Table 2.5: Annual Peak Load and Load Factor

	2011	2012	2013	2014	2015	Average LDC
Load Factor	60.1%	58.9%	58.2%	60.8%	57.9%	58.3%
Peak Load (MW)	76.34	82.24	82.69	76.52	82.06	-

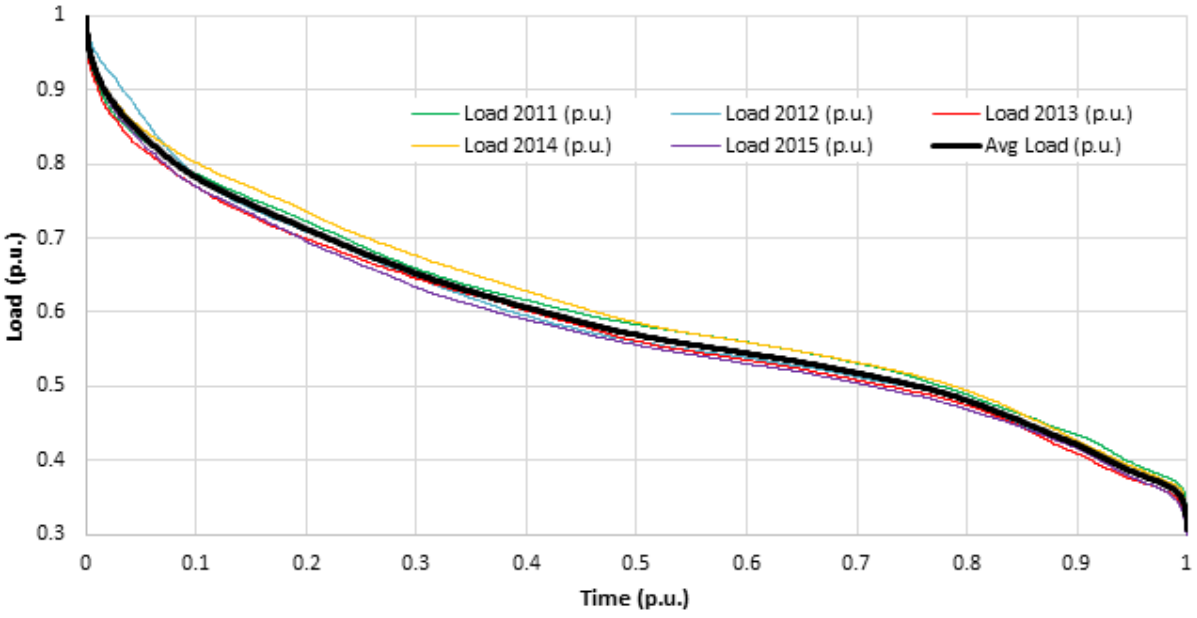

Figure 2.4. Annual Load Duration Curves, 2011 - 2015

2.3 System Evaluation and Models

A basic generating capacity adequacy evaluation was initially conducted for the YEC system using the model in Figure 2.1 without considering the seasonal capacity limitations of the Whitehorse and Mayo hydro plants. The generating unit data shown in the 4th and 5th columns of Table 2.1, and the outage data shown in the last column of Table 2.4 were used to create the overall system generation model. The annual LDCs were used as the system load model. The system LOLE were calculated for a range of peak loads using the average and the five LDCs for each of the past years. The LOLE results are shown in Table 2.6 and Figure 2.5.

Table 2.6: System LOLE Obtained Using the Load Models for the Different Years

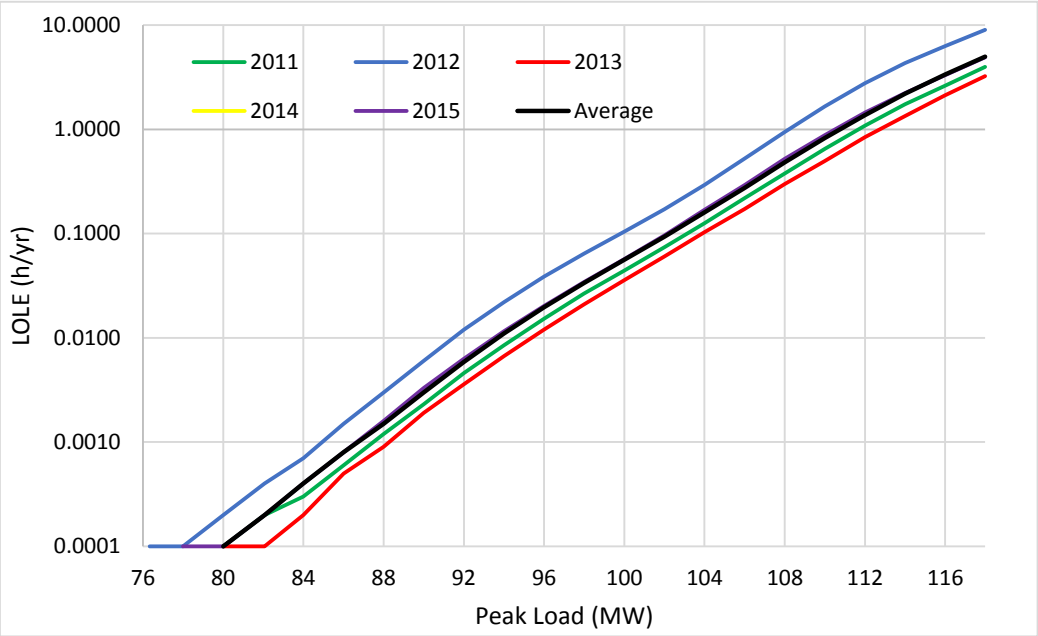

Figure 2.5: System LOLE Obtained Using the Load Models for the Different Years

A comparison of the LOLE results shown in Table 2.26 and Figure 2.5 indicates that there is insignificant difference in the results obtained using the 2015 load model and the average load model. The 2015 load model can therefore be used instead of the average load model in adequacy study. It should however be noted that the above results do not consider the seasonal hydro capacity constraints, which can have significant impact on the LOLE and LOEE indices.

It was shown in the 2011 report [3] that the reliability indices calculated for the winter period were practically the same as those calculated for the entire year, since the summer indices were insignificant relative to the annual indices. A comparative adequacy study similar to the one discussed above using the load models for the different years was next carried out for the winter period recognizing the seasonal hydro capacity limitations. The 5 months between the months of November and March were considered in the winter period. The generating unit data shown in the 4th and 6th columns of Table 2.1 were used to create the overall system generation model in this case. The winter LDCs were used as the system load model. Figure 2.6 shows the winter LDC for the 5 years. The average winter LDC is also shown in the figure.

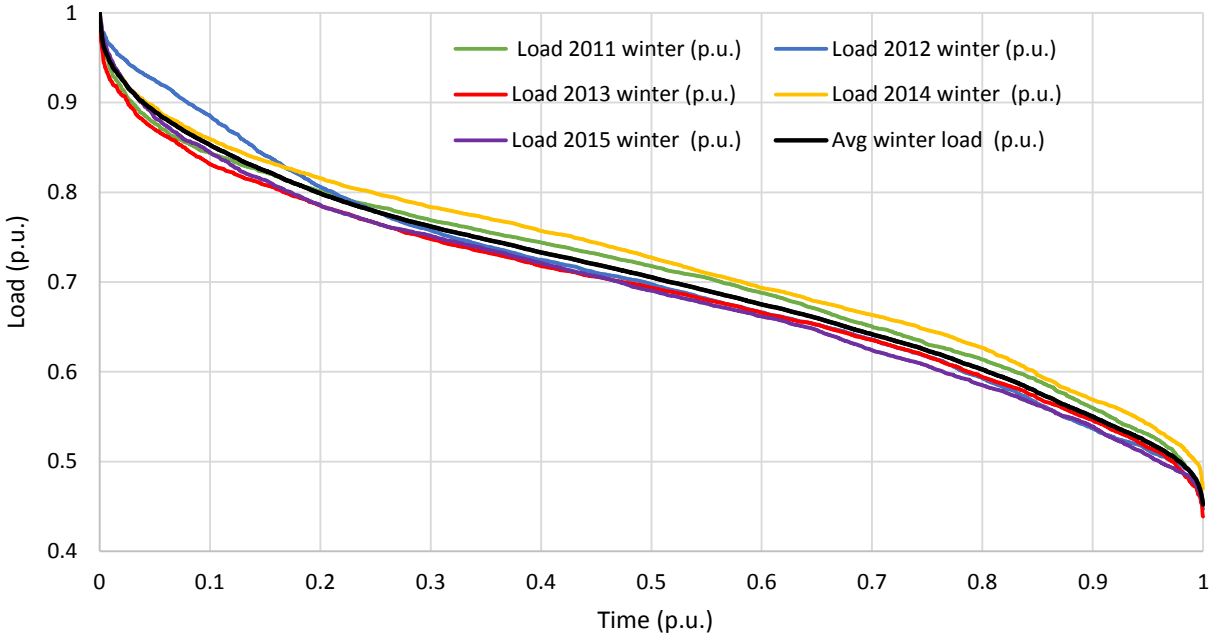

Figure 2.6. Winter Load Duration Curves, 2011 - 2015

The system LOLE and LOEE were calculated for the range of peak loads using the average winter LDC and the five winter LDCs for each of the past years. The results are shown in Table 2.7 and 2.8 respectively. The results shown in bold font are the system LOLE and LOEE obtained from HL-I generation adequacy evaluation in the past five years assuming that the same amount of system capacity existed in the past five years. The system LOLE and LOEE are also shown as a function of the system peak loads in Figures 2.6 and 2.7 respectively.

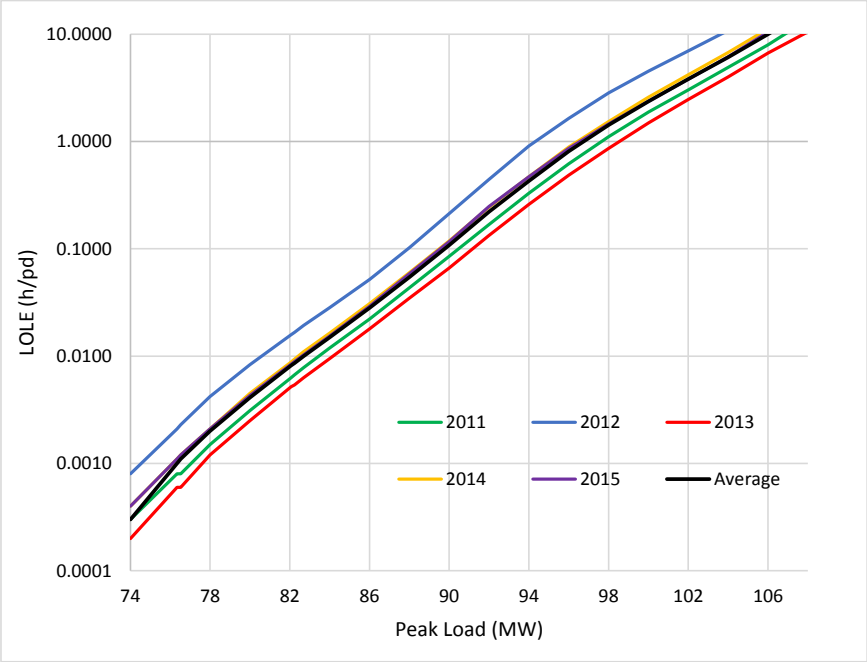

Figure 2.6: Winter LOLE Obtained Using the Winter Load Models for the Different Years

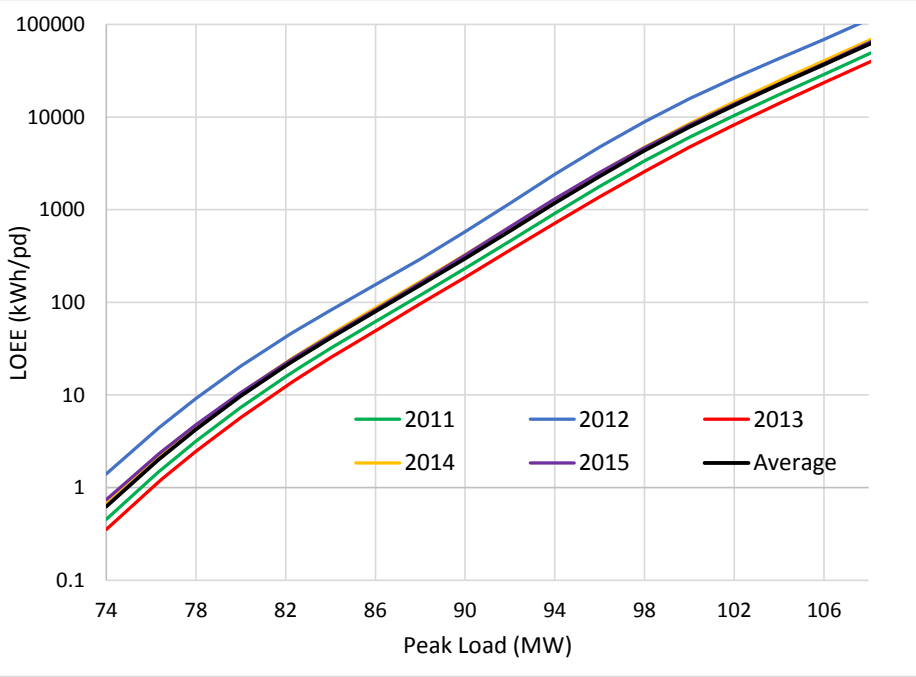

Figure 2.7: Winter LOEE Obtained Using the Winter Load Models for the Different Years

A comparison of the LOLE and LOEE results shown in Figures 2.6 and 2.7 indicates that there is insignificant difference in the results obtained using the 2015 winter load model and the average winter load model. The 2015 load shape can therefore be used as a representative load profile for the YEC adequacy study.

It should be noted from the comparison of the LOLE results in Tables 2.5 and 2.6 that the system LOLE are substantially increased when winter capacity limitations are incorporated in the evaluation. An annual assessment done without considering seasonal capacity limitations result in highly optimistic LOLE indices. It is therefore necessary to carry out period analysis that recognizes the seasonal capacity constraints of the hydro plants.

A period analysis was next carried out considering the seasonal hydro capacity constraints. A study year was divided into two periods; (1) winter period from November to March and (2) summer period between April to October. Separate generation and load models were created for each period. The winter and summer load models obtained from the 2015 load data were used in the study, and are shown in Figure 2.8. The reliability indices calculated for each period were then aggregated to obtain the overall annual indices. The results are shown in Table 2.9.

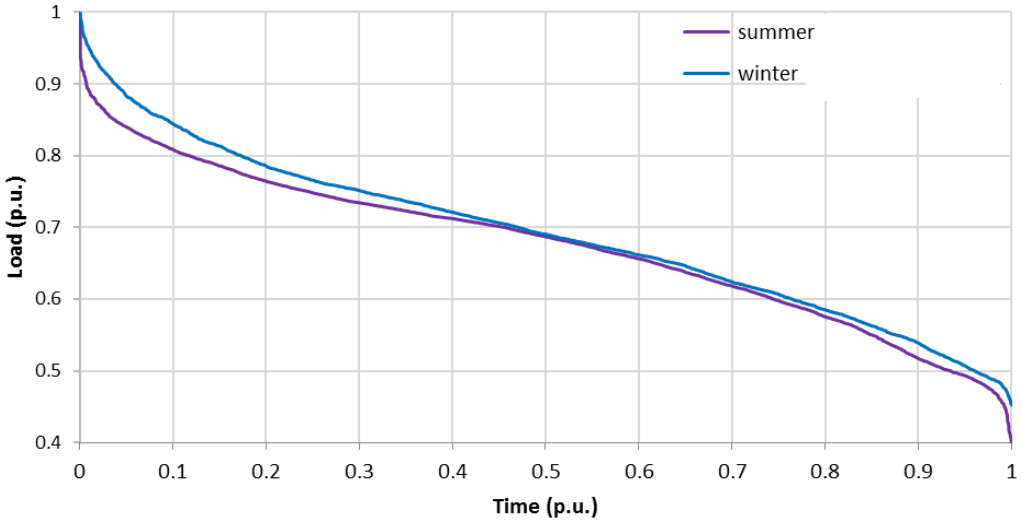

Figure 2.9: Winter and Summer Load Models in Per Unit of their Respective Peaks

96	0.0061	0.8643	0.8704	-0.70%	0.0172	2.5327	2.5499	-0.67%
98	0.0109	1.4583	1.4692	-0.74%	0.0321	4.6678	4.6999	-0.68%
100	0.0194	2.3792	2.3986	-0.81%	0.0582	8.2089	8.2671	-0.70%
102	0.0338	3.7970	3.8308	-0.88%	0.1042	13.8402	13.9445	-0.75%
104	0.0564	6.1686	6.2250	-0.91%	0.1818	22.9164	23.0981	-0.79%
106	0.0940	10.4473	10.5413	-0.89%	0.3123	37.8679	38.1802	-0.82%

It can be observed from Table 2.9 that the winter LOLE and LOEE are proximately equal to the annual LOLE and LOEE, and the error between the winter and annual indices as shown in the table are insignificant for all practical purposes. The LOLE and LOEE results are also shown in Figures 2.10 and 2.11 respectively. The peak load carrying capability (PLCC) of the YEC system at a LOLE criterion of 2.0 h/yr was also calculated using the period analysis. The PLCC considering both the summer and winter periods was found to be 99.22 MW. The PLCC obtained using only the winter models was 99.25 MW. It can therefore be concluded that the winter indices obtained using the winter generation and load models can be used to represent the annual indices in generation adequacy evaluation of the YEC system.

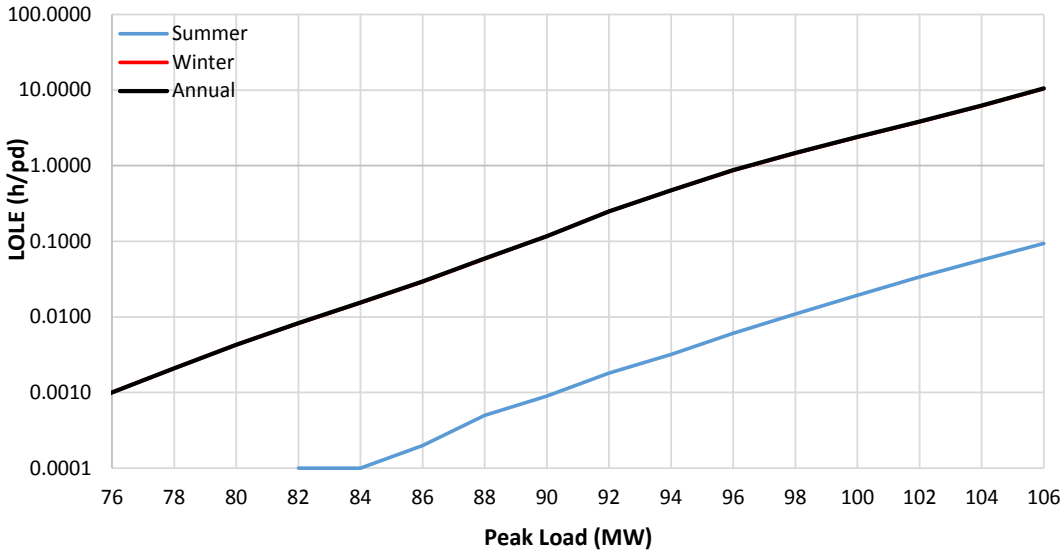

Figure 2.10: Summer, Winter and Annual System LOLE

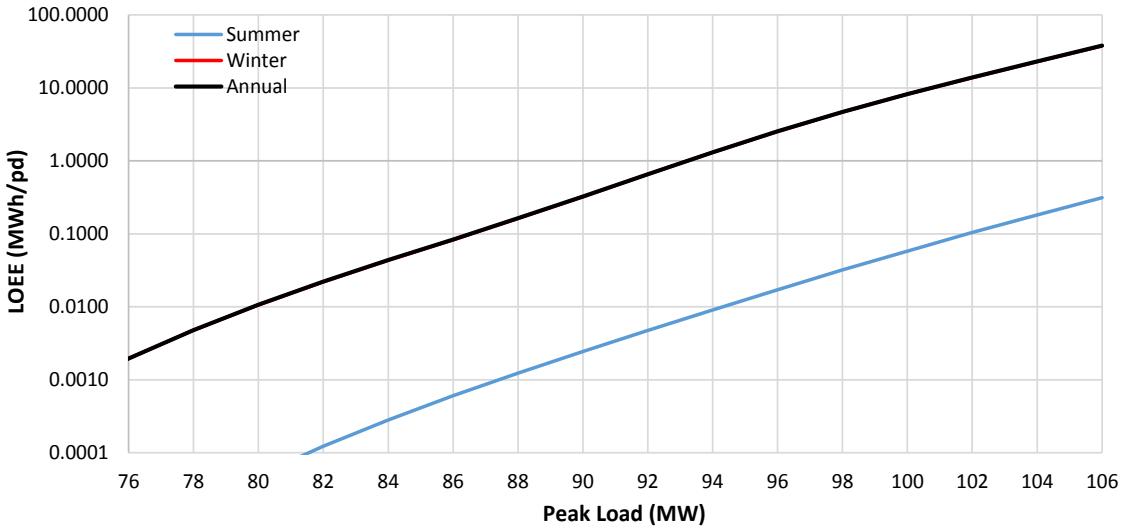

Figure 2.11: Summer, Winter and Annual System LOEE

It should be noted that the adequacy evaluation results presented in this section do not consider the transmission system. This is the typical approach in large power systems that have balanced transmission networks. In such systems, an LOLE of 0.1 days per year is the recommended reliability criterion in capacity planning. A daily peak load variation curve (DPLVC) is used as the load model instead of the LDC when evaluating the LOLE in days per year. A DPLVC curve is obtained by sorting the daily peaks in the decreasing order, and the load model is shown in Figure 2.12. Using the LOLE of 0.1 days per year as the criterion, the PLCC of the YEC system was evaluated, and found to be 94.36 MW. The LOLE in hours per year is 0.52 h/yr at the peak load of 94.36 MW.

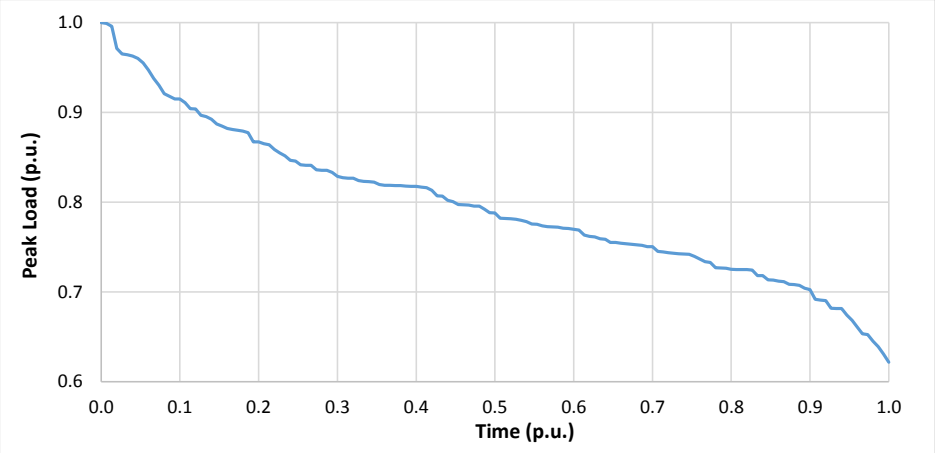

Figure 2.12: Year 2015 Winter DPLVC

2.4 Selected Task 1 Studies

As noted earlier, many large power systems conduct generation adequacy evaluation during generation planning, and these studies do not normally consider the transmission system. This type of evaluation is carried out in Task 1 using generating unit data from Table 2.1 and the forced outage data in the last column of Table 2.4. The hydro plant capacity limited by the winter water

conditions as shown in the 6th column of Table 2.1 are used in the evaluation. The 2015 winter LDC is used as the load model which includes the local loads and the line losses. The system LOLE and LOEE for a range of peak loads are shown in Table 2.9.

A FOR of 15% was used in the adequacy study based on the CEA data [5]. A study was also done assuming the Whitehorse natural gas units have the same FOR as the diesel generating units, which is 4%. The LOLE and LOEE results for a range of peak loads can be compared in Table 2.10. A comparison of the LOLE results is also shown in Figure 2.13.

Table 2.10: Impact of Natural Gas Unit FOR on Task-1 LOLE and LOEE Results

Peak Load (MW)	LOLE (h/yr)		LOEE (MWh/yr)	
	FOR=15%	FOR=4%	FOR=15%	FOR=4%
74	0.0004	0.0001	0.743	0.215
76	0.0010	0.0004	1.962	0.663

84	0.0154	0.0092	43.453	24.161
86	0.0292	0.0162	83.278	47.343
88	0.0587	0.0299	162.524	89.069
90	0.1165	0.0569	321.692	167.778
92	0.2475	0.1240	654.127	330.894
94	0.4702	0.2563	1306.969	673.851
96	0.8643	0.5405	2532.747	1396.100
98	1.4583	0.9747	4667.780	2793.316
100	2.3792	1.6655	8208.876	5250.518
102	3.7970	2.5858	13840.248	9172.959
104	6.1686	4.0635	22916.385	15253.594
106	10.4473	6.4940	37867.875	24757.285
108	17.5478	10.8929	63699.516	40629.656
110	29.6536	19.4732	106803.742	67901.023

The difference in PLCC using the two different FOR data for the natural gas units can be seen in Figure 2.13. The difference in PLCC at the LOLE criterion of 2 hours per year is 1.56 MW. The system PLCC results are shown in Table 2.11. The system PLCC at the LOLE criterion of 0.1 days per year is also shown in the table.

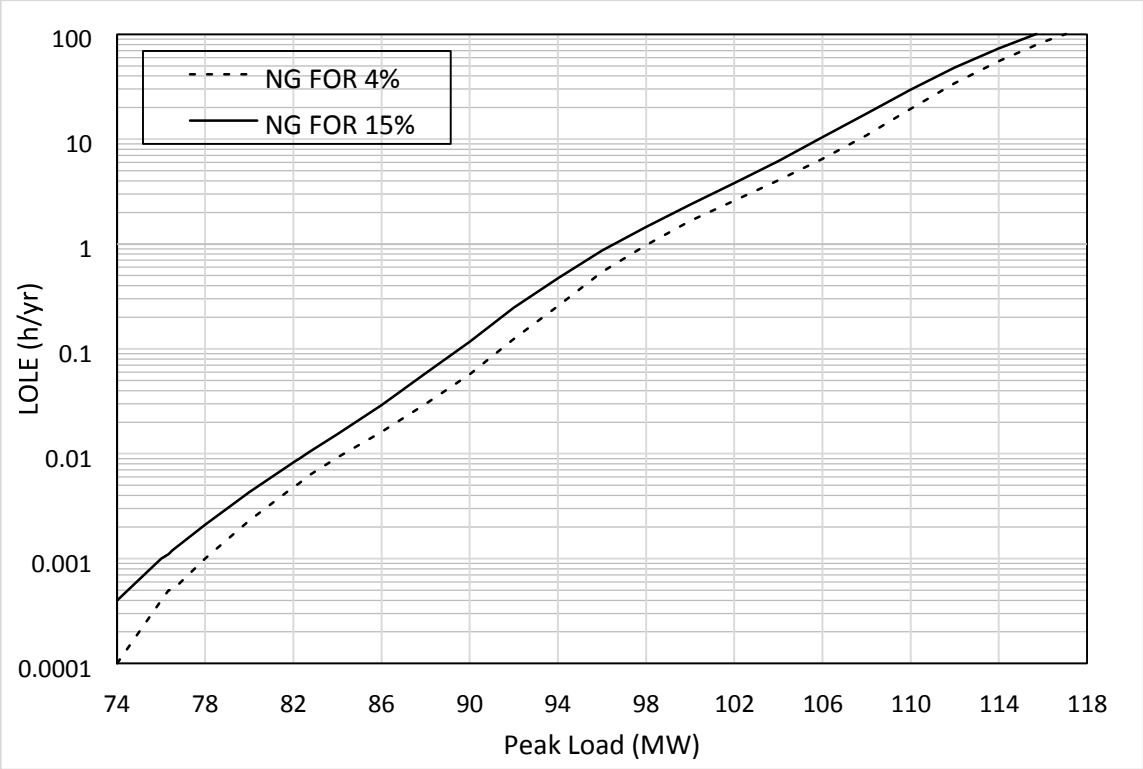

Figure 2.13: Comparison of the System LOLE Using Different FOR Data for the Natural Gas Units

Table 2.11: Comparison of System PLCC Using Different FOR Data for the Natural Gas Units

LOLE Criterion	PLCC (MW)	
	FOR=15%	FOR=4%
2.0 h/yr	99.2487	100.8139
0.1 d/yr	94.3608	95.5425

The adequacy studies includes the YEC generation data shown in Table 2.1. A Task 1 generation adequacy study was also carried out including the ATCO/YECL diesel generating units shown in Table 2.12 in addition to the data in Table 2.1. The FOR of 4% is used in the adequacy study for the ATCO diesel generating units. The system PLCC at LOLE criteria of 2 hours per year and 0.1 days per year are shown in Table 2.13. The system LOLE and LOEE for a range of peak loads are shown in Table 2.14 considering two different FOR for the natural gas units in Whitehorse, i.e. 4% and 15%.

114	18.2479	11.4256	66277.711	42149.414
116	30.8129	20.7405	111452.039	71426.867
118	49.0267	35.4309	186063.719	123988.352
120	73.6220	56.5360	299618.188	209177.094

The 8 ATCO generating units in Table 2.12 have a total generating capacity of 5.74 MW. A comparison of the PLCC results in Tables 2.11 and 2.14 shows that the increase in PLCC due to the consideration of the ATCO units is 5.69 MW at the LOLE criterion of 0.1 days per year. The increase in PLCC at the LOLE criterion of 2 hours per year is 5.94 MW. These values are calculated considering 15% FOR of natural gas units at Whitehorse. The local peak loads served by the ATCO generating units must be considered in assessing the peak load that can be carried by the system.

3. IMPACT OF TRANSMISISON LINE OUTAGE ON GENERATING SYSTEM ADEQUACY

This section presents reliability studies on the impacts of the forced outages of the major transmission lines on the YEC generation system adequacy. The major transmission lines linking the YEC generation plants to the bulk system load at Whitehorse is shown in Figure 3.1.

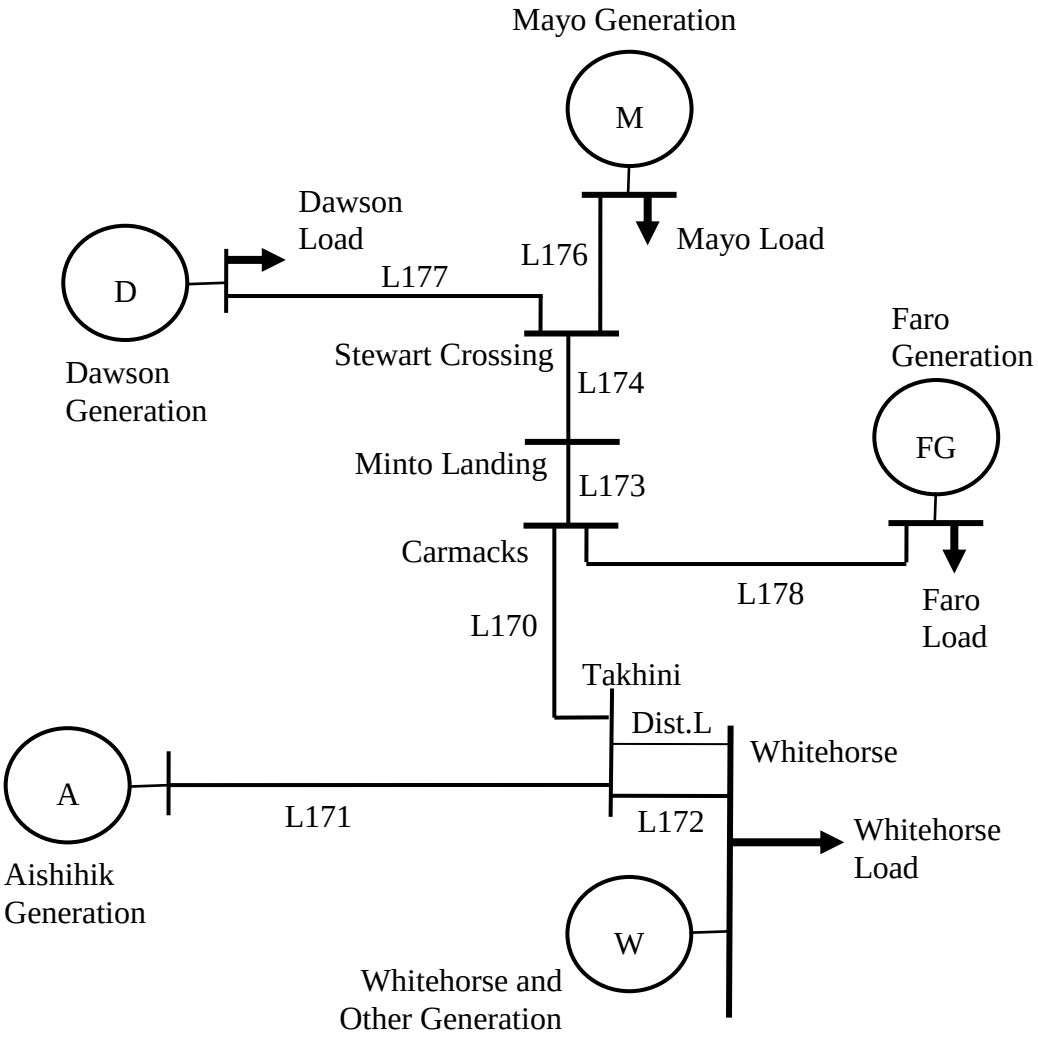

Figure 3.1: YEC Major Transmission Lines and Generation Plants

The impact of individual line segments on the ability of the YEC generation to satisfy the bulk load at the Whitehorse area is evaluated, and the resulting LOLE, LOEE and PLCC indices are calculated and compared with the base case in which the transmission system is not considered. The objective of the studies is to identify the major line segments that significantly affect the generation adequacy indices, and therefore, need to be considered in the development of the generation adequacy model of the YEC system.

3.1 Major Transmission Line Data

Table 3.2 shows the major YEC transmission system data that are used in the study. It should be noted that the line ID numbers have changed since the work done in the 2011 report [3].

Table 3.2: YEC Major Transmission System Data

Line Segment		Line Length (km)	Volt. Rating (kV)	Structure Type
Stations	Line ID			
Dawson – Stewart Crossing	L177	172	69	wood, single pole
Mayo – Stewart Crossing	L176	52	69	wood, single pole
Stewart C. – Minto Landing	L174	95	138	wood, double pole
Minto Landing - Carmacks	L173	71	138	wood, double pole
Faro - Carmacks	L178	190	138	wood, double pole
Carmacks - Takhini	L170	152	138	wood, double pole
Ashihik - Takhini	L171	130	138	wood, double pole
Takhini - Whitehorse	L172	25	138	wood, double pole
Distribution line parallel to L172		17	34.5	wood, single pole

All the transmission lines listed in Table 3.2 are capable of transferring the maximum power generated at the generation plants. The 34.5 kV distribution line parallel to L172 has a maximum load carrying capability of 19.6 MW, considering the overload protection setting at 20 MVA during the outage of line L172, and a power factor of 0.98.

The unavailability parameter for the 34.5 kV - 69 kV wood single pole and 138 kV wood double pole transmission lines were calculated using the 2014 CEA [6] data shown in Tables 3.3 and 3.4 respectively.

Table 3.3: CEA 2014 Transmission Line Data for < 110 kV, Wood Single-pole Structure

Outage Type	Failure Rate (failures/year)	Mean Down Time (hours)	Unavailability (%)
Sustained	3.0548/100 km	19.0	-
Transient	3.4406/100 km	-	-
Station	0.1614	-	0.146

Table 3.4: CEA 2014 Transmission Line Data for 110 – 149 kV, Wood Double-pole Structure

Outage Type	Failure Rate (failures/year)	Mean Down Time (hours)	Unavailability (%)
Sustained	0.9782/100 km	21.4	-
Transient	0.9087/100 km	-	-
Station	0.1295	-	0.085

Table 3.5 shows a sample calculation of the unavailability data for line L171 using the CEA data in Table 3.4. The sustained and transient failure rate for the 130 km lines are 1.27166 (i.e. 0.9782*130/100) and 1.18131 failures per year respectively.

Table 3.5: Transmission Line L171 Unavailability Calculation

Line and outage Component	Failure rate (failures/year)	Mean Down Time (hours)	Unavailability	
			(hours/year)	(%)
Sustained	1.27166	21.4	27.21352	0.3107
Transient	1.18131	0	0	0
Station (one end)	0.1295	-	-	0.085
Station (other end)	0.1295	-	-	0.085
			Total	0.4807

Table 3.6 shows the unavailability of all the major lines in the YEC system using the CEA 2007 [3] and CEA 2014 outage statistics for comparison.

Table 3.6: YEC Major Transmission System Unavailability Data

Line Segment (Note old line ID in brackets)	Line length (km)	Unavailability (%)	
		CEA 2007 data [3]	CEA 2014 data
L177 (L174W)	172	1.1827	1.4316
L176 (L174E)	52	0.5225	0.6365
L173+L174 (L173)	166	0.2237	0.5667
L178 (L170B)	190	0.2476	0.6240
L170 (L170A)	152	0.2267	0.5332
L171	130	0.2028	0.4807
L172	25	0.0984	0.2297
Distribution line parallel to L172	17	-	0.4046

Table 3.7 and Table 3.8 show the line losses in the major transmission lines for peak load and typical load scenarios that were obtained from load flow studies done by YEC. The data has been analyzed to obtain line losses as a percentage of the line loading for the major transmission lines. The losses in the distribution line between Takhini and Whitehorse at full loading is 443 kW.

Table 3.7: YEC Major Transmission Losses at Peak Load Scenario

Line Segment	Length (km)	Loading (kW)	Line Losses		
			(kW)	% of loading	%/100km
L177	172	4958	99	2.00%	1.16%
L176	52	9037	268	2.97%	5.70%
L174	95	4597	41	0.89%	0.94%
L173	71	981	5	0.51%	0.72%
L178	190	3276	67	2.05%	1.08%
L170	152	1606	96	5.98%	3.93%
L171	130	27079	1185	4.38%	3.37%
L172A	10	2227	2	0.09%	0.90%
L172B	15	25591	136	0.53%	3.54%
Total Losses at Peak Load			1899		

Table 3.8: YEC Major Transmission Losses at Typical Load Scenario

Line Segment	Length (km)	Loading (kW)	Line Losses		
			(kW)	% of loading	%/100km
L177	172	2381	35	1.47%	0.85%
L176	52	6970	149	2.14%	4.11%
L174	95	4225	29	0.69%	0.72%
L173	71	686	9	1.31%	1.85%
L178	190	7641	31	0.41%	0.21%
L170	152	4282	158	3.69%	2.43%
L171	130	24752	1010	4.08%	3.14%
L172A	10	2911	1	0.03%	0.34%
L172B	15	17454	62	0.36%	2.37%

3.2 Local Load Data

The local loads at the major generation plants at Dawson, Mayo and Faro that occurred in the year 2015 are shown in Table 3.9. The Elsa Keno load is combined with the Mayo load considering that they will be served by Mayo generation. The Minto Mine and Pelly loads are mainly served by the respective local diesel generation, and they will have little impact on the transmission lines or the ability of the overall system to meet the main system load. The Minto Mine and Pelly generation and loads are therefore not considered in the reliability evaluation model. The Haines Junction load is primarily met by the local diesel generation, and therefore, will not impact the ability of the system to meet the bulk load at Whitehorse through the line L171. The Haines Junction load is therefore lumped with the Whitehorse load in the reliability model.

Table 3.9: Local Loads at Major Generation Plants

Locations	Dawson	Mayo + Elsa Keno	Faro
Load (MW)	3.62	1.48 + 0.38 = 1.86	2.12

3.3 System Risk Evaluation Considering Line Outages

A conditional probability approach is used to evaluate the impact of a transmission line segment on the generating system adequacy. The generating system risk indices (i.e. LOLE and LOEE) are evaluated for the two conditions of the line segments being available and unavailable due to forced outage, and resulting risk index is calculated using Equation 3.1. The local loads isolated due to the outage of the line segment, and the corresponding line losses are subtracted from the bulk system load at the Whitehorse area when evaluating the risk indices for the condition that the line segment is on forced outage.

$$LOLE = (LOLE \mid L_out) \times U_L + (LOLE \mid L_in) \times (1 - U_L) \quad (3.1)$$

Where U_L is the unavailability of the line segment L, and LOLE|L_out and LOLE|L_in are the system LOLE given the line segment L is forced out and available respectively.

Equation 3.2 is used to calculate the system LOLE and LOEE when evaluating the impact of the parallel lines (i.e. L172 and the distribution line, DL) between Takhini and Whitehorse. Given the condition that the line L172 is out and the distribution line is available to transfer a maximum capacity of 19.6 MW to Whitehorse, the local loads at Mayo, Dawson and Faro are subtracted from the generation capacity model before passing it through the distribution line to Whitehorse. The line losses are proportionally reduced when considering this condition that has only 19.6 MW transfer capability.

$$LOLE = (LOLE \mid \text{both lines out}) \times U_{L172}.U_{DL} + (LOLE \mid L172_out) \times U_{L172}(1-U_{DL}) + (LOLE \mid DL_out \text{ OR no line outages}) \times (1-U_{L172}) \quad (3.2)$$

Figure 3.2 shows the system LOLE as a function of the annual peak load considering the impact of the major transmission lines illustrated in Figure 3.1. The LOLE was calculated considering the impact of one transmission line at a time, except for the parallel lines between Takhini and Whitehorse indicated as L172+DL in the figure. Also, the lines L173 and L174 were combined and considered as a single line and indicated as L174+L173 in the figure. The base case results are

also shown which does not consider the impact of the transmission lines. Figure 3.3 shows a similar graph for system LOEE.

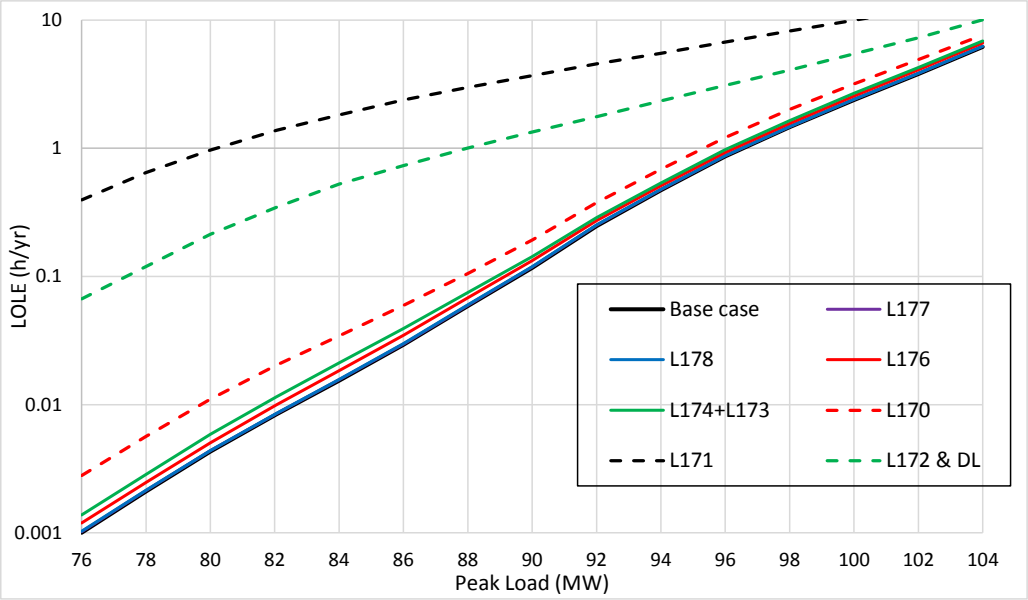

Figure 3.2: Impact of Individual Line Outage on the System LOLE

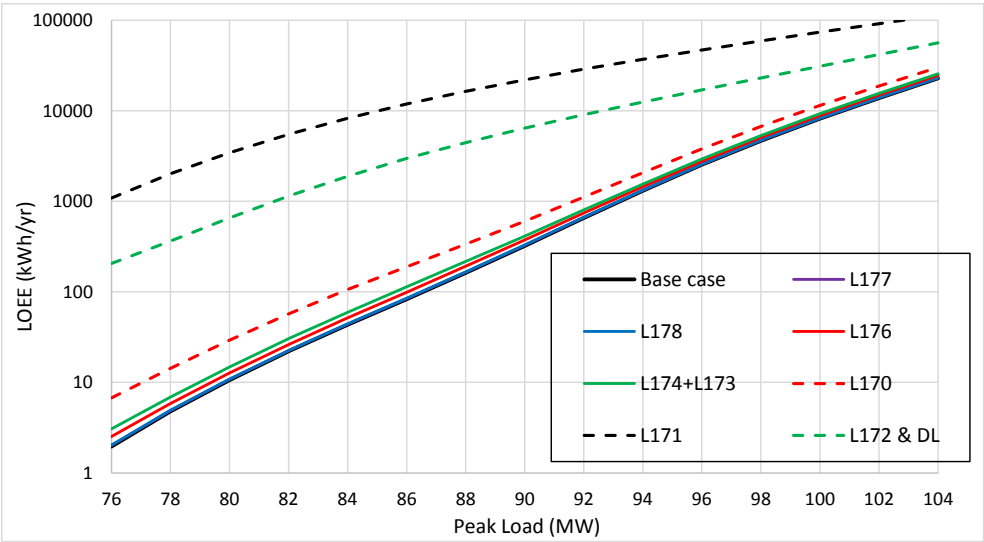

Figure 3.3: Impact of Individual Line Outage on the System LOEE

The LOLE and LOEE results for the different cases were compared with the Base Case results to assess the impacts of the different line segments on the system indices. It can be seen from Figure 3.2 that the different transmission line segments have varying impacts on the system LOLE. The lines are arranged in increasing order of their impacts on the system LOLE below:

L177 (connecting Dawson)
L178 (connecting Faro)
L176
L174+L173
L170
L172 parallel with Distribution Line
L171 (connecting Ashihik)

Figure 3.2 shows that the impacts of the lines L177 (connecting Dawson) and Line L178 (connecting Faro) have very little impact on the system LOLE as the results are almost the same as that obtained for the Base Case that does not consider the impact of the transmission lines. These lines therefore do not need to be considered in the generation adequacy model of the YEC system. The line L171 (connecting Ashihik) has the largest impact on the LOLE results. The impact of the parallel lines L172 and the distribution lines connecting Takhini and Whitehorse also have significant impact on the system indices. These line segments should therefore be considered in the generation adequacy model of the system. The lines L176, L174+L173 and L170 connect the Mayo hydro generation to the bulk system load at Whitehorse, and the impact of these lines increases with their proximity to Whitehorse area load. Similar observation can be noted from the LOEE results in Figure 3.3.

Redundancy in a transmission system can significantly improve its reliability, and this can be achieved by adding parallel transmission lines. It should be noted that the distribution line between Takhini and Whitehorse provides redundancy to the line L172. The load carrying capability of the distribution line, however, restricts its reliability contribution to the overall system. A study was carried out considering 2 different cases to analyze the reliability impact of the parallel lines

between Takhini and Whitehorse. Case 1 assumes that the distribution line was not installed and L172 is the only line to connect Takhini to Whitehorse. Case 2 is the actual scenario with 19.6 MW capacity of the distribution line in parallel to L172. Figure 3.4 shows the system LOLE for the 2 cases as a function of the system peak load. It should however be noted that all the other transmission lines are assumed to be 100% reliable and have no transfer restrictions in these studies. The results for the Base Case (that does not consider transmission constraints) and the case that considers only the impact of L171 alone are shown in the figure for comparison.

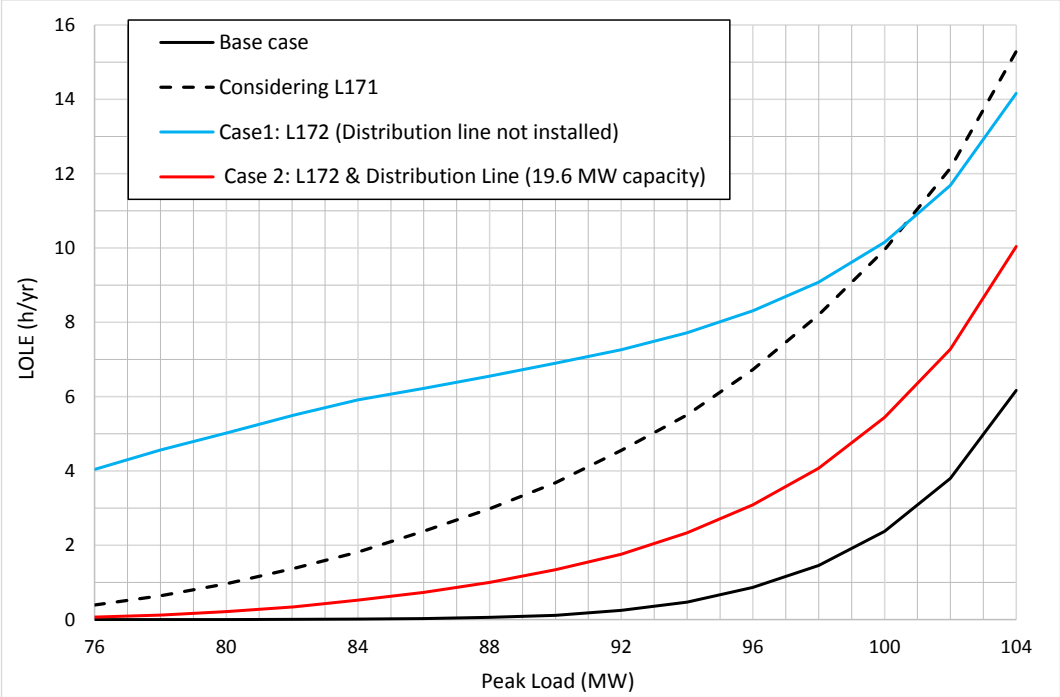

Figure 3.4: Impact of Line L172 Redundancy on the System LOLE

It can be seen from Figure 3.4 that the impact of the line L172 on the system LOLE was much greater than that of the line L171 prior to the commissioning of the distribution line between Takhini and Whitehorse. The figure shows that there has been a significant improvement in system reliability due to the distribution line between Takhini and Whitehorse despite the capacity transfer capability restriction of 19.6 MW. It can also be seen in the figure that the impact of the parallel lines between Takhini and Whitehorse would be negligible, and the LOLE results would be very close to the Base Case results if there was no restriction on the transfer capability of the distribution lines.

4. DEVELOPMENT OF GENERATING SYSTEM ADEQUACY MODEL CONSIDERING MAJOR DELIVERY CONSTRAINTS

This section presents the development of a generating system adequacy model for the YEC considering the capacity delivery constraints imposed by the major transmission lines. The results of the generation system adequacy impacts of the individual transmission lines presented in Section 3 were analyzed to develop five different models for YEC generation adequacy evaluation. The details of the five models are described in following sub-sections.

This section illustrates results from reliability studies conducted using the different adequacy models, and presents comparative analysis to determine an appropriate generation adequacy model for the YEC electric power system.

4.1 Analysis of Alternate Generation Adequacy Models

The following five different models were developed for the YEC generation adequacy evaluation based on the analysis of the results presented in Section 3. The order of the five models listed below is arranged such that the amount of input data requirements and evaluation complexity increases from Items 1 to 5 in the list.

1. Basic Generation Adequacy Model
2. WAFSREL Model
3. Extended WAFSREL Model
4. Hydro Plants Interconnection Model
5. Generation-Transmission Model

The first model or the Basic Generation Adequacy Model only considers the ability of the overall system generating capacity to meet the system load, and does not consider the transmission system. The analyses in Section 2 were done using this model. This model is shown in Figure 4.1.

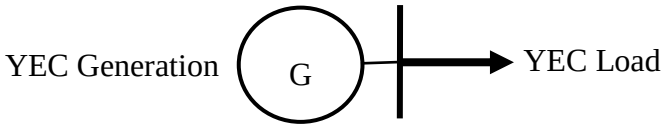

Figure 4.1: Basic Generation Adequacy Model

The LOLE and LOEE results shown in Figures 3.2 and 3.3 from comparative studies of the transmission line impacts on system adequacy clearly shows that the line L171 has the largest impact on these indices. The second model, i.e. the WAFSREL Model, considers the line L171 in the adequacy model, and is shown in Figure 4.2. The WAFSREL program [2] was developed based on this model which considers the ability of the Ashihik hydro generation capacity and its delivery through line L171 to the YEC system. The generation capacity at Whitehorse, Faro, Mayo and Dawson are also considered but their delivery constraints are not considered in this model.

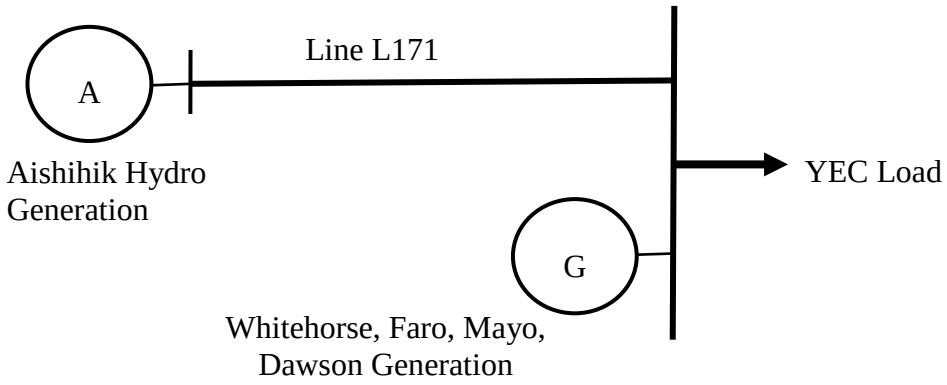

Figure 4.2: WAFSREL Model

The comparative LOLE and LOEE results in Figures 3.2 and 3.3 show that the parallel lines between Takhini and Whitehorse have the second largest impact on the adequacy indices after the line L171. The third model, i.e. the Extended WAFSREL Model shown in Figure 4.3 includes the line L171 and the parallel lines between Takhini and Whitehorse in the adequacy model. The delivery constraints of the Whitehorse, Faro, Mayo and Dawson generation are not considered in this model.

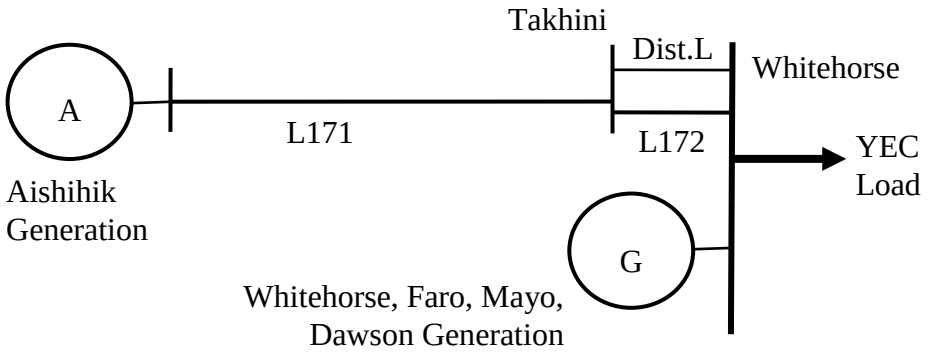

Figure 4.3: Extended WAFSREL Model

The comparative results in Figures 3.2 and 3.3 show that the transmission lines L176, L174, L173 and L170 delivering the Mayo hydro generation to the YEC system load have reasonable impact on the system LOLE and LOEE. The fourth model, i.e. the Hydro Plants Interconnection Model, considers the delivery constraints on the hydro generation from Aishihik and Mayo to serving the YEC system load, and is shown in Figure 4.4. The transmission lines L171, L176, L174, L173, L170, and the parallel lines (L172 and the distribution line between Takhini and Whitehorse) that are responsible for delivering generating capacity from Ashihik and Mayo hydro plants are considered in this model. The delivery constraints of diesel generation at Faro, Mayo and Dawson are not considered in this model. The assumption is that the diesel generation mainly meet their own local loads and have very little impact on their delivery to the rest of the YEC system.

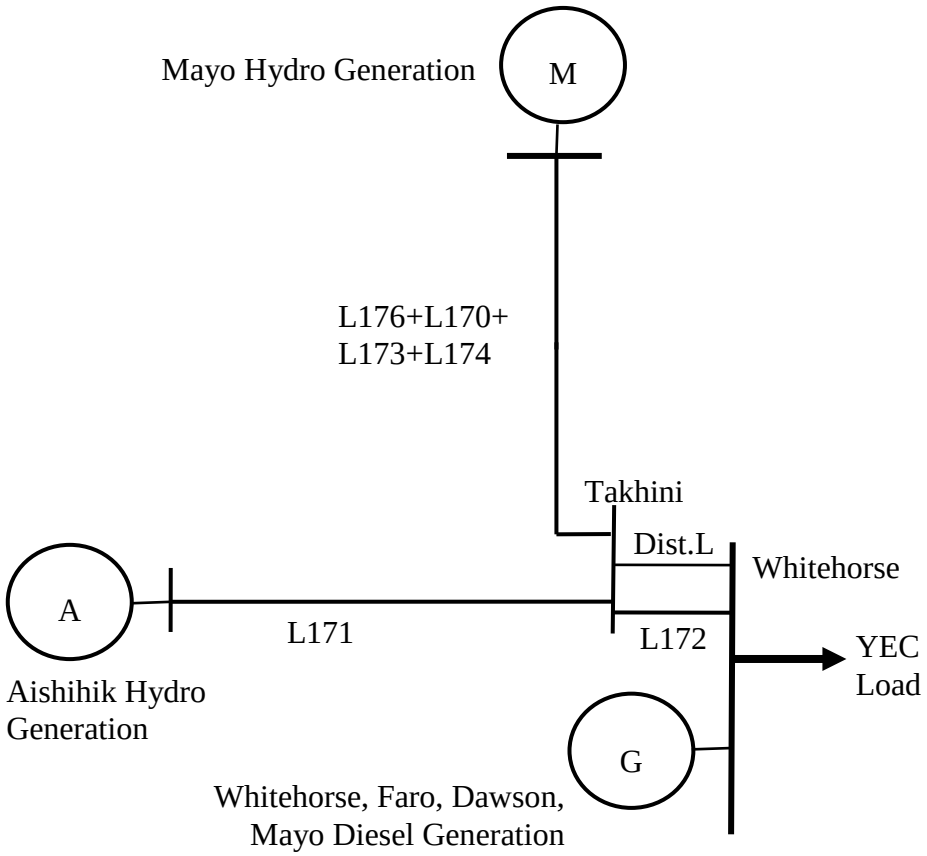

Figure 4.4: Hydro Plants Interconnection Model

The fifth model, or the Generation-Transmission Model considers the transmission constraints of the hydro plants in Ashihik and Mayo, and the diesel plants in Faro, Dawson and Mayo in serving the main system load at Whitehorse after satisfying their respective local loads at Faro, Mayo and Dawson. This model is shown in Figure 4.5.

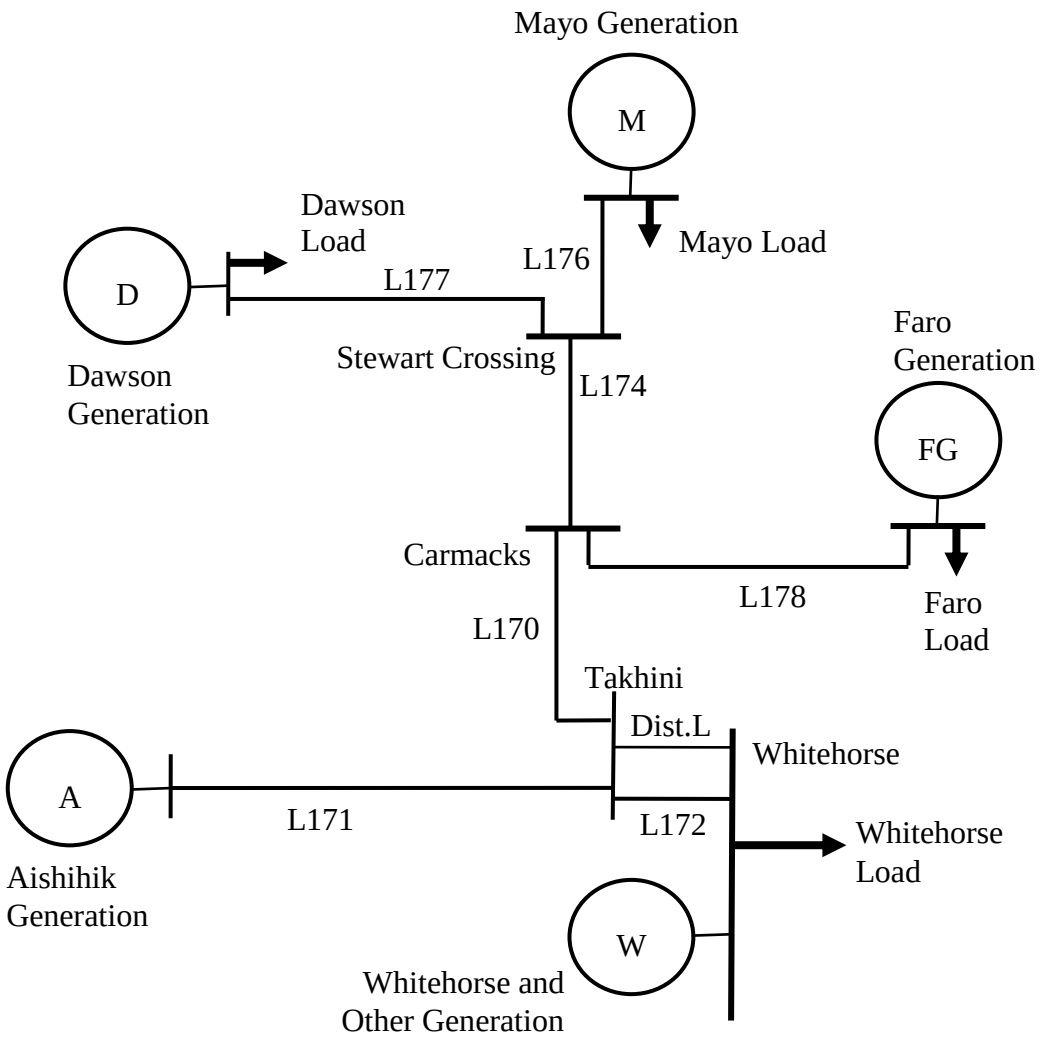

Figure 4.5: Generation-Transmission Model

4.2 Adequacy Evaluation Results from Alternate Models

The five adequacy models described in the previous sub-section are analyzed using generating unit data provided in Table 2.1 and the forced outage data shown in the last column of Table 2.4. The studies presented in Section 2 clearly show that the reliability indices calculated for the winter period were practically the same as those calculated for the entire year, since the summer indices were insignificant relative to the annual indices. The 5 months between the months of November and March were considered in the winter period. The hydro plant capacity limited by the winter water conditions as shown in the 6th column of Table 2.1 are used in the evaluation. A detailed analysis of the YEC load data for the past five years presented in Section 2 shows that the 2015 load model can be used instead of the average load model in adequacy studies. The 2015 winter LDC used as the load model in the following studies is shown in Figure 2.6 and Figure 2.9.

An evaluation of the YEC generation adequacy was first conducted using Model 1, the Basic Generation Adequacy Model. All the generating units listed in Table 2.4 were combined and convolved together to create the overall system generation model. The load model includes the local loads and the line losses. The system LOLE and LOEE were calculated for a range of peak loads. The results are shown in Table 4.1. It can be noted that the LOLE is 0.0084 hours per year at the system peak load of 82.06 MW. The peak load carrying capability (PLCC) is found to be 99.25 MW at the LOLE criterion of 2 hours per year when the system is represented by a basic generation adequacy model.

Table 4.1: LOLE and LOEE Results Using Model 1, the Basic Generation Adequacy Model

Peak Load (MW)	LOLE (h/yr)	LOEE (MWh/yr)
76.00	0.001	0.0020
78.00	0.0021	0.0048
80.00	0.0043	0.0106
82.06	*0.0084*	*0.0225*
84.00	0.0154	0.0435
86.00	0.0292	0.0833
88.00	0.0587	0.1625
90.00	0.1165	0.3217
92.00	0.2475	0.6541
94.00	0.4702	1.3070
96.00	0.8643	2.5327
98.00	1.4583	4.6678
100.00	2.3792	8.2089
102.00	3.797	13.8402
104.00	6.1686	22.9164
106.00	10.4473	37.8679
108.00	17.5478	63.6995
110.00	29.6536	106.8037
112.00	48.2345	179.4020
114.00	73.3794	291.5454
116.00	106.3985	457.0664

The evaluation method for Model 2, or the WAFSREL model consists of developing a winter capacity model for the Aishihik hydro plant, moving the capacity model through the transmission line L171 considering the line unavailability, and creating a tie-line constrained capacity model for the Aishihik hydro plant shown in Table 4.2. The transmission line unavailability data shown in the last column of Table 3.6 is used to incorporate the unavailability of the line L171 in this model.

Table 4.2: Tie-line (L171) Constrained Aishihik Hydro Capacity Model

Capacity (MW)	Probability
37	0.96563477
30	0.00975389
22	0.01950777
15	0.00019705
7	0.00009852
0	0.00480800

The model in Table 4.2 is then combined with the generation model that includes Whitehorse, Faro, Mayo and Dawson generation as shown in the model diagram of Figure 4.2. The overall generation system is then convolved with the winter load model to obtain the system LOLE and LOEE indices. The load model includes the local loads and the line losses. The results are shown in Table 4.3. It can be noted that the LOLE is 1.6131 hours per year at the system peak load of 82.06 MW when the system is represented by the WAFREL model, and the PLCC is 83.60 MW at the LOLE criterion of 2 hours per year.

Table 4.3: LOLE and LOEE Results Using Model 2, the WAFSREL Model

Peak Load (MW)	LOLE (h/yr)	LOEE (MWh/yr)
76.00	0.5183	1.5429
78.00	0.8136	2.7522
80.00	1.1894	4.5467
82.06	*1.6131*	*7.1156*
84.00	2.1179	10.2818
86.00	2.6931	14.4412
88.00	3.3093	19.5618
90.00	4.0615	25.7731
92.00	4.9137	33.2534
94.00	5.9141	42.1817
96.00	7.1566	52.9000
98.00	8.5885	65.7743
100.00	10.3129	81.1949
102.00	12.4845	99.7989
104.00	15.5179	122.8235
106.00	20.4168	152.6036
108.00	28.116	194.0624
110.00	40.7508	253.4741
112.00	59.7554	342.9590
114.00	85.2351	472.4052
116.00	118.5495	655.5268
118.00	158.5265	903.0183
120.00	204.8483	1224.7960

The third model, i.e. the Extended WAFSREL model consists of developing a winter capacity model for the Aishihik hydro plant, moving this model through the transmission line L171 to obtain the L171-constrained capacity model shown in Table 4.2. This model is then moved through the parallel lines between Takhini and Whitehorse considering their line unavailability and power transfer capability. The resulting tie-line constrained capacity model for the Aishihik hydro plant is shown in Table 4.4. The distribution line between Takhini and Whitehorse was considered to have a maximum power transfer capability of 19.6 MW. The transmission line unavailability data shown in the last column of Table 3.6 is used.

Table 4.4: Tie-line (L171, L172 and DL) Constrained Aishihik Hydro Capacity Model

Capacity (MW)	Probability
37	0.96341671
30	0.00973148
19.6	0.00227603
15	0.00019705
7	0.00009852
0	0.00481724

The capacity model in Table 4.4 is then combined with the generation model for Whitehorse, Faro, Mayo and Dawson. The generation model thus obtained is convolved with the system load model which includes the local loads and the line losses. The resulting system LOLE and LOEE indices are shown in Table 4.5. It can be seen that the LOLE is 1.6166 hours per year at the system peak load of 82.06 MW, and the PLCC is 83.58 MW at the LOLE criterion of 2 hours per year. It should be noted that the results obtained from this model are very close to that obtained using the WAFREL model.

Table 4.5: LOLE and LOEE Results Using Model 3, the Extended WAFSREL Model

Peak Load (MW)	LOLE (h/yr)	LOEE (MWh/yr)
76.00	0.5193	1.5459
78.00	0.8152	2.7575
80.00	1.1918	4.5556
82.06	*1.6166*	*7.1300*

The evaluation method of model 4, i.e. the Hydro Plants Interconnection Model, considers the delivery constraints on the hydro generation from Aishihik and Mayo to serving the YEC system load as shown in Figure 4.4. The approach is to develop a winter constrained generation model for the Mayo hydro plants and then move the developed model through the transmission lines L176, L174, L173 and L170 to the Takhini station. The line-constrained Mayo hydro capacity model is shown in Table 4.6.

Table 4.6: Tie-line (L176, L174, L173 and L170) Constrained Mayo Hydro Capacity Model

Capacity (MW)	Probability
0	0.0172343061
2550	0.0000019459
5000	0.0000019459
5100	0.0000963209
7550	0.0003852835
9000	0.9822801978

The model in Table 4.6 is convolved with the L171- constrained Aishihik hydro capacity model in Table 4.2. The probability distribution of the resulting capacity model is shown in Figure 4.6. The left graph shows the entire probability distribution, whereas, the right graph excludes the maximum capacity state of 46 MW which has a probability of 94.8524%. The spikes in the right graph show the capacity and corresponding probability resulting from first order contingencies.

The combined model is further moved through parallel lines (L172 and the distribution line between Takhini and Whitehorse) to the Whitehorse load point. The probability distribution of the capacity model, thus obtained, is shown in Figure 4.7. It can be seen that the probability of getting the maximum capacity state of 46 MW is 94.6345%. A comparison between the right plots of Figure 4.6 and 4.7 shows that there is a new spike in Figure 4.7 due to the 19.6 MW capacity limit of the distribution line between Takhini and Whitehorse. This model is then combined with Whitehorse, Faro, Dawson, and Mayo diesel generation to get the overall generation model, which is convolved with the winter load model at Whitehorse that includes the line losses and the local loads. The results for the system LOLE and LOEE for a range of peak loads are shown in Table 4.7.

It can be seen that the LOLE is 1.7603 hours per year at the system peak load of 82.06 MW, and the PLCC is 82.94 MW at the LOLE criterion of 2 hours per year. The results obtained from this model provide slightly pessimistic results when compared to the WAFREL or the extended WAFSREL models. Although the YEC generation system is presently adequate based on the WAFREL, extended-WAFSREL or the Hydro Plants Interconnection Model, a capacity expansion should be considered if load growth is expected in the near future.

The fifth model, or the Generation-Transmission Model considers the transmission constraints of the hydro plants in Ashihik and Mayo, and the diesel plants in Faro, Dawson and Mayo in serving the main system load at Whitehorse after satisfying their respective local loads at Faro, Mayo and Dawson. The capacity reserve models are first created for Faro, Mayo and Dawson by subtracting the respective loads from the generation models developed for these generating plants. The YEC

data indicates that the system peak load does not coincide with the peak loads at the Faro, Mayo or Dawson areas. The evaluation therefore does not consider the correlation of the loads at these locations with the system peak load, and the load model is represented by the average load at these locations when developing the reserve capacity models. The local peak load data shown in Table 3.9 was used in the evaluation, and the system winter load factor was considered to obtain the average load.

The reserve capacity models developed for the Dawson and Mayo sites are moved through the respective transmission lines L177 and L176 to Stewart Crossing. The resulting capacity model at Stewart Crossing incorporates the line losses and unavailability of the lines L176 and L177. The line losses at the different generation capacity levels in the multi-state capacity model are estimated using the line losses per unit loading data provided in Table 3.7. The unavailability data is provided in the last column of Table 3.6. The capacity model thus obtained at Stewart Crossing is then similarly moved through lines L174+L173 to Carmacks, and the capacity model is modified by incorporating the line losses and unavailability data of the line L174 and L173. This model is then combined with the modified reserve capacity model from Faro through the line L178. This evaluation procedure can be visualized by referring to the model diagram in Figure 4.5. The combined capacity model developed at Carmacks is then moved through line L170 to Takhini, and combined with the L171-constrained Aishihik generation model shown in Table 4.2. The resulting capacity model is further moved through the parallel lines (L172 and the distribution line between Takhini and Whitehorse) and combined with the Whitehorse generation model to create the overall system generation model. This system generation model is convolved with winter load model at Whitehorse that excludes the transmission line losses and the local loads at Faro, Mayo and Dawson. The system risk indices for this model are shown in the Table 4.8. The system PLCC is 82.54 MW.

Table 4.8: LOLE and LOEE Results Using Model 5, the Generation-Transmission Model

Peak Load (MW)				LOLE (h/yr)	LOEE (MWh/yr)

4.3 Comparative Analysis of Alternate Models

Table 4.9 shows the system PLCC and Figures 4.8 and 4.9 show the LOLE and LOEE for the different alternate models for comparison. The PLCC is evaluated at the LOLE criterion of 2 hour per year.

Table 4.9: System PLCC for the Different Adequacy Models

Adequacy Model	PLCC (MW) at LOLE = 2 h/yr
Basic Generation Adequacy Model	99.25
WAFSREL Model	83.60
Extended WAFSREL Model	83.58
Hydro Plants Interconnection Model	82.94
Generation-Transmission Model	82.54

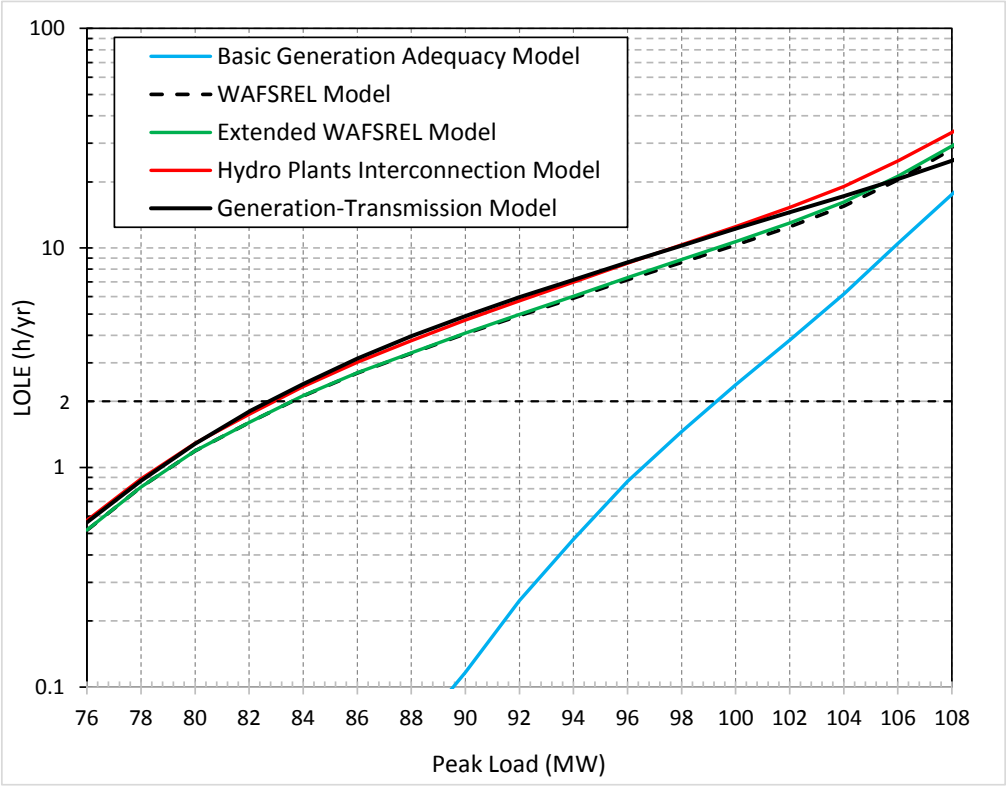

Figure 4.8: System LOLE for the Different Adequacy Models

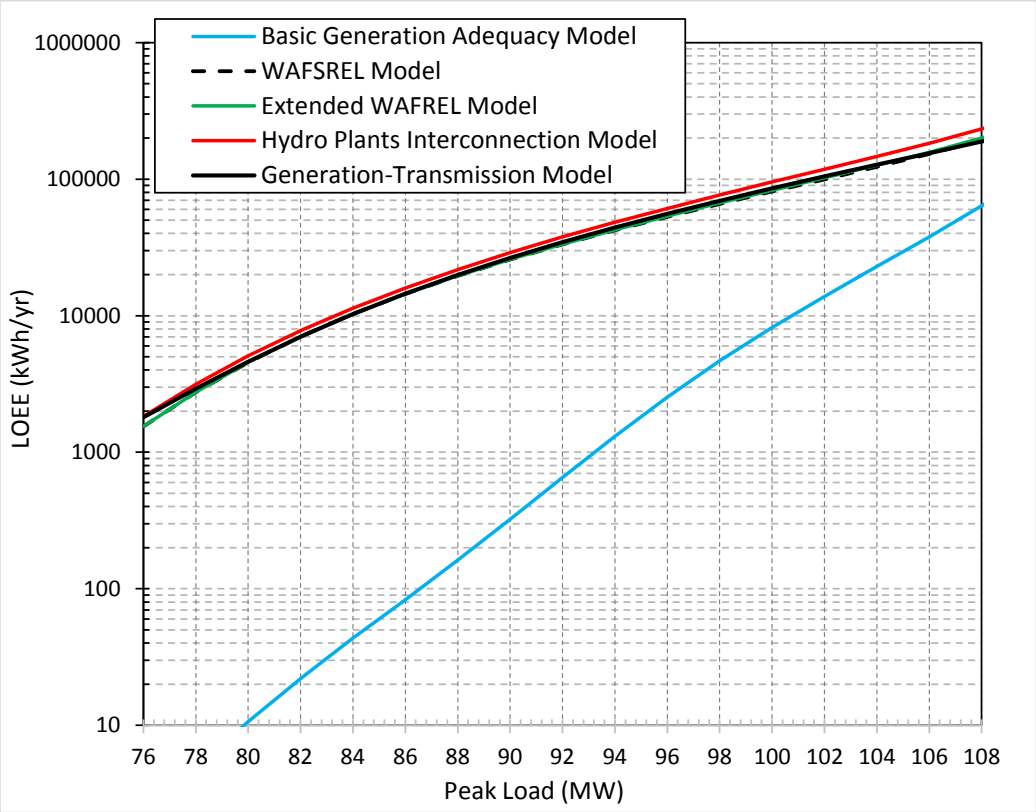

Figure 4.9: System LOEE for the Different Adequacy Models

A comparison of the LOLE results in Figure 4.8 indicates that the "Basic Generation Adequacy Model" that does not consider transmission system provides highly optimistic results. There is insignificant difference in the LOLE and PLCC results obtained from the "WAFSREL" and the "Extended WAFREL" models. The results from these two models are slightly more optimistic than that obtained from the "Hydro Plants Interconnection" and the "Generation-Transmission" models. The LOLE and PLCC results obtained from the "Hydro Plants Interconnection" and the "Generation-Transmission" models are very close for all practical purposes. It should be noted that the results become more pessimistic as the evaluation model includes more transmission system.

A composite generation and transmission system reliability evaluation, also known as HLII (Hierarchy Level II) study [4], was also carried out on the YEC electric system incorporating the locational impacts of the generation plants, transmission lines and load points considering the network in Fig. 4.5. A contingency enumeration approach [4] was applied to determine the

probabilities of energy curtailment at the different load points, and the transmission losses were evaluated based on the power flow. Since the Expected Energy Not Supplied (EENS) or the LOEE is the most widely used HLII reliability index, this index was calculated for each load point and aggregated to obtain the system EENS. Fig. 4.10 compares the EENS obtained from the HLII evaluation with the LOEE values obtained using the 5 different generation adequacy (or HLI) models.

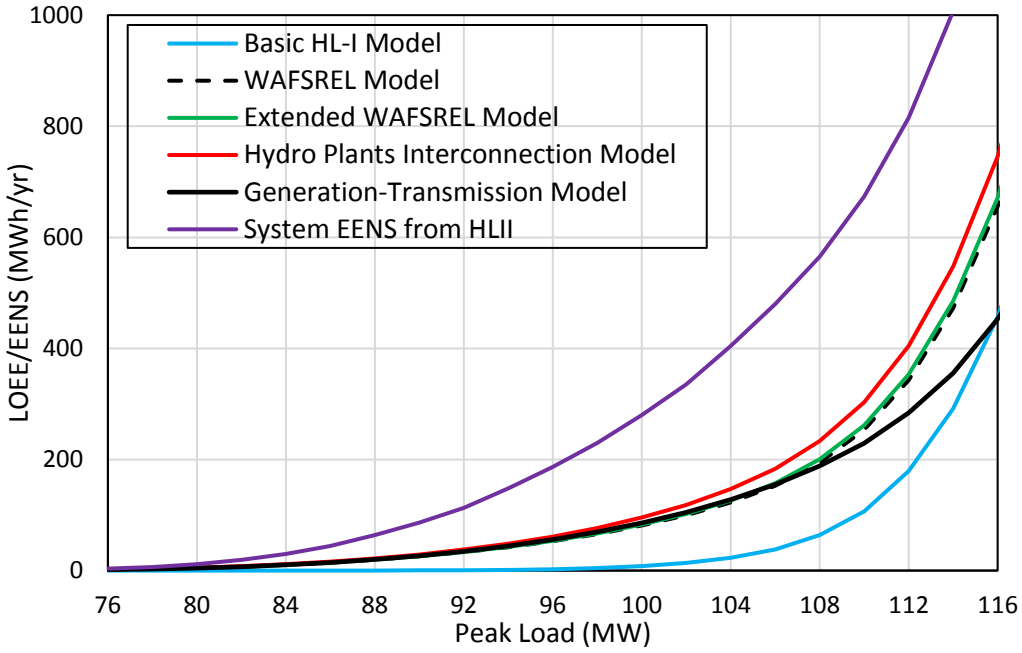

Figure 4.10: System LOEE/EENS Obtained from HLII and the 5 Different HLI Adequacy Models

As noted earlier, the order of the five generation adequacy or HLI models described above are arranged such that the amount of input data requirements and evaluation complexity increases from Models 1 to 5 in the list. In this order, the models also deviate further away from a basic generation capacity adequacy model towards a composite generation and transmission adequacy or HLII model. It should be noted that the objective of reliability study in generation capacity planning is to assess the generation system's ability to meet the system demand over the planning horizon considering only the major capacity delivery constraints, and not the entire transmission system. It should also be noted that the capacity planning criterion of LOLE of 2 hours per year

was determined by conducting comparative studies [1] of the previous YEC firm capacity criterion using the WAFSREL model.

It can be seen from Figure 4.10 that the LOEE/EENS plots for all the models, except the Generation-Transmission Model, increase with similar slopes as the system peak load increases. The Generation-Transmission model provides highly optimistic results at high peak loads since it is assumed in this model that the local generation provides support to the Whitehorse load only after satisfying their respective local loads. This results in the local load points being highly reliable and also reduced constraints on power delivery. It should be noted that the Generation-Transmission model assumes the local loads to increase in the same proportional to the system load, similar to that assumed in the HLII model. The "Generation-Transmission Model" is also more complex than the "Hydro Plants Interconnection Model", and requires more input data, such as, losses in the individual lines at different loading levels, correlation between local loads and the load at Whitehorse, the priority of the local loads and the Whitehorse load, etc. A comparative analyses of the results from the 5 different HLI models suggest that the "Hydro Plants Interconnection Model" is a suitable generation adequacy model for the YEC system since it is relatively simple and provides the least optimistic results among the five HLI models based on LOEE, and comparable results to the "Generation-Transmission Model" at reasonable peak load levels.

5. CASE STUDIES CONSIDERING POTENTIAL SYSTEM SCENARIOS

This section presents results from different case studies that are assumed to be likely system scenarios in the future. The evaluation was carried out with the recommended generating system adequacy evaluation model, i.e. Hydro Plants Interconnection Model. It is expected that two of the existing YEC system diesel units, FD1 and WD3, will retire in the year 2021, and all of the remaining diesel units in the YEC system will retire in the year 2026. The impact of these unit retirements on the generation system adequacy has been evaluated and presented in this section. This section also presents study results with and without considering the YECL hydro and diesel generating units in the Yukon electric system adequacy. The YEC system also has four mobile diesel units with a total capacity of 435 kW. Their impact on the system adequacy is carried out in the study. It is likely that the YEC system can benefit from capacity assistance through the proposed Skagway-Whitehorse transmission line. The adequacy impact of the assistance through this interconnection is also analyzed and presented in this section. It should be noted that the existing capacity of the distribution line parallel to L172 is considered to be 19.6 MW in the studies presented in the previous sections of this report. This section also includes results from case studies carried out to analyze the impact of upgrading this line. The reliability impact of twining the line L171 is also presented.

The generation data of the YECL Fish Lake hydro units is shown in Table 5.1 with a total capacity of 1295 kW. The unit ID and MCR of YECL Diesel units are shown in Table 2.12. The total diesel capacity is 5740 kW. The total YECL capacity considered in this study is therefore 7035 kW. The unavailability of the hydro and diesel units are assumed to be the same as that of YEC units. The FOR of 4% is used in the adequacy study for the YECL diesel generating units. Table 5.2 shows the unit ID, MCR and FOR of the mobile diesel units of YEC. The FOR of 4% is used for these diesel units as well.

Table 5.1: YECL Hydro Generating Unit Data

Unit ID	MCR (kW)	FOR (%)
Fish Lake #1	815	1
Fish Lake #2	480	1

Table 5.2: Mobile Diesel Generating Unit Data Included in the Study

Unit ID	MCR (kW)	FOR (%)
YM2	150	4
YM3	125	4
YM4	35	4
YM5	125	4

The Skagway-Whitehorse transmission line is rated at 138 kV. The line is considered to have a length of 170 km, and mainly supported by wood double pole tower structure. The unavailability of the line is calculated to be 0.5762%. The calculation of the line unavailability is shown in Table 5.3, using the 2014 CEA [6] data shown in Table 3.4.

Table 5.3: Proposed Skagway-Whitehorse Transmission line Unavailability Calculation

Line and outage component	Failure rate (failures/year)	Mean down time (hours)	Unavailability	
			(hours/year)	(%)
Sustained	1.66294	21.4	35.586916	0.4062
Transient	1.54479	0	0	0
Station (one end)	-	-	-	0.085
Station (other end)	-	-	-	0.085
			Total	0.5762

The Skagway-Whitehorse Transmission line is proposed to have a load carrying capability of 25 MW. The capacity assistance to the YEC electric system through this line is modeled as an equivalent 2-state generating unit with 25 MW capacity, and a FOR of 0.6%.

5.1 Considering Existing Generation Facilities

An adequacy study was carried out considering all the existing generation facilities, i.e. the YEC generating units listed in Table 2.1, YECL diesel and hydro generating units listed in Table 2.12 and 5.1, and the YEC mobile generating units listed in Table 5.2. The total winter generating capacity in this case is 116.278 MW. The system LOLE and LOEE as a function of the system peak load are shown in Table 5.4. The LOLE and LOEE results are also on shown graphically in Fig. 5.1 and 5.2 respectively.

Table 5.4: LOLE and LOEE Results Obtained Considering All Existing Generation

Peak load(MW)	LOLE(h/yr)	LOEE(MWh/yr)
76	0.0539	127.828
78	0.1099	276.769
80	0.2037	562.556
82	0.3580	1076.232
84	0.5783	1931.139
86	0.861	3235.328
88	1.2239	5110.522
90	1.6550	7678.792

110	14.5850	111758.500
112	18.6151	139684.100
114	24.9623	176714.900
116	34.2808	227841.400

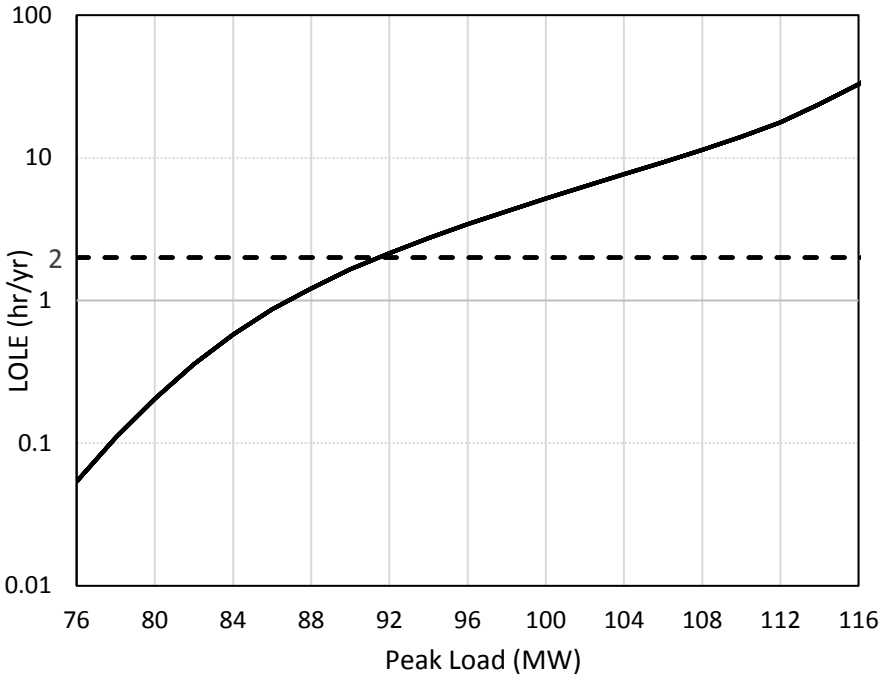

Figure 5.1: System LOLE Considering All Existing Generation

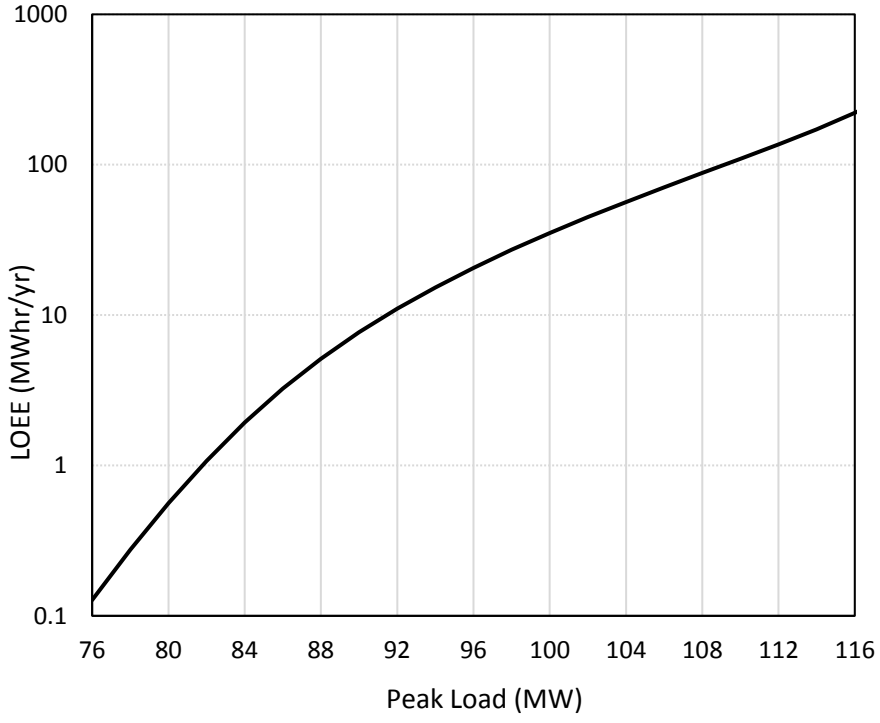

Figure 5.2: System LOEE Considering All Existing Generation

The impact of the mobile generation and the YECL generation on the overall YEC system adequacy was also analyzed. Fig. 5.3 shows the contribution of the mobile generation and the YECL generation on the system LOLE as a function of the system peak load.

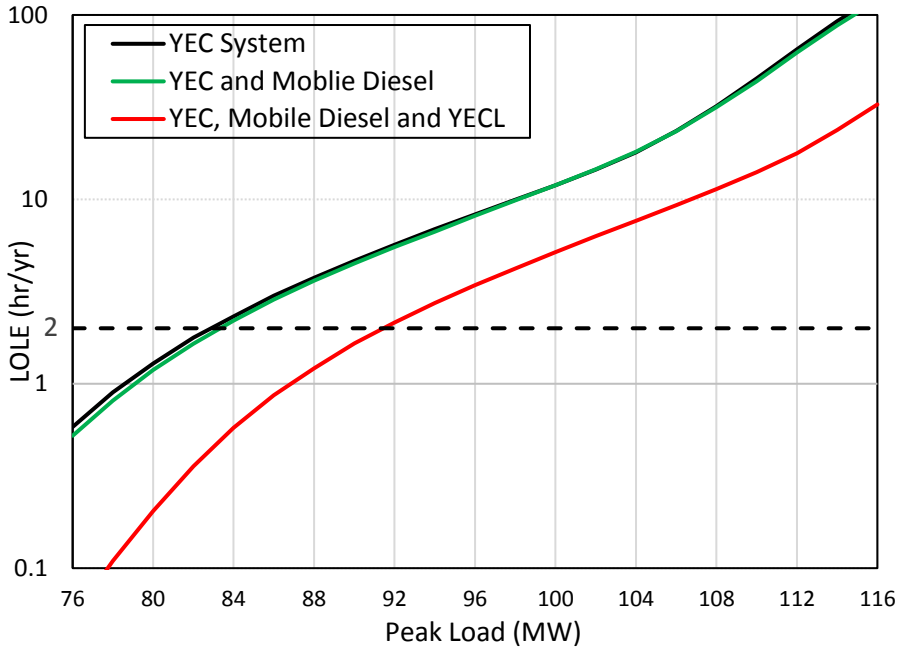

Figure 5.3: Impact of Mobile and YECL Generation on the System LOLE

The YECL and mobile generation enables the YEC electric system to carry an increased load. The peak load carrying capability of the YEC system while maintaining a reliability criterion of LOLE = 2 hours/year was evaluated, and the impact of the mobile and the YECL generation on the system PLCC is shown in Table 5.5.

Table 5.5: Impact of Mobile and YECL Generation on the System PLCC at the LOLE Criterion of 2 hours/year

Generating Units Considered	PLCC (kW)
YEC Generation listed in Table 2.1	82811.5
Plus mobile units listed in Table 5.2	83336.7
Plus YECL units listed in Table 2.12 and Table 5.1	91391.3

The YEC has improved the reliability of its electric system by adding redundancy to the line L172 with a parallel distribution line. An evaluation was done to quantify the reliability impact of the parallel line addition in terms of the increase in peak load carrying capability of the system while considering all the existing generation facilities. Table 5.6 shows the increase in PLCC (IPLCC) due to the distribution line is 7072 kW. A further upgrade of this line by increasing its load transfer capability can only increase the PLCC of the system by 342 kW.

Table 5.6: Impact of the Distribution Line Addition and its Upgrade on the System PLCC at the LOLE Criterion of 2 hours/year Considering All Existing Generation

Study Cases	PLCC (kW)	IPLCC (kW)
Before addition of the distribution line	84319.4	-
With the line addition (19.6 MW transfer capacity)	91391.3	7071.9
Upgrade the line (no transfer capacity restriction)	91733.3	342

5.2 Considering Unit Retirement Scenario in the Year 2021

It is expected that two of the YEC system diesel units FD1 and WD3 will retire in the year 2021. The system PLCC at the LOLE criterion of 2 hours/year with the retirement of the two diesel units are shown in Table 5.7. The table shows the results for the following case studies:

i. Considering only YEC generating units listed in Table 2.1
ii. Considering YEC generation, YECL generation and the mobile generating units
iii. Considering all the generation in Case ii and the assistance from the Skagway-Whitehorse transmission line
iv. Considering all the generation in Case ii and the upgrade of the distribution line between Takhini and Whitehorse
v. Considering all the generation in Case ii and twining the line L171 between Aishihik and Takhini

Table 5.7: System PLCC at LOLE criterion of 2 hours/year for different scenarios assumed for the Year 2021 after the retirement of units FD1 and WD3

Study Cases	PLCC (MW)
i. YEC generation only	73.1831
ii. YEC, YECL and mobile generation	81.8042
iii. All generation and assistance from Skagway line	109.9031
iv. All generation and upgrade of the distribution line	82.0146
v. All generation and twining line L171	95.1002

5.3 Considering Unit Retirement Scenario in the Year 2026

It is expected that all the diesel units of within the YEC system will retire in the year 2026. The system PLCC at the LOLE criterion of 2 hours/year with the retirement of all the YEC diesel units are shown in Table 5.8. The table shows the results for the following case studies:

i. Considering only YEC generating units listed in Table 2.1
ii. Considering only YEC generating units and YECL units listed in Tables 2.12 and 5.2.
iii. Considering all the generation in Case ii and the assistance from the Skagway-Whitehorse transmission line
iv. Considering all the generation in Case ii and the upgrade of the distribution line between Takhini and Whitehorse
v. Considering all the generation in Case ii, assistance from the Skagway-Whitehorse transmission line and the upgrade of the distribution line between Takhini and Whitehorse
vi. Considering all the generation in Cases ii and twining the line L171 between Aishihik and Takhini
vii. Considering all the generation in Cases ii, assistance from the Skagway-Whitehorse transmission line, and twining the line L171 between Aishihik and Takhini

Table 5.8: System PLCC at LOLE criterion of 2 hours/year for different scenarios assumed for the Year 2026 after the retirement of all YEC diesel units

Study Cases	PLCC (MW)
i. YEC generation only	48.1696
ii. YEC and YECL generation	56.3378
iii. All generation and assistance from Skagway line	85.3039
iv. All generation and upgrade of the distribution line	56.3733
v. All generation, assistance from Skagway line, and upgrade of the distribution line	85.5520
vi. All generation and twining line L171	71.2489

1 EXECUTIVE SUMMARY

There is an increase in concern around the world regarding environmental issues, including the use of natural resources, water, soil and air quality, deforestation, pollution, and emissions. The performance of products, services and processes in terms of its environmental impact has become a key global focal point for policy makers and industry leaders alike. As such, a critical analysis of negative environmental impacts that result from human activity must be performed. One of the most common analytical tools to weigh such impacts is the life cycle assessment (LCA). The purpose of the LCA is to examine and evaluate the overall environmental impact of using a certain product or implementing a certain technology by considering all stages of its life, from raw materials acquisition, to production, transportation, application, energy generation, recycling, and disposal, i.e., from "cradle to grave."

The results of an LCA can assist decision makers in choosing the most appropriate process or product that has the least environmental impact. LCAs are used in conjunction with other factors, such as performance, cost and feasibility, to assist in the selection of a process or product. With careful selection of the system boundaries, the LCA benefits end-users by exposing the environmental impacts that may be transferred from one medium to another, or from one life cycle stage to another, that may otherwise go unnoticed and unaccounted for.

Yukon Energy Corporation decided to perform a comparative LCA study of various energy resource options as part of their 2016-2035 Resource Plan. The goal of this study is to determine the amount of greenhouse gas (GHG) emissions that would be generated from 13 preselected energy resource options that are available to Yukon Energy for future use, which include both renewable and non-renewable resources. The pathways analysed are as follows:

1. Biomass gasification (combined heat and power, CHP)
2. Waste to energy (municipal solid waste alone and with biomass conventional combustion CHP plant)
3. Biogas (generated from organic waste)
4. Geothermal
5. Wind
6. Solar
7. Pumped storage hydro power plant
8. Small hydro power plant
9. Energy storage (lithium ion batteries)
10. Thermal – diesel
11. Thermal – LNG
12. New transmission line
13. Water diversion project

Included in the study is an analysis of energy storage in the form of batteries as well as the construction of a new transmission line. These options are modelled separately as they may form a part of another energy production pathway.

Each resource option is analyzed for GHG emissions using the Global Warming Potential (GWP) for both the 20 year and 100 year time horizon. The GWP factors without feedback are taken from the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (AR5). The significant

difference among the two GWP values is seen in methane emissions (84 and 28 for the 20 year and 100 year time horizons, respectively), which affects GHG emissions results when analyzing resource options that generate significant amounts of methane. Results from estimating the GHG emissions for both time horizons can illustrate immediate and future emissions concentrations released into the atmosphere. This can assist decision makers in deciding which energy resource scenario best addresses their short-term and long-term climate strategy.

This study is based on LCA principles and includes a definition of the system boundary, selection of relevant data (site-specific where possible and North American or European data when Canadian data were unavailable), and calculations of total GHG emissions for each energy resource per functional unit. The functional unit selected is MWh of energy delivered to the grid. In the battery storage and transmission line scenarios, the results are also presented per MWh of energy stored and MWh-km, respectively, to accommodate the appropriate energy source addition in future environmental studies.

Results in kg of CO_2e/MWh of energy delivered for both the 20 and 100 year GWPs are presented in Figure E.1. Certain pathways (biogas, biomass gasification, waste to energy, small hydro, pumped storage and water diversion) have biogenic CO_2 emissions due to biomass combustion and/or decomposition. Since it is planned to utilize various biomass waste (e.g. dead trees, logging residues, and sawmill residues) as a source of biomass in biomass gasification and waste to energy pathways and municipal organic wastes in biogas pathway, one can argue in support of carbon neutrality of these pathways and exclude the biogenic CO_2 emissions from the total life cycle emissions. The biogenic CO_2 emissions in small hydro, pumped storage and water diversion scenarios originate from biomass decomposition after land inundation. Biomass decomposition is a slow process that lasts several years during which forest may be re-grown in other parts of the territories and recapture CO_2 from the atmosphere. Moreover, the inundated area represents a small fraction of the territories' forest reserves. Therefore, one may consider the emitted CO_2 to be carbon neutral.

The overall results indicate that the diesel and LNG pathways are the greatest GHG emitters with 1,059 and 1,051 kg CO_2e/MWh emitted for the 20 year time horizon, respectively, and 951 and 728 kg CO_2e/MWh emitted for the 100 year time horizon, respectively. The next highest emitters are waste to energy (MSW and MSW + biomass) and biogas pathways. The smallest GHG emitters for both time horizons are solar (approximately 40 kg CO_2e/MWh), followed by biomass gasification, pumped storage, small hydro, water diversion, battery storage, wind, and geothermal (all with less than 18 kg CO_2e/MWh). The 170 km of new transmission line produces just over 0.17 kg CO_2e/MWh for the 20 year and 0.16 CO_2e/MWh for the 100 year time horizon.

Wind, solar, geothermal, battery storage, transmission line, biomass gasification, and waste to energy produce emissions that are almost the same for both the 20 and 100 year time horizons. However, the most notable differences come from the analysis of biogas, diesel, liquefied natural gas (LNG), and hydro projects. These energy resource options emit significant amounts of methane; therefore, their overall GHG emissions vary between the 20 year and 100 year time horizons: (260 kg CO_2e/MWh versus 114 kg CO_2e/MWh for biogas, respectively; 1,059 kg CO_2e/MWh versus 951 kg CO_2e/MWh for diesel, respectively; and 1,051 kg CO_2e/MWh versus 728 kg CO_2e/MWh for LNG, respectively). Methane emissions in biogas pathway originate mainly from anaerobic digestion and waste storage processes, while in the diesel pathway they originate from crude oil extraction. Methane emissions in hydro energy pathways come from biomass decomposition after land inundation.

	Wind	Solar	Geothermal	Small Hydro	Pumped Storage	Battery Storage	Water diversion	Transmission line

Figure E.2. GHG Emissions from Energy Production Pathways - Contribution Analysis (biogenic CO_2 emissions excluded)

Analysis of the results includes a contribution analysis to determine the contribution each life cycle process has on the total GHG emissions and a sensitivity analysis whereby the effects on the final results by changing parameters are considered. The results of contribution analysis are shown in Figure E.2.

It is seen that operation of the energy generating plant is by far the most significant in terms of GHG emissions in biogas, waste to energy, diesel, and LNG pathways. For wind, solar, geothermal, transmission line and battery storage pathways, the majority of GHG emissions originate from upstream life cycle stages (e.g. materials extraction, components manufacturing). Diesel and LNG thermal plants also had notable GHG emissions contributions from fuel extraction and production life cycle stages.

The fixed and variable GHG emissions are shown in Table E.1. The fixed emissions are emissions associated with power plant and infrastructure construction and include raw materials acquisition, transportation, site preparation, and construction of the plant and transmission line. In the diesel, LNG, biomass gasification and waste to energy pathways, the emissions related to diesel, LNG, biomass and MSW transportation are considered variable emissions. The fixed emissions are expressed in tonnes CO_2e per facility, while variable emissions that originate from power plant operations are expressed in kg CO_2e/MWh.

Table E.1. Fixed and variable GHG emissions from energy production pathways (20 and 100 year GWP)

Energy Production Pathway	Fixed GHG emissions tonnes CO_2e		Variable GHG emissions kg CO_2e/MWh		Variable GHG emissions (biogenic CO_2 excluded) kg CO_2e/MWh	
	20 year GWP	100 year GWP	20 year GWP	100 year GWP	20 year GWP	100 year GWP
Biomass Gasification	679.1	651.7	769.3	768.9	14.53	14.14
Waste to energy: MSW	7,775	7,496	699.8	687.9	444.4	432.5
Waste to energy: MSW + biomass	7,775	7,496	666.0	654.1	310.1	298.2
Biogas	420.9	404.1	1151.2	1005.8	249.1	103.7
Geothermal	6,647	6,077	0.0230	0.0145	0.0230	0.0145
Wind	3,641	3,499	0.7379	0.7108	0.7379	0.7108
Solar	6,726	6,067	0.1284	0.0988	0.1284	0.0988
Pumped storage	16,294	16,098	18.77	10.56	13.09	4.88
Small hydro	6,704	6,630	17.31	9.77	12.02	4.48
Battery storage	904.5	820.9	0.00	0.00	0.00	0.00
Thermal - Diesel	675.2	649.1	1058.48	950.70	1058.48	950.70
Thermal - LNG	1,065	1,023	1050.09	727.04	1050.09	727.04
New transmission line (170km)	29,498	27,284	0.0324	0.0304	0.0324	0.0304
Water diversion project	237.8	223.2	21.30	11.99	14.86	5.43

The sensitivity analysis reveals that the choice of the technology and location of the manufacturing facilities (e.g. in North America versus oversees) can significantly impact the total life cycle emissions in

the case of renewable energy sources where upstream life cycle stages are the largest contributors to the total life cycle GHG emissions.

The technology pathways that can potentially support other energy generation options such as small hydro are geothermal, as well as wind and solar coupled with battery storage. Hydro options, in turn, make it feasible to utilize other renewable sources. Pumped storage offers operational flexibility, since it can immediately respond to fluctuations in the demand for electricity. The flexibility and storage capacity of hydro options make them efficient and economical in supporting the use of intermittent sources of renewable energy, such as solar and wind, especially if these energy options are not coupled with battery storage. The waste to energy option has a potential to displace some fossil fuel-based sources, such as diesel and LNG, especially if the produced heat is utilized to make the technology economically viable. However, the waste to energy pathway produces a significant amount of fossil GHG emissions due to MSW combustion.

In summary, this LCA reveals the environmental impacts related to climate change for various energy options for renewable and non-renewable resources which can be used for enhanced decision making and improved strategies regarding long term energy planning for the Yukon Territory.

2 INTRODUCTION

Yukon Energy Corporation is committed to providing long-term, sustainable and reliable energy options for its customers. As part of the long term resource planning process (Resource Plan 2016-2035), Yukon Energy is in the process of evaluating different resource options for energy production. The goal of this study is to estimate greenhouse gas emissions (GHG) from the life cycle of different energy generation options. At the conclusion of this study, a detailed energy sources assessment of the overall GHG emissions associated with each energy source, including fossil fuels and several renewable energy production pathways, are presented. A final analysis of the contributions to the Global Warming Potential (GWP) from each resource option over a 20 year and 100 year timeframe is given. This will allow Yukon Energy to employ best management practices and make informed decisions in planning for future energy developments.

The study follows the current state-of-the-science practices with regard to LCA and is based on ISO 14040 principles and guidelines. Specifically, ISO 14040 and 14044 (2006) standards are applied to determine the key GHG contributors for each life cycle stage of the energy production technologies. Table 1 represents the energy resources pathways that are compared in this study. The studied projects are used as proxy for potential similar projects that may be implemented by Yukon Energy.

Table 1. Energy Resources Pathways

#	Resource option and location	Installed capacity	Annual energy (net)	Impacted area & Transmission line
1	Biomass gasification (Combined Heat and Power, CHP) Haines Junction	Gross power 0.5MW_e Net power 0.369 MW_e, 1,150 kW_{th}	2,585 MWh_e/yr 8,059 MWh_{th}/yr	Brownfield
2	Waste to Energy Municipal Solid Waste (MSW) with biomass conventional combustion (CHP) Whitehorse landfill	1.6MW_e (Scenario 1: 23,750 tonnes MSW/year Scenario 2: 16,100 tonnes MSW per year and 7,650 tonnes biomass per year)	9,975 MWh_e/yr 23,700 MWh_{th}/yr	Brownfield
3	Biogas Whitehorse landfill	185kW (second 100kW unit added in 2020)	885.9 MWh_e/yr	Brownfield
4	Geothermal McArthur Springs	7MW_e gross or 5.5MW_e net (3.86 MW_e taking into account the losses and decrease in production of 3% per year)	48.2 GWh_e/yr	Greenfield 42 km x 30 m of 138kV line
5	Wind Mount Sumanik	6MW_e	14.558 GWh_e/yr	Greenfield (impact area 100 ha) 7.6 km x 30 m of 138kV line
6	Solar Whitehorse Copper	5MW_e	5.2 GWh_e/yr	Brownfield
7	Pumped storage Moon Lake	20.2MW_e	54 GWh_e/yr	Greenfield Inundation area 352.4 ha

#	Resource option and location	Installed capacity	Annual energy (net)	Impacted area & Transmission line
				2.6 km x 30 m of 138kV line
8	Small hydro Drury Creek	8.1MW_e	31.7 GWh_e/yr	Greenfield Inundation area 190 ha 0.5 km x 30 m of 138kV line
9	Energy storage – lithium ion batteries Takhini Substation	8MW_e	2.8 GWh_e/yr 5hr discharge time	Greenfield/Brownfield 0.42 ha cleared area footprint
10	Thermal-diesel Takhini Substation	5MW_e	39.42 GWh_e/yr	Greenfield/Brownfield 4.5-5.5 ha of cleared area footprint
11	Thermal-LNG Takhini Substation	5MW_e,	39.42 GWh_e/yr	Greenfield/Brownfield 6.5 ha of cleared area footprint
12	New transmission line Whitehorse to Skagway	443 MW reliable transfer capacity	N/A	Greenfield/ Brownfield 170 km of 230kv line and 68 km of an existing 34.5kv line (306 ha plus 102 ha of cleared area footprint)
13	Enhancement – Gladstone Water diversion	Would utilize existing hydro unit capacity	29.7 GWh_e/yr	Partial greenfield Inundation area 220 ha

The following issues are examined in this study:

- The amount of the greenhouse gas emissions originating from different energy production technologies that could potentially be implemented in the Yukon,
- Contribution of each life cycle stage to the environmental impact through the determination of an environmental “hot spot” (i.e. any life cycle stage with the highest GHG emissions) in the life cycle of each technology, and
- The technology pathways that either support other energy generation options (e.g. hydro) and/or have the potential to displace another energy source (e.g. fossil fuel-based sources, such as diesel fuel).

The report consists of the following parts:

Chapter 3 – Goal and Scope Definition;

Chapter 4 – Greenhouse Gas Assessment results;

Chapter 5 – Conclusions and Recommendations.

3 STUDY GOAL AND SCOPE

This section of the report provides a general description of the energy systems under study, definition of the system boundaries, and the functional unit. Data quality, assumptions, limitations and GHG assessment methodology are also discussed.

3.1 OBJECTIVES AND INTENDED APPLICATION

The project has the following objectives:

- Using the "cradle-to-grave" approach, develop greenhouse gas emission inventories associated with different energy production pathways in the Yukon Territory,
- Inform decision-makers of the overall contribution of the different technology pathways to the Global Warming impact,
- Rank the energy generation technologies based on their greenhouse gas emissions,
- Provide comparative study results with recommendations on which technology pathways support other energy generation options (e.g. hydro) and which ones have a potential to displace another energy source (e.g. fossil fuel-based sources, such as diesel fuel), and
- Provide input into the evaluation of energy resource options against technical, financial, social and environmental attributes.

The results of this study are intended for the internal use by Yukon Energy to assist with the long term resource planning process (Resource Plan 2016-2035). Results of the LCA study may be made public by Yukon Energy.

3.2 SYSTEMS FUNCTION AND FUNCTIONAL UNIT

The main function of the system under study is to produce energy. In order to compare the environmental footprints of the various energy production scenarios considered in this study, a common functional unit is selected – a unit that provides a reference to which the input and output data are normalized. The functional unit best suited for this study is **MWh of energy delivered to the grid**.

The GHG emissions per MWh of energy delivered to the grid are obtained by dividing the life cycle inventory data (e.g. plant construction data) by total net energy output of the power plant during its lifetime.

The lithium-ion battery storage (scenario #9) LCA is limited to the manufacturing of the battery and site preparation, including materials extraction, production of materials, battery assembly, transportation, and land clearing. The results are presented per MWh of energy stored.

Analysis of the transmission line (scenario #12) is limited to the construction of the line itself, including materials, transportation, and change in land use. The LCA does not consider the potential proximity of the transmission line to the point of energy production or the type of energy source being used. These results are given per MWh-km such that future environmental assessments may include the appropriate energy resource option at that time (transmission line results per MWh-km are presented in section 4.2.12). The results per MWh-km are then used to estimate the environmental impact of 170km of new transmission line.

3.3 DESCRIPTION OF ENERGY RESOURCE PATHWAYS AND SYSTEM BOUNDARIES

This section provides a description of the systems under study and their system boundaries. The system boundary defines the unit processes to be included in the system.

The "cradle-to-grave" approach is applied, which includes the life cycle activities from resource extraction and production of materials through to the generation of electrical energy at the generating station, as well as all transportation stages (Figure 1). Downstream stages (decommissioning, recycling and site remediation) are excluded from the analysis. Exclusion of these activities is a common practice where it is expected that these processes contribute to less than 1% of total impact from the energy resource life cycle[1].

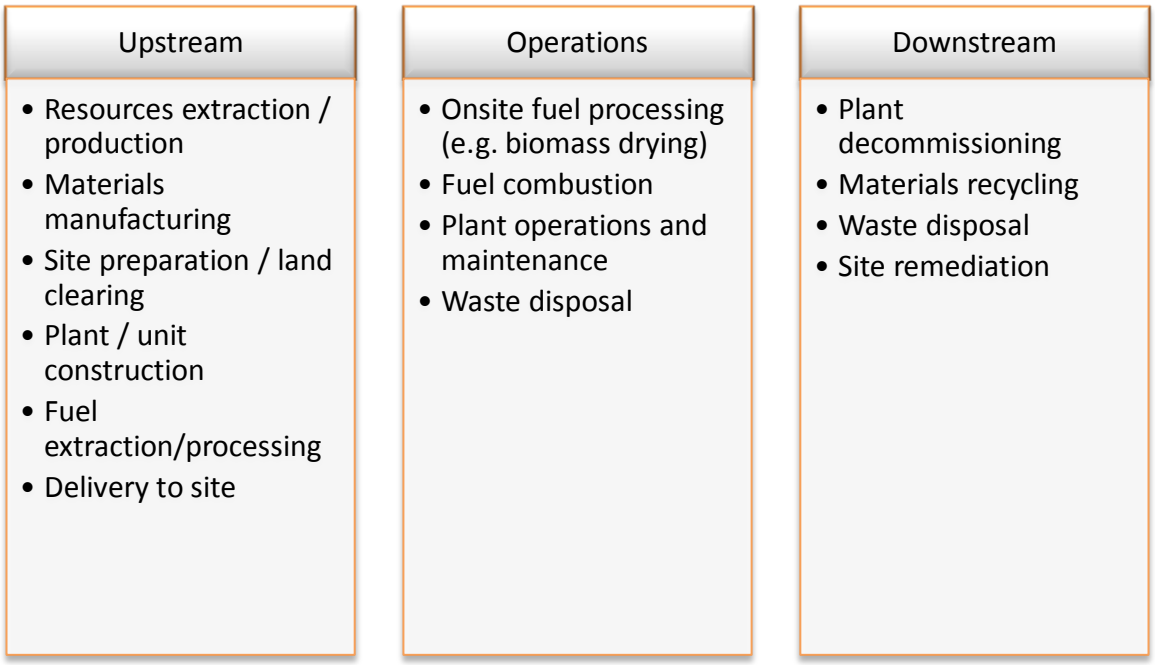

Figure 1. Generalized Life Cycle Stages of an Energy Generation Technology

Most of the processes included in the system boundaries occur in Yukon or Western Canada. However, some unit processes may occur in other Canadian provinces, the US and worldwide. Life Cycle Inventory supporting information that includes a description of all data sources used in the analysis is presented in Appendix A.

[1] Baumann, H. and Tillman, A. (2004) The Hitch Hiker's Guide to LCA. Studentlitteratur AB, Lund, Sweden.

3.3.1 System Description: Biomass Gasification Plant

The biomass gasification combined heat and power plant (CHP) with a 0.5 MW_e and 1,150 kW_{th} capacity was chosen to be located in the centre of Haines Junction[2]. The potential project includes two 250 kW_e biomass gasification units that will be supplied by Community Power Corporation (CPC). The plant is expected to produce 2,585 MWh_e net and 8,059 MWh_{th} energy annually. The biomass supply would be primarily sawmill and forest harvesting residues, as well as dead trees from the spruce beetle infestation.

The system boundary is presented in Figure 2 with a description following in Table 2.

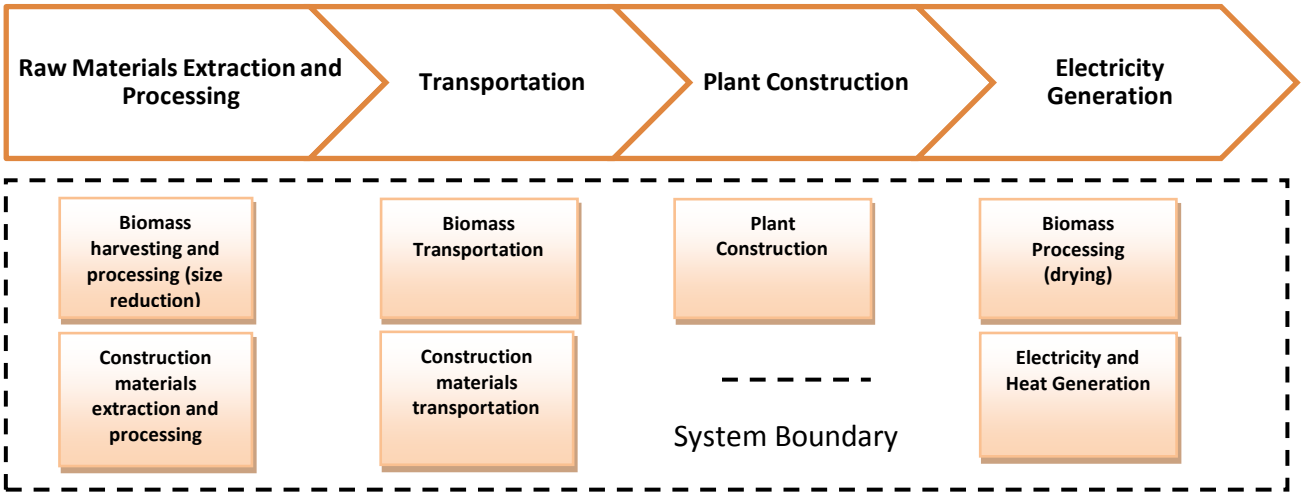

Figure 2. System Boundary of Biomass Gasification Electricity Generation

Table 2. Description of Biomass Gasification Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	<u>Biomass harvesting and processing</u> Sawmill and forest harvesting residues, dead trees from the spruce beetle infestation. Required feedstock: • Oven dry tonnes – 3,000 tonnes/year • With 15% moisture content – 3,789 tonnes/year • Forest harvesting residues: 1,603 tonnes/year • Sawmill residues – 2,190 tonnes/year Biomass processing includes size reduction in the field. <u>Construction materials extraction and processing</u> Raw materials extraction and production of construction materials (steel, aluminum, concrete, etc.)
Transportation	<u>Biomass transportation</u> Sawmill residues are transported 50km by truck, 9t payload Forest harvesting residues - 70km by truck, 9t payload

[2] Stantec. (2013). Front End Engineering Design (FEED) Study. Yukon Bioenergy Demonstration project in Haines Junction, Yukon. Final FEED Report. June 7, 2013.

Life Cycle Activity	Description
	Construction materials transportation Transportation by truck, 22t payload (assumed average distance of 2,400 km)
Plant Construction	Location: Whitehorse landfill Brownfield – no site preparation included
Electricity Generation	Biomass processing Biomass processing includes drying to 15% moisture content Electricity generation 1-Stage Downdraft Gasifier (BioMax), 2xIC Engines, 2 x 250 kW_e Annual energy production (net): • 2,585 MWh_e -682 kWh_e/tonne of biomass • 8,059 MWh_{th} – 2,127 kWh_{th}/tonne of biomass Waste disposal Disposal of waste (e.g. ash) is excluded from analysis
End of life	Lifetime: 20 years

In the CHP plant, heat and electricity are generated simultaneously from the same input of fuel. This increases the plant efficiency and reduces GHG emissions per MWh of energy produced. Although, the produced electricity is more valuable than heat, no allocation of GHG emissions to electricity and heat separately is performed as the goal of the project is to assess total GHG emissions produced by the CHP plant.

3.3.2 System Description: Municipal Solid Waste (MSW) Waste to Energy Plant

For this analysis, a municipal solid waste (MSW) conventional combustion waste to energy (WTE) facility with nominal design capacity of 25,000 tonnes per year has been chosen for evaluation. The actual annual throughput is 95% of the total design capacity or 23,750 tonnes year. In order to maximize the facility efficiency, a CHP plant is selected. The CHP plant will generate up to 4MW of heat and 1.6 MW of electricity. Approximately 16,100 tonnes of MSW and 7,650 tonnes of wood biomass per year until 2035 would be required[3].

The operating life of the WTE facility is assumed to be 25 years (to year 2040). It is likely that the WTE facility will operate longer (if there is waste still available), and the landfill will continue to accept waste/ash past 2040.

Two scenarios are modelled:

1. 2015 feedstock: MSW (16,100 tonnes) + biomass (7,650 tonnes) conventional combustion, and
2. 2035 feedstock: MSW (23,750 tonnes) conventional combustion.

The system boundary is presented in Figure 3 with a description following in Table 3.

Similar to the biomass gasification pathway, no allocation of GHG emissions to electricity and heat is performed.

[3] Morrison Hershfield. (2012). Waste to Energy Updated design Basis and Business Case Analysis. April 24, 2012.

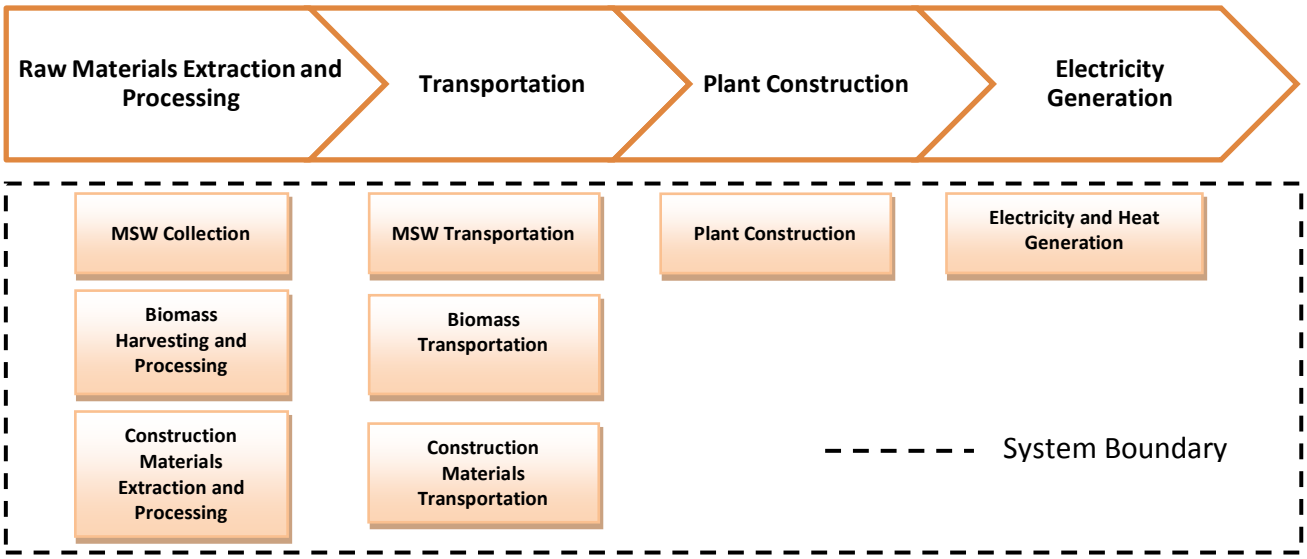

Figure 3. System Boundary of MSW Waste to Energy Electricity Generation

Table 3. Description of MSW Waste to Energy Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	MSW Collection MSW generated within Whitehorse and surrounding communities, used tires, waste oil and abattoir waste Biomass Harvesting and Processing (in Scenario 1 only) Biomass as a supplement fuel during winter (7,650 tonnes/year) Sources: Forest harvesting residues and sawmill residues Biomass processing includes size reduction in the field Construction materials extraction and processing Raw materials extraction and production of construction materials (steel, aluminum, concrete, etc.)
Transportation	MSW transportation 8-9 truckloads of waste per day (truck payload 9t); approximate distance 16 km Biomass transportation Sawmill residues are transported 50km by truck, 9t payload Forest harvesting residues - 70km by truck, 9t payload Construction materials transportation Transportation by truck, 22t payload (assumed average distance of 2,400 km)
Plant Construction	Location: Whitehorse landfill Brownfield (min 2 ha)– no site preparation included
Electricity Generation	Technology (EcoWaste Solutions): Controlled-air two stage conventional combustion WTE facility capacity: 25,000 tonnes/year Annual throughput: 23,750 tonnes/year (95% of total design capacity) Weighted HHV (Higher Heating Value): 14.45 GJ/tonne MSW

Life Cycle Activity	Description
	Electricity production (net): 9,975 MWh_e/year Heat production (net): 23,700 MWh_{th}/year Total electricity produced (net): • 420 kWh_e per tonne of MSW or MSW + biomass (10% electrical efficiency) • 998 kWh_{th} per tonne of MSW or MSW + biomass <u>Waste disposal</u> Disposal of waste (e.g. ash) is excluded from analysis
End of life	Lifetime: 25 years

3.3.3 System Description: Biogas Plant

The site identified for the biogas plant is the Whitehorse Municipal Landfill near the composting site. A dry (high solids) garage style anaerobic digester will be used to treat Whitehorse residential and commercial organic waste and produce electricity and heat. The produced heat will be used on-site to heat the digester to 35°C. Some of the produced electricity will be used internally to operate the digester. Initially, one 100 kW_e unit will be installed and the second 100 kW_e unit will be added in 5 years (2020)[4].

The system boundary is presented in Figure 4 with a description following in Table 4.

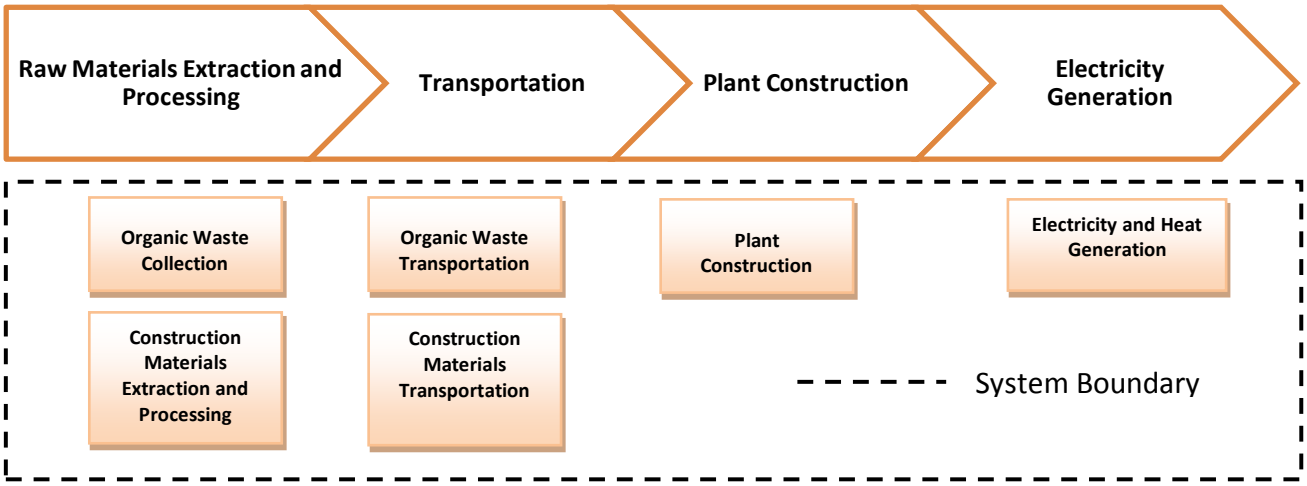

Figure 4. System Boundary of Biogas Electricity Generation

[4] WSP. (2016). Biogas Plant in Whitehorse. Feasibility Study, Whitehorse, Yukon. January 2016.

Table 4. Description of Biogas Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Organic waste collection Food waste, green yard waste, dry yard waste Construction materials extraction and processing Raw materials extraction and production of construction materials (steel, aluminum, concrete, etc.)
Transportation	Organic waste transportation Approximate distance: 16 km, truck payload 9 tonnes Construction materials transportation Transportation by truck, 22t payload (assumed average distance of 2,400 km)
Plant Construction	Location: Whitehorse landfill Brownfield – no site preparation included
Electricity Generation	Dry garage style anaerobic digester CHP unit Capacity: 185 kW_e (takes into account addition of a second 100 kW unit in 2020) Electric efficiency: 35% Thermal efficiency: 40% (heat production 28.7%, internal heat use 11.3%) Energy loss: 25% Electric output: 56kW_e (33kW_e in April and 100 kW_e in August) Thermal output: 64 kW_{th} (37 kW_{th} in April and 114 kW_{th} in August) Total electricity produced (net): 885.9 MWh_e/yr
End of life	Lifetime: 20 years

3.3.4 System Description: Geothermal Power Plant

McArthur Springs, in Northeast Yukon, was chosen as a geothermal power plant location. The site is located approximately 42 km East of Highway #2 southeast of Stewart Crossing, and approximately 75 km south of Mayo. The net capacity of the plant is 5.5MW[5]. The plant is estimated to produce water at 160°C using a binary cycle Organic Rankine Cycle (ORC) system.

The capacity of a geothermal reservoir decreases over time; thus, a constant decrease of 3% per year has been assumed. The net electricity output of the plant is 48.2 GWh_e/yr taking into account the losses and decrease in production output of 3% per year.

The system boundary is presented in Figure 5 with a description following in Table 5.

[5] KGS. (2016). Geothermal Review and Site Inventory. Draft Report – Rev. A. KGS Group. May 2016.

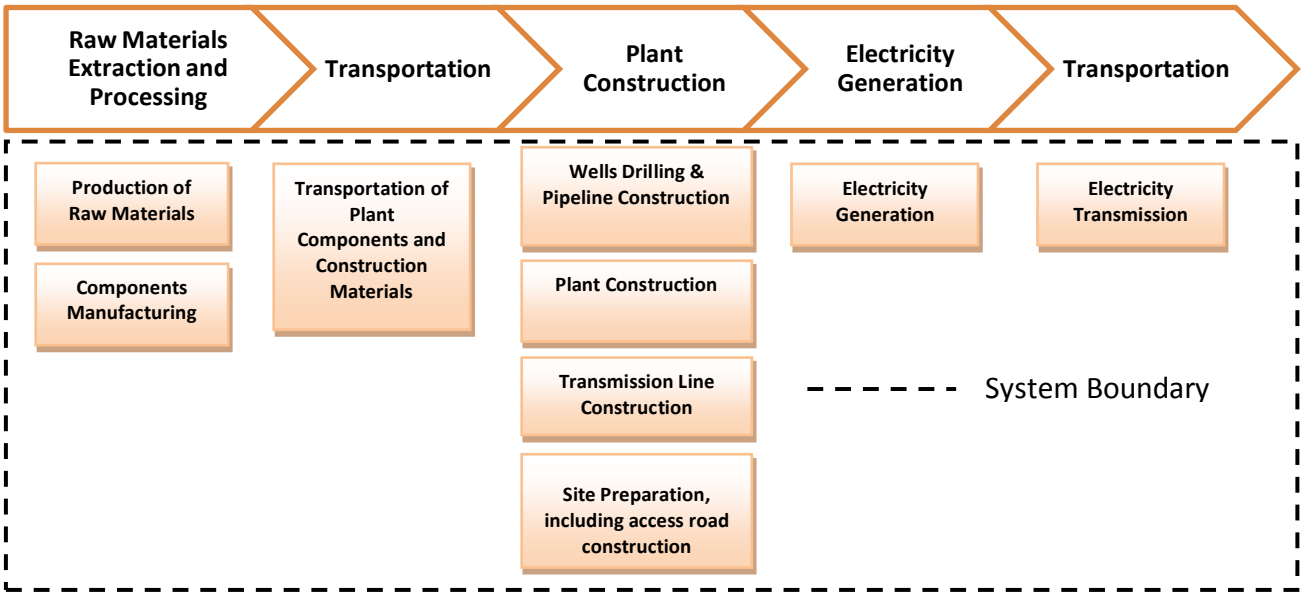

Figure 5. System Boundary of Geothermal Electricity Generation

Table 5. Description of Geothermal Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials for plant construction are extracted and processed. Construction materials (aggregates) are assumed to be sourced locally (within 15 km of the site).
Components Manufacturing and Transportation	Power generation and transmission line components are manufactured and transported 2,400km by truck, 22t payload.
Plant Construction	Greenfield site 2 production and 1 injection wells are drilled approximately 1 km apart. Wells are equipped with line-shaft pumps, located in a small building. Pipeline construction to connect the wells to the power plant, access road, wells, and transmission line construction are included in the assessment. One exploration well drilling is included.
Electricity Generation	Binary Organic Rankine Cycle (ORC) geothermal plant with 70% efficiency. Net electricity output: 48.2 GWh_e/yr
Electricity transmission	Produced electricity is transported from MacArthur through 42km of 138kV transmission line.
End of life	Lifetime: 30 years

3.3.5 System Description: Wind Plant

The site chosen for proposed wind power plant is Mount Sumanik in southern Yukon. Mount Sumanik, a large, broad hill complex equipped with Lidar for ongoing wind resource assessment study, is located immediately west of Whitehorse[6]. A three-turbine, 6 MW wind farm with 27% capacity factor is studied.

The system boundary is presented in Figure 6 with a description following in Table 6.

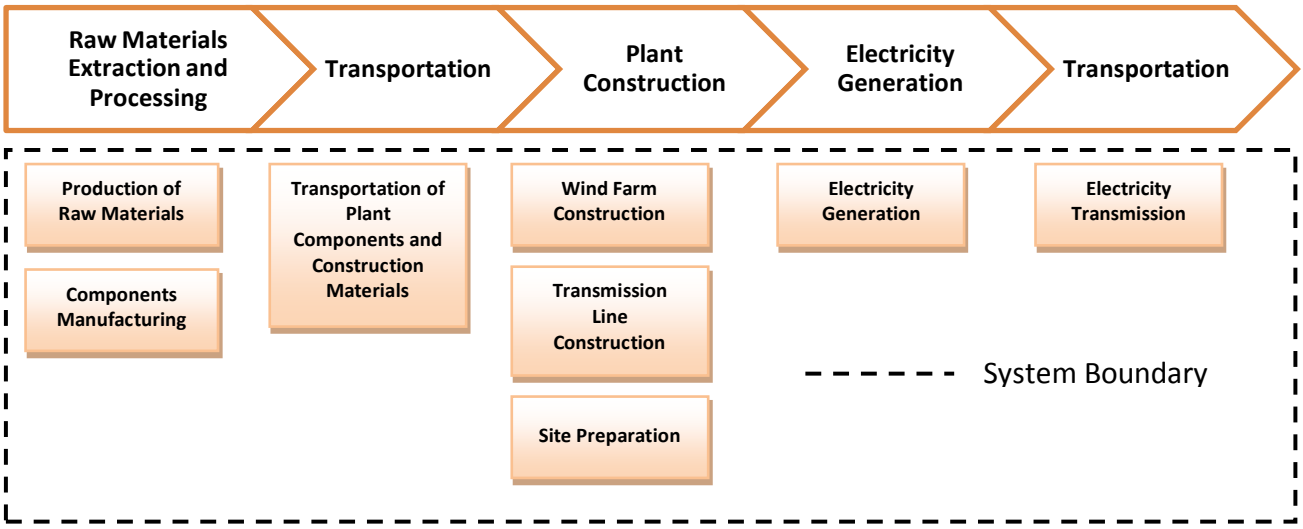

Figure 6. System Boundary of Wind Electricity Generation

Table 6. Description of Wind Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials for plant construction (i.e. concrete, steel, etc.) are extracted and processed.
Components Manufacturing and Transportation	It is assumed that wind turbines are manufactured in Denmark. Turbine transport by sea – 5,578 km (Denmark – Montreal) Turbine transport by road – 5,560 km (Montreal – Whitehorse) Transmission line components are transported 2,400km by truck, 22t payload.
Plant Construction	Greenfield site This stage includes construction and installation of the plant at Mount Sumanik and construction of 7.6km transmission line. Total road, transmission line, and wind farm area is 100 ha.
Electricity Generation	Three Vesta V-90 2MW turbines with 27% capacity factor or similar turbines. Gross annual energy production: 16.45 GWh_e/yr; Net (88.5% of theoretical gross output): 14.558 GWh_e/yr
Electricity transmission	Produced electricity is transported to Whitehorse through 7.6km transmission line
End of life	Plant lifetime: 25 years

[6] CBER Ltd., ENVINT Consulting, V3 Energy, LLC. (2016). Yukon Wind Site Inventory. Draft Report. May 16, 2016.

3.3.6 System Description: Solar Plant

A 5 MW photovoltaic solar farm is chosen to be located at the old Whitehorse Copper Mine site near Whitehorse[7]. It is a brownfield site and has an established road access.

The system boundary is presented in Figure 7 with a description following in Table 7.

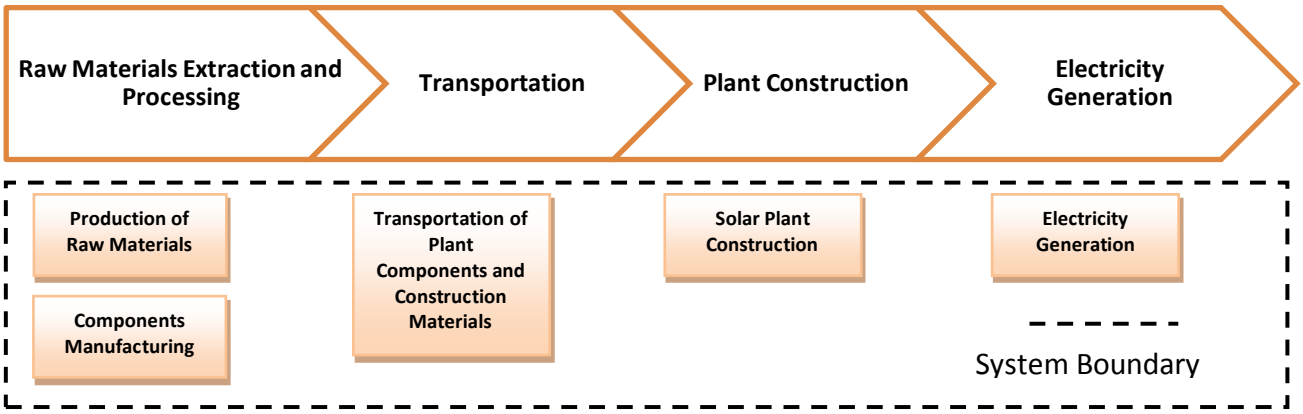

Figure 7. System Boundary of Solar Electricity Generation

Table 7. Description of Solar Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials for plant construction (i.e. concrete, steel, etc.) are extracted and processed.
Components Manufacturing and Transportation	Solar PV components (e.g. module, racking, inverter) are manufactured in Japan and transported to Vancouver by sea (7,664 km) and then from Vancouver to Whitehorse 2,400km by truck, 22t payload.
Plant Construction	Brownfield, no site preparation or access road construction is included. Solar PV system is assembled in Whitehorse Copper.
Electricity Generation	Panasonic HIT 330W n-type silicon modules produce electricity at 20% efficiency. Net electricity production: 5.2 GWh_e/yr
End of life	Lifetime: 30 years

3.3.7 System Description: Pumped Storage

The Tutshi-Moon pumped storage project with a capacity of 20.2MW and 54 GWh energy storage is located between Tutshi and Moon Lakes in BC (110 km from Whitehorse and 18 km south of the BC-Yukon border) [8]. This is a greenfield site with the proposed inundation area of 352.4 ha. The site is 2.6 km away from the transmission line.

The system boundary is presented in Figure 8 with a description following in Table 8.

[7] Solvest Inc. Solar Site Inventory. Draft report for RFP #2015-058.
[8] Knight Piésold Ltd. (2016). Based on data from Yukon Energy Corporation Pumped-Storage Assessment, Preliminary Assessment. April 14, 2016.

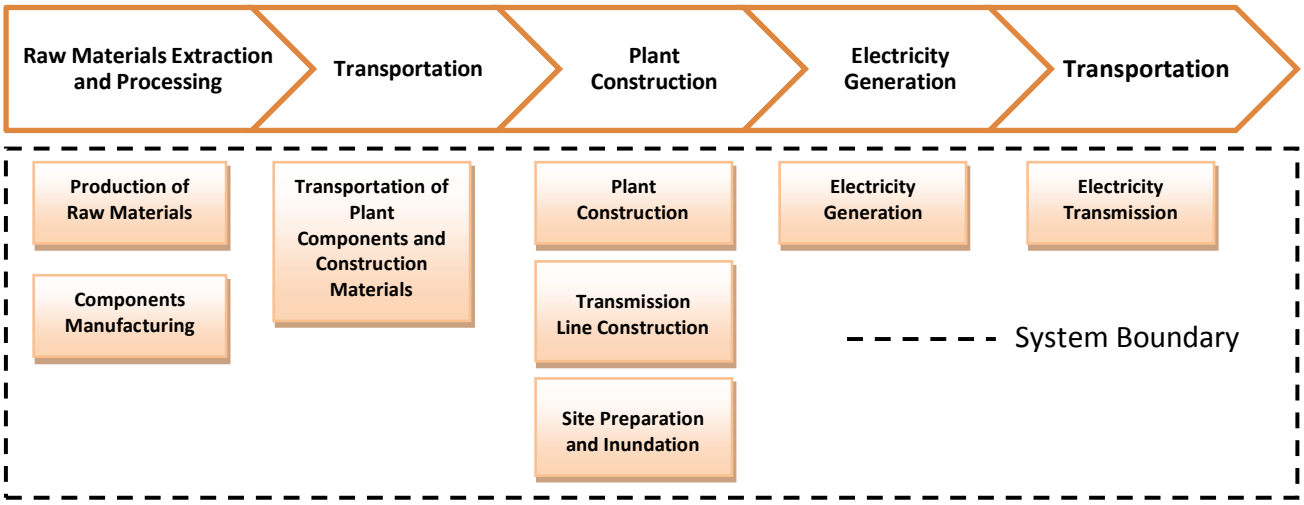

Figure 8. System Boundary of Pumped Storage Electricity Generation

Table 8. Description of Pumped Storage Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials for plant construction (i.e. concrete, steel, etc.) are extracted and processed.
Components Manufacturing and Transportation	Plant components are manufactured and transported 2,400km by truck. Equipment manufacturing (motor-generator, transformer, pump-turbine, pressure pipes, etc.) is included in the system boundaries.
Plant Construction	This stage includes construction and installation of the plant and transmission line construction. The main components of the plant are: diversion, dam, spillway, reservoir, intake penstock, substation, and powerhouse with equipment[9]. The concrete dam construction is modelled. The site specifications are as follows: • Upper Reservoir Area (ha): 610 • Lower Reservoir Area (ha): 5600 • Penstock Length (km): 5.8 • 2m wide and 300m long gated concrete spillway • Inundation area is 352.4 ha • Greenfield site
Electricity Generation	Power house (contains a turbine and generator unit, most likely a vertical axis Pelton turbine), located at Tutshi Lake. Net electricity production: 54 GWh/yr
Electricity Transmission	Once electricity is produced, it moves to 2.6 km transmission line (138 kV).
End of life	The lifetime of the plant is 65 years.

[9] Midgard Consulting Inc. (2015). Moon Lake – Pumped Storage, Conceptual Study Report. December 14, 2015.

3.3.8 System Description: Small Hydroelectricity Plant

The Drury Lake project is a small hydro with storage power station with an installed capacity of 8.1 MW[10]. The proposed station location is on Drury Creek between Drury Lake and Little Salmon Lake, in the Yukon River watershed. The site is approximately 170 km north of Whitehorse and is situated within 1 km of the Robert Campbell Highway and the existing Yukon Integrated Grid transmission line.

The system boundary is presented in Figure 9 with a description following in Table 9.

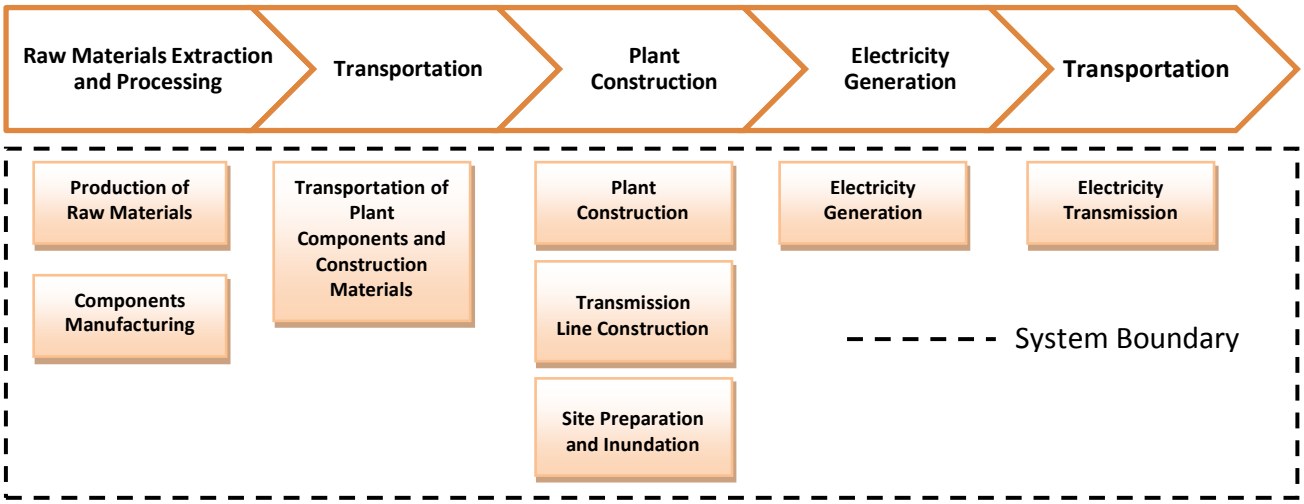

Figure 9. System Boundary of Pumped Storage Electricity Generation

Table 9. Description of Small Hydroelectricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials for plant construction (i.e. concrete, steel, etc.) are extracted and processed.
Components Manufacturing and Transportation	Plant components are manufactured and transported 2,400km by truck. Equipment manufacturing is included in the system boundaries.
Plant Construction	This stage includes construction and installation of the plant and transmission line. Plant specification: • 5km of access roads. • Concrete Faced Rockfill Dam (CFRD) or earthfill control dam at the outlet of Drury Lake to provide 5m of storage (operating storage of 135 Mm^3). The concrete dam construction is modelled. The dam would be constructed with an Instream Flow Requirement (IFR) discharge system and a spillway to Drury Creek for flood water management. • Intake weir across Drury Creek, approximately 4 km downstream of the lake outlet. • 4.8 km penstock located on the south side of Drury Creek, comprising 3.6 km of low pressure pipe (LPP) and 1.2 km of high

Life Cycle Activity	Description
	pressure pipe (HPP). • Powerhouse and substation at the edge of Drury Creek, upstream of the Robert Campbell Highway and the river mouth at Little Salmon Lake. • 0.5 km of 138 kV transmission line
Electricity Generation	Net electricity production: 31.7 GWh_e/yr
Electricity Transmission	Once electricity is produced, it moves to 0.5 km transmission line, to the existing grid (Yukon Integrated Grid).
End of life	The lifetime of the plant is 65 years.

3.3.9 System Description: Battery Storage

For this portion of the study, a lithium-ion battery was chosen for the analysis. The battery's capacity is 8 MW with 5 hours discharge time[11]. The energy storage system will be treated as a separate substation and the anticipated location is near the S164 Takhini 138 kV / 34.5 kV substation. The energy storage system will connect to the 34.5 kV system (not included in the current analysis). By connecting to the relatively low transmission line voltage of 34.5 kV, the need for a second step-up transformer is avoided.

The system boundary of the battery storage pathway is presented in Figure 10.

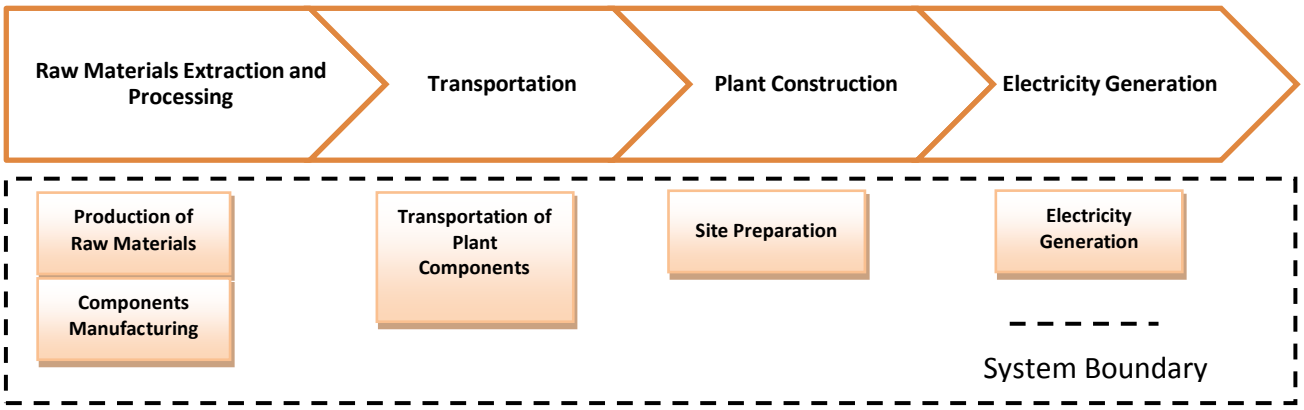

Figure 10. System Boundary of Battery Storage

Table 10. Description of Battery Storage by Life Cycle Stage

Life Cycle Activity	Description
Production of Raw Materials	Raw materials for battery manufacturing are extracted and processed.
Components Manufacturing and Transportation	Battery components are manufactured and transported to the plant location: California to Alaska by sea – 3,226 km Alaska to Whitehorse -1,133 km by truck, 22t payload

Life Cycle Activity	Description
Plant Construction	Equipment Two (2) PCS Modules packaged in two 40' trailers. Each module includes the following: • Two (2) 2 MW inverters with AC and DC circuit breakers; thermal management; control and protection • Two (2) 2000 kVA padmount transformers : 35 kV : 454 VAC • One (1) MUC (Multiple Unit Control) Greenfield/Brownfield The site preparation includes clearing of 4,200 m^2 (0.42 ha) area
Electricity Generation	Electricity is stored in the battery cell and released when needed. Annual energy storage: 2,780 MWh_e
End of life	Project lifetime: 20 years Battery lifetime: 10-15 years

3.3.10 System Description: Thermal Diesel Plant

The thermal diesel energy production pathway is based on previous LCA studies[12],[13]. The crude oil comes from Alaska North Slope and Alberta and is refined at Puget Sound refinery in Washington State, US. The crude oil is transported to the refinery via ocean freighter. The diesel fuel is transported from Puget Sound refinery to Skagway, Alaska via ocean freighter and from Skagway to Whitehorse via truck transport. A Caterpillar diesel engine (CAT Continuous 3300 generator) with electrical efficiency of 41.6% is used to generate electricity at the plant. The proposed diesel plant will be based at Takhini Substation outside of Whitehorse. The plant capacity is $5MW_e$ and annual net electricity production is 39.42 GWh/yr.

The system boundary is presented in Figure 11 with a description following in Table 11.

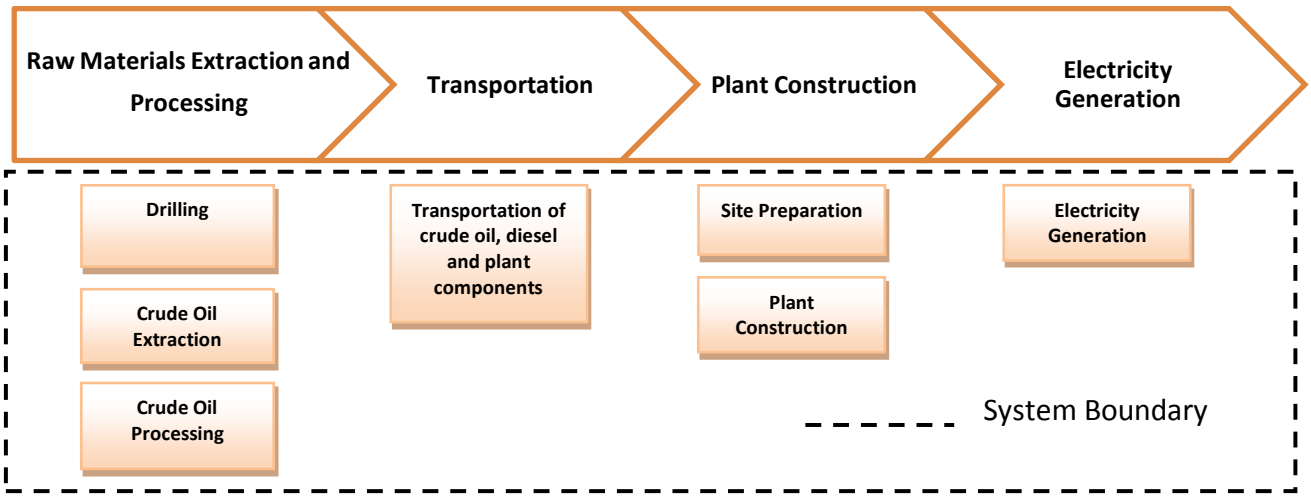

Figure 11. System Boundary of Diesel Electricity Generation

Table 11. Description of Diesel Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Extraction of Raw Materials	Crude oil is extracted from Alaska's North Slope and Alberta and transported to Puget Sound refinery via ocean vessel.
Processing and Transportation	Crude oil is refined into diesel fuel and other refined petroleum products. Diesel fuel is transported from Puget Sound refinery to Skagway, AK via ocean barge and from Skagway to Whitehorse via truck transport.
Electricity Generation	Diesel is combusted for power in a CAT Continuous 3300 generator operating at 41.6% efficiency. Net electricity production: 39.42 GWh/yr
Plant Construction	Greenfield/Brownfield Includes 4.5-5.5 ha of land clearing.
End of life	Lifetime: 20 years

3.3.11 System Description: Thermal LNG Plant

Three LCA studies on thermal LNG pathway have been conducted in the period from 2013 to 2014. These are ICF Marbek, 2013[14], Pembina, 2013[12] and (S&T)[2] Consultants Inc., 2014[13]. An analysis of the studies with the focus on upstream emissions from LNG is given in Appendix A.11. The uncertainty of methane emissions estimates is discussed in section 3.4.1.

The LNG comes from the Fortis BC LNG facility at Tillbury Island in Delta, BC. Tillbury has been in operation since 1971 and can liquefy 120,000 cubic meters (4,500 GJ) of natural gas per day. The facility uses electricity to drive the liquefaction process. The energy requirement is 0.5 kWh/kg of LNG (0.039 joules of power per joule of LNG). The LNG is transported from Tillbury to Whitehorse via truck transport. The proposed thermal LNG plant will be based at Takhini Substation outside of Whitehorse. The plant capacity is $5MW_e$ and annual net electricity production is 39.42 GWh/yr. The system boundary is presented in Figure 12 with a description following in Table 12.

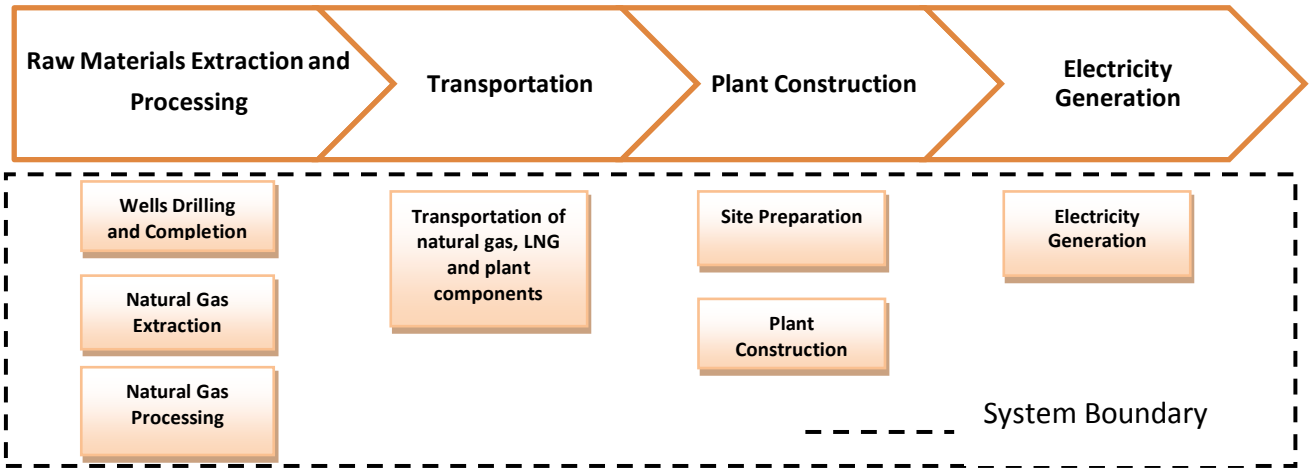

Figure 12. System Boundary of LNG Electricity Generation

[14] ICF Marbek (2013). Yukon Power Plant Fuel Life Cycle Analysis. Final Report. July 2, 2013.

Table 12. Description of Diesel Electricity Generation by Life Cycle Stage

Life Cycle Activity	Description
Extraction of Raw Materials	Natural gas comes from conventional gas fields predominantly in Northeast BC (some NW Alberta natural gas) and delivered to the Fortis BC Tillbury facility from Spectra at Huntington Gate by pipeline.
Processing and Transportation	LNG is treated to remove impurities and liquefied. LNG is transported 5,440 km round trip by truck.
Electricity Generation	LNG is vapourized and combusted to produce power in a Jenbacher generator operating at 46.3% efficiency (47% @ 90% load). Net electricity production: 39.42 GWh/yr
Plant Construction	Greenfield/Brownfield Includes 6.5 ha of land clearing
End of life	Lifetime: 20 years

3.3.12 System Description: New Transmission Line (Whitehorse-Skagway)

A new electric 230kV transmission line, 170 km in length, will be constructed from Whitehorse Generating Station to Skagway. The electricity will be generated at Whitehorse Rapids Generating Station (WRGS) and delivered to the Town of Skagway, Alaska or in the winter generated in Skagway and delivered to Whitehorse. From the WRGS, the corridor follows Highway 1 southeast for 17 km to Carcross Cutoff (the junction of Highways 1 and 2). From Carcross Cutoff, the corridor follows Highway 2 southward, through the town of Carcross for 77 km, to the BC-Yukon border. Once in BC, the corridor continues along Highway 2 for an additional 56 km to the BC-Alaska border. In Alaska, the corridor continues along the same highway (now named Highway 98) for an additional 21 km to Skagway, Alaska. Sixty-eight km of 15m wide 34.5 kV distribution line from Whitehorse to Carcross[15] is included in the analysis.

The full life cycle of Whitehorse-Skagway transmission line is considered. The system boundary is presented in Figure 13.

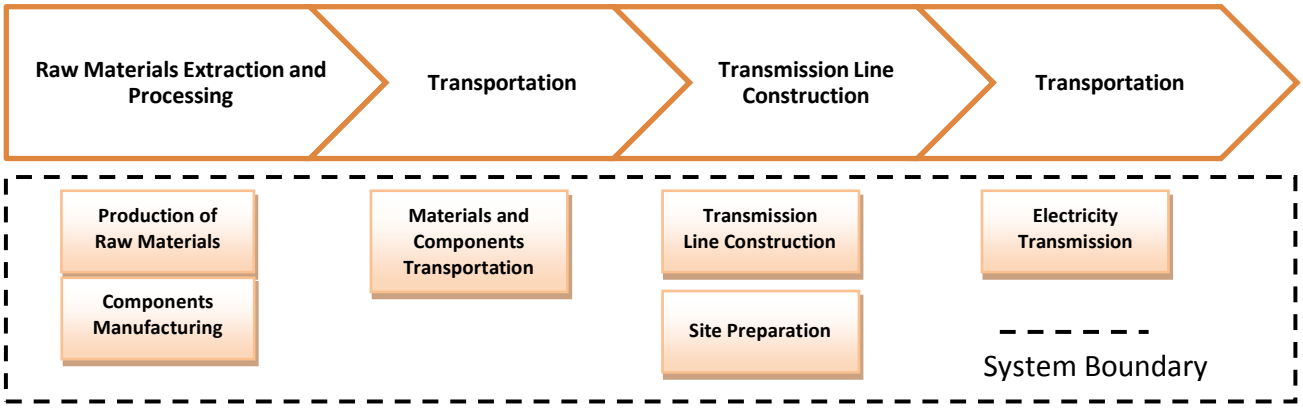

Figure 13. System Boundary of Whitehorse-Skagway Transmission Line

[15] Midgard Consulting Inc. (2016). Yukon Energy Corporation Transmission Options Evaluation. June 2, 2016.

Table 13. Description of Whitehorse-Skagway Transmission Line by Life Cycle Stage

Life Cycle Activity	Description
Production of Raw Material	Raw materials for transmission line construction (i.e. concrete, wood, copper, etc.) are extracted and processed.
Components Manufacturing and Transportation	Transmission line components are manufactured and transported 2,400 km by truck, 22t payload.
Transmission Line Construction	This stage includes site clearing and installation of the transmission line (poles, transmission towers, etc.). Transfer Capacity: 443 MW, 230 kV transmission line Transmission Conductor: Hawk 477 MCM 102 km line, 30m wide right of way clearing and 68 km of an existing 34.5kv line (306 ha plus 102 ha of cleared area footprint)
Electricity Transmission	3880.7 GWh/yr (100% reliable capacity) Transmission Voltage: 230 kV
End of life	Lifetime: 55 years

3.3.13 System Description: Gladstone Diversion Project

The Gladstone Diversion project has been used as a proxy for a potential diversion project. The project will give some additional storage to an existing generating Station. A dam and channels will be constructed on the Gladstone Lake across the divide between the Gladstone Creek and Isaac Creek watershed. This will increase the diverted drainage basin area. The project will utilize capacity of existing hydro units.

The system boundary is presented in Figure 14 with a description following in Table 13.

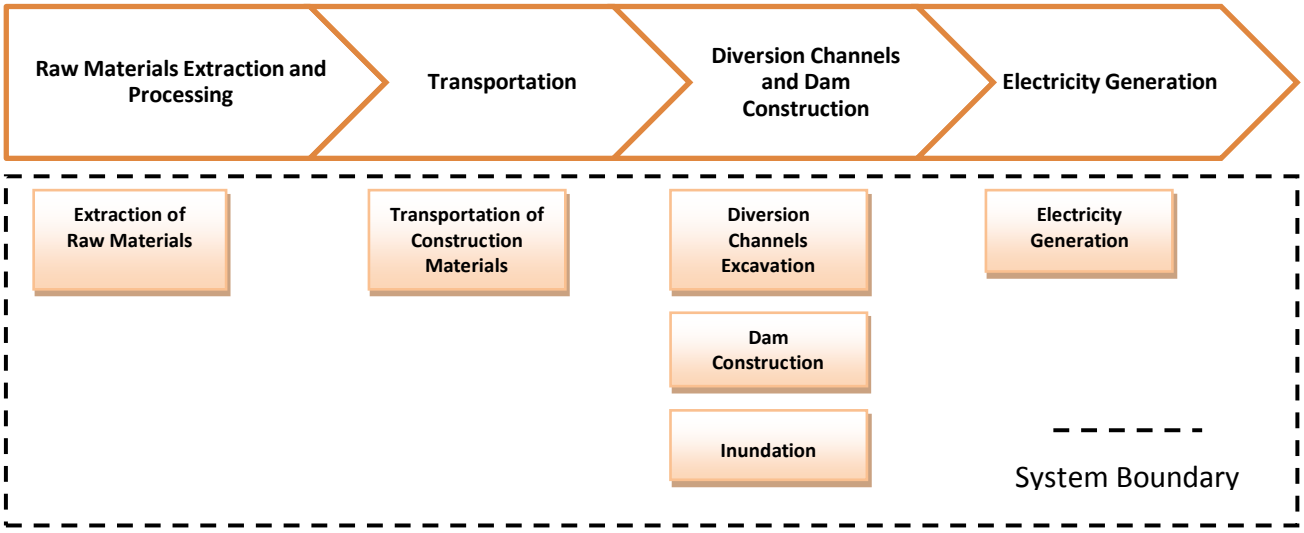

Figure 14. System Boundary of the Gladstone Diversion Project

Table 14. Description of Water Diversion Project by Life Cycle Stage

Life Cycle Activity	Description
Raw Materials Extraction and Processing	Raw materials (gravel, sand) for dam construction are sourced locally
Transportation	Transport distance: 15 km by truck, 22 t payload
Diversion Channels and Dam Construction	Partial greenfield site with inundation area of 220 ha This stage includes diversion channels excavation and dam construction.
Electricity Generation	Net electricity production: 29.7 GWh_e/yr - the project would utilize existing hydro units.
End of life	The lifetime of the project is 24 years. 65 years lifetime is modelled to compare results to other hydro power scenarios.

3.4 DATA QUALITY, DATA SOURCES AND ASSUMPTIONS

Data quality requirements specify the characteristics of the data needed for the study. Description of data quality, sources and assumptions is important to understand the reliability of the study results and properly interpret the outcome of the study[16].

Several different methods of data collection were available, such as personal interaction, previous LCA studies and technical reports prepared for Yukon Energy, and both peer-reviewed and un-reviewed published literature.

The majority of the data used in this project is specific to Yukon and Western Canada. In the absence of the Western Canadian data, information was drawn from other Canadian sources, followed by North American and European sources and, finally, from pre-existing life cycle databases, most notably the Ecoinvent library and GaBi database. The Ecoinvent library is a European database considered to be the most comprehensive and up-to-date inventory currently available[17]. Canadian data was directly substituted into the Ecoinvent library where possible, and the default European data remained when Canadian data was unavailable.

More information on life cycle inventory data, assumptions and data sources can be found in Appendix A: Life Cycle Inventory Supporting Information.

3.4.1 UNCERTAINTY

The quality and reliability of LCA results depend on the quality of data used in the inventory analysis. It is therefore important to identify sources of uncertainty in the inventory data and understand how they affect the results of the study.

Materials and equipment manufacturing locations

The study evaluates potential energy resource options available to Yukon Energy. The studied scenarios are based on the results of feasibility studies conducted for each resource option. A specific

[16] ISO - International Organization for Standardization (2006) 14040. (2006). Environmental Management - Life cycle assessment - Principles and Framework.
[17] Ecoinvent Centre. (2009). Swiss Centre for Life Cycle Inventories Website. http://www.ecoinvent.ch/.

technology or manufacturer is not always identified in the feasibility study. Thus, several assumptions were made and a sensitivity analysis was conducted on selected parameters, such as technology choice (e.g. battery storage pathway) and plant components manufacturing location (e.g. wind pathway).

The manufacturing locations of power plant components are also unknown. It is therefore assumed that most of the materials (e.g. steel, concrete, iron) and plant components are produced in Canada and transported 2,400km by truck to the power plant location.

Power plant construction data

Moreover, site specific data such as plant construction data (e.g. area of land to be cleared, type of dam, excavation area, quantities of construction materials) is available only for some of the pathways.

The power plant construction data in the waste to energy pathways originates from Spath and Mann[18] and is representative of a North American power plant. Small hydro and pumped storage power plant construction data is based on Flury and Frischknecht, 2012[19] and represents a mix of North American and European small hydro and pumped storage power plants. The data is obtained per MWh of energy produced; if the emissions data expressed per MWh is converted back to the total GHG emissions from plant construction using the total energy output of the plant over plant's lifetime, it increases the uncertainty of the results. Site specific data need to be obtained to better understand GHG emissions from power plants construction. It is recommended to update this data when site specific data become available.

Diesel and LNG combustion data

GHG emissions from diesel and LNG combustion are estimated based on emissions factors, not specific operating data, which was not available at the time of the study. The emissions factors are derived from GHGenius 4.03 that are based on the US EPA non-road model for large diesel and natural gas engines. The Jenbacher natural gas engine has up to 2.5% of the methane in the exhaust emissions, while the EPA non-road emission model uses a methane emissions factor of approximately 2.8%[13]. A sensitivity analysis is performed to better understand an effect of different emissions factors on the results.

Upstream emissions in LNG pathway

The accuracy of methane emissions from natural gas extraction, processing, transportation, and storage is an area of concern. Significant differences exist among data reported by industry. The application of correct emissions factors in order to estimate methane emissions is therefore challenging. The 2006 IPCC Guidelines suggests a range of +/-100% uncertainty when applying their values to estimate natural gas methane emissions.

Many emissions in the oil and gas industry are unintentional and do not necessarily correlate with default emissions factors; rather, they are dependent on the operation and condition of the specific equipment itself. The method in which data are collected, various modelling techniques, and the location where the data are collected contribute to the variability. When emissions factors are

[18] Spath, P.L. and Mann, M. K. (1997). Life Cycle Assessment of a biomass Gasification Combined-Cycle System. NREL. December 1997.
[19] Flury, K. and Frischknecht, R. (2012). Life Cycle Inventories of Hydroelectric Power Generation. ESU- Services. Commissioned by Öko-Institute e.V.

unavailable, studies and assessments are forced to use generic emissions factors, regardless of the range of uncertainty. Therefore, understanding the inherent uncertainty is key to applying emissions factors in life cycle assessments. This report used the Canadian data from CAPP, 2004[20] and GHGenius v4.03. A detailed discussion and an overview of the latest research on the LNG upstream emissions are given in section A.11 of the report.

3.5 LIFE CYCLE ASSESSMENT METHODOLOGY

Life cycle assessment (LCA) is a method for examining the environmental effects of a product or process across its lifespan. It is a "cradle-to-grave" analysis in which complex systems are broken down into elementary flows. The flows are then grouped and categorized based on the effects they have on the environment.

This LCA study follows the general principles set forth by the International Organization for Standardization (ISO) in ISO 14040[15] and ISO 14044[21] for conducting and reporting LCA studies and examines GHG emissions only. The ISO 14040 LCA framework consists of four steps (Figure 15):

1. Definition of goal and scope;
2. Inventory analysis;
3. Impact assessment; and
4. Interpretation of results.

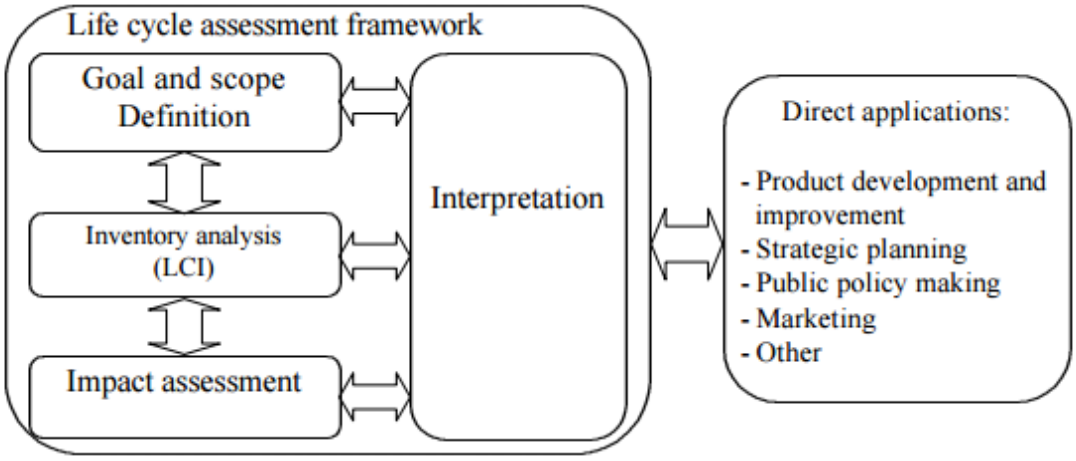

Figure 15. LCA phases

[20] CAPP. (2004). A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H_2S) Emissions by the Upstream Oil and Gas Industry.

[21] ISO - International Organization for Standardization 14044. (2006). Environmental Management – Life Cycle Assessment - Requirement and Guidelines.

3.5.1 Life Cycle Inventory and Life Cycle Impact Assessment Analyses

The second phase of the LCA is life cycle inventory analysis where the energy use and raw material inputs and environmental releases associated with each stage of the life cycle are grouped and quantified.

In the life cycle impact assessment phase the Global Warming Potential (GWP) factors are applied to the life cycle inventory data to calculate the global warming impact of each energy resource pathway. The results are presented as carbon dioxide equivalents (CO_2e). The GWP factors (without feedback) based on the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (AR5) are used to quantify GHG emissions (Table 15).

Table 15. Greenhouse Gases

GHG	Life time[22]	GWP time horizon (IPPC AR5)	
		20 years	100 years
Carbon dioxide (CO_2)		1	1
Methane (CH_4)	12.4	84	28
Nitrous oxide (N_2O)	121	264	265
HFC-23	222	10,800	12,400
HFC-134a	13.4	3,710	1,300
CF_4 (PFC)	50,000	4,880	6,630
Sulphur hexafluoride (SF_6)	3,200	17,500	23,500
Nitrogen trifluoride (NF_3)	500	12,800	16,100

3.5.1.1 Methane Global Warming Potential over 20- and 100-year time horizon

This study recognizes the importance of short-term and long-term mitigation strategies for the release of GHG emissions. To fully understand the environmental impact of each energy source under analysis, both the 20-year and 100-year time horizon are applied. The analysis quantifies and evaluates the released emissions and their respective levels of radiative forcing relative to the CO_2 reference gas.

A GWP for a particular GHG is determined by the gas's ability to absorb certain types of radiation and the length of time the gas remains in the atmosphere.

GWP values are currently reported for time scales of 20 and 100 years by the IPCC. They are regularly updated as newer modelling techniques are developed and as GHG lifetimes and absorption efficiencies are revised[23]. The GWP values are relative to the reference gas CO_2, which has a GWP set to one, regardless of the time period it is reported for. GWPs quantify the amount of radiated energy that will be absorbed by one ton of gas, compared to one ton of CO_2. Hence, larger GWP values indicate a greater warming effect compared to CO_2 for the chosen time horizon under investigation.

[22] The lifetime of a greenhouse gas refers to the approximate amount of time for the atmospheric pollutant to return to its natural level as a result of either being converted to another chemical compound or being taken out of the atmosphere via a sink.

[23] Boucher, O., Friedlingstein, P. Collins, B., and Shine, K.P. (2009). The indirect global warming potential and global temperature change potential due to methane oxidation. *Environ. Res. Lett*. 4, 044007.

LCA standard practice is to use GWPs with a predetermined time horizon regardless of when the emissions occurred[24]. However, the lack of available information on the application of different GWP time scales in LCAs increases the level of uncertainty in the calculated emissions[25]. For example, LCA studies have not focused on the use of different time horizons despite it being a well known factor in the analysis of biofuels, which contribute to methane emissions[26,27]. As well, the choice of timeframe in which to analyze the GHG is somewhat arbitrary. In a 2009 study, data showed that the most optimum GWP time horizon to correlate methane emissions with equivalent CO_2 emissions using to historical temperature data was 44 years[28]. Interestingly, the data could not provide any particular time horizon where N_2O emissions accurately corresponded with historical data. As well, GWP values are weighted equally across the entire time period regardless of any change in their absorption efficiency during that time period[29]. Therefore, analysis with multiple time horizons can provide additional insight into the short and long term environmental effects caused by various GHGs.

The choice of time scale used to report GWP values can significantly affect the actual GWP value due to the varying atmospheric lifespan of each greenhouse gas. The most widely accepted time scale is 100 years, which adequately represents most GHGs due to their significantly long lifetime (Table 14 – GWP for 20 and 100 years). That is, the reported GWP value does not change considerably for the different time scales. It is the most commonly used metric for comparing GHGs and was used under the Kyoto Protocol[30].

Greenhouse gases with shorter lifetimes that are in the order of decades rather than centuries or millennia can have a GWP value that increases by a factor of three for the 20 year time horizon versus the 100 year time horizon. Specifically, methane (CH_4) emissions typically last approximately one decade before being oxidized into CO_2. Additionally, methane's higher energy absorption is significantly greater than CO_2. Over 100 years, it is 28 more times effective at trapping heat compared to CO_2, but over 20 years, it is 84 times more potent at retaining heat. The impact of methane's shorter lifetime and greater ability to trap energy is revealed in its GWP value. Comparatively, CF_4, which has a 50,000 year lifetime, has a lower 20-year GWP value than the 100-year value. Therefore, examining global warming potential effects over shorter timeframes will be included in order to address the immediate effects of methane on global temperatures.

In this study, the application of the 20 year time horizon for GWP values, in addition to the 100 year time horizon, prioritizes gases with shorter lifetimes rather than focusing on longer-term impacts from GHGs[31]. Carbon dioxide, and many other GHGs, remains in the atmosphere longer than methane by factors greater than 100. The rationale for addressing short term GHG impacts, such as methane emissions, is that it allows additional time to implement more effective means to regulate and reduce CO_2 emissions that ultimately have longer term effects and are necessary for overall climate stabilization. Given that methane is the second most prominent human-induced GHG present in the atmosphere with a short lifespan, a decrease in current CH_4 emissions will reduce anthropogenic-induced warming relatively quickly as the results can be seen in the subsequent few decades, whereas the effects of reduced CO_2 emissions will not be seen for centuries[32,33]. Due to its short lifespan, methane has become an appealing objective for climate mitigation strategies.

The hypothesis that a reduction in methane concentrations will have a significant positive impact on the overall atmospheric burden is supported by the 20 year time horizon in LCA studies. It is suggested that the immediate benefit of reducing short lived GHGs will help avoid the 2^0C increase in the temperature threshold, or the so-called "tipping point" in climate change[34,35]. Moreover, recent studies have shown that the GWP for methane increases substantially for the 20 year time horizon when interactions with aerosols are considered in the calculations[36,37]. A 2015 study on the LCA of biofuels revealed that the choice of GWP timeframe by which to analyze the carbon footprint should be carefully considered, rather than simply choosing the standard 100 year time horizon[38]. The analysis showed that the methane emitted through biogas use had a greater carbon footprint for the 20 year timeframe compared to the 100 year time horizon.

This study recognizes the importance of short-term and long-term mitigation strategies for the release of GHG emissions. To fully understand the environmental impact of each energy source under analysis,

both the 20-year and 100-year time horizon are applied. This information is critical to stakeholders in order to make an informed decision as they prepare for future energy scenarios.

3.5.2 RESULTS INTERPRETATION

In the final stage of the LCA, results of the impact assessment phase are interpreted and presented. Two major analyses in determining the validity of the results are conducted:

- Contribution analysis - a measure of the effect each process has on the complete environmental profile of the life cycle. The processes that make up the largest portions of the total impact assessment are then subjected to rigorous data quality checks and sensitivity analyses, and
- Sensitivity analysis - determines the effect of changing parameters and assumptions on the final results. It is essential to determine whether the final results are resistant to small changes through the life cycle.

4 GREENHOUSE GAS EMISSIONS ASSESSMENT RESULTS

4.1 LIFE CYCLE INVENTORY

Life cycle inventory models have been developed to quantify and compare GHG emissions for the 13 scenarios under study. Detailed descriptions of the life cycle inventory data used in this study are presented in Appendix A: Life Cycle Inventory Supporting Information.

4.2 RESULTS

The results are presented per MWh of energy delivered, including the transmission line results that are converted to MWh by multiplying the results in kg CO_2e/MWh-km by the transmission line length of 170km. The contribution analysis results are grouped into three categories:

1. Materials and Fuel Acquisition, Production and Construction
2. Transport of Materials and Fuel, and
3. Operation.

Materials and fuel acquisition, production and construction include raw materials for plant construction acquisition, processing, components manufacturing, site preparation, and plant and transmission line construction. In the diesel pathway, crude oil extraction (includes leakage, vented and flared emissions), diesel production, crude oil and diesel storage, and power plant construction (extraction and processing of raw materials, site preparation) are included in this stage.

Transport of materials and fuels include transportation of raw materials and components, as well as transportation of fuel such as biomass, MSW, diesel, and LNG.

Operation category includes onsite fuel processing (e.g. biomass drying), fuel combustion, plant operations and maintenance, as well as yearly right of way clearing in the transmission line pathway. In the hydro pathways, emissions from land inundation are also included in the operation category.

A comparison of total GHG emissions (including biogenic CO_2) produced by all resource options under consideration for the 20 and 100 year GWP time horizons is presented in Figure 16. The resource options can be grouped into three categories of emitters: those producing GHGs just over 1,000 kg CO_2e/MWh, resources producing well over 600 kg CO_2e/MWh, and those that produce GHGs below 45 kg CO_2e/MWh. In the first category, the top three overall GHG emitters are biogas, diesel and LNG, where each pathway produces more than 1,000 kg CO_2e/MWh. However, it should be noted that biogas pathway has biogenic CO_2 emissions included in the operation stage. More information on accounting for biogenic CO_2 emissions can be found in the next section (4.2.3). Biomass gasification produces 772 kg CO_2e/MWh, and MSW and MSW with biomass combustion produce around 700 kg CO_2e/MWh. Both plants are combined heat and power plants that have higher efficiencies due to produced heat utilization. Last, the remaining resources (geothermal, wind, solar, battery storage, transmission line, small hydro, pumped storage and water diversion) produce approximately 43 kg CO_2e/MWh or less.

In most of the scenarios, except for the biogas, LNG and hydro options, the GHG emissions among the two time horizons are similar. The difference in GHG emissions for the biogas, LNG and hydro options for the 20 year and 100 year time horizons is due to the larger amounts of methane produced and the significantly larger difference between the two GWPs, as previously discussed.

	Wind	Solar	Geothermal	Small Hydro	Pumped Storage	Battery Storage	Water diversion	Transmission line
20 year GWP	10.74	43.24	4.62	20.56	23.41	16.15	21.43	0.17
100 year GWP	10.30	38.99	4.22	12.99	15.15	14.66	12.10	0.16

	Biomass Gasification	MSW	MSW + Biomass	Biogas	Diesel	LNG
20 year GWP	772.49	709.08	675.24	1161.71	1058.91	1050.76
100 year GWP	771.97	696.81	662.98	1015.88	951.11	727.68

Figure 16. Comparison of total GHG emissions (including biogenic CO_2) from energy production pathways (20 and 100 year GWP)

4.2.1 Comparison of GHG Emissions from Energy Production Pathways for 20 Year GWP

The contribution analysis results for the 20 year time horizon presented in Figure 17 reveal that wind, geothermal, transmission line, battery storage and solar energy options GHG emissions come primarily from materials acquisition, production and construction rather than operation of the plant. It is also seen that operation of the energy generating plant is by far the most significant in terms of GHG emissions in biogas, biomass gasification, waste to energy, diesel, and LNG pathways. The hydro power pathways' GHG emissions originate mainly from the operation life cycle stage due to land inundation. The CO_2 emissions from land inundation are considered biogenic and further discussed in section 4.2.3 of the report.

4.2.2 Comparison of GHG Emissions from Energy Production Pathways for 100 Year GWP

Figure 18 compares GHG emissions under the 100 year time horizon for all resource pathways. The trends are nearly identical to the results shown in Figure 17 for the emitted GHGs under the 20 year time horizon. Overall, total GHG emissions are lower when applying the 100 year GWP. This is expected due to the lower GWP for methane for the 100 year time horizon.

In the 100 year GWP scenario, there is only one energy resource option (biogas) that is greater than 1,000 kg CO_2e/MWh. After biogas, diesel and LNG were the next highest emitters, similar to the results using the 20 year GWP. However, while biogas, diesel and LNG were calculated to have less GHG emissions for the 100 year GWP, LNG emitted significantly less compared to the calculated value using the 20 year GWP. The remaining energy resource options produced approximately 40 kg CO_2e/MWh or lower, in a similar manner to the calculated GHG emissions under the 20 year time horizon.

4.2.3 Analysis of Biogenic CO_2 Emissions

Biogenic CO_2 emissions are those that relate to either the natural carbon cycle or the use of biological material to produce energy, through processes such as combustion, fermentation, digestion and decomposition. Bioenergy is often assumed to be "carbon-neutral". This is due to photosynthesis sequestering CO_2 from the atmosphere in the biogenic material in a short timeframe[39]. However, according to the EPA Science Advisory Board's Biogenic Carbon Emissions Panel, biomass energy does not necessarily guarantee carbon neutrality[40]. In some cases, the production, processing and combustion of biomass can be done in a carbon neutral manner; however, it should not always be assumed that carbon neutrality will be the case unless a complete life cycle assessment of production and consumption cycle of the feedstock is performed.

Figure 18. Contribution analysis of GHG emissions (including biogenic CO_2) from energy production pathways (100 year GWP)

The recent study of using forest wood for energy in Massachusetts, US examined the carbon-neutrality and showed that using wood to produce energy results in an initial "carbon debt", because burning wood releases more CO_2 into the atmosphere per unit of energy than fossil fuels[41]. However, when forests grow back and recapture CO_2 from the atmosphere, the "carbon dividend" is realized. The length of time it takes to get carbon dividends depends on the type of biomass used to produce energy, the fossil fuel that biomass replaces, the bioenergy combustion technology and the forest management practices. For example, using forest biomass in district heating in Massachusetts can provide carbon dividends within 10 to 20 years.

The biomass feedstock used in this study consists of forest logging residues, dead trees, and sawmill residues. Since the waste material is used as biomass feedstock, one can argue in support of carbon neutrality of the studied pathways.

Biogenic CO_2 Originating from Studied Pathways

The biomass gasification, biogas, waste to energy (MSW and MSW & biomass combustion) and hydro (small hydro, pumped storage and water diversion) scenarios have biogenic emissions that originate from operations stage. A comparison of total GHG emissions with the results where biogenic CO_2 emissions are excluded is presented in Figure 19. The results that exclude biogenic CO_2 emissions are further presented in Figures 20 - 22.

Biogenic CO_2 emissions in the biogas and biomass gasification pathways originate from biogas combustion and biomass gasification life cycle stages, while fossil emissions come from raw materials acquisition, transportation and plant construction stages. If biogenic CO_2 emissions are excluded, it results in significantly lower life cycle emissions (260 and 114 kg CO_2e/MWh for biogas and 17.72 and 17.20 kg CO_2e/MWh for biomass gasification over the 20 and 100 year time horizons, respectively).

While GHG emissions from fossil sources are quite small in the biogas and biomass gasification scenarios, waste to energy pathways (MSW and MSW with biomass combustion) have notable fossil GHG emissions. This is due to higher quantities of waste in the MSW that contribute to fossil GHG emissions as well as fossil GHG emissions originating from plant construction and MSW collection. Paper, wood waste, and organics in the MSW are assumed to contribute to the biogenic CO_2 emissions. All other groups of waste contribute to fossil CO_2 emissions.

In the hydro pathways (pumped storage, small hydro, water diversion), after exclusion of biogenic CO_2 emissions that originate from biomass decomposition after land inundation, the GHG emissions are significantly lower, especially for the 100 year time horizon.

4.3 CONTRIBUTION ANALYSIS

Contribution analysis is a measure of the effect each process has on the complete environmental profile of the life cycle. The impact each process or life cycle stage has on the total life cycle GHG emissions is identified and discussed below.

4.3.1 BIOMASS GASIFICATION

The biomass gasification is a CHP plant. The total amount of electricity and heat produced from the plant is considered in the calculations. No allocation of emissions to electricity or heat was performed.

Figure 23 presents GHG emissions from biomass gasification in Haines Junction. The total GHG emissions are 771.97 kg CO_2e/MWh based on the 100 year GWP. The primary source of emissions is the operation of the plant, which contributes to almost 99% of the total emissions with 97.7% coming from biogenic CO_2 emissions. The remaining 1.1% of emissions are produced from materials acquisition, transportation of materials and biomass, and plant construction.

According to current GHG accounting protocols and standards, biogenic CO_2 emissions should be accounted and reported separately from all other GHG emissions[42]. The biomass combustion is considered carbon-neutral and biogenic CO_2 emissions are reported separately from other emissions (Table 16).

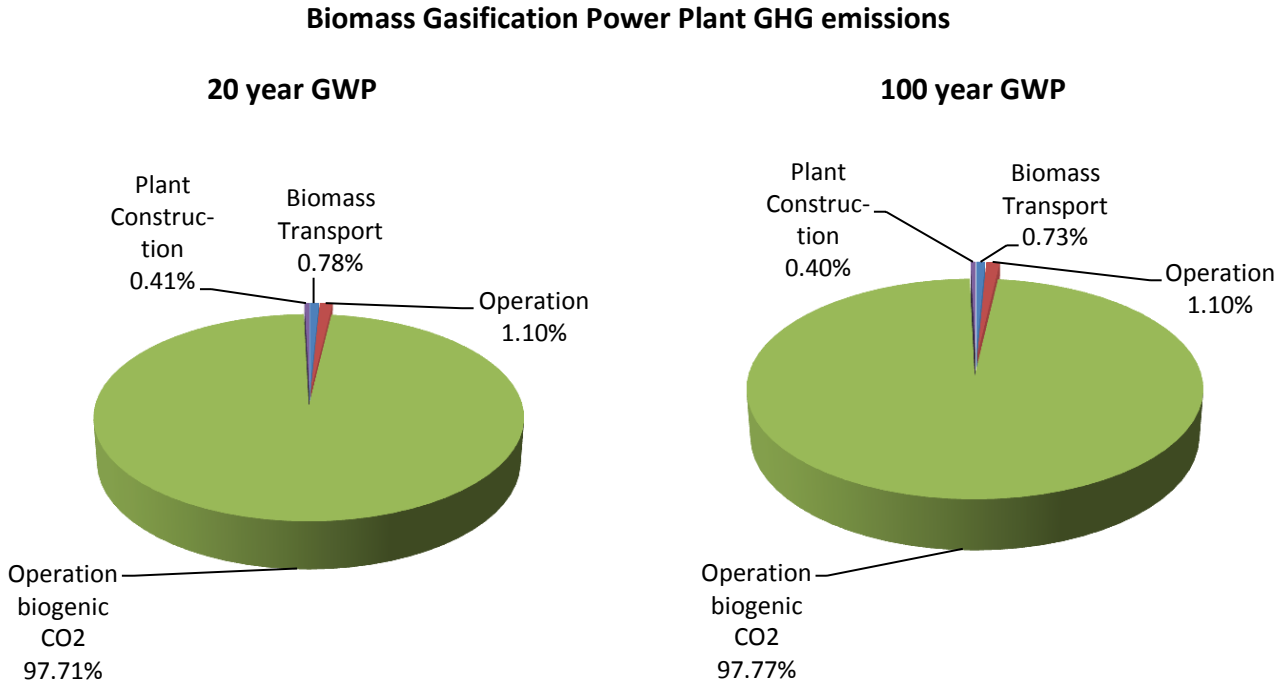

Figure 23. Biomass Gasification Power Plant GHG emissions (20 and 100 year GWP)

[42] Greenhouse Gas Accounting Protocol (2016). http://www.ghgprotocol.org/

Table 16. Biomass Gasification Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.2 WASTE TO ENERGY MSW

There are two scenarios considered for the MSW combustion power plant.

Scenario 1: MSW & Biomass Conventional Combustion

Scenario 1, which is based on a combined combustion of 16,100 tonnes of waste and 7,650 tonnes of biomass, is presented in Figure 24. The amount of emitted GHGs is 675.24 kg CO_2e/MWh based on the 20 year GWP, with plant operation accounting for nearly all of the GHGs (98%) for both time horizons. Nearly 53% of the GHGs from operations originate from biogenic CO_2. The remaining 1.8% of GHGs is produced by transportation of materials and plant construction.

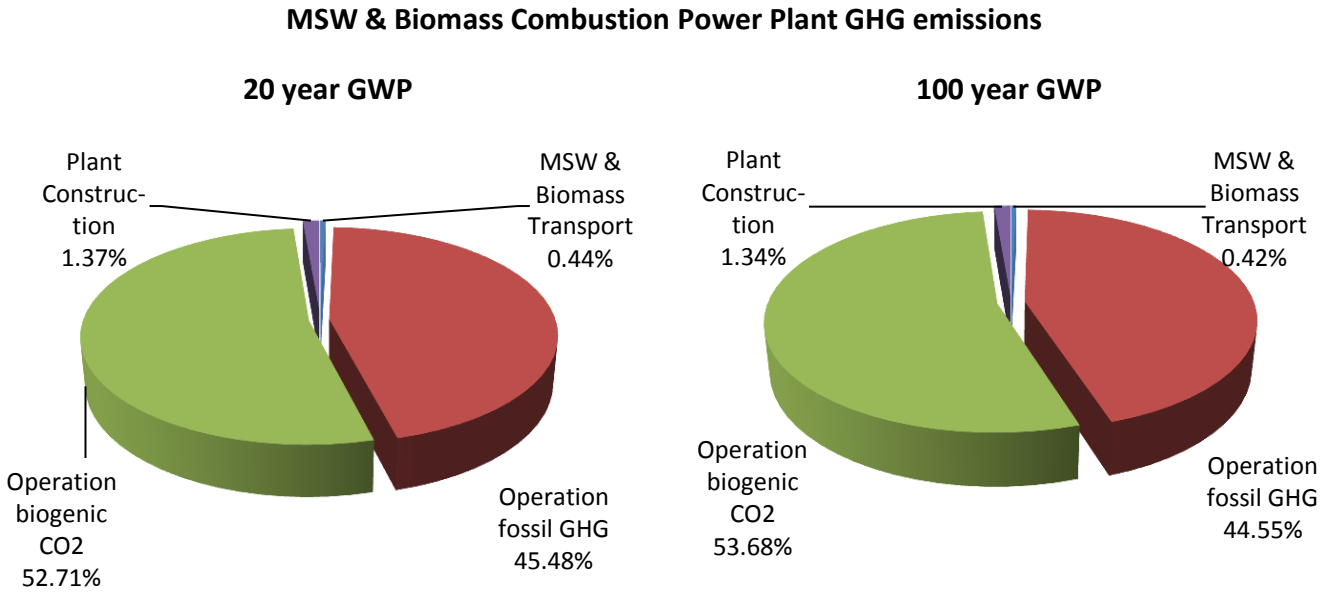

Figure 24. MSW & Biomass Combustion Power Plant GHG emissions (20 and 100 year GWP)

Table 17. MSW & Biomass Combustion Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%
	CO_2	CO_2 Biogenic	N_2O	SF_6	CH_4				
Materials Acquisition	8.0435	0.0000	4.99E-05	7.62E-11	0.0051	8.4856	1.26	8.1997	1.24

Scenario 2: MSW Conventional Combustion

In Scenario 2 (Figure 25), where 23,750 tonnes of MSW are combusted, the amount of GHG emissions is slightly higher at 709 kg CO_2e/MWh based on the 20 year GWP. The source of the GHGs is divided among the pathways in the same manner as Scenario 1, with operations accounting for 98% of GHG emissions for both GWPs under consideration. The biogenic CO_2 contributes to over 36% of total GHG emissions from operations.

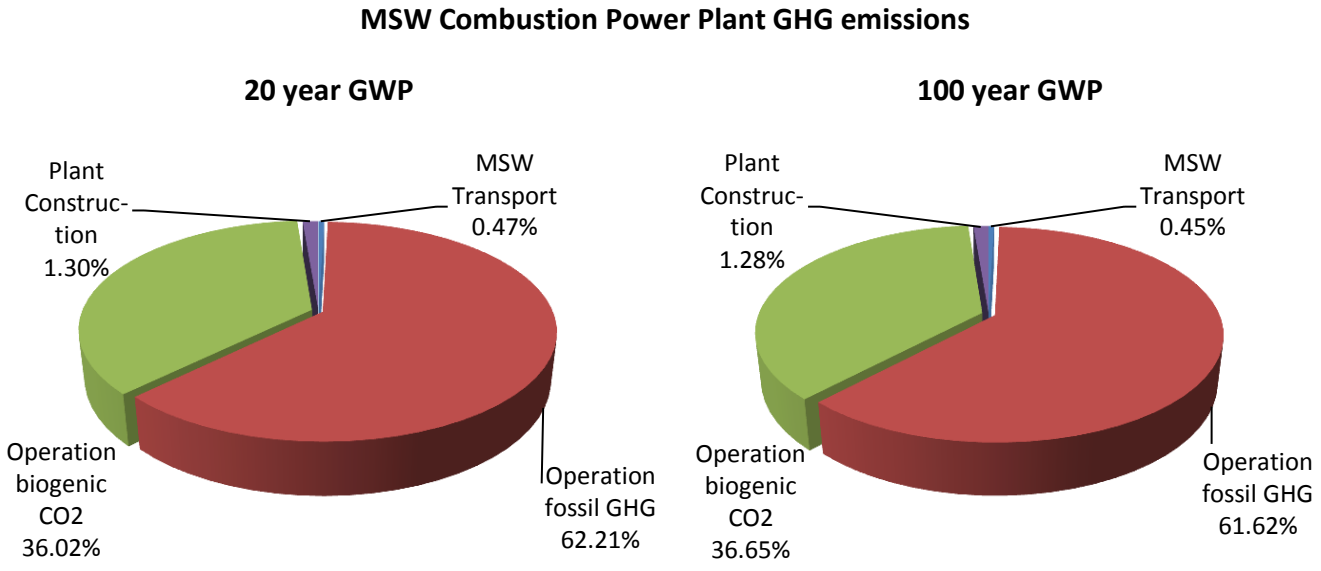

Figure 25. MSW Combustion Power Plant GHG emissions (20 and 100 year GWP)

Table 18. MSW Combustion Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%
	CO_2	CO_2 Biogenic	N_2O	SF_6	CH_4				
Materials Acquisition	8.0435	0.0000	4.99E-05	7.62E-11	0.0051	8.4856	1.20	8.1997	1.18

4.3.3 BIOGAS

Results of the biogas resource option located at the Whitehorse landfill are shown in Figure 26. The biogas power plant (AD operation) produces a large amount of methane emissions. As such, the amount of GHGs produced over a 20 year timeline versus 100 years is significantly different due to the difference in the GWPs. Calculations using the 20 year GWP show the plant releasing 1,162 kg CO_2e/MWh whereas only 1,016 kg CO_2e/MWh are released based on the 100 year GWP. The combustion of biogas (CHP operation) releases 902.11 kg CO_2e/MWh of biogenic CO_2.

4.3.4 GEOTHERMAL

Figure 27 shows the results for a geothermal plant that will be located at McArthur Springs with 4.6 kg CO_2e/MWh GHG emissions produced based on the 20 year GWP and 4.2 kg CO_2e/MWh based on the 100 year GWP. For both GWPs, plant and transmission line construction account for more than 99% of the emitted GHGs. The length of the transmission line in this pathway is 42 km and the line construction and operation accounts for 0.74% and 0.17% of the total impact in the 20 year scenario, respectively and 0.75% and 0.18% in the 100 year scenario, respectively (Table 20).

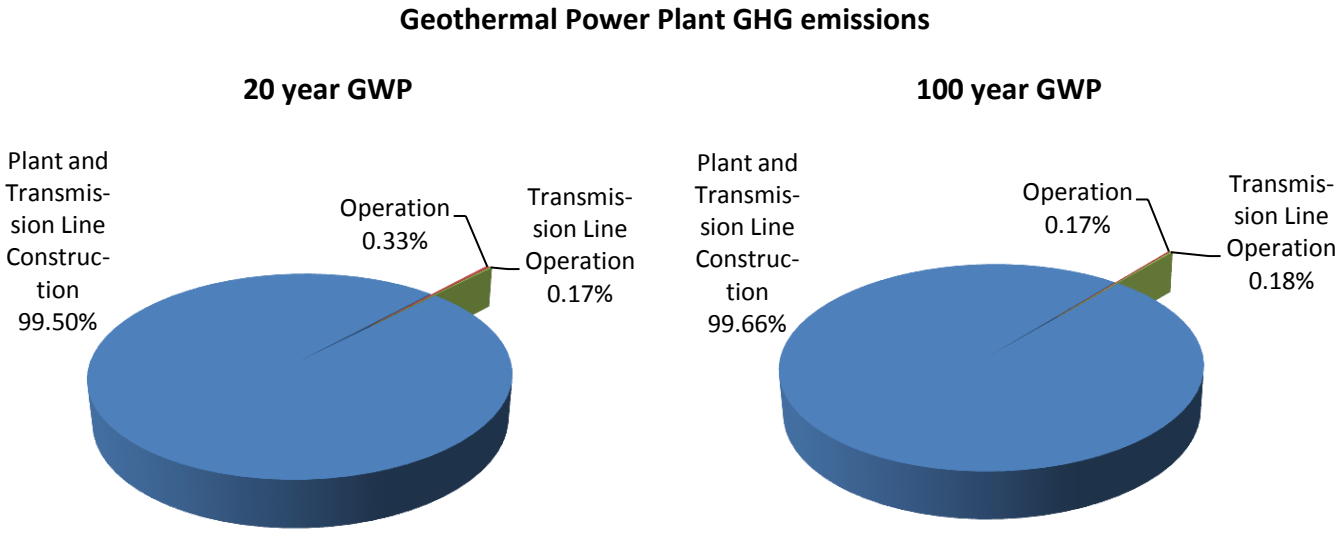

Figure 27. Geothermal Power Plant GHG emissions (20 and 100 year GWP)

Table 20. Geothermal Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.5 WIND

Figure 28 presents GHG emissions from wind power generation. The total GHG emissions are 10.7 kg CO_2e/MWh using the 20 year GWP. The majority of the emissions (62%) originate from plant and transmission line construction life cycle stages. The wind turbines are transported by sea freighter from Denmark to Montreal and then by truck to Whitehorse. This accounts for 30% of the total life cycle impact. Almost 7% of GHG emissions come from wind power plant operations and transmission line operations. Since the length of the transmission line is only 7.6km, most of GHGs from operations originate from wind plant operations. The difference in emissions between the two time horizons is very small.

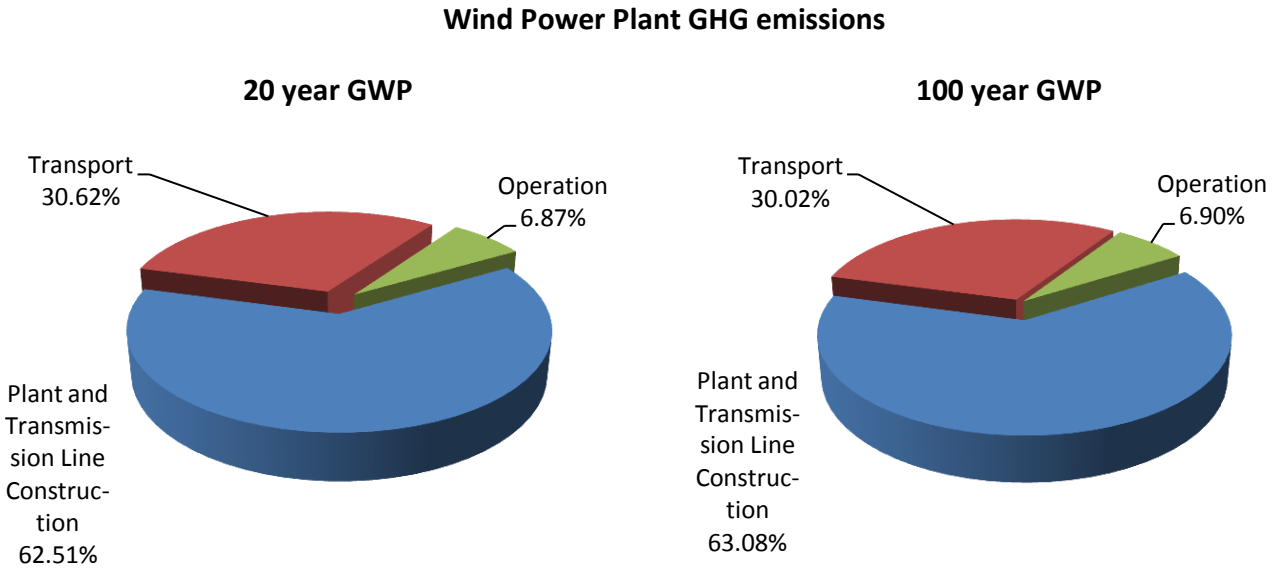

Figure 28. Wind Power Plant GHG emissions (20 and 100 year GWP)

Table 21. Wind Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.6 SOLAR

Results for the solar resource option are shown in Figure 29, where GHGs are mostly generated by PV panels manufacturing (93%) for both the 20 and 100 year GWPs. The Panasonic 330W panels are manufactured in Japan and transported to Vancouver by sea freighter and then to Whitehorse by truck. The amount of GHGs emitted is 43.24 kg CO_2e/MWh for the 20 year time horizon and 38.99 kg CO_2e/MWh for the 100 year time horizon.

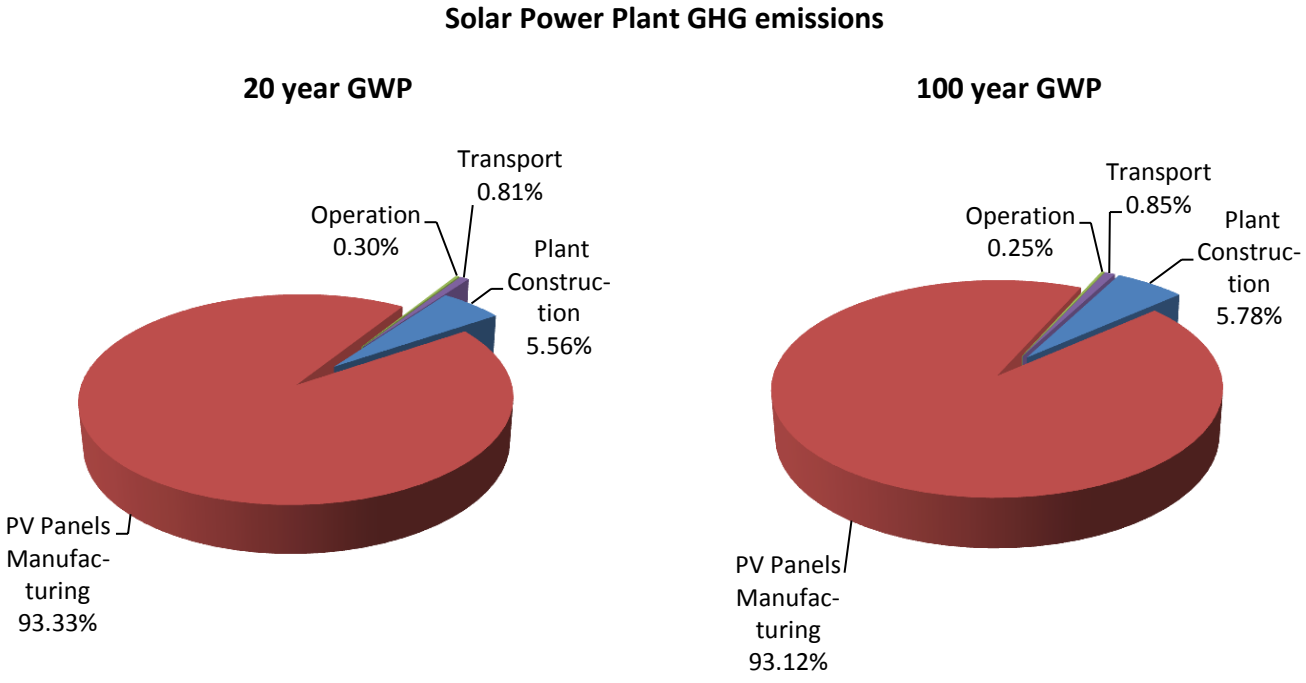

Figure 29. Solar Power Plant GHG emissions (20 and 100 year GWP)

Table 22. Solar Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.7 PUMPED STORAGE HYDRO POWER PLANT

Located at Moon Lake, pumped storage results are shown in Figure 30. The total GHG emissions are 23.41 kg CO_2e/MWh under the 20 year time horizon GWP factor, with 15.15 kg CO_2e/MWh for the 100 time horizon GWP. Nearly 70% of emissions came from the operation of the plant calculated using the 100 year GWP while 80% came from the 20 year GWP calculation. These emissions originated from biomass decomposition after land inundation. Biogenic CO_2 emissions from land inundation are shown separately and are 24% for the 20 year GWP and over 37% for the 100 year GWP. Plant and transmission line construction accounted for over 30% of GHG emissions using the 100 year GWP but only 19.83% for the 20 year GWP. The differences in distribution of GHG emissions over the 20 and 100 year time horizons are due to different methane GWP values.

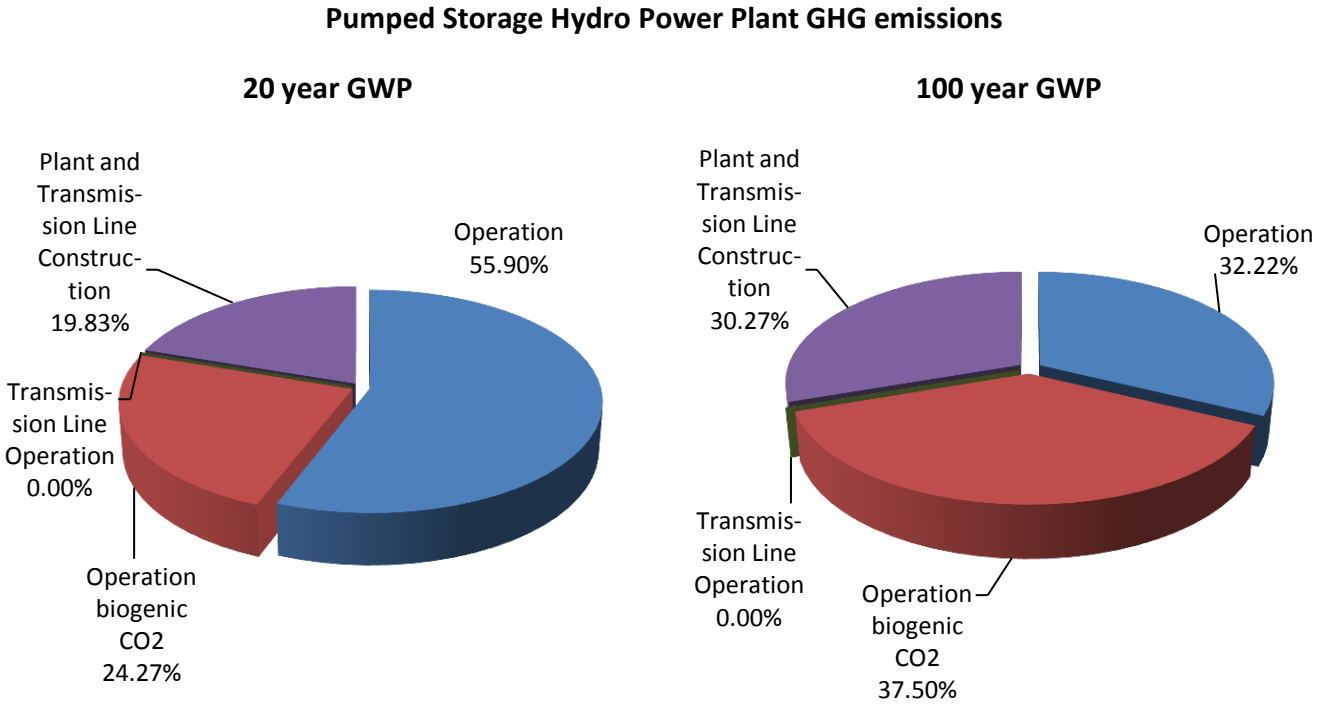

Figure 30. Pumped Storage Power Plant GHG emissions (20 and 100 year GWP)

Table 23. Pumped Storage Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.8 SMALL HYDRO

The scenario of constructing a small hydro plant at Drury Creek generated 20.56 kg CO_2e/MWh for the 20 year GWP and nearly 12.99 kg CO_2e/MWh for the 100 year GWP. The results, shown in Figure 31, show that the largest difference is in plant operation, where 84% of emissions are calculated using the 20 year GWP and 75% calculated in the 100 year GWP. As with the pumped storage option, these emissions come from land inundation. The other two differences are similar to the pumped storage results in the above section: 16% versus 25% are attributed to plant and transmission line construction and transmission line operation for the 20 year versus 100 year GWP, respectively.

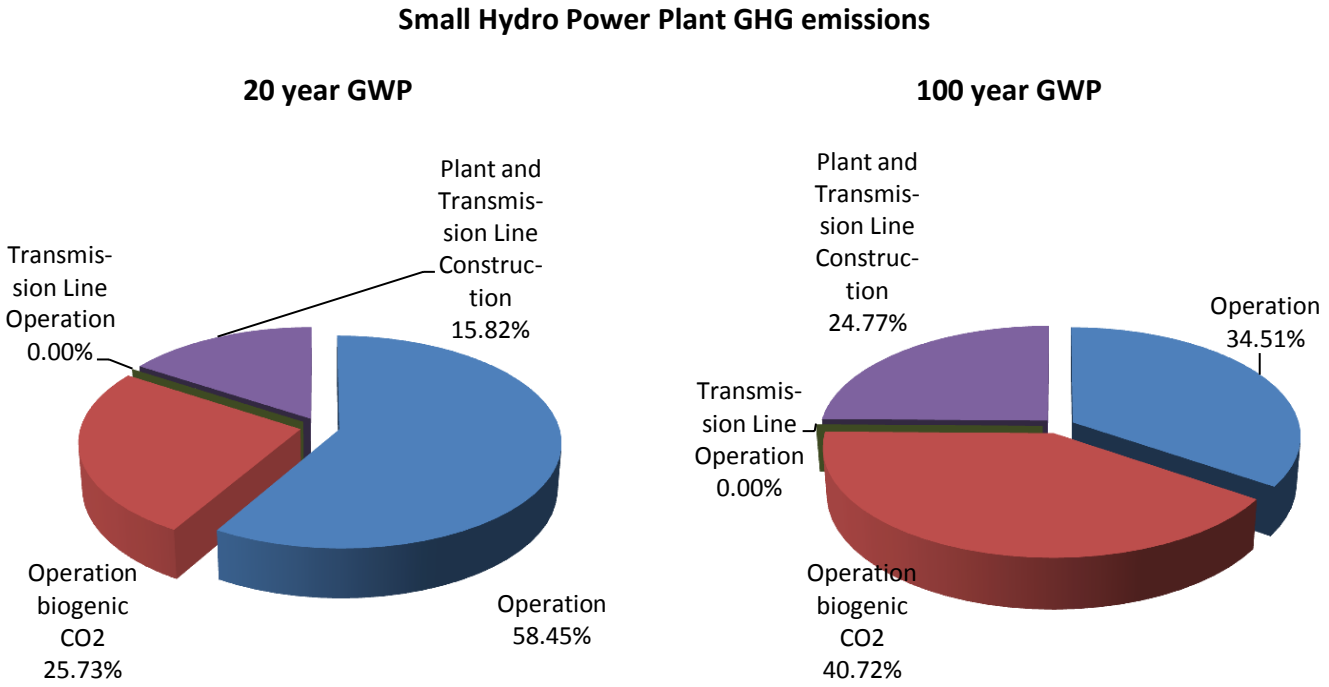

Figure 31. Small Hydro Power Plant GHG emissions (20 and 100 year GWP)

Table 24. Small Hydro Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.9 Energy Storage: Lithium Ion Batteries

Lithium ion batteries were chosen as the preferred means to store energy and results are shown in Figure 32. The functional unit for this application is MWh of energy stored. Almost the entire amount of GHG emissions is from battery manufacturing (98%) for both time horizons (Table 25). The total GHG emissions are 16.15 kg CO_2e/MWh for the 20 year time horizon and 14.66 kg CO_2e/MWh for the 100 year time horizon.

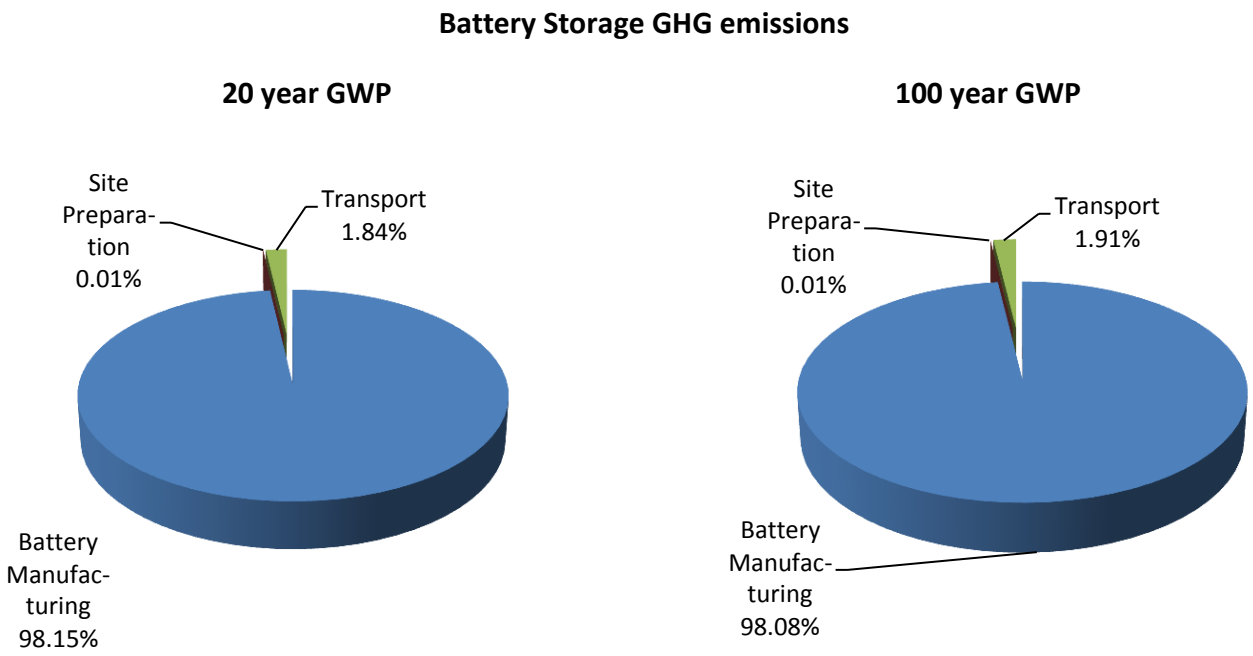

Figure 32. Lithium Ion Battery GHG emissions (20 and 100 year GWP)

Table 25. Lithium Ion Battery GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh						Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.10 THERMAL-DIESEL

Figure 33 shows the results for a Diesel plant at Takhini Substation. Total GHG emissions are 1,058.91 kg CO_2e/MWh under the 20 year time horizon, where operations account for over 65%, extraction of resources accounts for nearly 19%, and fuel production and transportation accounts for over 15% of the produced GHGs. The remaining 0.04% comes from plant construction. A slightly smaller amount of GHGs were calculated using the 100 year GWP values, giving an estimate of 951.11 kg CO_2e/MWh. In this case, plant operation contributed to over 72% of the GHG emissions, fuel production and transportation accounted for 15%, and extraction of resources was only 12% - a 7% decrease compared to the 20 year time horizon. This is due to a lower GWP of methane emissions from crude oil extraction under the 100 year time horizon. Similar to the results from the 20 year time horizon, plant construction accounts for the remaining 0.04% of GHGs.

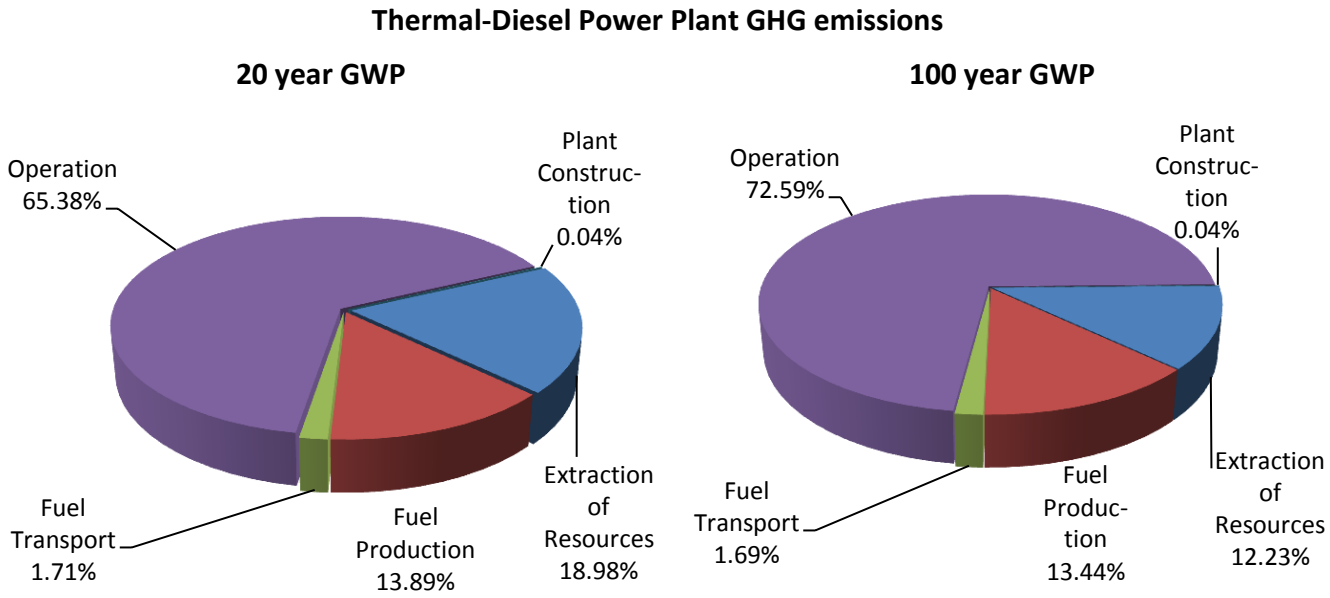

Figure 33. Thermal-Diesel Power Plant GHG emissions (20 and 100 year GWP)

Table 26. Thermal-Diesel Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

Operation	620.30	0.2607	0.0000	0.0378	692.29	65.38	690.43	72.59
Total	**825.72**	**0.2693**	**9.60E-14**	**1.9297**	**1058.91**	**100**	**951.11**	**100**

Figure 33 show GHG emissions that originate from five life cycle stages. The processes included in each life cycle stage are described below.

- Resource Extraction - crude oil extraction, leakage, vented and flared gas emissions;
- Fuel Production – crude oil transport via ocean vessel, diesel production at the refinery, crude oil and diesel storage;
- Fuel Transportation – diesel fuel transport by ocean barge and truck to Yukon Energy;
- Plant Construction (includes materials acquisition and transportation) – extraction and processing of raw materials, transport of materials, site preparation;
- Operation – diesel fuel combustion.

4.3.11 THERMAL-LNG

Results for a thermal LNG plant located at the Takhini Substation are shown in Figure 34. In this scenario, an LNG power plant produces approximately one-third more GHGs when analyzed using the 20 year GWP values (1,050.76 kg CO_2e/MWh) in comparison to the 100 year GWP values (727.68 kg CO_2e/MWh). This is primarily due to the different methane GWP values. Extraction of resources (6.6% versus 4.9%), fuel production and transportation (12% versus 15%) and plant operation (81% versus 79%) are the primary differences in GHG emission for the 20 year versus 100 year time horizon, respectively. Using the 20 year GWP, GHG emissions were double for extraction of resources (70 kg CO_2e/MWh) and approximately one-third higher for plant operation (847 kg CO_2e/MWh).

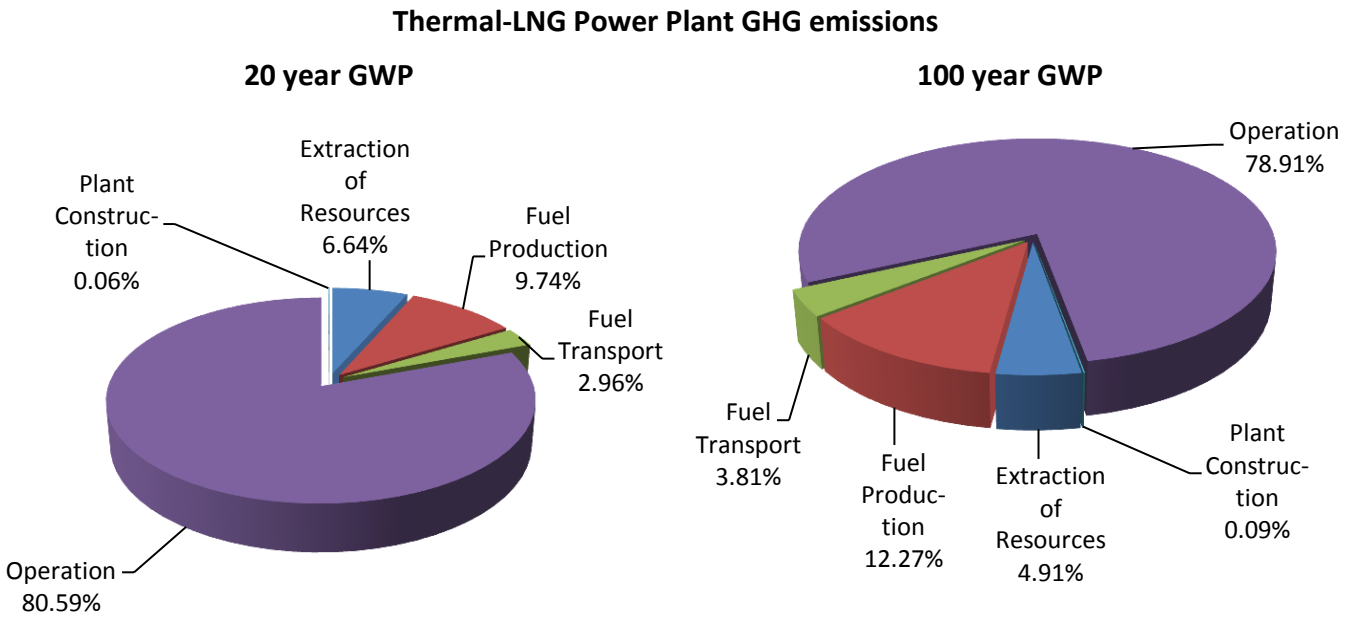

Figure 34. Thermal-LNG Power Plant GHG emissions (20 and 100 year GWP)

Figure 34 show GHG emissions that originate from five life cycle stages. The processes included in each life cycle stage are described below.

- Resource Extraction - natural gas extraction, leakage and flare emissions;
- Fuel Production – fuel processing (treatment & liquefaction), distribution by pipeline, fuel storage;
- Fuel Transport – LNG transport by truck to Yukon Energy;
- Plant Construction – extraction and processing of raw materials for plant construction, transport of materials , site preparation;
- Operation – LNG combustion.

Table 27. Thermal-LNG Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.3.12 New Transmission Line

Figure 35 and Table 28 present the results for the completion of a new 230 kV transmission line from Whitehorse to Skagway. It is assumed that the line operates at 100% reliable capacity (3880.7 GWh/yr). The functional unit for this scenario is MWh-km. Total GHG emissions per MWh-km are 0.001 kg CO_2e/MWh-km under the 20 year time horizon and 0.0009 CO_2e/MWh-km under the 100 year time horizon. Materials acquisition accounts for 78% of the GHGs in both scenarios. The line operation accounts for 19% of the total impact with the majority of impact originating from yearly vegetation clearing. The difference in results between the 20 year and 100 year time horizons is quite small.

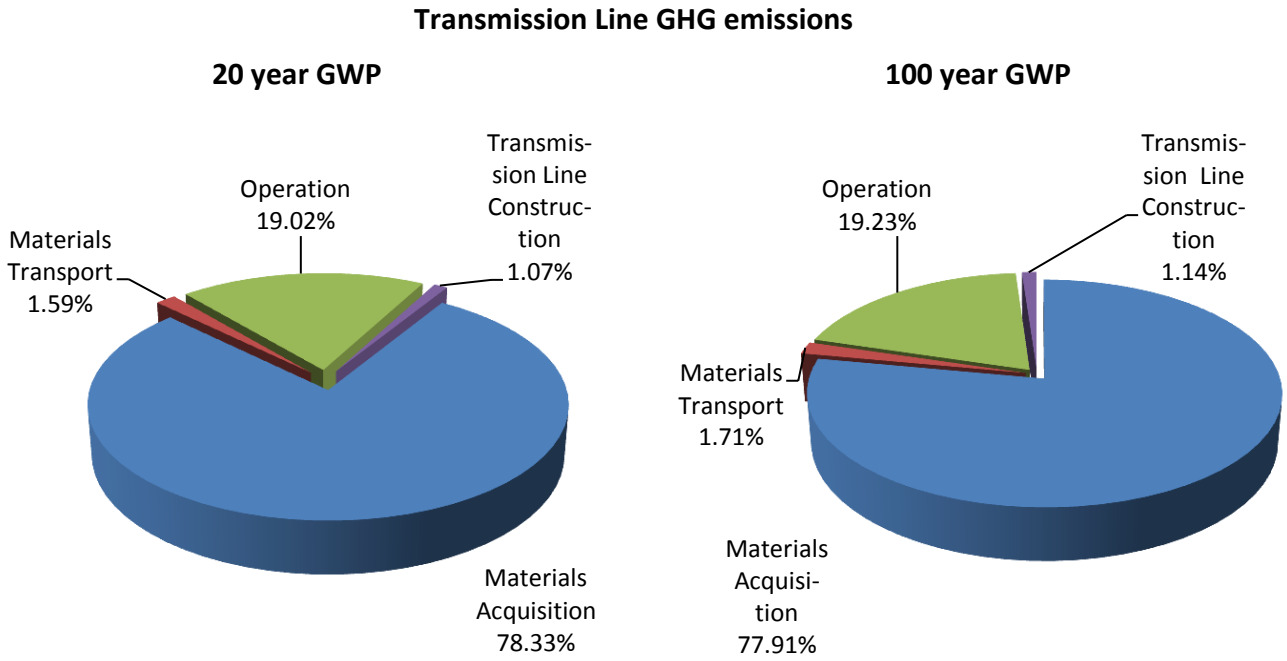

Figure 35. Transmission Line GHG emissions (20 and 100 year GWP)

Table 28. Transmission Line GHG emissions summary of results per MWh-km

Life Cycle Stage	Emissions, kg/MWh-km				Total, kg CO_2e/MWh-km (20 year GWP)	%	Total, kg CO_2e/MWh-km (100 year GWP)	%

4.3.13 WATER DIVERSION PROJECT

Figure 36 and Table 30 present the results for the Water Diversion Project. Total GHG emissions for the 24 year project lifetime are 58.03 kg CO_2e/MWh-km under the 20 year time horizon and 32.78 CO_2e/MWh-km under the 100 year time horizon. The GHG emissions from operation originate from land inundation. These emissions are higher per MWh than in the small hydro and pumped storage pathways due to a shorter project life of 24 years, instead of 65 years in other pathways.

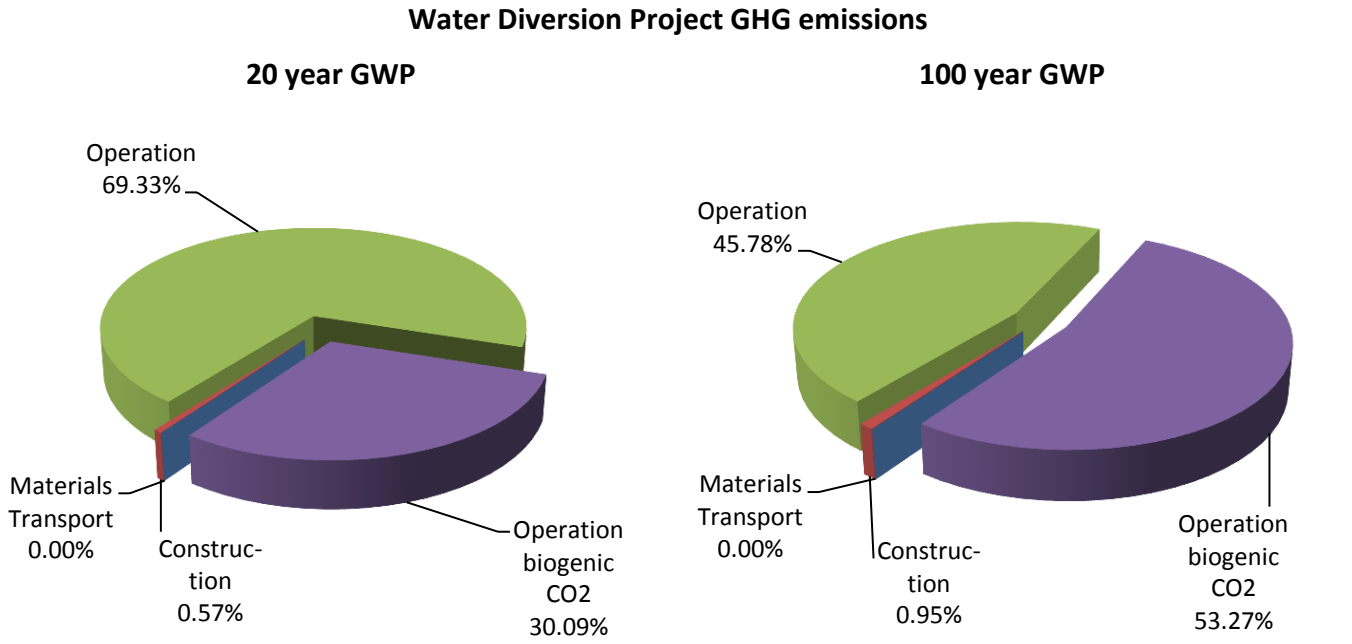

Figure 36. Water Diversion Project GHG emissions (20 and 100 year GWP)

Table 30. Water Diversion Project GHG emissions summary of results – 24 years lifetime

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%

4.4 FIXED AND VARIABLE EMISSIONS ANALYSIS

The fixed GHG emissions are emissions associated with power plant and infrastructure construction and include raw materials acquisition, transportation, site preparation, and construction of the plant and transmission line. In the diesel, LNG, biomass gasification and waste to energy pathways, the emissions related to diesel, LNG, biomass and MSW transportation are considered variable emissions. The fixed emissions are expressed in tonnes CO_2e per facility, while variable emissions that originate from power plant operations are expressed in kg CO_2e/MWh.

Table 32. Fixed and variable GHG emissions from energy production pathways (20 and 100 year GWP)

Energy Production Pathway	Fixed GHG emissions tonnes CO_2e		Variable GHG emissions kg CO_2e/MWh		Variable GHG emissions (biogenic CO_2 excluded) kg CO_2e/MWh	
	20 year GWP	100 year GWP	20 year GWP	100 year GWP	20 year GWP	100 year GWP
Biomass Gasification	679.1	651.7	769.3	768.9	14.53	14.14
Waste to energy: MSW	7,775	7,496	699.8	687.9	444.4	432.5
Waste to energy: MSW + biomass	7,775	7,496	666.0	654.1	310.1	298.2
Biogas	420.9	404.1	1151.2	1005.8	249.1	103.7
Geothermal	6,647	6,077	0.0230	0.0145	0.0230	0.0145
Wind	3,641	3,499	0.7379	0.7108	0.7379	0.7108
Solar	6,726	6,067	0.1284	0.0988	0.1284	0.0988
Pumped storage	16,294	16,098	18.77	10.56	13.09	4.88
Small hydro	6,704	6,630	17.31	9.77	12.02	4.48
Battery storage	904.5	820.9	0.00	0.00	0.00	0.00
Thermal - Diesel	675.2	649.1	1058.48	950.70	1058.48	950.70
Thermal - LNG	1,065	1,023	1050.09	727.04	1050.09	727.04
New transmission line (170km)	29,498	27,284	0.0324	0.0304	0.0324	0.0304
Water diversion project, 24 years lifetime	237.8	223.2	57.69	32.47	40.23	15.01
Water diversion project, 65 years lifetime	237.8	223.2	21.30	11.99	14.86	5.43

The site specific data for plant construction (e.g. area of land to be cleared, type of dam, excavation area, quantities of construction materials, energy generation technology) was available for wind, solar, geothermal, battery storage, transmission line, diesel, LNG, biomass gasification, biogas, and the water diversion pathway. The power plant construction data in the waste to energy pathway is representative of a North American power plant. Small hydro and pumped storage power plant construction data represents a mix of North American and European small hydro and pumped storage power plants. The plant construction data is obtained per MWh of energy produced; if the emissions data expressed per MWh is converted back to the total GHG emissions from plant construction using the total energy output of the plant over plant's lifetime, it increases the uncertainty of the results. Site specific data on construction material requirements need to be obtained to better understand GHG emissions from power plants construction in these pathways. It is recommended to update the fixed GHG emissions of waste to energy, small hydro and pumped storage when site and technology specific data become available.

4.5 SENSITIVITY ANALYSIS

A sensitivity analysis was performed to determine the effect of changing parameters and assumptions on the final results. As it was discussed earlier in section 3.4.1, a number of uncertainties in the life cycle inventory data are identified. For example, materials and equipment manufacturing locations are not known in the wind and battery storage pathways. However, it is expected that the equipment and materials manufacturing location will greatly affect the results of the study, since the GHG emissions originate mainly from the upstream life cycle stages in these pathways. The effect of these and other uncertainties (e.g. CHP plant efficiency, LNG combustion emission factors, and transmission line capacity) on the results of the study is assessed in this section. The results are presented below.

4.5.1 WIND

The wind pathway results presented in the section 4.3.5 are for a 3 turbine wind plant. The modelled wind turbines are Vesta V80 2 MW turbines manufactured in Denmark.

An alternative scenario was modelled to present results for an average mix of wind technologies currently in use in the U.S. This scenario assumes that 55% of wind turbine components are manufactured in China and then transported to Canada by sea freighter and truck. The remaining 45% of wind plant materials and components come from the U.S. Four (4) wind turbines with a capacity of 1.5 MW each are installed. The results of this scenario are shown in Figure 37 below.

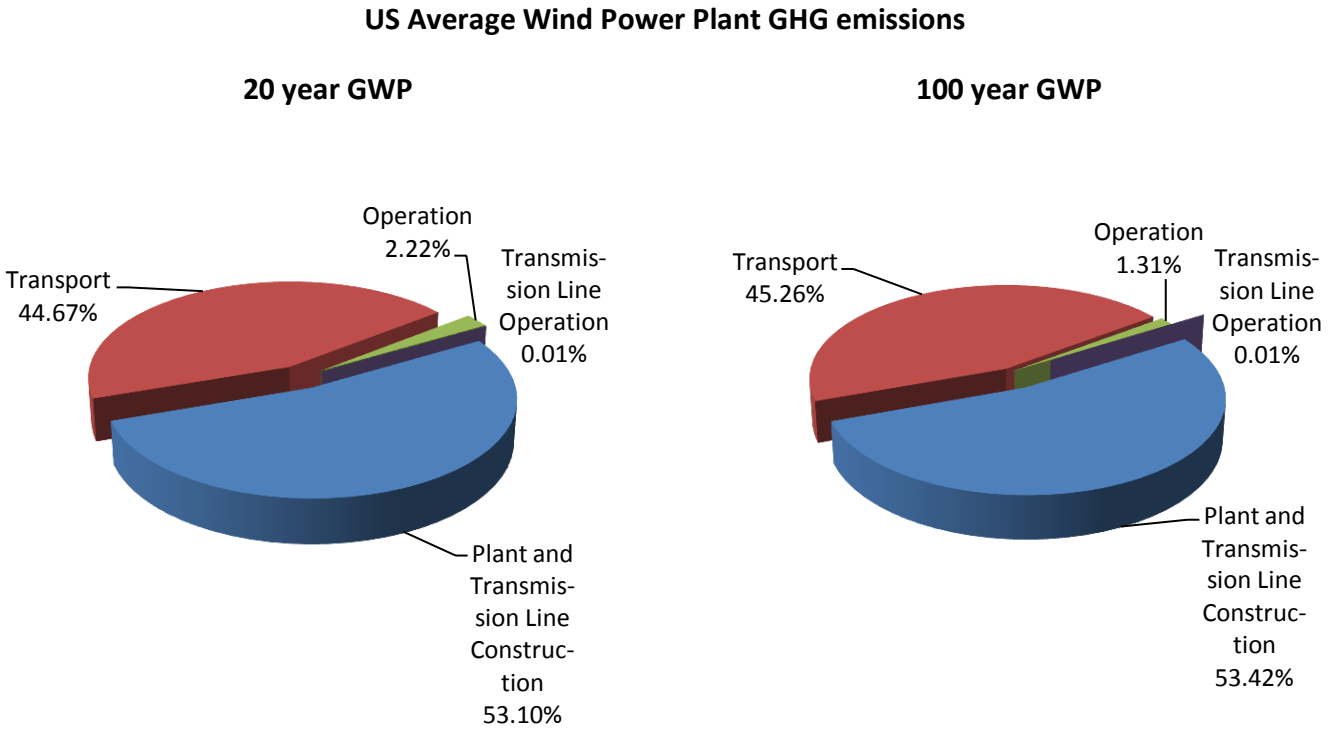

Figure 37. U.S. Average Wind Power Plant GHG emissions (20 and 100 year GWP)

Table 33. U.S. Average Wind Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh				Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%
	CO_2	N_2O	SF_6	CH_4				
Plant and Transmission Line Construction	10.1515	3.03E-05	7.84E-10	4.05E-04	10.3069	53.10	10.2087	53.42
Materials Transportation	8.6400	7.15E-07	0.0014	3.67E-04	8.6710	44.67	8.6505	45.26
Operation	0.1440	6.17E-05	9.30E-11	0.0032	0.4315	2.22	0.2507	1.31
Transmission Line Operation	0.0013	1.71E-07	4.71E-12	1.59E-06	0.0014	0.01	0.0014	0.01
Total	**18.9367**	**9.29E-05**	**0.0014**	**0.0040**	**19.4109**	**100.00**	**19.1112**	**100.00**

As it can be seen from Tables 34, the total GHG emissions are significantly higher in the average U.S. wind plant scenario compared to the Vesta turbines manufactured in Denmark. This is due to the higher GHG emissions from transportation and turbine components manufacturing in China. The choice of the turbine manufacturer should be carefully considered when selecting wind turbines for the project, as wind turbines manufactured in Asia tend to have higher environmental impact.

Table 34. Wind scenarios comparison (100 year GWP)

Wind Plant	Total GHG, kg CO_2e/MWh (100 yr GWP)	Plant and Transmission Line Construction	Materials Transportation	Operation (plant and transmission line)
Baseline scenario 3 Vesta V80 2 MW turbines	10.33	6.49	3.09	0.71
Average U.S. wind plant Four 1.5MW turbines	19.11	10.21	8.65	0.25

4.5.2 BATTERY STORAGE

Two batteries from different manufacturers – UltraLife Corporation and SAFT Batteries were evaluated. A 1,000-kWh lithium-ion battery manufactured by SAFT is currently installed at the Wind and Storage Demonstration project site in the Cowessess First Nations, Saskatchewan[43]. A specific power density of different batteries varies significantly from one manufacturer to another. The UltraLife Corporation's battery has a specific power density of 149 W/kg and the SAFT Batteries' specific power density is 60 W/kg.

The effect from the number of batteries required for a 20-year plant lifetime was also modelled. The baseline scenario (UltraLife battery) described in the previous section assumes that 1.5 batteries are

[43] Natural Resources Canada. (2016). Wind and Storage Demonstration in a First Nations Community, Cowessess First Nation. http://www.nrcan.gc.ca/energy/funding/current-funding-programs/cef/4983

needed. The sensitivity scenario assessed the effect of battery's lifetime of 10 years. In this case, two batteries are required. The results for the 100 year GWP are presented in Table 35 below.

Table 35. Battery storage sensitivity analysis results (100 year GWP)

Battery manufacturer	Battery lifetime, years	Number of batteries	GHG, kg CO_2e/MWh (100 yr GWP)
UltraLife (baseline scenario)	15	1.5	14.66
Ultralife	10	2	19.44
Saft	15	1.5	35.64
Saft	10	2	47.48

A significant increase in GHG emissions from one type of the battery to another is observed. The Saft battery's specific power density is only 60 W/kg. This means that the weight of a 8MW battery (132 tonnes) is much higher compared to the UltraLife battery with the specific power density of 149 W/kg (53.6 tonnes). This results in higher GHG emissions from battery manufacturing and transportation life cycle stages.

4.5.3 BIOMASS GASIFICATION

An alternative scenario for biomass gasification was modelled. It assumes that only 1,283 MWh of heat per year will be delivered and consumed in Haines Junction compared to 8,059 MWh_{th}/yr in the baseline scenario. Table 36 presents GHG emissions from this scenario. The total GHG emissions are 1,678.26 kg CO_2e/MWh based on the 100 year GWP. The GHG emissions are significantly higher compared to the baseline scenario where more heat is utilized. This scenario has lower overall plant efficiency and thus, higher emissions.

Table 36. Biomass Gasification Power Plant GHG emissions summary of results

Life Cycle Stage	Emissions, kg/MWh					Total, kg CO_2e/MWh (20 year GWP)	%	Total, kg CO_2e/MWh (100 year GWP)	%
	CO_2	CO_2 Biogenic	N_2O	SF_6	CH_4				
Materials Acquisition	1.7673	0.0000	9.29E-06	2.71E-13	0.0008	1.8388	0.11	1.7928	0.11
Materials Transportation	1.2247	0.0000	9.77E-06	5.36E-13	1.47E-03	1.3511	0.08	1.2685	0.08
Biomass Transportation	5.4245	0.0000	0.0001	2.37E-12	0.0065	5.9921	0.36	5.6268	0.34
Operation	0.0000	1669.57	0.0000	0.0000	0.0000	1669.57	99.45	1669.57	99.48
Total	**8.4165**	**1669.57**	**0.0001**	**3.18E-12**	**0.0088**	**1678.75**	**100**	**1678.26**	**100**

A comparison of the two scenarios is shown in Table 37 below. The GHG emissions in the sensitivity analysis scenario are more than 2 times higher than in the baseline scenario. This is due to the lower efficiency of the CHP plant since only a small portion of produced heat is utilized.

Table 37. Biomass gasification scenarios comparison

Scenario	Total GHG, kg CO_2e/MWh (100 yr GWP)	Materials Acquisition	Materials Transportation	Biomass Transportation	Operation
Baseline scenario (65% electrical and heat production efficiency)	771.97	1.7928	1.2685	5.6268	763.28
Sensitivity analysis scenario (only 1,283 MWh of heat is utilized in Haines Junction)	1,678.26	1.7928	1.2685	5.6268	1,669.57

4.5.4 LNG COMBUSTION EMISSIONS

GHG emissions from LNG combustion are estimated based on emissions factors, not specific operating data that was not available at the time of the study. The emissions factor is derived from GHGenius 4.03 that is based on the US EPA non-road model for large natural gas engines. A sensitivity analysis is performed to better understand an effect of different emissions factors on the results.

Two different LNG combustion emissions factors are selected for the sensitivity analysis:

1. Canadian Energy Partnership for Environmental Innovation, CEPEI (Pembina, 2013):
    a. CO_2 emission factor – 49,300 ng/J NG combusted (4-stroke lean burn)
    b. CH_4 emission factor – 537 ng/J NG combusted (4-stroke lean burn)
2. 2016/2017 B.C. Best Practices Methodology for Quantifying Greenhouse Gas Emissions, Ministry of Environment, May, 2016. Stationary fuel combustion emission factors are based on Environment Canada (2014). National Inventory Report: Greenhouse Gas Sources and Sinks in Canada 1990-2012., and British Columbia (2014). British Columbia Greenhouse Gas Inventory Report 2012.
    a. CO_2 emission factor – 1.926 kg/m^3
    b. CH_4 emission factor – 0.000037 kg/m^3
    c. N_2O emission factor – 0.000035 kg/m^3

The results are presented in Table 38.

Table 38. LNG combustion emissions

Scenario	kg CO_2e/MWh (20 yr GWP)	kg CO_2e/MWh (100 yr GWP)
Baseline scenario, US EPA	846.86	574.23
CEPEI, Pembina 2013	734.06	500.24
2016/2017 B.C. Best Practices	390.49	390.08

The emissions factors selected for the baseline scenario are in the upper range of emissions and therefore conservative. Actual natural gas engine GHG emissions would likely be lower and will be based on actual operating conditions of the unit. The direct measurement of emissions from the unit is recommended to determine the precise emissions factor.

4.5.5 TRANSMISSION LINE CAPACITY

The GHG emissions from transmission line pathway are modelled using 80%, 60% and 40% transmission line capacity. The baseline scenario assumes that the transmission line operates at 100% of reliable capacity. It is expected that the actual transmission line capacity will vary over the life time of the transmission line. The results are presented in Table 39 below.

Table 39. 170 km transmission line capacity modelling

Scenario	GWh/yr	kg CO_2e/MWh (20 yr GWP)	kg CO_2e/MWh (100 yr GWP)
Baseline scenario, 100% reliable capacity	3880.7	0.1706	0.1582
80% capacity	3104.5	0.1784	0.1631
60% capacity	2328.4	0.2380	0.2175
40% capacity	1552.3	0.3561	0.3254

5 CONCLUSIONS AND RECOMMENDATIONS

The use of an LCA allows decision makers to better understand the impacts on human health and the environment that may not be traditionally seen when selecting an energy source. The results of this study illustrate the vast differences in GHG emissions generated by various energy resource technologies. Careful consideration is crucial in determining the most amenable resource option in light of current policies and climate change strategies. Cost, long-term access to the resources, land availability, and energy demand forecasts must be examined in conjunction with the LCA results. The LCA results provide a means to more fully understand the impacts of choices among energy options, including those impacts that occur outside the project location, which can ultimately lead to a more balanced approach.

This analysis provides insight into the estimated GHG emissions from several renewable and non-renewable energy resources. Key conclusions from this analysis are summarized below.

- The overall results indicate that the biogas pathway is the greatest GHG emitter with over 1,000 kg CO_2e/MWh of GHG emitted for both time horizons, if biogenic CO_2 is included. The next highest emitters are diesel and LNG pathways with 1,059 and 1,051 kg CO_2e/MWh emitted for the 20 year time horizon, respectively, and 951 and 728 kg CO_2e/MWh emitted for the 100 year time horizon, respectively. The smallest GHG emitters for both time horizons are solar (approximately 40 kg CO_2e/MWh), followed by pumped storage, small hydro, water diversion, battery storage, wind, and geothermal (all with less than 25 kg CO_2e/MWh). The 170 km of new transmission line produces 0.17 kg CO_2e/MWh for the 20 year and 0.16 CO_2e/MWh for the 100 year time horizon.
- Renewable energy resources (hydro, solar, wind and geothermal) produced significantly less amounts of GHG emissions per MWh. This may ultimately lead to the replacement of fossil thermal energy generation (diesel and LNG) in the long term, especially when these sources are coupled with battery storage technology and supported by hydro power. However, this must be considered in combination with a cost-benefit analysis.
- The application of 20 year and 100 year GWPs did not significantly change the results except for diesel, biogas, LNG and hydro options. This is due to the higher amounts of methane emissions since methane's GWP is three times higher in the 20 year time horizon scenario than it is for the 100 year time horizon. Methane emissions in biogas pathway originate mainly from anaerobic digestion and waste storage processes, while in the diesel pathway they originate from crude oil extraction. Methane emissions in hydro energy pathways come from biomass decomposition after land inundation. Wind, solar, geothermal, battery storage, transmission line, biomass gasification, and waste to energy produce emissions that are almost the same for both time horizons.
- The GHG emissions from biomass gasification, MSW conventional combustion, and MSW and biomass conventional combustion pathways strongly depend on the CHP plant efficiency and are reduced significantly (per MWh) when plants operate at higher efficiencies and all heat produced is utilized.
- Operations are the highest contributing life cycle stages to GHG emissions across all energy resources, except solar, wind, transmission line, battery storage and geothermal pathways

where materials acquisition, transportation, and plant construction (upstream life cycle stages) are the highest contributors. Diesel and LNG thermal plants also had notable GHG emissions contributions from upstream (fuel extraction and production) life cycle stages. Transmission line had 19% of GHG emissions from operation due to fuel consumption for yearly land clearing.

- Biogenic CO_2 emissions are reported separately as these emissions are considered carbon-neutral. The resource options that comprise biogenic emissions are biogas (902 kg biogenic CO_2/MWh), MSW (255 kg biogenic CO_2/MWh), combined MSW and biomass (356 kg biogenic CO_2/MWh), biomass gasification (755 kg biogenic CO_2/MWh), small hydro (5.29 kg biogenic CO_2/MWh), pumped storage (5.68 kg biogenic CO_2/MWh), and water diversion (17.46 kg biogenic CO_2/MWh and 6.45 kg biogenic CO_2/MWh for the 24 and 65 years lifetime, respectively).
- While GHG emissions from fossil sources are quite small for biogas and biomass gasification energy resources, waste to energy scenarios (MSW and MSW with biomass combustion) have notable fossil GHG emissions.
- The sensitivity analysis reveals that the choice of the technology and location of the manufacturing facilities (e.g. in North America versus oversees) can significantly impact the total life cycle emissions in the case of renewable energy sources where upstream life cycle stages are the largest contributors to the total life cycle GHG emissions.
- The technology pathways that may have a good potential to support other energy generation options such as small hydro are geothermal, as well as wind and solar coupled with battery storage. Hydro options, in turn, make it feasible to utilize other renewable sources. Pumped storage offers operational flexibility, since it can immediately respond to fluctuations in the demand for electricity. The flexibility and storage capacity of hydro options make then efficient and economical in supporting the use of intermittent sources of renewable energy, such as solar and wind, especially if these energy options are not coupled with battery storage. The waste to energy option has a potential to displace some fossil fuel-based sources, such as diesel and LNG, especially if produced heat is utilized to make the technology economically viable. However, the waste to energy pathway was found to produce a significant amount of fossil GHG emissions due to MSW combustion.
- The fixed GHG emissions originate from the plant construction (materials acquisition, transportation, components manufacturing, site clearing, etc.), while variable emissions come from the operation life cycle stage. The fixed emissions remain constant; however, variable emissions vary with power plant energy output. If power plant runs only occasionally (e.g. diesel and LNG power plants), the variable emissions are minimal.
- Site specific data on construction material requirements need to be obtained to better understand fixed GHG emissions from power plants construction in the waste to energy, small hydro, and pumped storage pathways. It is recommended to update fixed GHG emissions in these pathways when site and technology specific data become available.

APPENDIX A: LIFE CYCLE INVENTORY – SUPPORTING INFORMATION

A.1 Scenario 1: Biomass Gasification

Table 1.1 Data sources and assumptions for processes in the system boundaries

Process	Assumptions	Source
Construction materials extraction and processing	Concrete Steel Aluminum	Athena, 2005 GaBi Professional database (region: Canada)
Available biomass	Wood residues, spruce (left at the landing, in the harvest block and standing dead) – 5,600 tonnes/yr Sawmill residues – 2,000 tonnes/yr	Stantec, 2013[44]
Required biomass (based on net energy production)	Oven dry tonnes – 3,000 tonnes/year With 15% moisture content – 3,789 tonnes/year • Forest harvesting residues: 1,603 tonnes/year • Sawmill residues – 2,190 tonnes/year	Stantec, 2013
Biomass collection	Diesel consumption: 2.37 L/tonne Average collection distance is 100 km	Jones et al. 2010[45]
Size reduction by mobile wood chipper (roadside chipping)	Diesel consumption: 1.7 L/tonne of biomass	Jones et al., 2010
Transport of wood residues to the plant	Forest harvesting residues – 70km, truck, 9t payload Sawmill residues – 50 km, truck, 9t payload	Stantec, 2013
Transport of construction materials	2,400 km by truck, 22t payload	
Plant construction	No site preparation included – brownfield site 37.4 x 36.4 pre-engineered building (steel) +foundation (concrete) 2 x 250 kVA wood gasification generators <u>Plant Materials Requirements:</u> • Concrete: 6.2387 kg/MWh electricity produced • Steel: 1.7345 kg/MWh electricity produced	Stantec, 2013 Yukon Energy, 2016a[46] Stantec, 2016a[47]

Process	Assumptions	Source
Biomass drying and gasification	Annual energy production (net): • 2,585 MWh_e -682 kWh_e/tonne of biomass • 8,059 MWh_{th} – 2,127 kWh_{th}/tonne of biomass Gasification and Energy Production GHG emissions (based on Nexterra Energy gasifier)[48] • CO_2 biogenic – 1,495.63 kg/tonne of biomass • CH_4 – trace only • N_2O – trace only	Stantec, 2016[49] Chan et al. (2008)[50]

A.2 Scenario 2: Municipal Solid Waste Combustion

Waste volumes potentially available to a WTE facility are presented in the Table below.

Table 2.1 Waste volumes potentially available to a WTE facility in Whitehorse[51]

Waste Stream	Current Diversion Rate		
	Annual Heating Value (GJ/yr)	Annual Waste Flow (tpy)	Weighted HHV (GJ/tonne)
MSW Generated within the City of Whitehorse	337,409	23,595	14.3
MSW Generated outside Whitehorse	35,231	2,669	13.2
Tires	8,970	299	30.0
Waste Oil	8,891	239	37.2
Abattoir Waste	500	250	2
Totals	***391,000***	***27,052***	***14.45****

** Annual Average HHV*

[48] Nexterra's gasifier emissions factors were used instead of the Community Power Corporation's (CPC) gasifier emissions factors. CPC couldn't be reached.

The City of Whitehorse MSW composition and heating values are shown in the Table 2.2.

Table 2.2. City of Whitehorse Waste Composition[52]

Material	Waste Composition Weighted Average (%)	Weight, Tonne/Year	Heat Content, Million BTU/Tonne
Paper	13.5	3545.64	6.7
Glass	1.3	341.43	0
Metal	6.7	1759.69	0
Plastic	9.1	2147.15	20.45
Organics	17.1	4491.14	5.2
Composite	9.3	2442.55	18.1
Wood Waste	15.3	4018.39	9.96
Inert Materials	2.3	604.07	0
Gypsum Wallboard	6.3	1654.63	0
Textiles	2.8	735.39	13.8
Rubber	0.4	105.06	26.86
Carpet and Underlay (PVC)	2.2	577.81	16.5
Electronic Waste	3.2	840.45	0
Personal Hygiene Products	2.5	656.60	7.51
Hazardous Waste	1.6	420.22	18.1
Biomedical Waste	0.5	131.32	18.1
Pet Waste	1.2	315.17	9.7
Fines	0.3	78.79	18.1
Fiberglass Insulation (Glass)	0.6	157.58	0
Other	3.7	971.77	18.1
MSW Total		**25994.86**	
Tires		299.00	
Waste Oil		239.00	
Abattoir Waste		250.00	
Total		**26782.86**	

Paper, wood waste, and organics are assumed to contribute to the biogenic CO_2 emissions. All other groups of waste contribute to fossil CO_2 emissions.

Process	Assumptions	Source
	factors were used to estimate GHG emissions from waste combustion. MSW combustion emission factors Emissions factors, kg/TJ: CO_2 / CH_4 / N_2O Waste oil: 73300 / 30 / 4 MSW non biomass: 91700 / 30 / 4 Wood waste: 112000 / 30 / 4 Biomass: 100000 / 30 / 4	IPPC, 2006[56]

A.3 Scenario 3: Biogas Plant

The feedstock is residential and commercial organic waste collected in Whitehorse.

Organic waste characteristics are based on WSP, 2016[57].

Feedstocks	%TS	%VS	M³ Biogas/T VS	Density (KG/L)	Methane (%CH_4)
SSO from residential collection	36%	82%	600	0,9	60%
Green yard waste	31%	81%	380	0,8	55%
Dry yard waste	44%	86%	100	0,8	55%
SSO from ICI	23%	83%	600	0,9	60%

Note: %TS and %VS come from Wisconsin laboratory results and the other parameters come from the consultant's database.

TS – Total solid concentration, expressed as a fraction of the wet mass of the prepared feedstock.

VS – Volatile solid concentration, expressed as a function of the total solid mass.

Table 3.1 Data sources and assumptions for processes in the system boundaries

Process	Assumptions	Source
Construction materials extraction and processing	Concrete Steel	Athena Institute, 2005
Collection and transport of organic waste	Organic waste transportation 16 km, truck, 9t payload 3.6144 tonnes of waste/MWh	WSP, 2016 (Based on mass balance - 2016)
Transport of construction materials	2,400 km by truck, 22t payload	Estimated

A.4 Scenario 4: Geothermal Power Plant

A binary Organic Rankine Cycle (ORC) plant uses the high temperature steam and/or water from the production wells (called "geofluid") to heat a binary fluid, which most often is a hydrocarbon, with a low boiling point in a heat exchanger. The hydrocarbon fluid evaporates, producing the high-pressure vapour that is then expanded through a turbine. The turbine drives a generator to produce electric power.

Binary cycle power plants are closed-loop systems, and virtually nothing (except water vapor) is emitted to the atmosphere. The process diagram is shown in the Figure A.1.

After the geothermal fluid has heated the hydrocarbon fluid in the heat exchanger, it is reinjected into the reservoir through a reinjection well.

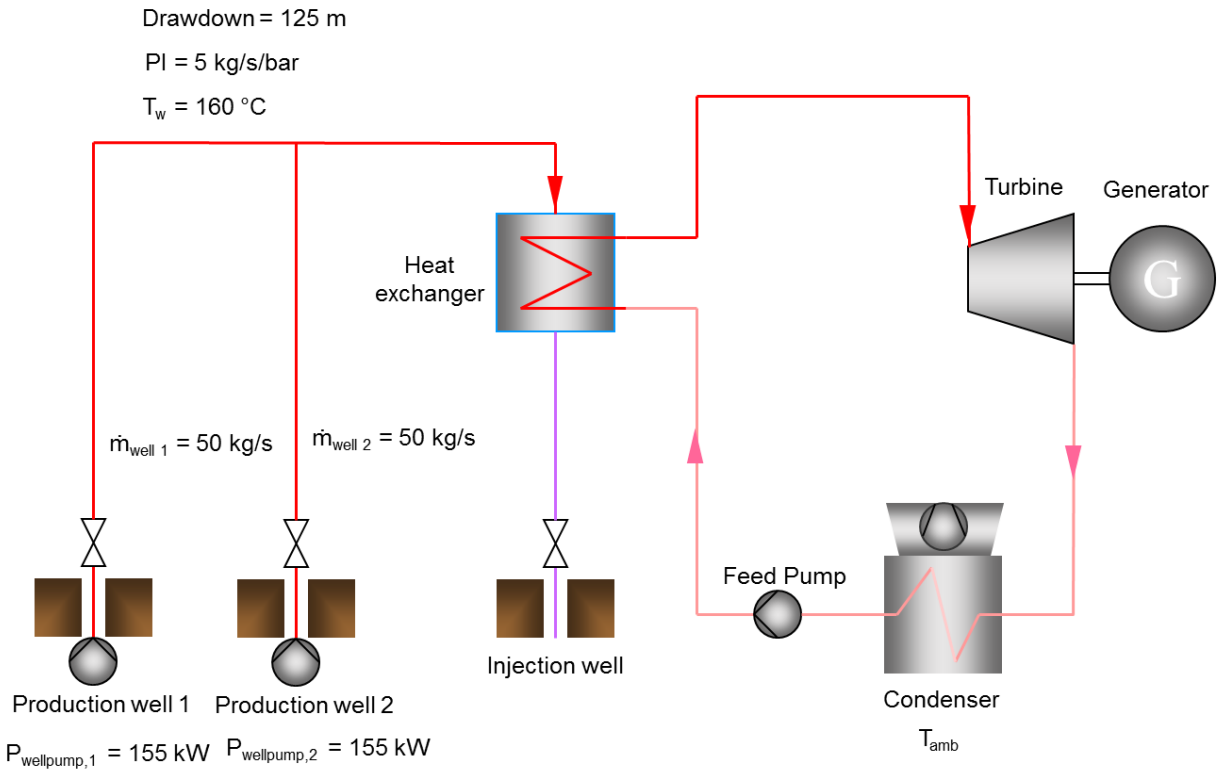

Figure A1. Organic Ranking Cycle Flowchart[62]

[62] KGS Group. (2016). Geothermal Review and Site Inventory. KGS Group, Winnipeg, Manitoba, May 2016.

Table 4.1 Data sources and assumptions for processes in the system boundaries

Process	Assumptions	Source
Construction materials extraction and processing	Raw materials extraction and processing (steel, concrete, aluminum, cast iron)	Athena, 2005 GaBi Professional database (region: Canada)
Transport of construction materials	2,400 km by truck, 22t payload	
Plant and transmission line construction	<u>Wells construction and installation (1.5km wells, including an exploration well)</u> Two production wells and one injection well would be located approximately 1 km apart. One exploration well will be drilled. • Steel, pipe welded: 0.566 kg/MWh • Cement: 0.373 kg/MWh • Diesel: 0.333 kg/MWh <u>Plant construction and installation</u> • Aluminum: 0.240 kg/MWh • Concrete: 2.385 kg/MWh • Cast Iron: 0.0222 kg/MWh • Steel, pipe welded: 1.200 kg/MWh • Diesel: 0.113 kg/MWh <u>Pipeline construction and installation (1,000m of piping)</u> • Diesel: 0.00162 kg/MWh • Steel, pipe welded: 1.85 kg/MWh • Cement: 0.456 kg/MWh <u>Greenfield site: Site preparation and access gravel road construction</u> Access road construction: • Diesel: 0.000232 kg/MWh • Gravel: 0.611 kg/MWh Site preparation: • Diesel: 800 L/km Transmission line construction (42 km of 138kV line)[63]	NETL, 2012[64] Sullivan et al., 2010[65] Yukon Energy, 2016[66]

[63] Refer to Scenario 12: Transmission Line for more information on line construction and operation.

Process	Assumptions	Source
Electricity Generation	Binary Organic Ranking Cycle (ORC) geothermal plant with 70% efficiency. Net electricity production: 48.2 GWh_e/yr	

A.5 Scenario 5: Wind Power Plant

The wind farm has a total capacity of 6 MW. Two different scenarios were modelled:

1. 4 wind turbines with a capacity of 1.5 MW each (sensitivity analysis scenario)
    a. Based on average wind farm technology used in the U.S.
    b. 55% of components are manufactured in China. The remaining 45% come from the U.S.
2. 3 wind turbines with a capacity of 2 MW each
    a. Based on Vesta V80 2 MW turbine manufactured in Denmark

Table 5.1 Data sources and assumptions for processes in the system boundaries – Scenario 1 – The U.S. average wind turbine

Process	Assumptions	Source
Construction materials extraction and processing	Raw materials extraction and processing (steel, concrete, aluminum, cast iron)	NETL, 2012a[67]
Transport of construction materials	It is assumed that 55% of wind farm components are manufactured oversees (China). The remaining 45% come from the US. Transmission line components are transported 2,400km by truck.	NETL, 2012a Estimated
Plant and transmission line construction	<u>Manufacture of Turbine Components</u> *Rotor (turbine rotor diameter 63m)* • Blades Glass fibers – 2,713 kg Carbon fibers – 399 kg Resin glue – 598kg Steel – 279 kg Electricity – 15,958 MJ • Hub Cast iron – 10,082 kg Electricity – 44,675 • Spinner, nose cone Glass fibers – 309.8 kg Resin glue – 464.7 kg	NETL, 2012a

Electricity Generation	Net electricity production: 54 GWh_e/yr	IEA, 2002[74]

Intergovernmental Panel on Climate Change Tier 1 approach to estimate GHG emissions from reservoirs (IPPC, 2003).

The IPCC has developed guidelines for estimating GHG emissions from flooded lands. The Tier 1 approach provides a simplified method for estimating GHG emissions. Only the first 10 years post-inundation are considered to be at the level estimated by the following equations. After 10 years, emissions are assumed to be negligible.

[72] IPPC (2003). *Good Practice Guidance for Land Use, Land-Use Change and Forestry*. J. Penman, M. Gytarsky, T. Hiraishi, T. Krug and D. Kruger (eds.). Institute for Global Environmental Strategies (IGES). 944 pp.

[74] IEA. (2002). Environmental and Health Impacts of Electricity Generation. A comparison of the Environmental Impacts of Hydropower with those of other Generation Technologies. The International Energy Agency – Implementing Agreement for hydropower Technologies and Programmes.

Equation 1: Tier 1 CO_2 Emissions from Flooded Lands

$$CO_{2\ emissions} = P * E(CO_2)_d * A_r$$

Where:

$CO_{2\ emissions}$ = total CO_2 emisisons from flooded lands, kg CO_2/yr;

P = period of emissions, usually 365 days for annual inventory estimates, d/yr;

$E(CO_2)_d$ = averaged daily diffusive emissions, with a default value of 15.5 kg CO_2 / ha /day;

A_r = total flooded surface area, ha.

Based on Equation 1, the Tier 1 CO_2 emissions for 354.2 ha of flooded area are 1,993,703 kg CO_2/yr or 5.68 kg CO_2/MWh.

Equation 2: Tier 1 CH_4 Emissions from Flooded Lands

$$CH_{4\ emissions} = P * E(CH_4)_d * A_r + P * E(CH_4)_b * A_r$$

Where:

$CH_{4\ emissions}$ = total CH_4 emisisons from flooded lands, kg CH_4/yr;

P = period of emissions, usually 365 days for annual inventory estimates, d/yr;

$E(CH_4)_d$ = averaged daily diffusive emissions, with a default value of 0.11 kg CH_4 / ha /day;

$E(CH_4)_b$ = averaged bubbles emissions, with a default value of 0.29 kg CH_4 / ha /day;

A_r = total flooded surface area, ha.

Based on Equation 2, the Tier 1 CH_4 emissions for 354.2 ha of flooded area are 51,450.4 kg CH_4/yr or 0.1466 kg CH_4/MWh.

Equation 3: Tier 1 N_2O Emissions from Flooded Lands

$$N_2O_{emissions} = P * E(N_2O)_d * A_r$$

Where:

$N_2O_{emissions}$ = total N_2O emisisons from flooded lands, kg N_2O/yr;

P = period of emissions, usually 365 days for annual inventory estimates, d/yr;

$E(N_2O)_d$ = averaged daily diffusive emissions, with a default value of 0.008 kg N_2O / ha /day;

A_r = total flooded surface area, ha.

Based on Equation 3, the Tier 1 N_2O emissions for 354.2 ha of flooded area are 1,029 kg N_2O/yr or 0.0029 kg N_2O/MWh.

A.9 Scenario 9: Battery Storage

A lithium ion battery with an 8MW capacity and 5 hours discharge time was studied. The battery is a lithium iron phosphate cathode (hydrothermal) battery.

Lithium iron phosphate (LiFePO4) is a cathode material for lithium-iron batteries. It can be prepared hydrothermally or through a solid state technique. The hydrothermal pathway is selected (Dunn et al, 2014)[75].

Specific power density of different batteries varies significantly from one manufacturer to another. Two batteries from different manufacturers – UltraLife Corporation and SAFT Batteries were evaluated. The UltraLife Corporation's battery has a specific power density of 149 W/kg and the SAFT Batteries' specific power density is 60 W/kg.

Lead Acid and Lithium-Ion Batteries Comparison

Lead acid and lithium ion batteries are two of the most popular energy storage technologies available, but have a significant impact on the environment. The environmental performance is primarily dependent on its lifetime durability and efficiency[79].

Lead acid batteries have been widely used for approximately 150 years and have proven to be a robust technology. However, extraction and processing of lead require significant amounts of energy and produce large amounts of pollution. Lead is a toxic substance, but the manufacturing and packaging technologies make the risk to humans insignificant. Fortunately, close to 98% of lead acid batteries are recycled in the United States[80]. Nevertheless, lead acid batteries include hazardous, flammable and explosive materials that present serious environmental risks[81,82]. In one study, analysis of a lead acid battery grid-connected to a photovoltaic system revealed that the overall climate change impact of the battery had a comparable CO_2e/year effect as driving over 4,000 km per year in a typical gasoline car. The overall conclusion was that there was a significant environmental impact[83]. Moreover, lead acid batteries are known for limitations in their useable capacity and number of charging cycles causing the need for early replacement. Their charging time can take longer compared to other battery types, and they have limited charging efficiency in that they may not store the full amount of power, which is problematic when charging using certain energy resources such as solar, where storing as much energy as possible is desirable before nightfall or cloud coverage. Another inefficiency of lead acid batteries is voltage sag, where lead acid batteries slowly lose their charge over time regardless of power use[84].

In the last few decades, lithium ion batteries have increased in use worldwide. They are known to perform better in colder climates, charge more quickly, can be charged more often before they reach

their end of life, and have a longer lifespan compared to lead acid batteries[85,86]. Additionally, they can more easily deliver their full rated capacity of power and weigh about one-third to one-half of a standard lead acid battery, thus making them easier to transport. However, lithium ion technology does have its own environmental challenges[87]. Lithium ion batteries are comprised primarily of mined lithium carbonate, iron ore, aluminum and copper. Lithium mining is resource intensive, but lithium itself is only a small fraction of the battery. Therefore, the production and processing of the aluminum, copper and iron ore contribute more significantly to the overall environmental impacts. Additionally, compared to lead acid batteries, lithium ion batteries have a low recycling rate. However, it is expected that as the recovery and recycling technology matures, the battery materials will be recovered at rates comparable to lead acid batteries.

Methane Emissions from Natural Gas Life Cycle

Natural gas has been touted as a more environmentally friendly fuel. However, the extraction, processing and transportation of natural gas are not without concern. Fugitive, vented and flared methane emissions are present throughout the process, and the uncertainty surrounding the amount of emissions is disconcerting[88]. In order to fully understand the advantages of using natural gas, all emissions, from extraction to delivery and use, must be considered.

Fugitive emissions related to natural gas production and processing consist of (in this study, these emissions are included in the extraction of resources and fuel production life cycle stages):

- Emissions from venting and flaring of natural gas, waste gas, and vapour streams during production or processing;
- Emissions unrelated to venting and flaring, which are comprised of gas wellheads, well servicing, gas transportation, disposal activities, gas processing, storage, and combustion of fossil fuels that do not generate usable heat or electricity.

The key emission assessment issues are: (a) use of simple production-based emission factors is susceptible to excessive errors; (b) use of rigorous bottom-up approaches requires expert knowledge to apply and relies on detailed data which may be difficult and costly to obtain; and (c) measurement programmes are time consuming and very costly to perform.

The reported data for fugitive methane emissions vary widely[89]. This is due to the following key factors: 1) where the measurements are taken, 2) the method by which the measurement is taken, and 3) the implementation of measurement programmes is both costly and time consuming, and requires expert knowledge[90]. If there is an emission "hot spot" which has a higher-than-normal methane release, such as due to pipe or equipment failure, the reported data will not be representative of the entire gas stream. Conversely, if data are collected in an area that always has little to no leakage, fugitive emissions will be under-reported. As a result, there is a high degree of uncertainty in the available data on fugitive emissions[91].

Two different methods to collect fugitive emissions data are used. However, both of these also produce varying results. The first is a "bottom-up" approach. In this case, emissions are measured at a particular source, such as along a pipeline or the home that the fuel is being supplied to. While this provides a very accurate picture of a particular location, this method may miss critical components of the system that may lead to an inaccurate estimate. The second approach is "top-down" which measures methane concentrations at a pre-determined height (such as from an airplane or tall building) above a particular area. This method ensures that both high-emitting and low-emitting areas

[88]Greenhouse Gas Institute. (2016). Methane emissions from the oil and gas industry: is the world getting it right? http://ghginstitute.org/2016/07/18/methane-emissions-from-the-oil-and-gas-industry-is-the-world-getting-it-right/?utm_source=July+Newsletter+2016&utm_campaign=July+Newsletter+2016&utm_medium=email

[90]IPCC. "Fugitive emissions from oil and natural gas activities." http://www.ipcc-nggip.iges.or.jp/public/gp/bgp/2_6_Fugitive_Emissions_from_Oil_and_Natural_Gas.pdf

[91] NREL. (2015). Estimating U.S. Methane Emissions from the Natural Gas Supply Chain: Approaches, Uncertainties, Current Estimates, and Future Studies. http://www.nrel.gov/docs/fy16osti/62820.pdf

are accounted for. However, methane emissions unrelated to natural gas extraction are also included, thus giving higher concentrations. Additionally, this method does not identify specific troublesome areas since the measurements do not pinpoint which particular area contributed most to the measured methane levels[92]. To address this, some researchers have developed predictive models to determine which wells, or other emissions sources, may be at the greatest risk for releasing higher methane levels.

The difference in reported CH_4 emissions estimates can be seen when considering the available data in the 2015 and 2016 U.S. GHG inventories by the EPA[93,94]. The 2015 inventory reports data from 2012 that includes 23.3 MMT CO_2e from petroleum systems, and 154.4 MMT CO_2e from natural gas systems. However, the 2016 submission estimates emissions from 2012 to be 58.4 MMT CO_2e from petroleum systems, and 172.6 MMG CO_2e from natural gas. These comparisons are shown in Figure A.2 below.

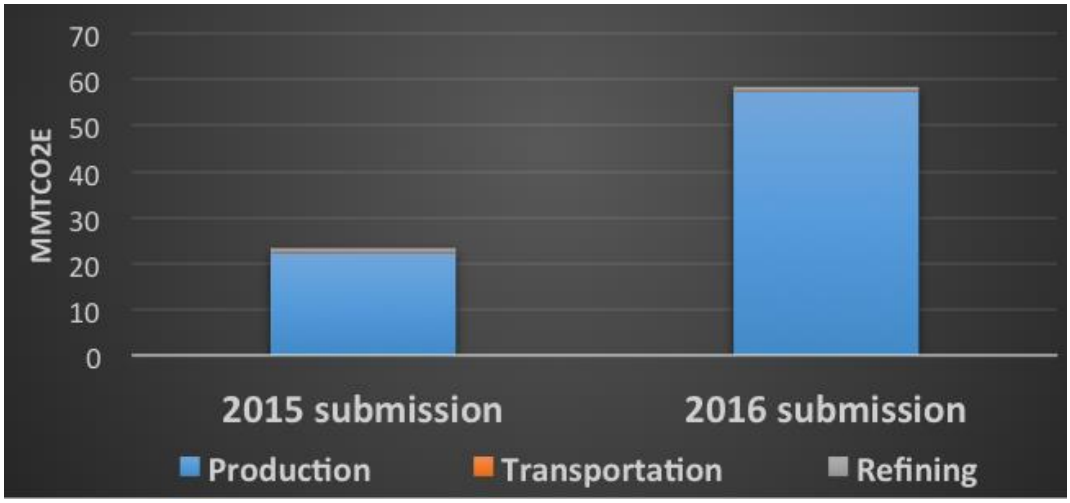

Figure A.2. Methane emissions from petroleum systems for the year 2012 in the 2015 and 2016 inventory submissions (Adapted from GHG Institute, 2016)

[92] EPA. Comparing top-down & bottom up estimates of oil & gas CH4 emissions: A spatially-resolved emission inventory for the Barnett Shale Region. (2015). https://www.epa.gov/sites/production/files/2015-09/documents/lyon_pres.pdf
[93] EPA. (2015). https://www3.epa.gov/climatechange/Downloads/ghgemissions/US-GHG-Inventory-2015-Main-Text.pdf
[94] EPA. (2016). https://www3.epa.gov/climatechange/ghgemissions/usinventoryreport.html

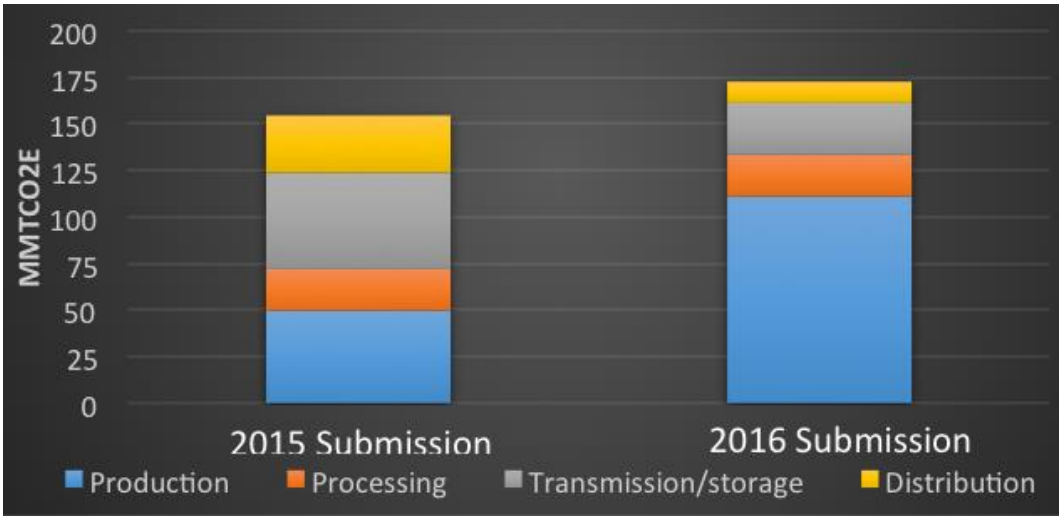

Figure A.3. Comparison of 2015 and 2016 inventory submissions for 2012 estimates of GHG emissions from natural gas (Adapted from GHG Institute, 2016)[95]

Improvements in reported estimates of GHG emissions are expected as new data and modelling techniques become available. In some estimates, only partial data sets are available when the inventory is performed, with the foreknowledge that they will be updated in the next inventory. In other instances, data may be extrapolated or recalculated based on more recent emission factors. Therefore, changes in the reported data are not surprising and are evidence of an industry and regulatory bodies working hard to determine emission impacts. This is a positive sign that suggests an evolving area of science attempting to keep abreast of the demands of climate change initiatives. However, this also signals that the accuracy of estimated emissions and the ability to carefully track the data is of concern. As a result, the 2006 IPCC Guidelines suggests a range of +/-100% uncertainty when applying their values to estimate natural gas methane emissions.

The application of correct emissions factors in order to estimate emissions is challenging. Many emissions in the oil and gas industry are unintentional and do not necessarily correlate with default emission factors; rather, they are dependent on the operation and condition of the specific equipment itself. When emission factors are unavailable, studies and assessments are forced to use generic emissions factors, regardless of the range of uncertainty. Therefore, understanding the inherent uncertainty is key to applying emissions factors in life cycle assessments.

Fugitive Emissions and Choice of Emission Factors

Significant differences can exist among data reported for fugitive emissions. The method in which data are collected, various modelling techniques, and the location where the data are collected contribute to the variability. Data on GHG emissions from natural gas extraction, transport and processing used in the LCA study of LNG pathway by Pembina Institute (Pembina, 2013) was extracted from CAPP, 2004[96]. While somewhat dated, the advantage is that the data are from Canadian sources.

[95] Production means natural gas extraction.
[96] CAPP. (2004). A National Inventory of Greenhouse Gas (GHG), Criteria Air Contaminant (CAC) and Hydrogen Sulphide (H_2S) Emissions by the Upstream Oil and Gas Industry.

The current standard in GHG accounting and reporting is to apply methodologies and emissions factors from the 2009 Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Natural Gas Industry developed by the American Petroleum Institute (API). This report included very specific data on fugitive emissions for equipment, components used in the natural gas field, facility use, onshore and offshore production, processing, transmission and storage equipment, stations and pipe material. However, close examination revealed that their source data was from the 1990s. Specifically, three reports from the EPA[97,98,99] are frequently referenced. The flare data for developed countries in the API 2009 Compendium came from a 2006 IPCC report.

The province of British Columbia published a Ministry of Environment Information Note (File: 280-30, CLIFF/tracking #: 197083) to address the amount of methane deliberately and/or accidentally vented into the atmosphere[100]. The emission intensity of CH_4 for the actual vented amount, according to the table below, is 0.00226 kg CH_4/m^3 of natural gas.

Table 11.2. Methane emissions into the atmosphere in BC in 2010 and 2011

Year	NG Production	Methane mass density	Methane amount	CO_2e amount if all released into Atm.	Actual Venting	% Vented out of Total Production	GWP
	m^3	kg/m^3	t CH_4	Mt CO_2e	Mt CO_2e		100 yr
2010	34,991,762,000	0.678	23724415	498.21	1.97	0.40%	21
2011	41,441,414,000	0.678	28097279	590.04	1.97	0.30%	21

The most updated fugitive emissions information come from a publication by Argonne National Laboratories dated 2015 that uses the GREET model[101]. The data used in the report originates from several sources, including data from the 1990s up to at least 2011. The model also included site-specific data and measurements from processing plants, urban distribution systems and natural gas gathering facilities. The reported data is shown in the Table 11.3 below.

Distribution	Distribution	g CH_4/million Btu NG	83.1	83.1	88.9	88.9	7%	7%
Distribution	Distribution (station pathway)	g CH4/million Btu NG	63.6	63.6	69.1	69.1	9%	9%
Total		**g CH_4/million Btu NG**	**253.2**	**267.5**	**262.4**	**270.5**	**4%**	**1%**
Total (station pathway)		**g CH_4/million Btu NG**	**233.8**	**248.1**	**242.5**	**250.6**	**4%**	**1%**

According to the API 2009 report, uncertainties in methane emissions can be as high as +/- 200%, therefore, it becomes challenging to compare numbers from one set of calculations to another.

In this study, the Canadian data from CAPP, 2004 and GHGenius v4.03 was used. Emissions due to gas leaks and flares are captured under a separate category ("gas leaks and flares") in GHGenius. This helps to separate these emissions from other GHG emissions resulting from, for example, well exploration, well drilling, well completion, and acid gas removal.

Dear Mr. Lavigne:

Re: Resource Options Evaluation – Revised Final Report

Please find enclosed a PDF version of the revised final report for the Yukon Energy Corporation Resource Options Evaluation prepared by InterGroup Consultants Ltd. in association with EDI Environmental Dynamics Inc., Ecofor Consulting Ltd. and Campbell's North Consulting. The revised report contains updated economic information as provided by Yukon Energy on specific resource options, including an evaluation of one new option (i.e., the Anvil Creek small hydro site option).

This study supports Yukon Energy's current 2016 Resource Plan update by providing a comparative evaluation of more than 45 power generation and transmission resource options in Yukon and northern British Columbia against more than 40 environmental, social and economic indicators. No attempt is made to evaluate resource options in the context of forecast grid loads. The ratings for each indicator show on a common scale (low, medium and high) which indicators are particularly relevant to each resource option, without attempting to provide an overall ranking of these options.

This final revised report addresses comments received from Yukon Energy on the earlier report. We thank you for the opportunity to work on this project.

Yours truly,

INTERGROUP CONSULTANTS LTD.

1.0 INTRODUCTION AND OVERVIEW

This report supports Yukon Energy Corporation's (Yukon Energy's) current 2016 Resource Plan (RP) update by providing an evaluation against environmental, social and economic attributes of potential power generation and transmission resource options as inventoried by Yukon Energy to meet long-term load forecasts (2016-2035).

InterGroup Consultants Ltd. (InterGroup) has prepared this report in association with EDI Environmental Dynamics Inc. (EDI), Ecofor Consulting Ltd. (Ecofor) and Campbell's North Consulting (CNC). The evaluation is based on publicly available information and information from inventoried resource option project reports and other reports provided by Yukon Energy. No attempt is made in this report to evaluate resource options in the context of forecast Yukon Energy loads. Resource portfolio option definition and assessment in the context of long-term load forecasts will be done subsequently by Yukon Energy as part of the current RP update.

Section 1 of this report provides an overview of the resource options examined and the evaluation approach adopted. Section 2 provides the summary evaluation of the resource options against the environmental, social and economic criteria and indicators. Section 3 provides an overall summary and conclusions.

This report summarizes more detailed analysis provided in the following appendices:

- **Appendix A: Project Summaries**, which summarizes key information from Yukon Energy's resource option reports.
- **Appendix B: Evaluation Approach - Criteria & Indicators**, which reviews overall criteria, indicators, metrics and methods used to compare and rank resource options.
- **Appendix C: Environmental Evaluation - Technical Report**, which provides details on methodology, ranking approach and evaluation of resource options against environmental criteria.
- **Appendix D: Social Evaluation - Technical Report**, which provides details on methodology, ranking approach and evaluation of resource options against social criteria.
- **Appendix E: Economic Evaluation - Technical Report**, which provides details on methodology, ranking approach and evaluation of resource options against economic criteria.

1.1 OVERVIEW OF RESOURCE OPTIONS

The more than 45 resource options evaluated in this report are summarized below by technology groups. (See Table 1 for a list of the options and a summary of locations and key attributes. See Appendix A for added details.)

- **Fossil Thermal:** Diesel and Liquefied Natural Gas (LNG) 20 MW options - each in Whitehorse with two site options.

- **Non-Fossil Thermal:** Waste-to-energy and Biogas in Whitehorse, Biomass in Haines Junction (each small scale, i.e., less than 2 MW).
- **Other Non-Hydro Renewable:** Storage Battery option at Whitehorse (2 technologies); Solar PV in Whitehorse and Haines Junction (different scale options up to 10 MW); Wind farms (seven 20 MW site options examined); and Geothermal options (2 sites, average 1.6 to 3.8 MW).
- **Hydro Generation:** 8 pumped storage site options (2 scales of development at 2 sites - overall range 15 to 40 MW), 6 small hydro site options (5.7 to 20 MW range), 4 other hydro options to enhance existing generation (diversion or storage), and 2 refurbishment options (1 to 2.3 MW).
- **Transmission Corridors:** 6 options (the Stewart-Keno City transmission option, which was recently recommended in a Yukon Environment and Socio-economic Assessment Board [YESAB] report, is the only option that addresses an existing corridor).

Table 1: Overview of Resource Options Evaluated

Resource Options	Installed Capacity (MW)	Annual Average Energy (GWh)	Assumed Economic Life (years)	Comments
Fossil Thermal				
Diesel: 20 MW - Whitehorse	20.0	up to >166	20-40	Largest scale options at 2 locations (Whitehorse landfill & Takhini substation). Economic life reflects expected backup use.
Diesel: 20 MW - Takhini	20.0	up to >166	20-40	
LNG: 20 MW - Whitehorse	20.0	up to >166	20-40	
LNG: 20 MW - Takhini	20.0	up to >166	20-40	
Non-Fossil Thermal				
Waste to Energy	1.6	10.0	25	Unspecified Whitehorse location - need sale of waste heat.
Biogas (CHP)	0.2	0.4	20	Whitehorse landfill
Biomass 0.5 MW Boiler / Steam Turbine	0.5	3.2	20	Haines Junction-sale of waste heat-beetle-kill biomass.
Other Non-Hydro Renewable				
Storage Battery: 4 MW, 40 MW.h (lead acid, 10hrs)	4.0	0.04	30	Whitehorse-Takhini substation & some use of adjacent land. (Two technology options noted).
Storage Battery: 8 MW/40 MWh (lithium ion, 5hrs)	8.0	0.04	30	
Solar PV: Whitehorse Fixed Tilt: 1 MW	1.0	1	30	Range of development scales at two potential locations with lowest LCOE of technologies examined (Whitehorse Copper Mine Quarry location, and Haines Junction location at about 1 km from dump). Evaluations focus on largest scale option at each location.
Solar PV: Whitehorse Fixed Tilt: 5 MW	5.0	5	30	
Solar PV: Whitehorse Fixed Tilt: 10 MW	10.0	10	30	
Solar PV: Haines Junction Fixed Tilt: 1 MW	1.0	1	30	
Solar PV: Haines Junction Fixed Tilt: 5 MW	5.0	5	30	
Wind: Cyprus Mine Hill, 20 MW	20.0	50	25	Seven preferred site options, each evaluated at largest scale examined (20 MW). Kluane site requires added transmission to grid (unless Aishihik-Destruction Bay Transmission Corridor is developed).
Wind: Kluane Lake, 20 MW	20.0	48	25	
Wind: Miller's Ridge, 20 MW	20.0	57	25	
Wind: Mt. Sumanik , 20 MW	20.0	42	25	
Wind: Sugarloaf Mountain, 20 MW	20.0	32	25	
Wind: Tehcho (Ferry Hill), 20 MW	20.0	33	25	
Wind: Thulsoo Mountain, 20 MW	20.0	54	25	
Geothermal: McArthur Springs (3.8 MW Av.)	3.8	25	30	Two site options. Scale of development shown in each case is average of potential range identified (need drilling to define).
Geothermal: Vista Mountain (1.6 MW Av.)	1.6	11	30	
Hydro Generation				
Pumped Storage: Moon Lake (Tutshi-Moon)	20.2	54	65	Eight preferred site options evaluated (two sites also have 2 scale options for development). Evaluations focus normally on site and largest option for that site (current initial estimates for land areas affected not typically sensitive to scale options at a site). Moon Lake option based on Midgard report, and Vangorda Pit option based on EP report (all other sites based on KP report). All sites other than Canyon-Ittlemit and Vangorda Pit require added transmission to connect to grid (unless relevant Transmission Corridor developed). Most sites are in B.C. (i.e., all except the last three listed).
Pumped Storage: Racine - Moon	15.0	50	65	
Pumped Storage: Lindeman-Fraser	15.0	50	65	
Pumped Storage: Racine - Mt. Brown	15.0	50	65	
Pumped Storage: Racine - Mt. Brown	25.0	100	65	
Pumped Storage: Atlin - Black Mountain	15.0	50	65	
Pumped Storage: Atlin - Black Mountain	25.0	100	65	
Pumped Storage: Squanga - Dalayee	25.0	100	65	
Pumped Storage: Canyon - Ittlemit	25.0	100	65	
Pumped Storage: Vangorda Pit	40.0	134	50-65	
Small Hydro: Drury Lake	8.1	32	65	Six preferred site options evaluated - each site has storage, except for Wolf River (run of river). Atlin/Pine Creek option is expansion of existing hydro site (Morrison Hershfield report) in B.C., with transmission connection needed to Yukon grid. Drury Lake and Anvil Creek are only site options not requiring added transmission to connect to grid (absent Transmission Corridor development).
Small Hydro: Tutshi - Windy Arm	7.2	57	65	
Small Hydro: Wolf River	20.0	96	65	
Small Hydro: Finlayson River	17.6	139	65	
Small Hydro: Anvil Creek	9.8	41	65	
Small Hydro: Atlin/Pine Creek	5.7	36.3 avail to Yukon	65	
Other Hydro: Gladstone Diversion	NA	37	65	Diverts waters into Aishihik existing hydro reservoir.
Other Hydro: Southern Lakes Storage	1.0	6	NA	Extends storage into fall for existing Whitehorse hydro.
Other Hydro: Mayo Lake Storage	NA	2 to 4	NA	Adds bottom storage for existing Mayo hydro.
Other Hydro: Mayo Dredging	NA	1 to 2	NA	Removes sediment built up in Mayo Lake Outlet Channel.
Aishihik Re-runnering	1.0	3	NA	Refurbishing existing hydro generation units at Aishihik and at Mayo.
Mayo A Refurbishment	2.3	10	65	
Transmission Corridors	Transfer Capacity			
Transmission: Whitehorse - Atlin (138 kV)	97	NA	45	Six options examined for transmission corridors (options are not tied to any specific loads or generation projects, but many would provide transmission connection for other generation resource options [wind or hydro generation]). The Stewart-Keno City option was recently recommended in YESAB Screening Report (replace end-of-life line and enhance overall voltage).
Transmission: Whitehorse - Skagway (230 kV)	443	NA	45	
Transmission: Whitehorse - Teslin (138 kV)	95	NA	45	
Transmission: Faro - Watson Lake (230 kV)	190	NA	45	
Transmission: Aishihik - Destruction Bay (230 kV)	484	NA	45	
Transmission: Stewart-Keno City (138 kV & substations)	NA	NA	45	

In order to simplify the evaluations, variations in technologies for a specific resource option and/or smaller scale development alternatives for a specific resource option are generally ignored in this report. Where new transmission is required to connect an option to the grid, this requirement is reflected in the assessment where feasible. In order to avoid variances related to different possible utilization levels and/or ownership options, all options are assumed to be fully utilized (with the potential exception of fossil fuel thermal generation) and to be developed by Yukon Energy. A weighted average cost of capital of 3.38% (net of inflation) reflective of Yukon Energy costs is assumed when reviewing Levelized Cost of Energy (LCOE) for different resource options over an option's economic life.

GIS mapping of resource options to assist in the evaluations was developed to the extent feasible and based on available Yukon Energy reports, which in most cases were preliminary initial assessments. Buffer areas were assumed in the land area assessments where appropriate. Best management practices (BMPs) were assumed for each resource option's construction and operation, and each option was examined assuming that feasibility planning and environmental/socio-economic impact assessment was not yet feasible (although hydro storage enhancement options, Mayo Lake Outlet Channel Dredging, Stewart-Keno City transmission, and Gladstone Diversion have each already been subject to extensive examinations as compared to most other options).

The resource options in Table 1 cover a wide range of energy and/or capacity scales, as well as varying energy attributes:

- Fossil fuel thermal generation options (Diesel and LNG) each provide firm capacity of 20 MW and a wide range of dispatchable energy generation options up to 166 GWh/yr.; economic life varies from 20 to 40 years depending on whether these options are used for backup generation (e.g., for peak, winter, emergency or drought periods), which tends to extend unit life versus regular annual full use of capacity which would imply a 20 year life. Current resource studies have not examined waste heat use options for fossil fuel thermal generation options.
- Non-fossil thermal generation options, as well as geothermal options are each relatively small:
    - Capacity ranges from 0.2 to 3.8 MW (Geothermal estimates are an average of potentials for each site).
    - Annual energy initial year generation ranges from 0.4 GWh/year (biogas) to 33.4 GWh/year (geothermal option at McArthur Springs), with economic lives from 20 to 30 years (biogas and biomass at 20 years, waste-to-energy at 25 years, geothermal at 30 years).
    - These options are assumed to run year round with high utilization; waste-to-energy and biomass option waste heat is assumed to be fully utilized to displace other heating fuels.
    - Geothermal net capability is enhanced in winter, and declines at about 2% per year over the economic life without drilling of additional maintenance wells. e.g., lifetime average annual generation approximates 75.6% of the initial year generation.

- Other renewable energy generation-related options show a wide range of installed capacity and annual energy generation:
    - Solar PV is relatively small (1.1 to 10.2 GWh/year with 1 to 10 MW), with energy focused from March to August and limited from November through February. Options have an assumed 30 year life.
    - Wind at 20 MW per site ranges from 32.3 to 57.3 GWh/year, depending on site attributes and an assumed 25 year life. One of the seven wind site options (i.e., Kluane) requires added transmission corridor development to connect with the grid.
    - Small hydro sites range from 31.7 to 138.9 GWh/year, reflecting installed capacity ranging from 5.7 to 20 MW per site; except for Wolf River (which is run-of-river), each site has storage (requires a dam), which allows energy to be focused in winter months. Options were constrained to 20 MW, and some sites, such as Wolf River and Finlayson River, could likely accommodate higher capacities and energy generation than assumed in this evaluation. All small hydro options have an assumed 65 year life. All but two of the six small hydro site options (i.e., all but Drury Lake and Anvil Creek) require added transmission corridor development to connect with the grid. The Atlin-Pine Creek small hydro site is in B.C.
    - Pumped storage hydro sites range from 50 to 134 GWh/year, reflecting installed capacity ranging from 15 to 40 MW; generation is focused in winter months. All pumped storage options have an assumed 65 year life. These options also each need adequate non-winter surplus energy for the required pumping during summer months. All but two of the eight pumped storage hydro site options (i.e., all but Vangorda Pit and Canyon-Ittlemit) require added transmission corridor development to connect with the grid. Five of the eight pumped storage hydro sites are in B.C.
    - Gladstone Diversion provides up to 36.6 GWh of winter energy and has an assumed 65 year life.
    - Other hydro projects, which range from 2 to 10 GWh/year, affect existing hydro operations, e.g., storage enhancements, channel dredging, refurbishments.
- Other resource options are not directly related to generation of energy:
    - The energy storage battery option would facilitate energy storage to support variable renewable generation, e.g., wind or solar generation. This option has an assumed 30 year economic life.
    - Transmission corridor development options would facilitate access to some of the hydro and wind generation sites, as well as potential new markets for renewable generation (e.g., Skagway cruise ships, new mine developments that otherwise would be supplied by fossil fuel generation, diesel generation communities that are not currently connected to the hydro grid). Transmission corridor options have an assumed 45 year economic life.

1.2 OVERVIEW OF EVALUATION APPROACH

The evaluation approach displays key differences among the resource options, rather than attempting an overall ranking of these options. Accordingly, separate summary evaluation matrix tables are provided for each of the three main sets of attributes (i.e., environmental, social, and economic), and each evaluation matrix table has a range of separate criteria and indicators to be addressed:

- Each evaluation matrix includes multiple criteria (five environmental criteria, five social criteria, and two economic criteria) to address different aspects of each attribute that are important.
- Multiple indicators are also included for each criteria (with only one exception), resulting in 16 environmental indicators, 17 social indicators (including one that is also a criteria) and 8 economic indicators.
- Each resource option is evaluated separately for each indicator adopted for each of the criteria.

Table 2 provides an overview of the criteria, indicators and metrics adopted for each of the three main evaluations (see Appendix B for added details).

Criteria	First Nation Lands (S1)	Traditional Lifestyle (S2)				Heritage Resources (S3)		Tourism, Recreation & Other Resources and Land Use (S4)					Cultural & Community Well-being (S5)		
Indicators	First Nation Settlement Lands / Interim Protected Lands (S1-1)	Footprint Land Area Impact (S2-1)	Land Area Loss Re: Traditional Lifestyle (S2-2)	Land Quality Effects on Traditional Lifestyle (S2-3)	Cabins, Camps & Structures (S2-4)	Country Foods (S2-4)	Density of Heritage Resources (S3-1)	Importance / Cultural Value of Heritage Resources (S3-2)	Recreational Values (S4-1)	Tourism Values (S4-2)	Aesthetics (S4-3)	Non-renewable Resources (S4-4)	Other Renewable Resources (S4-5)	Land Use & Renewable Resources Plans (S4-6)	Infrastructure & Services (S5-1)	Public Safety, Worker Interaction, Human & Community Health (S5-2)	Community, First Nation & Personal Development (S5-3)
Metric	Overlap and/or access with these lands (Y/Potential/N)	Total area (ha) of direct land use	Total area (ha) of Traditional Use land area loss	Indirect effects on land or access for such pursuits (+/-; L/M/H)	Number in footprint that may be affected	Effects to opportunity to harvest (+/-, L/M/H)	Density of known or potential heritage resources	Importance/ Cultural Value of resources & land area (L/M/H)	Effect on nature & scale of rec. values (+/-; L/M/H)	Effect on nature & scale of tourism values (+/-; L/M/H)	Effect on auditory or visual aesthetics (+/-; L/M/H)	Effect on non-renewable resources (+/-; L/M/H)	Effect on other renewable resources (+/-; L/M/H)	Consistent with Land Use & Renewable Resources Plans (Y/N/NA)	Effect on Infrastructure & Services (+/-; L/M/H)	Risks to Community Health & Safety const. & operation (L/M/H)	Effect on local jobs, business, training & development (L/M/H)

Evaluation of Resource Options - Economic Criteria & Indicators

Criteria	Local Economic Impacts (Ec1)			Climate Change Risk affecting Resource Financial Attributes (Ec2)				
Indicators	Yukon Opportunities During Construction (Ec1-1)	Yukon Opportunities during Operation (Ec1-2)	Community & Other Development Opportunity (Ec1-3)	Susceptible to Extreme Heat / Drought (Ec2-1)	Susceptible to Extreme Precipitation - flood/snow (Ec2-2)	Susceptible to Extreme Wind Events (Ec2-3)	Susceptible to Ice Related Processes / Events (Ec2-4)	Conditions Susceptible to Climate Change (Ec2-5)
Metric	Capital cost -civil & other local share (L/M/H)	Operating costs - Yukon labour & business opp. (L/M/H)	Community, industry development opp. (L/M/H)	Susceptibility (L/M/H)	Susceptibility (L/M/H)	Susceptibility (L/M/H)	Susceptibility (L/M/H)	Extent of permafrost in project footprint (L/M/H)

The overall objective of the evaluation approach is to identify on a common scale (low, medium, and high) which indicators are particularly relevant to each resource option. A high rating indicates that potential effects on an indicator are high for a specific resource option compared with the other resource options under review. A low rating indicates that potential effects on an indicator are low for a specific resource option compared with the other resource options under review. A medium rating indicates an evaluation that falls between the high and low ratings.

The evaluation approach involves criteria that address a diverse range of risks, benefits, and potential linkages with the resource options. The following examples demonstrate this range, and highlight the need to consider in each instance the nature of the indicator when interpreting the ratings of high, medium or low for different resource options:

- **Adverse Effects Indicators:** Many of the environmental and social criteria and indicators focus on potential risks of adverse effects on specific criteria and indicators, where a high or red rating means a high relative risk of an adverse effect, e.g., effects on fish and fish habitat, effects on terrestrial species and habitat, effects on air quality, effects on First Nation lands, effects on traditional lifestyle, effects on heritage resources, and some indicators related to cultural and community well-being. When rating adverse effects for a resource option on an indicator, red means a high rating, yellow means a medium rating, and green means a low rating.
- **Positive Effects Indicators:** Some social and economic indicators focus on potential beneficial effects on specific criteria and indicators, where a high rating means a high relative level of potential benefits, e.g., effects on criteria such as Local Economic Impacts and Community, First Nation and Personal Development. In this instance, a red colour rating as adopted for adverse effects indicators might suggest (incorrectly) that a high rating has adverse rather than positive effects, while a green colour rating to suggest "positive" outcomes could also be confusing given that green means low level effects when assessing adverse effects indicators. Accordingly, no colour rating is used for the few indicators that focus on positive effects and tables simply show the rating as high positive, medium positive or low positive.
- **Linkage/Overlap Effects Indicators:** Some environmental, social and economic criteria and indicators address overall magnitudes related to linkages or overlaps, where a high or red rating means a high level of linkage or overlap without directly addressing specific adverse or positive effects that may occur, e.g., footprint territorial area, footprints land area effect, linear development distances, flow changes, relative scale of impoundment/flooding.
- **No Linkage included as Low Rating:** For many resource options there is no linkage with various environmental indicators (or the indicator is not applicable to the resource option). A low or green rating includes these situations (thereby highlighting no basis for special attention in the future with regard to this indicator when pursuing the resource option).

At this initial stage of the resource option review, effects on any indicator are often best characterized as "potential" given the need to rely on existing information without project specific baseline or assessment studies to verify existing conditions as well as expected effects. For most resource options evaluated here, current information is at a preliminary level of assessment.

In assessing potential adverse or positive effects, the evaluation assumes adoption of well understood mitigation measures or best management practices to manage potential effects. However, to provide a common evaluation approach for all options, customized mitigation developed for a specific resource option is not considered even for the few options where more detailed studies and assessments have been carried out, e.g., Stewart-Keno City Transmission, Mayo Lake and Southern Lakes hydro storage enhancement projects. This is particularly relevant to understanding the evaluations of environmental criteria for the enhanced storage projects. Detailed explanations behind the ratings are provided in Appendix C (Table C 2-5, Table C 3-5 and Table C 4-8).[1]

Accordingly, a high or red rating related to potential adverse effects on an environmental or social indicator does not in any way signify that the resource option is infeasible. Such a rating only shows that these effects will need to be addressed and managed/mitigated in order for the project to proceed.

In summary, the ratings for the evaluation of each indicator are classified in terms of high, medium and low as follows (see also Figure 1):

- **High (red when non-positive and no colour when positive effect)** means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, positive or simply signify linkage and/or overlap without much additional guidance);
- **Medium (yellow when non-positive and no colour when positive effect)** means the resource option has potential expected linkage to the indicator that falls between high and low ratings; and
- **Low (green when non-positive and no colour when positive effect)** means the resource option likely has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, positive or simply signify no linkage/overlap with the indicator, i.e., no effects pathway).

[1] See Appendix C, Page C-14 which notes that the evaluations in Table C 2-5 do not take into account the specific mitigation and adaptive management measures developed to date as a result of detailed environmental assessment studies. Notably, for Mayo Lake Enhanced Storage Yukon Energy's Yukon Environmental and Socio-economic Assessment Board submission set out measures to address potential adverse effects based on studies and ongoing work with the local First Nation.

Figure 1: Rating Criteria for Indicator Evaluations

High	Classification of high means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, positive or simply signify linkage/overlap without much additional guidance). Red signifies a high rating for all non-positive effect indicators. • A red (high) rating related to potential adverse effects does not signify that the resource option is infeasible - such a rating only shows that these effects are high and will need to be addressed and managed/mitigated in order for the project to proceed. • No colour is used to signify a high rating related to potential positive effects. A high positive rating indicates that such effects for the resource option are high relative to the effects on the indicator from other options; associated with such a rating is a likely requirement to address specific benefit management or enhancement measures.
Medium	Classification of medium means the resource option has potential expected linkage to the indicator that falls between green (low) and red (high) ratings. Yellow signifies a medium rating for all non-positive effect indicators. • A yellow (medium) rating related to potential adverse effects indicates a likely need to proceed with caution and/or special attention to the management of certain potential adverse effects (without any determination today that a high expected effects linkage exists). • No colour is used to signify a medium rating related to potential positive effects. • In many evaluations of adverse effects, a yellow (medium) rating indicates a lack of information needed for a red (high) or green (low) rating.
Low	Classification of low means the resource option has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, positive, or simply signify no linkage/overlap with the indicator, i.e., no effects pathway). Green signifies a low rating for all non-positive effect indicators. • A green (low) rating related to potential adverse effects indicates that such effects are well understood and likely can be managed through best management practices or standard mitigation measures. • No colour rating is used to signify a low rating related to potential positive effects. A low positive rating indicates that such effects for the resource option are low relative to the effects on the indicator from other options, and unlikely to require special benefit management or enhancement measures. • A green (low) rating may also signify no linkage between the resource option and the indicator.

2.0 EVALUATION OF RESOURCE OPTIONS

2.1 OVERVIEW

Evaluations for each inventoried resource option are summarized separately below for the following three sets of criteria (see Table 2):

- **Environmental** criteria and indicators;
- **Social** criteria and indicators; and
- **Economic** criteria and indicators.

Evaluations are provided for each resource option and indicator, using the rating scheme outlined in Figure 1. The detailed evaluations are provided in Appendix C (Environmental), Appendix D (Social) and Appendix E (Economic).

2.2 ENVIRONMENTAL EVALUATION OF RESOURCE OPTIONS

Figure 2 provides the summary evaluation of the RP resource options for the environmental criteria and indicators, grouped by Aquatic Environment, Terrestrial Environment and Air. Within each of these three broad groupings, separate criteria are addressed:

- **Aquatic Environment:** Fish and Fish Habitat, and Water Quantity and Quality (the first criteria focuses on effects to selected indicators, the second criteria focuses on specific pathways for resource project effects to affect the aquatic environment).
- **Terrestrial Environment:** Terrestrial Species and Habitat, and Terrestrial Footprint and Land Use (the first criteria focuses on effects to selected indicators, the second criteria focuses on specific pathways for resource project effects to affect the terrestrial environment).
- **Air:** Greenhouse Gas (GHG) Emissions, and Other Air Pollutants.

All effects are rated adverse for the environmental criteria and indicators.

Summary by Criteria and Indicators

Red or yellow ratings in Figure 2 highlight resource options that have high or medium levels of adverse effects on an indicator. These ratings are summarized as follows:

- **Aquatic Environment**:
    - **Fish and Fish Habitat:** Red (high) and yellow (medium) adverse effect ratings occur only with hydro resource options that require modification to water regimes.
        - **Salmon and Habitat:** Red (high) rating for only one pumped storage option, yellow (medium) rating for only three small hydro options and one storage enhancement option.

- **Species at Risk and Habitat:** Red (high) rating for only one pumped storage option, yellow (medium) rating for only one small hydro option.
- **Commercial, Recreational and Aboriginal Fisheries Species and Habitat:** Red (high) rating for six of the eight pumped storage options, four of the six small hydro options, Gladstone Diversion and both of the storage enhancement options[2]; yellow (medium) rating for the two remaining pumped storage and two remaining small hydro options.

o **Water Quantity and Quality:** Red and yellow adverse effect ratings occur only with hydro resource options that require modification to water regimes.

- **New Impoundment/Flooding:** Red (high) rating for all eight pumped storage options and two small hydro options; yellow (medium) rating for two of the remaining five small hydro options.
- **Flow Changes:** Red (high) rating for Gladstone Diversion and both storage enhancement options[3]; yellow (medium) rating for all pumped storage and small hydro options.

- **Terrestrial Environment:**

o **Terrestrial Species and Habitat:** Red (high) and yellow (medium) ratings occur for many wind, hydro and transmission options and one geothermal option; a yellow (medium) rating also occurs with the biomass option.

- **Species at Risk and Habitat:** Red (high) rating for Gladstone Diversion and one hydro storage enhancement option; yellow (medium) rating for six of the seven wind options, seven of the eight pumped storage options, all small hydro options and one hydro storage enhancement option[4].
- **Protected and Conservation Areas:** Red (high) rating for one geothermal option, one pumped storage option, one hydro storage enhancement option[4] and one transmission option; yellow (medium) rating for one wind option, one pumped storage option, one small hydro option and one transmission option.
- **Wildlife Key Areas:** Red (high) rating for three wind options, one pumped storage option, Gladstone Diversion and one hydro storage enhancement option[4]; yellow (medium) rating for three of the four remaining wind options, all seven of the remaining pumped storage options, three small hydro options, all transmission options, one geothermal option and the biomass option.
- **Caribou Ranges:** Red (high) rating for only one transmission option; yellow (medium) rating for three wind options, one geothermal option, seven of the eight pumped storage options, three small hydro options and Gladstone Diversion.

[2] See Appendix C, Table C 2-5 which provides rationale for ratings for Southern Lakes and Mayo Lake.
[3] See Appendix C, Table C 3-5 which provides rationale for ratings for Southern Lakes and Mayo Lake.
[4] See Appendix C, Table C 4-8 which provides rationale for ratings for Southern Lakes.

- **Terrestrial Footprint and Land Use:** Red (high) and yellow (medium) ratings occur for many wind, hydro and transmission options and one geothermal option; a yellow (medium) rating also occurs for the largest solar PV option.
  - **Footprint Terrestrial Area:** Red (high) rating for all wind, pumped storage, small hydro and transmission options and for one geothermal option and Gladstone Diversion option; yellow (medium) rating for largest solar PV option.
  - **Linear Development for Roads/Transmission:** Red (high) rating for all transmission options; yellow (medium) rating for all wind options, one geothermal option, six pumped storage options, all small hydro options, and Gladstone Diversion option.
  - **Permafrost:** No red (high) rating; yellow (medium) rating for three pumped storage options, three transmission options, one small hydro option, and Gladstone Diversion option.
  - **Wetlands:** Red (high) rating for one hydro storage enhancement option; yellow (medium) rating for four pumped storage options and one small hydro option.

- **Air – Air Quality**:
  - **GHG Emissions:** Red (high) and yellow (medium) ratings limited to thermal generation options.
    - **With biogenic CO_2 emissions**: red (high) rating for all fossil and non-fossil thermal generation options.
    - **Excluding biogenic CO_2 emissions**: red (high) rating for all fossil generation options, yellow (medium) rating for waste-to-energy and biogas options.
  - **Other Air Pollutants**: No red (high) ratings; yellow (medium) ratings limited to thermal generation options and include all fossil and non-fossil thermal generation options.

Summary by Resource Options

Overall assessments are summarized below by indicator for each of the major sets of resource options:

1. **Fossil Thermal (Diesel and LNG in Whitehorse area):** Each of these resource options is rated as follows:
   a. Aquatic and Terrestrial criteria and indicators: green (low or no linkage);
   b. GHG Emissions Air Quality indicator: red (high); and
   c. Other Air Pollutants Air Quality indicator: yellow (medium).
2. **Non-Fossil Thermal (Waste-to-energy and Biogas in the Whitehorse area, and Biomass in the Haines Junction area):** Ratings for these resource options vary as follows:
   a. Aquatic and Terrestrial criteria and indicators:

- With the exception of wood biomass effects on Wildlife Key Areas, each of these resource options is rated green (low or no linkage) for all of the Aquatic and Terrestrial indicators.
- Wood biomass is rated yellow (medium) with respect to Wildlife Key Area effects to reflect potential effects of harvesting beetle-kill timber on key wildlife and related habitat, including moose winter range.

b. Air Quality criteria and indicators: These non-fossil thermal generation options are each rated as follows:

- GHG Emissions with biogenic CO_2 emissions: red (high);
- GHG Emissions without biogenic CO_2 emissions: yellow (medium) (waste-to-energy and biogas) or green (low) (biomass); and
- Other Air Pollutants: yellow (medium).

3. **Other Non-Hydro Renewable (Storage Battery in Whitehorse, Solar PV in Whitehorse and Haines Junction, Wind at seven different sites, and Geothermal at two sites):** Ratings for these resource options vary as follows:

a. Aquatic and Air Quality criteria and indicators:

- All of these resource options: green (low or no linkage).

b. Terrestrial criteria and indicators:

i. Terrestrial Species at Risk and Habitat

- Each wind site other than Tehcho: yellow (medium).
- Tehcho wind site, storage battery, solar PV (both sites), geothermal (both sites): green (low or no linkage).

ii. Protected and Conservation Areas

- McArthur Springs geothermal (reflects location within Ddhaw Ghro Habitat Protection Area): red (high).
- Kluane Lake (reflects proximity to Kluane National Park and Kluane Wildlife Sanctuary): yellow (medium).
- Each wind site other than Kluane Lake, storage battery, solar PV (both sites), geothermal at Vista Mountain: green (low or no linkage).

iii. Wildlife Key Areas

- Three wind sites (Kluane Lake, Mt. Sumanik, and Sugarloaf Mountain; see Appendix C, Table C 4-3 for specifics): red (high).
- Three wind sites (Miller's Ridge, Tehcho, and Thulsoo Mountain), McArthur Springs geothermal: yellow (medium).
- Cyprus Mine Hill wind site, storage battery, solar PV (both sites), Vista Mountain geothermal: green (low or no linkage).

iv. Caribou Range

- Three wind sites (Cyprus Mine Hill, Miller's Ridge, and Sugarloaf Mountain), McArthur Springs geothermal: yellow (medium).
- The remaining four wind sites, storage battery, solar PV (both sites), Vista Mountain geothermal: green (low or no linkage).

v. Total Terrestrial Footprint Areas

- Each wind site: red (high).
- Solar PV (10 MW at Whitehorse site): yellow (medium).
- Storage battery, solar PV (Haines Junction, 5 MW at Whitehorse), geothermal (both sites): green (low or no linkage).

vi. Linear Development Footprint

- Each wind site, McArthur Springs geothermal: yellow (medium).
- Storage battery, solar PV (both sites), Vista Mountain geothermal: green (low or no linkage).

vii. Permafrost and Wetlands indicators

- All wind sites, storage battery, solar PV (both sites), geothermal (both sites): green (low or no linkage).

4. **Hydro Generation (Pumped Storage at eight different sites, Small Hydro at six different sites, Other Hydro [Gladstone Diversion, two Storage Enhancement options, Mayo Lake Outlet Channel Dredging], and hydro refurbishment/re-runnering at Mayo A and Aishihik)** - All hydro options are rated green (low) for all Air Quality criteria and indictors. Hydro resource options rankings for Aquatic and Terrestrial indicators are summarized below (Hydro refurbishment/re-runnering and Mayo Lake Outlet Channel Dredging are each rated green [low or no linkage] for all of these indicators):

a. **Fish and Fish Habitat Indicators**

i. **Salmon and Habitat**

- Vangorda Pit pumped storage: red (high).
- Drury Lake, Wolf River and Anvil Creek small hydro, Southern Lakes Enhanced Storage: yellow (medium).
- All other hydro generation options: green (low or no linkage).

ii. **Species at Risk and Habitat**

- Squanga-Dalayee pumped storage: red (high) (due to presence of Squanga Whitefish).
- Finlayson River small hydro: yellow (medium).
- All other hydro generation options: green (low).

iii. **Commercial, Recreational and Aboriginal Fisheries Species and Habitat**

- All pumped storage options other than Moon Lake and Atlin-Black Mountain, all of the small hydro options other than Wolf River and Atlin/Pine Creek, and all of the Other Hydro options[5] other than Mayo Lake Outlet Channel Dredging: red (high).
- Moon Lake and Atlin-Black Mountain pumped storage, Wolf River and Atlin/Pine Creek small hydro: yellow (medium).
- Mayo Lake Outlet Channel Dredging: green (low or no linkage).

b. **Water Quantity and Quality indicators**

i. **Consumptive Water** - All hydro resource options have no linkage (green rating).

ii. **Relative Scale of New Impoundment/Flooding**

- All pumped storage options, Finlayson River and Anvil Creek small hydro and Gladstone Diversion: red (high).
- Drury Lake and Tutshi-Windy Arm small hydro: yellow (medium).
- All other hydro options are rated green (low or no linkage).

iii. **Flow Changes**

- Gladstone Diversion and the Storage Enhancement options (Mayo Lake and Southern Lakes): red (high).[5]
- All other pumped storage and small hydro options: yellow (medium).

c. **Terrestrial Species and Habitat indicators**

i. **Species at Risk and Habitat**

- Gladstone Diversion and Southern Lakes Enhanced Storage: red (high).[6]
- All pumped storage and small hydro site options other than Vangorda Pit, Mayo Lake Enhanced Storage: yellow (medium).
- Vangorda Pit pumped storage: green (low or no linkage).

ii. **Protected and Conservation Areas**

- Lindeman-Fraser pumped storage (Chilkoot Trail National Historic Site), Southern Lakes Enhanced Storage[6] (overlaps Lewes Marsh and Tagish Narrow Habitat Protection Areas: red (high).

[5] See Appendix C, Table C 2-5 and Table C 3-5. For Southern Lakes, changes to downstream flows are predicted to be over 20% higher in the late winter than historical flows. For Mayo Lake, changes to downstream flows are predicted on average to be over 20% higher in late winter/spring than flows without the enhancement (effects will vary for different years). Reductions of flows that occur during the summer are expected to be over 10% and perhaps slightly over 20% (depending on load conditions).
[6] See Appendix C, Table C 4-8. Project effects are primarily related to changes in water levels during different seasons or years.

- Squanga-Dalayee pumped storage and Wolf River small hydro: yellow (medium).
- All other hydro resource options: green (no linkage).

iii. **Wildlife Key Areas**

- Squanga-Dalayee pumped storage, Gladstone Diversion and Southern Lakes enhanced storage[6]: red (high).
- All other pumped storage options, all small hydro options other than Atlin/Pine Creek, and Mayo Lake enhanced storage: yellow (medium).
- Atlin/Pine Creek small hydro, Southern Lakes enhanced storage, Mayo Lake Outlet Channel Dredging, re-runnering/refurbishment options: green (low or no linkage).

iv. **Caribou Ranges**

- All pumped storage options other than Canyon-Ittlemit, three small hydro options (Tutshi-Windy Arm, Finlayson River and Anvil Creek) and Gladstone Diversion: yellow (medium).
- All other hydro options: green (low or no linkage).

d. **Terrestrial Footprint and Land Use Indicators**

i. **Footprint Terrestrial Area**

- All pumped storage and small hydro options, Gladstone Diversion: red (high).
- Other Hydro storage enhancements (Mayo and Marsh), Mayo Outlet Channel Dredging and the re-runnering/refurbishment options: green (low or no linkage).

ii. **Linear Development for Roads/Transmission**

- All small hydro options, all pumped storage options other than Moon Lake and Atlin-Black Mountain, Gladstone Diversion: yellow (medium).
- Moon Lake (Tutshi-Moon) and Atlin-Black Mountain pumped storage, the Other Hydro storage enhancements (Mayo and Marsh), Mayo Outlet Channel Dredging and the re-runnering/refurbishment options: green (low or no linkage).

iii. **Permafrost**

- Gladstone Diversion, Finlayson River small hydro, and three pumped storage options (Racine-Mt. Brown, Canyon-Ittlemit, and Vangorda Pit): yellow (medium).
- All other hydro options: green (low or no linkage).

iv. **Wetlands**

- Southern Lakes Enhanced Storage: red (high) (reflecting quality wetlands at the edges of this storage).
- Wolf River small hydro, and four pumped storage options (Moon Lake, Racine-Moon, Squanga-Dalayee, and Vangorda Pit): yellow (medium).
- All other hydro options: green (low or no linkage).

5. **Transmission Corridors (Six Transmission Corridor Options)** - These resource options are each rated green (low or no linkage) for all of the Aquatic and Air Quality criteria and indicators. The following are noted for Terrestrial ratings:

   a. **Species at Risk and Habitat**: all transmission options rated green (low or no linkage).

   b. **Protected and Conservation Areas**

   - Aishihik-Destruction Bay (assumed use of Kluane National Park): red (high).
   - Whitehorse-Atlin: yellow (medium).
   - All other transmission options: green (low or no linkage).

   c. **Wildlife Key Areas:** all transmission options rated yellow (medium).

   d. **Caribou Ranges**

   - Faro-Watson Lake: red (high).
   - All other transmission options: green (low or no linkage).

   e. **Footprint Terrestrial Area and Linear Development**: all transmission options rated red (high).

   f. **Permafrost**

   - Faro-Watson Lake, Aishihik-Destruction Bay, and Stewart-Keno City: yellow (medium).
   - All other transmission options: green (low or no linkage).

   g. **Wetlands**: all transmission options rated green (low or no linkage).

1. GHG Emissions considers Global Warming Potential (GWP) for each option for both 20-year and 100-year time horizons

2.3 SOCIAL EVALUATION OF RESOURCE OPTIONS

Figure 3 provides the summary evaluation of the RP resource options for the social criteria and indicators, building on the outcomes of the environmental evaluations.

- The first three groupings of criteria and indicators focus on First Nations, traditional lifestyle and heritage resources potential effects from the resource options.
- The last two groupings of criteria and indicators focus on a broader range of potential social effects.

Except for Community, First Nation and Personal Development (for which effects are rated positive), all effects are rated adverse for the social criteria and indicators.

Summary by Criteria and Indicators

Red or yellow ratings in Figure 3 highlight resource options that have high or medium levels of adverse effects on an indicator. High and medium adverse and positive ratings are summarized as follows:

- **First Nation Lands:** Red (high) and/or yellow (medium) ratings occur for all transmission options, many of the hydro options that modify water regimes, and some of the wind options; yellow ratings occur for both geothermal options and one of the fossil thermal site options.
    - **First Nation Settlement Lands/Interim Protected Lands:** Red (high) rating for three transmission options, three pumped storage options, three small hydro options, two wind options, one of the hydro storage enhancement options, and the Gladstone Diversion option; yellow (medium) rating for remaining transmission options, two of three remaining small hydro options, two of the remaining five pumped storage options, both geothermal options, one wind option, and the Takhini fossil thermal site option.
- **Traditional Lifestyle:** Red (high) and yellow (medium) ratings occur for most of the non-thermal options for total footprint areas impacted, but are limited to only a few hydro options and one transmission option for all other indicators.
    - **Footprint Land Area Impact:**[7] Red (high) rating for all transmission options, all pumped storage options, five of six small hydro options, six of seven wind options, one geothermal option, Gladstone Diversion and both hydro storage enhancement options; yellow (medium) rating for the remaining small hydro, geothermal and wind options and both solar PV options.
    - **Land Area Loss regarding Traditional Lifestyle:** No red (high) ratings; yellow (medium) rating for only one pumped storage option and one small hydro option.

[7] See Page D-8. Footprint Land Area Impact is a quantitative metric that considers only direct land loss. The total footprint or land area affected may not be permanently lost for the purposes of traditional lifestyle activities. This indicator is used only as background information and is not directly adopted for the assessment of effects on the Land Quality Effects on Traditional Lifestyle. The rating criteria were selected simply to help assign resource project options to clearly separate groups based on the indicator.

- **Land Quality Effects on Traditional Lifestyle:** No red (high) ratings; yellow (medium) rating for only one pumped storage option, one small hydro option, Gladstone Diversion and one hydro storage enhancement option.
- **Cabins, Camps and Structures:** A red (high) rating for one hydro storage enhancement option and a yellow (medium) rating for only one transmission option.
- **Country Foods:** A red (high) rating for Gladstone Diversion; yellow (medium) rating for only one pumped storage option and one small hydro option.

- **Heritage Resources:** Red (high) ratings are limited to only two hydro options; yellow (medium) ratings occur for many of the non-thermal options.
  - **Density of Heritage Resources:** Red (high) rating for one pumped storage option and one hydro storage enhancement option; yellow (medium) rating for three pumped storage options, four small hydro options, five transmission options, and Gladstone Diversion.
  - **Importance/Cultural Value of Heritage Resources:** No red (high) ratings; yellow (medium) rating for five wind options, three pumped storage options, two small hydro option, one geothermal option, one transmission option, Gladstone Diversion, and one hydro storage enhancement option.
- **Tourism, Recreation and Other Resources and Land Use:** Red (high) and yellow (medium) ratings occur for many hydro options with water regime changes, many of the wind options, one geothermal option, and the biomass option.
  - **Recreational Values:** Red (high) rating for four pumped storage options, and five small hydro options; yellow (medium) rating for three wind options, one geothermal option, one of the four remaining pumped storage options, the one remaining small hydro option, and Gladstone Diversion.
  - **Tourism Values:** Red (high) rating for three small hydro options; yellow (medium) rating for two wind options, one geothermal option, five pumped storage options, and two of the three remaining small hydro options.
  - **Aesthetics:** Red (high) rating for one geothermal option and one small hydro option; yellow (medium) rating for biomass option, four wind options, four pumped storage options, two small hydro options, and Gladstone Diversion.
  - **Non-renewable Resources:** Red (high) rating for one small hydro option; yellow (medium) rating for one wind option, one geothermal option, five pumped storage options, two small hydro option and Gladstone Diversion.
  - **Other Renewable Resources:** No red (high) ratings; one yellow (medium) rating (for one geothermal option).
  - **Land Use and Renewable Resource Plans:** Red (high) rating for three pumped storage options and one geothermal option; yellow (medium) rating for biomass option, three wind options, four of the five remaining pumped storage options, five of the six small hydro options, and Gladstone Diversion.

- **Culture and Community Well-being:** Red (high) adverse effects ratings occur for all pumped storage and small hydro options; yellow (medium) adverse effects ratings occur for most wind options, one geothermal option, and Gladstone Diversion; high and medium positive effects ratings occur for all transmission options, all pumped storage and small hydro options, most wind options, and Gladstone Diversion; medium positive effects ratings occur for one geothermal option and thermal options other than diesel.
    - **Infrastructure and Services:** Red (high) rating for all pumped storage and small hydro options; yellow (medium) rating for six of the seven wind options, one geothermal option, and Gladstone Diversion.
    - **Public Safety, Worker Interaction, Human and Community Health:** Red (high) rating for all pumped storage and small hydro options; yellow (medium) rating for six of the seven wind options, one geothermal option, and Gladstone Diversion.
    - **Community, First Nation and Personal Development:** High positive effects rating for three transmission options, five pumped storage options, four small hydro options, two wind options, and Gladstone Diversion; medium positive effects rating for the three remaining transmission options, the three remaining pumped storage option, the two remaining small hydro options, four of the five remaining wind options, one geothermal option, all non-fossil thermal options, and the LNG fossil thermal options.

Summary by Resource Options

Overall assessments are summarized below by indicator for each of the major sets of resource options:

1. **Fossil Thermal (Diesel and LNG in Whitehorse area):** Each of these resource options is rated green (low) or low positive for all of the social criteria and indicators, except for the following yellow or medium positive ratings:
    a. **First Nation Settlement Lands:** The Takhini substation site is rated yellow (medium), reflecting proximity of such lands to the site and possible transmission access routing.
    b. **Community, First Nation and Personal Development:** The LNG options are rated medium positive, reflecting medium benefit opportunity to facilitate LNG use to displace other fossil fuel use in Whitehorse/Yukon.[8]
2. **Non-Fossil Thermal (Waste-to-energy and Biogas in the Whitehorse area and Biomass in the Haines Junction area):** Each of these resource options is rated green (low) for all of the social criteria and indicators, except for the following yellow or medium positive ratings:
    a. **Aesthetics:** A yellow (medium) rating for the biomass option at Haines Junction, reflecting siting near school as well as commercial and residential areas.
    b. **Land Use and Renewable Resource Plans:** A yellow (medium) rating for the biomass option at Haines Junction, reflecting anticipated need for some zoning variance.

[8] See Appendix D, Page D 6-4 which notes that by comparison diesel has no specific local development opportunities.

c. **Community, First Nation and Personal Development:** A medium positive rating for each of these options, reflecting medium local benefit opportunity to use renewable energy and (except for biogas) and to supply waste heat to displace fossil fuel use.

3. **Other Non-hydro Renewable (Storage Battery in Whitehorse, Solar PV in Whitehorse and Haines Junction, Wind at seven different sites, and Geothermal at two sites):** The storage battery option is rated green (low) or low positive for all social criteria and indicators, and the solar PV option at both sites is also rated green (low) or low positive for all social criteria and indicators other than Footprint Land Area Impact, where it is rated yellow (medium).[9]

   Other non-hydro renewable resource options (wind and geothermal) display common rankings for some of the social indicators, but also display variances. Detailed review of the evaluations for these options is provided below:

   a. **First Nation Settlement Lands/ Interim Protected Lands**

      - Kluane Lake and Sugarloaf Mountain wind options: red (high).
      - Wind option at Miller's Ridge and both geothermal options: yellow (medium).
      - All remaining wind sites: green (low).

   b. **Traditional Lifestyle**

      i. **Footprint Land Area Impact**

         - All wind options other than Kluane Lake, and Vista Mountain geothermal: red (high).[10]
         - Kluane Lake wind option and Vista Mountain geothermal: yellow (medium).

      ii. **Other Traditional Lifestyle Indicators:** All other traditional lifestyle indicators are rated green for all wind and geothermal options.

   c. **Heritage Resources**

      i. **Density of Heritage Resources**

         - All wind and geothermal options are rated green (low).

      ii. **Importance/Cultural Value of Heritage Resources**

         - All wind options other than Cyprus Mine Hill and Kluane Lake and the geothermal option at McArthur Springs: yellow (medium).
         - Cyprus Mine Hill and Kluane Lake wind options and the geothermal option at Vista Mountain: green (low).

   d. **Tourism, Recreation and Other Resources and Land Use:** Variances among these indicators are summarized as follows for wind and geothermal resource options:

[9] See Appendix D, Table D 3-2 for explanation of rating for Solar PV in Whitehorse compared to Haines Junction.
[10] See Appendix D, Table D 3-2 for explanation of rating for Kluane Wind Project compared to other wind projects.

i. **Recreational Values**

- Thulsoo Mountain, Miller's Ridge, and Kluane Lake wind farms, McArthur Springs geothermal: yellow (medium).
- Cyprus Mine Hill, Sugarloaf Mountain, Tehcho, and Mt. Sumanik wind farms; Vista Mountain geothermal: green (low).

ii. **Tourism Values**

- Miller's Ridge and Kluane Lake wind farms, McArthur Springs geothermal: yellow (medium).
- Cyprus Mine Hill, Sugarloaf Mountain, Tehcho, Mt. Sumanik, and Thulsoo wind farms, Vista Mountain geothermal: green (low).

iii. **Aesthetics**

- McArthur Springs geothermal: red (high).
- Thulsoo Mountain, Miller's Ridge, Kluane Lake, Sugarloaf Mountain wind farms: yellow (medium).
- Cyprus Mine Hill, Mt. Sumanik, Tehcho wind farms; Vista Mountain geothermal: green (low).

iv. **Non-Renewable Resources**

- Thulsoo Mountain, McArthur Springs geothermal: yellow (medium).
- Cyprus Mine Hill, Mt. Sumanik, Tehcho, Kluane Lake, and Miller's Ridge wind farms, Vista Mountain geothermal: green (low).

v. **Other Renewable Resources**

- McArthur Springs: yellow (medium).
- All wind options and Vista Mountain geothermal: green (low).

vi. **Land Use and Renewable Resources Plans**

- McArthur Springs geothermal: red (high) (located in protected area).
- Thulsoo Mountain, Miller's Ridge, Sugarloaf Mountain wind farms: yellow (medium).
- Cyprus Mine Hill, Tehcho, and Mt. Sumanik wind farms, Vista Mountain geothermal: green (low).

e. **Cultural and Community Well-being**

i. **Infrastructure and Services**

- All wind options other than Mt. Sumanik, McArthur Springs geothermal: yellow (medium).
- Mt. Sumanik wind option, Vista Mountain geothermal: green (low).

ii. **Public Safety, Worker Interaction, Human and Community Health**

- All wind options other than Mt. Sumanik, McArthur Springs geothermal: yellow (medium).
- Mt. Sumanik wind option, Vista Mountain geothermal: green (low).

iii. **Community, First Nation and Personal Development**

- Kluane Lake and Sugarloaf Mountain wind options: high positive (high benefit potential reflects the need to secure agreements with First Nations for use of settlement lands for each wind farm site).
- All wind options other than Mt. Sumanik, Kluane Lake and Sugarloaf Mountain; McArthur Springs geothermal: medium positive.
- Mt. Sumanik wind option and Vista Mountain geothermal: low positive.

4. **Hydro Generation (Pumped Storage at eight different sites, Small Hydro at six different sites, Other Hydro [Gladstone Diversion, two Storage Enhancement options, Mayo Outlet Channel Dredging], and hydro refurbishment/re-runnering at Mayo A and Aishihik):** Hydro refurbishment/re-runnering and Mayo Lake Outlet Channel Dredging are each rated green (low) or low positive for each of the social criteria and indicators, and Mayo Lake Storage Enhancement is rated green (low) or low positive for all of these same indicators other than Footprint Land Area Impact (where the rating is not relevant as it reflects lake water area, i.e., the resource option at most lowers average lake levels and does not impact new land areas).

   Other hydro generation resource options display common rankings for some of the social indicators, but also display variances as noted below:

   a. **First Nation Settlement Lands/Interim Protected Lands:** These evaluations include consideration of new road and transmission access requirements for these hydro resource options.

      - Three pumped storage options (Squanga-Dalayee, Canyon-Ittlemit, Vangorda Pit), three small hydro options (Wolf River, Finlayson River, and Anvil Creek), Gladstone Diversion, and Southern Lakes Enhanced Storage: red (high).
      - Two pumped storage options (Racine-Mt. Brown and Atlin-Black Mountain) and two small hydro options (Drury Lake and Atlin/Pine Creek): yellow (medium).
      - Remaining hydro generation options: green (low).

   b. **Traditional Lifestyle**

      i. **Footprint Land Area Impact**

      - All pumped storage options, all small hydro other than Tutshi-Windy Arm, Gladstone Diversion, both enhanced storage options (Southern Lakes, Mayo Lake): red (high).
      - Tutshi-Windy Arm small hydro: yellow (medium).

- Aishihik re-runnering, Mayo A refurbishment: green (low).

ii. **Land Area Loss regarding Traditional Lifestyle**

- Vangorda Pit pumped storage, Finlayson River small hydro: yellow (medium).
- All other hydro options: green (low).

iii. **Land Quality Effects on Traditional Lifestyle**

- Canyon-Ittlemit pumped storage, Finlayson River small hydro, Gladstone Diversion, Southern Lakes enhanced storage: yellow (medium).
- All other hydro options: green (low).

iv. **Cabins, Camps and Structures**

- Southern Lakes enhanced storage: red (high).
- All other hydro options: green (low).

v. **Country Foods**

- Gladstone Diversion: red (high).
- Squanga-Dalayee pumped storage, Finlayson River small hydro: yellow (medium).
- All other hydro options: green (low).

c. Heritage Resources

i. **Density of Heritage Resources**

- Atlin-Black Mountain pumped storage and Southern Lakes Enhanced Storage: red (high).
- Three pumped storage options (Lindeman-Fraser, Squanga-Dalayee, Canyon-Ittlemit), four small hydro options (Tutshi-Windy Arm, Finlayson River, Anvil Creek and Atlin/Pine Creek), and Gladstone Diversion: yellow (medium).
- All other hydro options: green (low).

ii. **Importance/Cultural Value of Heritage Resources**

- Three pumped storage options (Lindeman-Fraser, Squanga-Dalayee, and Canyon-Ittlemit), Finlayson River and Anvil Creek small hydro, Gladstone Diversion, and Southern Lakes Enhanced Storage: yellow (medium).
- All other hydro options: green (low).

d. **Tourism, Recreation and Other Resources and Land Use**

i. **Recreational Values**

- Four pumped storage options (Racine-Moon, Racine-Mt. Brown, Squanga-Dalayee, Canyon-Ittlemit) and five small hydro (Drury Lake,

Tutshi-Windy Arm, Finlayson River, Anvil Creek, and Atlin-Pine Creek): red (high).

- Lindeman-Fraser pumped storage, Wolf River small hydro, Gladstone Diversion: yellow (medium).
- Three pumped storage options (Vangorda Pit, Moon Lake [Tutshi-Moon], Atlin-Black Mountain), storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

ii. **Tourism Values**

- Three small hydro options (Drury Lake, Finlayson River, and Atlin/Pine Creek): red (high).
- Five pumped storage options (Racine-Moon, Lindeman-Fraser, Racine-Mt. Brown, Squanga-Dalayee, Canyon-Ittlemit), Wolf River and Anvil Creek small hydro: yellow (medium).
- Vangorda Pit, Moon Lake (Tutshi-Moon), Atlin-Black Mountain, storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

iii. **Aesthetics**

- Atlin/Pine Creek small hydro: red (high).
- Four pumped storage options (Moon Lake [Tutshi-Moon], Lindeman-Fraser, Squanga-Dalayee, Canyon-Ittlemit), Wolf River and Anvil Creek small hydro, Gladstone Diversion: yellow (medium).
- Vangorda Pit, Racine-Mt Brown, Racine-Moon, Atlin Black Mountain, storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

iv. **Non-renewable Resources**

- Atlin/Pine Creek small hydro: red (high).
- Three pumped storage options (Moon Lake [Tutshi-Moon], Racine-Moon, Racine-Mt. Brown), Finlayson River and Anvil Creek small hydro, Gladstone Diversion: yellow (medium).
- Vangorda Pit, Lindeman Fraser, Atlin-Black Mountain, Squang-Dalayee, Canyon-Ittlemit, storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

v. **Other Renewable Resources**

- All hydro options: green (low).

vi. **Land Use and Renewable Resources Plans**

- Three pumped storage options (Racine-Moon, Racine-Mt. Brown, Atlin-Black Mountain): red (high).
- Four pumped storage options (Moon Lake [Tutshi-Moon], Lindeman-Fraser, Squanga-Dalayee, Canyon-Ittlemit), all small hydro options other than Atlin/Pine Creek, Gladstone Diversion: yellow (medium).
- Vangorda Pit pumped storage, Atlin/Pine Creek small hydro, storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

e. **Cultural and Community Well-being**:

i. **Infrastructure and Services**

- All pumped storage and small hydro options: red (high).
- Gladstone Diversion: yellow (medium).
- Storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

ii. **Public Safety, Worker Interaction, Human and Community Health**

- All pumped storage and small hydro options: red (high).
- Gladstone Diversion: yellow (medium).
- Storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: green (low).

iii. **Community, First Nation and Personal Development**

- Five pumped storage options (Lindeman-Fraser, Atlin-Black Mountain, Moon Lake [Tutshi-Moon], Racine-Moon, Racine-Mt. Brown), all small hydro options other than Drury Lake and Anvil Creek, Gladstone Diversion (potential benefit arrangements with First Nations): high positive (indicating high potential benefits).
- Three pumped storage options (Squanga-Dalayee, Canyon-Ittlemit, and Vangorda Pit) and two small hydro options (Drury Lake and Anvil Creek): medium positive.
- Storage enhancements (Southern Lakes, Mayo Lake), Mayo Lake Outlet dredging, Aishihik re-runnering, Mayo A refurbishing: low positive.

5. **Transmission Corridors (Six Transmission Corridor Options)**

a. **First Nation Lands**

- Whitehorse-Atlin, Whitehorse-Skagway, Whitehorse-Teslin options: red (high).
- Remaining three options: yellow (medium).

b. **Traditional Lifestyle**

   i. **Footprint Land Area Impact:** all options rated red (high) (this indicator simply reflects total areas and does not address Traditional Lifestyle effects directly).

   ii. **All Other Traditional Lifestyle Indicators**

   - Whitehorse-Skagway: yellow (medium) for Cabins, Camps and Structures.
   - All other transmission options and indicators: green (low).

c. **Heritage Resources**

   i. **Density of Heritage Resources**

   - Faro-Watson Lake transmission option: green (low).
   - All transmission options other than Faro-Watson Lake: yellow (medium).

   ii. **Importance/Cultural Value of Heritage Resources**

   - Whitehorse-Skagway transmission option: yellow (medium).
   - All transmission options other than Whitehorse-Skagway: green (low).

d. **Tourism, Recreation and Other Resources and Land Use** - all transmission options are rated green (low) for all indicators.

e. **Cultural and Community Well-being**

   i. **Infrastructure and Services** – green (low) of all transmission options.

   ii. **Public Safety, Worker Interaction, Human and Community Health**: green (low) of all transmission options.

   iii. **Community, First Nation and Personal Development**

   - Faro-Watson Lake, Aishihik-Destruction Bay, and Stewart-Keno City transmission options: high positive (indicating high potential benefits).
   - Whitehorse-Atlin, Whitehorse-Skagway, Whitehorse-Teslin transmission options: medium positive.

Mayo A Refurbishment																	Low Positive
Transmission Corridors																	
Transmission: Whitehorse - Atlin (138 kV)																	Medium Positive
Transmission: Whitehorse - Skagway (230 kV)																	Medium Positive
Transmission: Whitehorse - Teslin (138 kV)																	Medium Positive
Transmission: Faro - Watson Lake (230 kV)																	High Positive
Transmission: Aishihik - Destruction Bay (230 kV)																	High Positive
Transmission: Stewart-Keno City (138 kV & substations)																	High Positive

2.4 ECONOMIC EVALUATION OF RESOURCE OPTIONS

Figure 4 provides the summary evaluation of the RP resource options for the Economic criteria and indicators, building on the outcomes of the environmental and social evaluations.

- The first criteria (Local Economic Impacts) focuses on potential economic benefit effects during construction and operation of the resource options, as well as overall community and other development opportunities related to these options.
- The second criteria (Climate Change Risk) focuses on the potential effects of various climate change risks on resource option construction or operation, i.e., an overview of resource option financial attributes' relative vulnerability to these risks.

Economic indicators for the Local Economic Impacts criteria (Ec1) address potential positive effects from resource options. The ratings in such instances are highlighting where the magnitude or nature of potential positive effects is material. All effects for other economic criteria are rated adverse.

Summary by Criteria and Indicators

Red or yellow ratings in Figure 4 highlight resource options that have high or medium levels of adverse effects on an indicator. High and medium adverse and positive ratings are summarized as follows:

- **Local Economic Impacts:** High and/or medium positive ratings for all pumped storage options, most small hydro and wind options, most transmission options, waste-to-energy option, other thermal options other than diesel, one geothermal option and Gladstone Diversion.
    - **Yukon Opportunities during Construction:** High positive rating for all pumped storage options, two small hydro options, and two transmission options; medium positive rating for three of the four remaining transmission options, two of the four remaining small hydro options, one geothermal option and one wind option.
    - **Yukon Opportunities during Operation:** High positive rating for seven pumped storage options, all small hydro options, two wind options, and waste-to-energy option; medium positive rating for the one remaining pumped storage option, the five remaining wind options, and one geothermal option.
    - **Community and Other Development Opportunity**: High positive rating for three transmission options, five pumped storage options, four small hydro options, two wind options, and Gladstone Diversion; medium positive rating for the three remaining transmission options, the two remaining small hydro options, the three remaining pumped storage options, four of the five remaining wind options, one geothermal option, all of the non-fossil thermal options, and the LNG fossil thermal option.
- **Climate Change Risk Affecting Resource Financial Attributes:** Red (high) and/or yellow (medium) adverse effects ratings are noted for transmission options, hydro options, wind options, one geothermal option and the biomass option.

- **Susceptible to Extreme Heat/Drought:** Red (high) rating for all pumped storage and small hydro options, and Gladstone Diversion; yellow (medium) rating for three transmission options, both hydro storage enhancement options, and the biomass option.
- **Susceptible to Extreme Precipitation - Flood/Snow:** No red (high) ratings; yellow (medium) rating only for all transmission options.
- **Susceptible to Extreme Wind Events:** No red (high) ratings; yellow (medium) rating for all transmission options and all wind options.
- **Susceptible to Ice Related Processes/Events:** Red (high) rating for six of the seven wind options; yellow (yellow) rating for all transmission options.
- **Conditions Susceptible to Climate Change (Permafrost Conditions):** Red (high) rating for one wind option, one small hydro option, and one transmission option; yellow (medium) rating for all remaining transmission options, all remaining small hydro options, six of the eight pumped storage options, and one geothermal option.

Summary by Resource Options

Overall assessments are summarized below by indicator for each of the major sets of resource options:

1. **Fossil Thermal (Diesel and LNG in Whitehorse area)**: Each of these resource options is rated green (low) or low positive for all of the economic criteria and indicators, except for the following ratings:
    a. **Local Economic Impacts - Community and Other Development Opportunity**
        - LNG resource option: medium positive (reflects medium local benefit opportunities facilitated by the option [through its development of an LNG supply chain] to use LNG to displace other fossil fuel use in Whitehorse/Yukon).
        - Diesel resource option: low positive (reflects low local economic benefit impacts from this option).
2. **Non-Fossil Thermal (Waste-to-energy and Biogas in the Whitehorse area, and Biomass in the Haines Junction area)** - Each of these resource options is rated green (low) or low positive for all of the economic criteria and indicators, except for the following ratings:
    a. **Local Economic Impacts**
        i. **Yukon Opportunities during Operation**
            - Waste-to-energy: high positive (reflecting relatively high level of operating jobs and Opex cost level).
            - Biogas and biomass: low positive (relatively low local economic benefits).
        ii. **Community and Other Development Opportunity**
            - All non-fossil thermal options: medium positive (reflecting local opportunity to use renewable energy and [except for biogas] and to supply waste heat to displace fossil fuel use).

b. **Climate Change Risk**

i. **Susceptible to Extreme Heat/Drought**

- Biomass: yellow (forest fire risks).

3. **Other Non-Hydro Renewable (Storage Battery in Whitehorse, Solar in Whitehorse and Haines Junction, Wind at seven different sites, and Geothermal at two sites)**, **Storage Battery and Solar PV.**

a. **Local Economic Impacts:** Ratings tend to be similar across the site options for a resource technology option:

i. **Yukon Opportunities during Construction**

- Kluane Lake wind option, McArthur Springs geothermal: medium positive (Kluane Lake wind rating reflects added requirement for new transmission line to connect to grid at Haines Junction or Aishihik).
- All other non-hydro renewable options – low positive.

ii. **Yukon Opportunities during Operation, and Community and Other Development Opportunity**

- Kluane Lake and Sugarloaf Mountain wind options: high positive for both indicators (reflects added opportunities for First Nation lease revenues and [for Kluane Lake] the benefits of the added transmission connection which will allow Destruction Bay and likely Burwash Landing to stop relying on diesel generation).
- All other wind farm site options, except for Mt. Sumanik (for Community and Other Development Opportunity), and McArthur Springs geothermal option: medium positive for both indicators.
- Mt. Sumanik wind option (for Community and Other Development Opportunity) and Vista Mountain geothermal, Solar PV, storage battery for both indicators: low positive (reflecting relatively low local economic impacts).

b. **Climate Change Risk**

i. **Susceptible to Ice-related Processes/Events**

- All wind farm options other than Kluane Lake: red (high susceptibility risk).
- Kluane Lake wind option (reflects lower elevation and better weather conditions), storage battery, solar options, and both geothermal options: green (low susceptibility risk).

ii. **Susceptible to Extreme Heat/Drought** and **Susceptible to Extreme Precipitation (flood/snow):** all of the other non-hydro renewable options are rated green (low) for these indicators.

iii. Susceptible to Extreme Wind Events

- All wind options: yellow (medium).
- Storage battery, solar PV options, and both geothermal options: green (low).

iv. **Conditions Susceptible to Climate Change**: This indicator is focused entirely on relative risks related to permafrost.[11]

- Kluane Lake wind option: red (high) (reflects permafrost risks in this region).
- McArthur Springs geothermal option: yellow (medium).
- All wind options other than Kluane Lake, storage battery, solar PV options, and Vista Mountain geothermal option: green (low).

4. **Hydro Generation (Pumped Storage at eight different sites, Small Hydro at six different sites, Other Hydro [Gladstone Diversion, two Storage Enhancement options, Mayo Lake Outlet Channel Dredging], and hydro refurbishment/re-runnering at Mayo A and Aishihik):** The economic criteria and indicator ratings tend to be very similar for various site options within each hydro generation resource option:

a. **Local Economic Impacts**

i. Yukon Opportunities during Construction

- All pumped storage options, two small hydro options (Wolf River, Finlayson River): high positive.
- Three small hydro options (Tutshi-Windy Arm, Anvil Creek, Atlin/Pine Creek): medium positive.
- Drury Lake small hydro option, all other hydro options, Aishihik re-runnering, Mayo A refurbishment: low positive.

ii. Yukon Opportunities during Operation

- All pumped storage options other than Moon Lake, all small hydro options: high positive.
- Moon Lake (Tutshi-Moon) pumped storage: medium positive.
- All other hydro options, Aishihik re-runnering, Mayo A refurbishment: low positive.

iii. Community and Other Development Opportunity

- Five pumped storage options that each provide high development opportunity benefits related to major new transmission (Moon Lake, Racine-Moon, Lindeman-Fraser, Racine-Mt. Brown, Atlin- Black Mountain), all small hydro options except Drury Lake and Anvil Creek

[11] For discussion of ratings see Table E3-1.

(each of these four options require major new transmission), Gladstone Diversion (reflects opportunity for local First Nation income benefits if this option developed): high positive.

- Three pumped storage options (Squanga-Dalayee, Canyon-Ittlemit, and Vangorda Pit), Drury Lake and Anvil Creek small hydro: medium positive.
- Storage enhancement options (Southern Lakes, Mayo Lake), Mayo Lake Outlet Channel Dredging, Aishihik re-runnering, Mayo A refurbishment: low positive.

b. **Climate Change Risk**

i. Susceptible to Extreme Heat / Drought

- All pumped storage options, all small hydro options, Gladstone Diversion: red (high susceptibility).
- Storage enhancement option (Southern Lakes, Mayo Lake): yellow (medium).
- Mayo Lake Outlet Channel Dredging, Aishihik re-runnering, Mayo A refurbishment: green (low susceptibility).

ii. Conditions Susceptible to Climate Change (permafrost risks)[12]

- Drury Lake small hydro: red (high).
- All pumped storage options other than Canyon-Ittlemit and Vangorda Pit, all small hydro options other than Drury Lake: yellow (medium).
- Two pumped storage options (Canyon-Ittlemit and Vangorda Pit), all Other Hydro options, Aishihik re-runnering, Mayo A refurbishment: green (low).

iii. **All other Climate Change Risk indicators** - All hydro options are rated green for all other Climate Change Risk indicators (low susceptibility to Extreme Precipitation, to Extreme Wind Events, and to Ice Related Processes/Events).

5. **Transmission Corridors (Six Transmission Corridor Options):** Transmission corridor options tend to have similar economic criteria and indicator ratings, with a few exceptions as noted below:

a. **Local Economic Impacts**: variable ratings among these options reflect varying scales of development (capital costs), as well as related impacts known today from each development:

[12] For discussion of ratings see Table E 3-1. Each option other than Drury Lake has a medium rating reflecting potential permafrost conditions affecting material new transmission access development requirements. Drury Lake has a red rating based on geotechnical risks and presence of permafrost noted in previous KGS reports.

i. **Yukon Opportunities during Construction**

- Whitehorse-Skagway and Faro-Watson Lake Transmission Corridor options: high positive (high opportunities).
- Whitehorse-Atlin and Whitehorse-Teslin Transmission Corridor options: medium positive.
- Stewart-Keno City options: low positive.

ii. **Yukon Opportunities during Operation** - all of the Transmission Corridor options are rated low positive, indicating relatively low local economic impact opportunities.

iii. **Community and Other Development Opportunity**

- Three Transmission Corridor options (Faro-Watson Lake, Aishihik-Destruction Bay, and Stewart-Keno City): high positive (reflecting opportunities to displace local diesel generation (or sustain existing transmission capacity to do this), as well as to facilitate new mining and renewable generation (hydro or wind) development.
- Three remaining Transmission Corridor options (Whitehorse-Skagway, Whitehorse-Atlin, Whitehorse-Teslin): medium positive (reflecting potential local development impacts if the option facilitates renewable generation [pumped storage and small hydro] and, in the case of the Skagway connection, potential sale of summer renewable generation [hydro or wind] to cruise ships).

b. **Climate Change Risk**

i. **Susceptible to Extreme Heat/Drought** - this risk includes increased risk of forest fires:

- Three Transmission Corridor options (Faro-Watson Lake, Aishihik-Destruction Bay, and Stewart-Keno City): yellow (medium).
- Three Transmission Corridor options (Whitehorse-Atlin, Whitehorse-Skagway, Whitehorse-Teslin): green (low) (reflecting the extent that each route covers well developed areas and/or mountain areas).

ii. **Conditions Susceptible to Climate Change**[13]

- Aishihik-Destruction Bay Transmission Corridor: red (high) (risks regarding permafrost).
- All other Transmission Corridor options: yellow (medium).

iii. **All Other Climate Change Risk Indicators** - All Transmission Corridor options are rated yellow for all other Climate Change Risk indicators (medium susceptibility to Extreme Precipitation, to Extreme Wind Events, and to Ice Related Processes/Events).

[13] For discussion of ratings see Table E 3-1.

3.0 SUMMARY AND CONCLUSIONS

This study supports Yukon Energy's current 2016 Resource Plan update by providing a comparative evaluation of more than 45 power generation and transmission resource options in Yukon and northern British Columbia against more than 40 environmental, social and economic indicators.

The evaluation approach displays key differences among the resource options, rather than attempting an overall ranking of these options. The ratings for each criteria and indicator show on a common scale (low, medium, and high) which indicators are particularly relevant to each resource option. A high rating identifies when potential effects on an indicator are high for a specific resource option compared with the other resource options under review at this time. Medium ratings indicate when potential effects on an indicator are medium for a specific resource option, and therefore meriting attention as compared to options with a low rating. The indicators vary in focus; some highlight the need to manage potential adverse effects (where red indicates a high effect and yellow indicates a medium effect), while others highlight the need and opportunity to manage potential positive effects (no colours are used for these positive effect ratings in order to avoid possible confusion with the adverse effect ratings).

No attempt is made in this study to evaluate resource options in the context of forecast grid loads. Resource portfolio option definition and assessment in the context of long-term load forecasts will be done subsequently by Yukon Energy as part of the current Resource Plan update.

The more than 45 electricity resource options reviewed reflect a diverse range of technologies, scales of development, and locations within Yukon and northern British Columbia. Each option's assessment includes consideration of new transmission and/or road access requirements.

Ratings vary for different sets of resource options (e.g., thermal versus non-thermal, wind versus hydro or solar renewables), and for different renewable sites within each set of resource options. Tables 3, 4, 5 and 6 provide a summary of high and medium ratings for each of the major sets of resource options:

- **Thermal Generation Options (Table 3):** Fossil (diesel and LNG) and non-fossil (waste-to-energy, biogas and biomass) thermal generation options have high or medium ratings for only a few indicators:
    - **Environmental Indicators:** Red or yellow (high or medium adverse) ratings for Air Quality indicators for all of these options, and yellow rating for biomass option effects on Wildlife Key Areas. Air emission effects are sensitive to actual operation of the resource options.
    - **Social Indicators:** Yellow (medium adverse) ratings for the Takhini site (fossil thermal options) proximity to First Nation Lands and for biomass option effects on Aesthetics and Land Use and Renewable Resources; medium positive ratings for Community, First Nation and Personal Development indicator for the LNG, waste-to-energy, biogas and biomass options.
    - **Economic Indicators:** High or medium positive ratings for Local Economic Impacts for waste-to-energy, LNG, biogas and biomass options; yellow (medium adverse) rating for biomass option susceptibility to Extreme Heat/Drought.

- **Other Non-hydro Renewable Options (Table 4):** Storage battery, solar PV, wind and geothermal options have high or medium ratings that in many instances may be affected by specific site options:
    - **Environmental Indicators:** Red or yellow (high or medium adverse) ratings for various Terrestrial Species and Habitat indicators and Terrestrial Footprint and Land Area indicators occur for all wind options, one geothermal option, and (for only one indicator) the largest solar PV option.
    - **Social Indicators:** Red or yellow (high or medium adverse) ratings for various Social indicators occur for each of these resource options other than the storage battery option, but ratings for specific indicators typically vary among the different site options for a resource option; high or medium positive ratings for the Community, First Nation and Personal Development indicators occur for seven of eight wind options and for one geothermal option.
    - **Economic Indicators:** High or medium positive ratings for Local Economic Impact indicators occur for all wind options and one geothermal option and red or yellow (high or medium adverse) ratings occur for all wind options and one geothermal option with regard to at least one Climate Change Risk indicator.
- **Hydro Generation Options (Table 5):** Pumped storage, small hydro, Gladstone Diversion, and hydro storage enhancement options have high or medium ratings that in many instances may be affected by specific site options:
    - **Environmental Indicators:** Red or yellow (high or medium adverse) ratings for a range of Aquatic environment and Terrestrial environment indicators occur for all hydro resource options that require modified water regimes, with variations as to ratings among different site options.
    - **Social Indicators:** Red or yellow (high or medium adverse) ratings for various Social indicators occur for all hydro resource options that require modified water regimes, with variations as to ratings among different site options; high or medium positive ratings for the Community, First Nation and Personal Development indicators occur for all pumped storage and small hydro options and the Gladstone diversion option.
    - **Economic Indicators:** High or medium positive ratings for Local Economic Impact indicators occur for all pumped storage and small hydro options and the Gladstone diversion option and red or yellow (high or medium adverse) ratings for all pumped storage, small hydro, Gladstone Diversion and storage enhancement options occur with regard to at least one Climate Change Risk indicator.
- **Transmission Corridor Options (Table 6):** The six transmission corridor options have high or medium ratings that in many instances may be affected by the specific site option:
    - **Environmental Indicators:** Red or yellow (high or medium adverse) ratings for some of the terrestrial environment indicators occur for all transmission options (red ratings apply with regard to all of these options for Footprint Terrestrial Area and Linear Development, and yellow ratings apply for all of these options with regard to Wildlife Key

Areas; red or yellow ratings apply to only some transmission options for some of the other Terrestrial indicators).

- **Social Indicators:** Red or yellow (high or medium adverse) ratings for First Nation Lands and Footprint Land Area Impact occur for all transmission options, and yellow ratings also occur for some of these options with regard to a few other Traditional Lifestyle and Heritage Resources indicators; high or medium positive ratings for the Community, First Nation and Personal Development indicator occurs for all transmission options.
- **Economic Indicators:** High or medium positive ratings for at least one of the Local Economic Impact indicators occur for all transmission options and red or yellow (high or medium adverse) ratings for all transmission options occur with regard to several of the Climate Change Risk indicators.

Table 3: Summary of Thermal Generation Option High & Medium Evaluations

Criteria and Indicators	High	Medium
Fossil Fuel Thermal (Diesel & LNH in Whitehorse Area)		
Environmental		
Air Quality - GHG Emissions (with & without biogenic CO_2)	Diesel, LNG	
Air Quality - Other Emissions		Diesel, LNG
Social		
First Nation Lands		Takhini Site (Diesel & LNG)
Community, First Nation & Personal Development (positive effect)		LNG
Economic		
Community & Other Development Opportunity (positive effect)		LNG
Non Fossil Fuel Thermal (Waste-to-energy and Biogas in Whitehorse and Biomass in Haines Junction)		
Environmental		
Wildlife Key Areas		Biomass
Air Quality - GHG Emissions (with biogenic CO_2)	WTE, Biogas, Biomass	
Air Quality - GHG Emissions (without biogenic CO_2)		WTE, Biogas
Air Quality - Other Emissions		WTE, Biogas, Biomass
Social		
Aesthetics, Land Use & Renewable Resource Plans		Biomass
Community, First Nation & Personal Development (positive effect)		WTE, Biogas, Biomass
Economic		
Yukon Opportunities - Operation (positive effects)	WTE	
Community and Other Development Opportunity (positive effect)		WTE, Biogas, Biomass
Susceptible to Extreme Heat/Drought		Biomass

Table 4: Summary of Other Non-Hydro Renewable Option High & Medium Evaluations

Criteria and Indicators	High	Medium
Environmental		
Terrestrial Species at Risk & Habitat		All W sites ex Tehcho
Protected & Conservation Areas	G (McA S site)	W (Kluane L)
Wildlife Key Areas	W (Kluane L, Mt.Sumanik, Sugarloaf M)	W (Miller's R, Tehcho, Thulsoo M), G (McA S site)
Caribou Ranges		W (Cyprus Mine H, Miller's R, Sugarloaf M), G (McA S)
Footprint Land Area	All W, G (McA S site)	
Linear Development for Roads/Transmission		W (all sites), G (McA S site)
Social		
First Nation Lands	W (Kluane L, Sugarloaf M)	W (Miller's R), G
Footprint Land Area Impact	All W sites ex Kluane L, G at (McA S)	S sites, W (Kluane L), G (Vista M)
Importance/Cultural Importance of Heritage Resources		All W (ex Cyprus M, Kluane L), G (McA S)
Recreational Values, Tourism Values		W (Kluane L, Miller's R, Thulsoo M for rec.), G (McA S)
Aesthetics, Land Use & Renewable Resource Plans	G(McA S site)	W (Kluane L for aes., Miller's R, Thulsoo M)
Non-Renewable Resources, Other Renewable Resources		W (Thulsoo M for non-renewable), G (McA S)
Infrastructure & Services		All W (ex M Sumanik), G (McA S)
Public Safety, Worker Interaction & Community Health		All W (ex M Sumanik), G (McA S)
Community, First Nation & Personal Development (positive effect)	W (Kluane L, Sugarloaf M)	All W (ex M Sumanik, Kluane L, Sugarloaf M), G (McA S)
Economic		
Yukon Opportunities - Construction (positive effect)		W (Kluane L), G (McA S)
Yukon Opportunities - Operation (positive effect)	W (Kluane L, Sugarloaf M)	All W (ex Kluane L, Sugarloaf M), G (McA S)
Community and Other Development Opportunity (positive effect)	W (Kluane L, Sugarloaf M)	All W (ex M Sumanik, Kluane L, Sugarloaf M), G (McA S)
Susceptible to Ice-Related Processes/Events	W (all sites ex Kluane L)	
Susceptible to Extreme Wind Events		All W
Conditions Susceptible to Climate Change (permafrost risk)	W (Kluane L)	G (McA S)

Key: **Storage Battery (SB) in Whitehorse,**
Solar PV (S) in Whitehorse and Haines Junction,
Wind (W) at seven different sites, and Geothermal (G) at two sites.

1.0 INTRODUCTION

This appendix provides a summary of key information for resource options that is relevant to the evaluations, including identification of the specific sites and cases to be evaluated and the relevant report information to be utilized.

The project summaries are based on publicly available information and information from inventoried resource option project reports supplied by Yukon Energy Corporation (Yukon Energy). Geographic information system (GIS) and mapping information on each site option and its footprint (including road access and transmission interconnection) that is currently available for each resource option has been provided by Yukon Energy separately as required for each member of the Study Team to proceed with the resource options evaluation.

The current Resource Plan focuses in most instances on generation options that do not exceed 20 MW in scale. Referenced resource option project reports often examine a range of sites, scales of development, and different financial attributes, including interest cost assumptions. In order to simplify the resource options evaluation, key information for each resource option has been limited or assumed as noted below:

- **Sites** - Sites used for the evaluation of each resource option, when identified, are limited to those specifically noted below. In cases where referenced resource option project reports screened a wide range of site options, the following resource options evaluation typically focuses on the short list of top-ranked sites identified in the reports.
- **Linkage with Required Transmission Corridor Developments** - Referenced generation resource option reports include transmission interconnection to the grid as required for development of each site option; however, in several instances, the scope for the referenced report assumes separate development of a new transmission corridor that has been examined separately. For the purpose of the current resource options evaluation, it is necessary to highlight where a generation site development option presumes development of a new transmission corridor and/or an added transmission connection to the current grid (and to identify the linked transmission connection so that it is evaluated concurrently with the generation site option).
- **Development Scale** - Where a range of scales for development (e.g., MW or GWh/year) was examined in a referenced resource option project report, the following resource options evaluation focuses on one scale (usually the largest scale examined). In some cases (e.g., geothermal resource options), where uncertainty exists regarding the potential scale for development (due to the need for further site investigation), the resource options evaluation for convenience adopts where relevant the average of the potential scales that have been identified. For some pumped storage site options, two scales of development are included in the evaluation. For solar PV options, various scales of development for each site are included in the evaluation.
- **Utilization of Resource Options** - The resource options evaluation is being done without reference to any forecast grid load or economic opportunities for new generation or transmission, i.e., each renewable resource option (regardless of scale) is assumed to be fully utilized, unless it is designed to be dispatchable in response to load requirements (e.g., fossil or biomass thermal

generation). In practice, final selection of any resource option for development would require evaluation of its ability to supply forecast grid capacity and energy loads (including provision to meet capacity reliability requirements) on a least cost basis relative to all other available resource options.

- **Weighted Average Cost of Capital for Resource Development** - All resource options are assumed for this evaluation to be developed by Yukon Energy (rather than another party) at the Yukon Energy weighted average cost of capital (WACC) specified for the resource option reports, i.e., 3.38%/year real cost of capital (net of inflation). This WACC is used in the referenced resource reports to define one case for Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for each resource option over its assumed economic life (assuming full utilization of the resource over this period).

Summaries are grouped by four general sets of resource options as follows (as noted, there are multiple resource options within each set, and several of these resource options include multiple sites, i.e., approximately 51 different options overall are identified for discussion in this appendix):

1. **Fossil Fuel Thermal Generation:** (two resource options [diesel and LNG], each in Whitehorse - two sites are examined for each).
2. **Non-hydro Renewable Generation:**
    a. **Non-fossil Thermal Generation** (three resource options: biomass in Haines Junction, biogas in Whitehorse, and waste-to-energy [WTE] in Whitehorse);
    b. **Energy Storage Facility** (batteries) in Whitehorse;
    c. **Solar PV** (two site options are examined: Haines Junction and Whitehorse, each with various scales of development [total of five options]);
    d. **Wind Farms** (seven site options are examined); and
    e. **Geothermal** (two site options are examined).
3. **Hydro Renewable Generation:**
    a. **Pumped Storage** (nine site options are examined; two site options include two scales of development);
    b. **Small Hydro Projects** (five site options are examined, one of which is run-of-river and four of which include storage);
    c. **Gladstone Diversion** (feasibility work was done separately from the current Resource Plan, the project would enhance hydro generation at Aishihik);
    d. **Hydro Storage Enhancements** (two options: Mayo Lake Storage Enhancement to improve winter generation at Whitehorse Hydro [YESAB submission already been prepared], and Southern Lakes Storage Enhancement to improve winter generation at Mayo Hydro [considerable assessment and feasibility work has been done separately from the current Resource Plan]);
    e. **Mayo Lake Outlet Channel Dredging** (ongoing investigation of issues and options related to sediment build up in Mayo Lake Outlet Channel); and

f. **Refurbish Existing Hydro Generation** (two options: Mayo A Refurbishment, and Aishihik Re-runnering).

4. **Transmission Corridor Options:**

   a. **New Transmission Corridors** (five options are examined - several of these would facilitate specific pumped storage and small hydro project sites, as well as one wind site. In several instances, segments of a project would enhance an existing transmission corridor); and

   b. **Stewart-Keno Transmission Project** - (this project, which enhances an existing transmission corridor wherein a major segment is at end-of-life, has recently completed YESAB review and recommendation).

Each resource option project summary only includes information relevant to the current assessment and aims for simplicity across all projects. The information also reflects the specific stage of each Yukon Energy resource option report, i.e., many reports provided to the study team were still at draft stage and may have been materially changed thereafter in the process of being finalized.[1]

For convenience, a final section provides a summary of the specific options to be included in the current resource options evaluation.

[1] Cost estimates and LCOE estimates in particular may change materially between draft and final reports, and therefore specific numbers provided in this report may not reflect final numbers that are provided to Yukon Energy in other referenced reports. Given the broad rating approach used for this evaluation study, it is not expected that updated costs for specific projects would materially change ratings and conclusions in this evaluation study.

2.0 FOSSIL THERMAL GENERATION

A Stantec report is available for fossil fuel thermal generation ("2016-007 - Thermal Energy Plant Development Study", November 21, 2016).

Stantec examined stand-alone, greenfield installation on a four hectare parcel of new diesel or natural gas (LNG) thermal generation adjacent to brownfield sites in Whitehorse that are not near the existing Whitehorse Generating Station. The two sites examined were the Whitehorse Landfill (assumes use of brownfield land, owned by the City of Whitehorse near the McIntyre substation) and the Mayo Road Substation (a vacant greenfield site on Commissioner's Land adjacent to Takhini S164). Based on the potential site locations selected for the study, there are no existing potential heat customers nearby.

Plant capacities were examined at each site at 5 MW, 10 MW and 20 MW. These resource options provide dispatchable generation with no requirement for high utilization, waste heat sales or subsidy support in order to be economic (waste heat use and boil off gas use [for LNG storage] may be considered when such options are relevant).

The current resource option evaluation focuses only on the 20 MW options at each site:

- Diesel thermal generation has similar capital cost estimate ($62.2 to $62.5 million) at each site for 20 MW. Site layouts were provided for each site.
- Natural gas thermal generation has similar capital cost estimate ($100.0 to $100.1 million) at each site for 20 MW. Site layouts were provided for each site.

Assumed economic life for fossil thermal generation units is very dependent on assumed annual use levels, reflecting the adaptability and reliability of this option. Full use averaging 95% of capacity at 20 MW would provide 166.4 GWh/year for an assumed 20 year economic life (per the Stantec report). Fossil thermal generation on Yukon Energy's hydro grid, however, tends to provide backup generation for peak, winter, emergency or drought period use, resulting in low average annual generation and an economic life of 40 years.

The Stantec report estimated annual O&M costs (excluding fuel) for a 20 MW reciprocating engine facility at $1.19 million, excluding insurance, property taxes or asset management. This estimate assumed high annual usage of the facility (e.g., average 95% capacity factor for each year). Retaining the same use levels and a 20 year life for 20 MW options (WACC at 3.38% real), the Stantec report estimated LCOO at $349-$350/kW for natural gas generation and $217-$218/kW for diesel generation (lower cost for Takhini site). LCOE excluding fuel was estimated based on these same assumptions at $0.049/kW.h for natural gas generation and $0.033/kW.h for diesel generation.

Fossil fuel thermal generation includes material waste heat that is potentially available for heating uses that could displace other fossil fuels. However, such waste heat use tends to be uneconomic unless the thermal generation is expected to be operated throughout periods when the waste heat is required and the thermal generation is also located relatively close to a site able to use the waste heat. In light of these considerations, Yukon Energy's current resource studies have not examined waste heat use options for fossil fuel thermal generation.

3.0 NON-HYDRO RENEWABLE GENERATION

3.1 NON-FOSSIL FUEL THERMAL GENERATION

Three resource options are included in this resource option grouping for non-fossil thermal generation: waste-to-energy at Whitehorse (1.6 MW, no specific site), biomass at Haines Junction (0.5 MW if rely only on beetle-kill biomass, a site identified near school), and biogas at Whitehorse (0.2 MW, located at municipal landfill). Although these options are each technically dispatchable, economic assessments assume full utilization, i.e., these options are not suited to peaking or backup generation use. With the exception of biogas, Yukon Energy assessments of these options have assumed high levels of waste heat use in order to enhance project economics.

Overall, each of these options involves a small scale facility in either Whitehorse or Haines Junction that would be economically feasible only with material waste heat sales for biomass and WTE, tipping fees for WTE and biogas, and material capital cost subsidy for biomass and biogas.

There is limited basis for providing detailed environmental or social evaluations of these resource options, and GIS-related site details are not relevant to the current resource options evaluation.

For reference, the following summary information is noted for each of these resource options:

- **Waste-to-Energy Generation (WTE)** plant in Whitehorse (Morrison Hershfield [MH] report, "Waste to Energy Updated Design Basis and Business Case Analysis", April 24, 2012 for 1.6 MW plant option generating 9,975 MWh/year with controlled-air two-stage technology; Nov. 13, 2015 MH letter reviewing business case). The following are summarized from these MH reports:
    - The option assumes use of municipal solid waste (MSW) as fuel, augmented with higher cost wood biomass during winter when MSW volume is reduced, and potential to use waste heat from the electricity generation in a future District Energy System (DES).
    - Available MSW volumes was assumed to be reduced significantly coinciding with Zero Waste program in the City's Solid Waste Action Plan (City of Whitehorse 2013). Wood biomass was assumed to be obtained from a variety of sources (including spruce beetle-killed wood, local brushing and clearing, construction and demolition waste).
    - It was considered premature to select a 2 ha site for this option within Whitehorse (the 2012 report assumed site in the Marwell Industrial area because of proximity to potential heat customers, access to municipal services and compatibility with adjacent land uses).
    - Revenues from this option in the 2012 business case analysis were highly dependent on revenues from both MSW tipping fees (assumed $108 per tonne of MSW received) and sale of heat to a future DES in Whitehorse ($81/MWh derived from a DES study completed for Yukon Energy in 2013, "Whitehorse Community Energy Project: Community Energy System Feasibility Study Report", FVB Energy Inc).

- Base case cost of power was estimated at $0.31/kWh, assuming a 25 year economic life.[2] This cost would be lower if able to secure federal grants for about 39% of the capital cost ($0.21/kWh was estimated).
- WTE facilities have emissions to air, land and water (in the form of stack emissions, ash and waste water). Air emissions controls can account for up to one-third of facility capital costs. The most probable carbon credit opportunities are for emissions avoided from the displacement of fossil fuel electricity generation and oil and propane for heating.
- The facility has an annual water demand of 14,500,000 litres.

- **Wood Biomass Generation** plant near Haines Junction (Stantec report, "Final FEED Report, Front End Engineering Design [FEED] Study, Yukon Bioenergy Demonstration Project in Haines Junction. Yukon", Oct. 18, 2013; Jan. 15, 2016 "Biomass Technology Update" Stantec letter).

  The following are summarized from the 2016 and 2013 Stantec reports (for the current resource option evaluation, only the smaller 0.5 MW option [using 3,000 oven dry tonnes/year] is considered as it is likely able to proceed solely using beetle-kill biomass, plus forest harvest and sawmill residues):

  - A screening assessment was provided for options in the range of 0.5 to 2.0 MW, using gasification technology to combust biomass (wood chips) to heat a fluid for use in a turbine-generator. Beetle-kill biomass would offer a much lower moisture content (15%) than green (live) biomass (50%). The smaller plant option could likely be supplied with minimal impact to existing operators/policies (sawmill residues and forest harvesting residues, mostly dead trees from the spruce beetle infestation until that supply runs out); in contrast, the larger plant operation would require additional biomass supplied by new harvesting operations/policies and would extend into harvesting green trees sooner.
  - The 2013 Stantec report considered plant siting, noting the likely need to consider waste heat use options and a 400 m buffer zone around buildings that could use the waste heat. A location near the school was recommended to capture the school waste heating load.
  - A conventional boiler/steam turbine option was estimated (2016 Stantec) to have the following characteristics for the 0.5 and 2.0 MW scales (two other technology options were also examined):
    - Annual net generation 3,224 MWh to 14,708 MWh;
    - Capital cost of $11.3 to $14.9 million;
    - Annual operations and maintenance (O&M) cost of $615,000 to $750,000, excluding any biomass feedstock cost; and
    - A 20-year economic life is assumed.

[2] Assumed capital cost of $34.6 million (annual capital cost of $2.6 million assuming 25-year life and 5.5% interest), non-fuel operating cost of $3.3 million/year (including 18 staff), wood biomass cost of $0.8 million/year (7,652 wet tonnes/year), heat sales revenue of $1.9 million/year ($81/MWh), and tipping fees revenue of $1.7 million/year (16,098 tonnes MSW/year). Absent sale of waste heat the cost of power would be higher at $0.34/kW.h (with 625/kWh per tonne of biomass or 14,844 MWh/year and 2.0 MW capacity).

- Assuming full utilization of the energy provided, financial viability depends on subsidization of a large portion of the initial capital cost (2013 Stantec).
- The 2013 Stantec report included a draft Environmental and Socio-economic Impact Assessment.

- **Biogas Generation** plant in Whitehorse (WSP Canada Inc. [WSP], "Biogas Plant in Whitehorse, Feasibility Study", January 2016). The following are summarized from the 2016 WSP report:
  - The plant of about 200 kW capacity, with annual energy initially at about 0.4 GWh (increasing over 20 year life) would treat residential and commercial source separated organic (SSO) waste and utilize the biogas to produce power and/or heat. About 65% of generation would be in the warmer months from May to October.
  - The plant would be located at the Whitehorse municipal landfill next to the existing composting site (footprint of about 1800 m^2). Waste heat sale is not recommended given the location and seasonality issues.
  - Estimated capital cost is $7.1 million, with annual operating cost of $255,000.
  - Revenues would come from gate fees (assumed $38/tonne), electricity sales (assumed $0.21/kWh) and heat savings (assumed $12/GJ). Based on current market price assumptions, the project is not viable and would require significant capital subsidy support (e.g., 70%).

3.2 ENERGY STORAGE FACILITY (BATTERIES)

Energy storage facilities can enhance opportunities for renewable generation options that may be affected by interruptions to the resource, e.g., solar and wind. Non-hydro energy storage options were examined as part of the current Resource Plan. Pumped storage hydro options have been examined separately (see Section 4.1 below).

Trans Grid Solutions Inc. (TGS) provided Yukon Energy with a report "Energy Storage Technologies," April 18, 2016 that examined a wide range of energy storage options, including mechanical, chemical, electrochemical, high temperature batteries, electrical field, magnetic field and thermal. The report identified the following electrochemical battery technology options as the optimum options using lead acid batteries or lithium ion batteries to supply power and energy demands during peak load conditions, as well as mitigating power quality concerns on the grid:

- 3 lead acid based systems rated at 4 MW/40 MWh, 6 MW/60 MWh, and 8 MW/80 MWh; and
- 1 lithium ion based system rated at 8 MW/40 MWh.

Over an assumed 30 year life all of these Battery Energy Storage System (BESS) options had significantly higher costs compared to their respective benefits.[3] The smallest lead acid based system and the lithium

[3] Capital cost (including replacements and balance of plant) estimated at $39.1 million for lead acid based system (4000 kW, 10h) and $49.5 million for lithium ion system (replacements needed in 15 and 20 years respectively at $17.4 million and $22.1 million). Annual O&M at $210k and 260k per year respectively. Annual energy use estimated at 2.4 GW.h for lead acid based system and 2.8 GW.h for lithium ion system (about 60 and 70 days of operation respectively). LCOE in nominal values (5.45% WACC) estimated at

ion system had the best net present values. Footprints for these two facility options approximate 6,400 m^2 and 4,200 m^2, respectively. No specific site option was specifically examined, but Yukon Energy advises that this resource option is assumed to be located at the Takhini Substation (the facility footprint would be about 15% larger than can be accommodated on the existing substation site and some adjacent land already zoned for utility use would be required).

It is not expected that this option will require material evaluation under environmental, social or economic criteria in the existing study.

3.3 SOLAR PV

The Solvest final report is available for the utility scale photovoltaic (PV) solar energy resource option ("Solar Site Inventory," May 2016). Review of solar resource irradiance data for various communities in Yukon showed a variance of only 9% across all communities connected to the grid and only 6% variance from Whitehorse. Based on this information, two communities were selected (Whitehorse and Haines Junction) in order to control construction costs and keep the facility close to existing electrical infrastructure and points of use.

The Solvest report examines a range of PV technologies for modules, inverters and racking. Solar efficiency declines with lower temperatures. Overall, for both sites and the range of solar plant scales, the report indicates the lowest LCOE generally occurs with First Solar cells, the central inverter from ABB, and fixed tilt racking.[4] Plant scales were examined at 1 MW, 5 MW and (for Whitehorse site only due to site limits) 10 MW, assuming the above technology combination as a reflection of lowest LCOE cost. The 10 MW option displayed higher LCOE due to added complexities and the need to incorporate batteries.

Table A 3-1 summarizes the available information on energy production and economics for the options at each site with the lowest LCOE. Annual energy production for these options tends to range between 10% and 15% of installed capacity. The report provides a breakdown of this energy production by month, highlighting that low production can be expected during November through February (due to both sun availability and cold temperatures).[5]

The following summary information is provided on the two selected sites (global positioning system [GPS] coordinates are provided in the Solvest report for each site):

- **Whitehorse Quarry Site (120 acres, with about 110 acres useable for solar farm configuration)** - Located on the old tailings pile for the Whitehorse Copper Mine within Whitehorse city limits, with established road access and 120 acres of open land with minimal fluctuations in elevation across the pile. The site is 2.8 km from Mount Sima substation (connection will be at 34.5 kV). Estimated site area required for the option with the lowest LCOE i.e., First Solar with ABB central inverter at 1 MW is about 11 acres, at 5 MW is about 51.2 acres with fixed tilt tracking (71.2 acres with single axis tracking), and at 10 MW is about 102.4 acres

---

$1.01/kW.h and $1.06/kW.h respectively. [LCOE in real terms (3.38% WACC) would approximate $0.79/kW.h and $0.83/kW.h respectively.]

[4] The report suggests that this technology option with single axis tracking for 5 MW at the Haines Junction site may yield a very slightly lower LCOE ($0.141/kW.h) than with fixed tilt tracking ($0.142/kW.h).

[5] Information in the report suggests that irradiation is relatively strong in March through August.

with fixed tilt tracking (142.4 acres if using single axis tracking, i.e., single axis tracking with 10 MW First Solar does not fit on this site - only Sunpower, Panasonic HIT, or Prism Bi-facial would fit with single axis tracking).

- **Haines Junction Site North of Dump (65 acres, with about 55 acres useable for solar farm configuration)** - Located 1 km from the Haines Junction dump, in a largely open area with thin tree cover, minimal fluctuation in elevation across the site, and close proximity to the highway (500 m) and substation (3.4 km). Estimated site area required for the option with the lowest LCOE at 1 MW is about 11 acres, and at 5 MW is about 51.2 acres (71.2 acres if use single axis tracking, i.e., single axis tracking with 5 MW First Solar does not fit on this site - only Sunpower, Panasonic HIT, or Prism Bi-facial would fit with single axis tracking).

Table A 3-1: Solar PV Energy Production & Economics (2015$)
(Assumes First Solar Cells, ABB Central Inverter - 30 year life)

Solar Site Option	Net MW	Annual Energy GWh/year[1]	Average Capital Costs ($million)	Average O&M Costs ($million year 1)	LCOC ($million/MW-year)	LCOE ($/kWh)
Whitehorse (with fixed tilt tracking) Heliene Poly[2]	1 MW 5 MW 10 MW	1.076 5.239 11.471	$3.3 $12.7 35.6	0.0315 0.1426 0.3732	$0.658 $0.491 $0.804	$0.174 $0.141 $0.200
Haines Junction (with fixed tilt racking)	1 MW 5 MW	1.111 5.232	$2.9 $12.8	$0.0315 $0.1426	$0.553 $0.493	$0.147 $0.142

Notes:
1. Energy production is reduced materially from September through February, i.e., estimates indicate only 21% to 26% of annual energy for these options occurs in six months from September to February inclusive, and about 50% to 52% of annual energy in 5 months from June to October inclusive. Peak energy generation is in March-May period (37% to 41% of total annual generation is in these three months).
2. Heliene Poly is lowest LCOE of 10 MW options at Whitehorse with an estimated LCOE. Report does not provide cost or energy estimates for First Solar option at 10 MW at Whitehorse.

3.4 WIND FARMS

The Canadian Biomass Energy Research Ltd. (CBER), with ENVINT Consulting and V3 Energy, LLC, provided Yukon Energy with a final report on wind farm options ("Yukon Wind Site Inventory", August 24, 2016), identifying five potential new wind project sites near existing and planned power infrastructure plus the Tehcho and Mt. Sumanik sites, which Yukon Energy had previously examined in some detail.

Wind farms include the following infrastructure: towers with turbines, access road, turbine road, and transmission line to connect to the grid. The CBER study developed estimates of annual net generation, capital costs and annual operating costs for each of the seven identified sites at 6 MW, 10 MW and 20 MW scales of development. The CBER study provided estimates of monthly distribution of annual generation at each of the seven sites, indicating a clear pattern for each site of lower monthly mean power production during the summer months compared to winter (on average, three-fourths of wind energy generated for the seven sites would be during the seven months from October to April). The

study commented on reliable capacity contributions from wind farms[6], but did not address the potential requirements for other new facilities on the grid for reliability requirements.[7]

The current evaluation assumes the 20 MW capacity case from the CBER study for each site option, with 10 turbines each of 2 MW capacity with a 90-metre rotor diameter, and 80-metre hub height. For the representative wind turbine layouts provided in the CBER study, an approximate turbine separation of five rotor diameters, or 450m, was consistently assumed and was reported to be the conservative end of the three to five rotor diameter separation ranges generally recommended within the wind power industry for turbines oriented perpendicular to the prevailing wind.

The following seven short-listed 20 MW wind farm sites from the CBER report are to be evaluated (GIS information has been provided on these sites). See Table A 3-2 for summary of generation, capital cost, O&M annual cost, and LCOE for each site over an assumed 25 year life. Information on long-term average power generation by month will be provided in future.

- **Cyprus Mine Hill** - Located north of Faro mine on a brownfield site previously developed for this mine with 7.6 km transmission line to existing transmission and 12.5 km access road and turbine road.
- **Kluane Lake (west shore)** - Located on west side of Kluane Lake, northwest of Haines Junction and south of Destruction Bay, with transmission at 58.6 km to Haines Junction and 21.4 km underwater. Costing in Table A 3-2 assumes that the required transmission from the wind farm to the grid is developed independently of this wind farm project, e.g., the Aishihik-Destruction Bay transmission corridor would address this requirement. The CBER report indicates that this is the only relatively low elevation location in Yukon with projected high wind speeds, and it is at much lower elevation than the six other shortlisted sites. CBER notes that the lower elevation would mean that the wintertime rime icing that would be an operational challenge at the higher elevation sites would likely not exist at Kluane Lake or be significantly less problematic.
- **Miller's Ridge** - Located west of (and close to) Carmacks, with 13.6 km transmission to grid and 8.19 km access road and turbine road.
- **Sugarloaf Mountain** - Located south east of Carcross, with 3.77 km transmission to grid and 5.57 km access road and turbine road.
- **Mount Sumanik** - Located northwest of (and close to) Whitehorse, with 3.13 km transmission to grid and 10.64 km access road and turbine road. Yukon Energy has prior studies on this site.
- **Tehcho (Ferry Hill)** - Located north of (and close to) Stewart Crossing, with 3.30 km transmission to grid (upgrade) and 3.79 km access road and turbine road. Yukon Energy has prior studies on this site option.

[6] The study estimated reliable winter capacity as being equal to the mean annual power output, and estimates (based on all seven wind farms examined) that this would equal 5.2 MW (26% capacity factor) for a 20 MW wind farm. The study noted that additional wind farms would lower the capacity credit per farm but could also increase the ability of wind to provide base load power (firm capacity) when they are geographically distant.

[7] The 2011 Yukon Energy Resource Plan assumed that a 5 MW diesel rotary uninterruptible power (DRUPS) unit would be required for a 20 MW wind farm connection to provide for grid reliability requirements.

- **Thulsoo Mountain** - Located close to the Aishihik hydro generation station, with 10.6 km transmission to grid and 12.75 km access road and turbine road.

It has been noted by Yukon Energy that Kluane Lake and Tehcho are sites that obviously require clearing. To the extent other sites are located on mountain ridges, less clearing may be required for the turbines. The Cyprus Mine site is a brownfield site.

Table A 3-2: Wind Farm Sites Energy Production & Economics (2015$) (25-year life)[8]

Wind Site Option	MW	Annual Net Capacity Factor[1] (%)	Annual Net Energy GWh/year	Capital Costs ($million)	O&M Costs ($million/year)[3]	LCOC ($million/MW-year)	LCOE ($/kWh)[3]
Cyprus Mine	20 MW	28.3%	49.6	69	1.360	N/A	0.117
Kluane (ex. trans. to grid)[2]	20 MW	27.3%	47.8	62	1.307	N/A	0.110
Miller's Ridge	20 MW	32.7%	57.3	73	1.442	N/A	0.107
Sugarloaf	20 MW	18.4%	32.3	62	0.984	N/A	0.153
Sumanik	20 MW	23.7%	41.5	64	1.119	N/A	0.124
Tehcho	20 MW	19.1%	33.4	64	0.972	N/A	0.151
Thulsoo	20 MW	31.0%	54.4	72	1.390	N/A	0.109

Notes:
1. CBER estimates of annual average wind generation per site, less wake loss, and losses for de-icing electricity and turbine stalling, low-temperature downtime, transformer losses, sub-optimal performance, and maintenance.
2. Costs exclude capital and O&M adjustments for transmission connection from the local area to the grid (see Section 5.1 of this Appendix for current cost estimates).
3. O&M costs based on variable O&M costs for first five years at $15/MW.h gross generation (2015$) without provision for expected increases of variable O&M costs thereafter (the study estimates that variable O&M costs [2015$] will increase to $25/MW.h from years 6 to 10 and then to $30 after that).

3.5 GEOTHERMAL

The KGS Group provided YEC with a final report for the geothermal resource option ("Geothermal Review and Site Inventory", September 2016). After review of available information, this study concluded that two sites (Vista Mountain and McArthur Springs) have the largest production capacity for sites located close (i.e., within about 25 km) to Yukon Energy's existing and future planned grid infrastructure. As the exact amount of production capacity is unknown (i.e., no exploration wells have been drilled yet at either site), a best and worst case scenario (in terms of water production) was considered for each location.

A geothermal facility at either site includes the plant site (building and related fenced area), two production wells and one induction well (the wells are about 1 km apart), plus the access road and transmission connection to the grid. Geothermal production capability is higher in winter (lower temperatures) than in summer (the report provides generation by month). Energy generation and

[8] Estimates are per Tables 8 and 18 and Appendix D of CBER study.

capacity degenerate over time unless added maintenance wells are drilled - the study assumes 2% per year degeneration over an assumed 30 year project life. Operating employment is estimated at a half-time FTE for each plant option.

The following summary information is noted for the two site options identified (see Table A 3-3):

- **Vista Mountain** - This site requires about 5 km of new transmission (34.5 kV) for connection to the existing grid. It is close to the Whitehorse load centre, the existing Klondike Highway and the Takhini substation. It is located on Crown land and has the highest inferred temperature of options examined within 25 km of existing infrastructure. The plant site footprint is estimated to range from 1,840 to 2,900 m^2 (depending on the ultimate capacity that is confirmed).

  Expected plant annual average net capacity in first year of operation ranges from 0.9 MW to 2.3 MW (low and high estimates), with initial annual energy generation ranging from 8.15 GWh/year to 20.95 GWh/year (after 30 years this degenerates to the range of 4.54 GWh/year to 11.66 GWh/year). Average annual energy over the 30 year life is 11.03 GWh/year. Project capital cost for this range of capacity is $37.8 million to $45.2 million, and annual fixed operating costs range from $0.35 million to $0.8 million (2015$).

  LCOE estimates (2015$) over the 30 year life at 3.38% WACC range from $0.194 to $0.368 per kWh, depending on plant capacity, with the highest LCOE cost being associated with the low capacity.

- **McArthur Springs** - This site was the most promising of the options reviewed (highest inferred temperature), but it is located more than 25 km from the existing grid (estimated transmission and road development connection distance of 43 km with transmission at 138 kV). The site is located east of Highway no. 2, southeast of Stewart Crossing. It is located within the Ddhaw Ghro Habitat Protection Area, in an area designated for mine development by Selkirk First Nation. The plant site footprint is estimated to range from 2,900 to 5,000 m^2 (depending on the ultimate capacity that is confirmed).

  Expected plant annual average net capacity in first year of operation ranges from 2.1 MW to 5.5 MW (low and high estimate), with initial annual energy generation ranging from 18.62 GWh/year to 48.24 GWh/year (after 30 years this degenerates to the range of 10.37 GWh/year to 26.85 GWh/year). Average annual energy over the 30 year life is 25.33 GWh/year. Project capital cost for this range of capacity is $114 million to $127 million, and annual fixed operating costs range from $0.8 million to $1.8 million (2015$).

  LCOE estimates (2015$) over the 30 year life at 3.38% WACC range from $0.225 to $0.469 per kWh, depending on plant capacity, with the highest LCOE cost being associated with the low capacity estimate.

Table A 3-3: Geothermal Site Production & Economics (2015$) (30-year life)

Geothermal Site Option	Net MW (Average annual, initial year)[1]	Annual Energy GWh/yr. (initial year)[1]	Capital Costs ($million)	O&M Costs ($million/ year)	LCOC ($million/ MW-yr.)	LCOE ($/kWh)
Vista Mountain	0.9 to 2.3 MW Average 1.6 MW	8.15 to 20.95 GWh 1st yr. Average 14.55 GWh Lifetime average 11.03 GWh	$37.8 to $45.2 Average $41.5	$0.350 to $0.8 Average $0.575	$1.1 to $2.3 Average $1.71	$0.19 to $0.37 Average $0.281
McArthur Springs	2.1 to 5.5 MW Average 3.8 MW	18.62 to 48.24 GWh 1st year Average 33.43 GWh Lifetime average 25.33 GWh	$114 to $127 Average $120.5	$0.8 to $1.8 Average $1.3	$1.4 to $3.2 $2.30	$0.22 to $0.47 Average $0.347

Note:
1. Net capacity and annual energy degenerate at 2%/year over 30 year life; net capacity is higher in winter than in summer.

4.0 HYDRO RENEWABLE GENERATION

4.1 PUMPED STORAGE PROJECTS

Pumped storage resource options are identified below from three separate sets of reports.

Knight Piesold Report

Knight Piesold Consulting (KP) provided Yukon Energy with a report on pumped storage options ("Pumped-Storage Assessment, Preliminary Assessment", September 30, 2016), identifying viable pumped storage sites (outside parks and protected areas) within a 25 km radius of existing and proposed transmission infrastructure.

The pumped storage sites were assumed in the KP assessment to provide seasonal pumping from May through to September and seasonal generation from October through to April. Aside from an assumed variable O&M cost of $0.005/kWh, energy required for pumping is assumed in the KP report to have no cost, implicitly assuming adequate surplus renewable energy on the grid from May through September. Surplus renewable energy on the Yukon grid is affected by assumed grid loads, long-term average hydro generation by season, and renewable wind or solar generation. With current renewable generation, seasonal surplus generation is typically focused in the period from late May to early November.

Out of 473 potential reservoir basins and approximately 200 technically viable sites, the following 7 sites were selected by KP for further evaluation (see Table A 4-1 below for summary of capacity and energy options assessed by KP for each site that is retained for the current evaluation, including pumping annual energy requirements, resulting capital and O&M cost estimates, and resulting LCOE and LCOC estimates):[9]

- **Tutshi-Moon** - located near Tutshi Lake, BC (study assumed existence of Whitehorse-Skagway transmission corridor only 2.6 km from site. Without this line, the distance to the nearest point of intersection increases by approximately 35 km and that would only connect to the 34.5 kV network).
- **Racine-Moon** - located near Racine Lake, BC (study assumed existence of Whitehorse-Skagway transmission corridor 20.6 km from site. Without this line, the distance to the nearest point of intersection increases by approximately 35 km and that would only connect to the 34.5 kV network). KP only examined the 50 GWh/year option for this site.
- **Racine-Mt. Brown** - located near Racine Lake, BC (study assumed existence of Whitehorse-Skagway transmission corridor 24 km from site. Without this line, the distance to the nearest point of intersection increases by approximately 35 km and that would only connect to the 34.5 kV network).

[9] KP did not show comparative areas for natural versus flooded for these options. Reservoir areas with each project site show increase for the upper reservoir area in some cases if examine 100 GWh versus 50 GWh options, e.g., Tutshi-Moon goes from 500 to 61 ha, Racine-Mt. Brown goes from 210 to 290 ha, and Atlin-Black mountain goes from 230 to 313 ha; however, the lower reservoir changes are generally much more muted for these three sites when the larger option is examined.

- **Lindeman-Fraser** - located near Fraser, BC (study assumed existence of Whitehorse-Skagway transmission corridor only 5 km from site. Without this line, the distance to the nearest point of intersection increases by approximately 45 km and that would only connect to the 34.5 kV network). KP only examined the 50 GWh/year option for this site.
- **Atlin-Black Mountain** - located near Atlin, BC (study assumed existence of Whitehorse-Atlin transmission corridor within less than 1 km from site. Without this line, the distance to the nearest point of intersection increases by over 40 km and that would only connect to the 34.5 kV network).
- **Squanga-Dalayee** - located between Johnson's Crossing and Jake's Corner, Yukon (study assumed existence of Whitehorse-Teslin transmission corridor less than 2 km from site (the existing transmission is 34.5 kV). KP only examined a 100 GWh storage option for this site.
- **Canyon-Ittlemit** - located near Canyon Lake and the Aishihik Hydro Facility, Yukon (transmission connection 13.9 km to existing 138 kV grid). KP only examined a 100 GWh storage option for this site.

The KP report concluded as follows with regard to pumped storage site options and configurations:

- Tutshi-Moon site option was the most cost-effective option for all cases examined. The Atlin-Black Mt. and Racine-Mt. Brown options also have similarly competitive costs, particularly for the 50 GW.h configurations.
- Racine-Moon and Lindeman-Fraser site options have technical constraints that make them less promising.
- Squanga-Dalayee and Canyon-Ittlemit site options are less cost-effective than Tutshi-Moon, but have the advantage of being relatively closer to existing Yukon Energy infrastructure. It was noted that it is not known at this stage whether a viable project configuration can be found for the Canyon-Ittlemit facility that does not negatively impact the existing Aishihik Hydro Facility.
- Preliminary site visits were recommended as a next step to five of the short-listed sites, which excluded Racine-Moon and Lindeman-Fraser sites.
- The lowest LCOE ($0.19/kWh) is achieved with the 15 MW/100 GWh configuration; however, the lowest LCOC ($650/KW/year) is achieved with the 25 MW/50 GWh configuration. These costs exclude new transmission required from the site area to the Whitehorse grid.
- KP noted that reducing energy storage further may provide a lower cost of capacity and would be more in line with the development trend in pumped storage facilities worldwide (short duration storage of hours to days rather than seasonal storage, focusing on rapid response with variable-speed units, which make a facility able to provide grid stability, frequency control, voltage regulation, spinning reserve and other grid support ancillary services).

Sites were identified in the KP report with 15 to 25 MW and (for each capacity) 50 and 100 GWh/year energy storage. Annual pumping energy required can vary materially among site options depending on site features. For the purpose of the current resource options evaluation, Yukon Energy has requested

that the 15 MW capacity with 50 GWh/year option and the 25 MW with 100 GWh/year option be included.

Based on the above request, the 15 MW option with 100 GWh/year and the 25 MW option with 50 GWh/year are not included at any site in the current resource options evaluation (see Table A 4-1).

The current resource options evaluation also excludes the KP version of the Tutshi-Moon site option and instead looks at the Moon Lake resource option as examined in the Midgard report (see below).

Midgard Report

The Tutshi-Moon site in the KP desktop study is the same site assessed by Midgard Consulting Inc. (Midgard) in an earlier, more detailed conceptual study for Yukon Energy ("Moon Lake - Pumped Storage Conceptual Study Report", December 14, 2015). Yukon Energy has requested that the Midgard study be used for the Moon Lake pumped storage site option in the current evaluation study.

The following are noted from the Midgard study (see Table A 4-1 below for a summary of capacity and energy options assessed by Midgard for the Moon Lake site option assuming 54 GWh/year of annual energy generation for use on the grid, 48 GWh/year pumping annual energy requirements, resulting capital and O&M cost estimates, and resulting LCOE and LCOC estimates):

- Assumed 48 GWh/year of available pumping energy from weeks 20 to 44 (late May to early November, based on Yukon Energy 2022 forecast for surplus hydro and assumed wind generation - this forecast also indicated diesel generation to be displaced at 23.75 GWh). Surplus energy available for pumping with current renewable capacity declines as grid load increases (2030 forecast showed reduction to 31 GWh/year), and the report assumes adequate new renewable generation is provided to retain the surplus energy needed for this pumped storage site option.
- Assumed facility has 31m high, 700m long earth dam at outflow of Moon Lake, a 5.5 km long, 0.5m diameter buried steel penstock, and a concrete and structural steel powerhouse 400m below on the shore of Tutshi Lake. The project will create a 690 ha reservoir over the existing Moon Lake, and this reservoir level will vary from minimum operating level (MOL) of 1,114m [3.44 km^2 area] and a full supply level (FSL) of 1,125m [6.9 km^2 area]. Over 45 years of water records, water in the reservoir is estimated to spill 18 years and draw down to MOL 2 years.
- Capital cost and O&M cost estimates for this site option are lower than for the KP report, and the LCOE is also notably lower (assumed 65-year life with constant energy levels and WACC at 3.38%/year net of inflation).
    - Capital cost is $217.6 million in the Midgard report, compared with $237.6 million in the KP report for 15 MW and 50 GWh of pumped storage.
    - O&M cost is $1.896 million/year in the Midgard report, compared with $4.784 million/year in the KP report for 15 MW and 50 GWh of pumped storage. [KP O&M cost assumes 2.0% of capital cost before IDC plus $0.005/kWh variable cost for generation and pumped energy, without specific consideration of BC resource fees. Midgard's O&M cost estimate includes BC resource fees and explicit provision for general O&M, major

maintenance allowance, management/ administration/ overhead, insurance and property tax].

- LCOE is $0.189/kWh in the Midgard report, compared with $0.28/kWh in the KP report for 15 MW and 50 GWh of pumped storage.

EP Report

In addition to the above, EMC^2-Picacho (EP) provided Yukon Energy with a conceptual assessment of seasonal pumped storage options at the Faro Mine Complex (EP Technical Memo, May 16, 2016).

The overall approach in the EP report assumes the use of the existing infrastructure of the Faro Mine Complex (e.g., pits, roads, transmission) to develop seasonal pumped storage to provide four to five months of winter generation. The upper reservoir would be created in or close to existing or future (i.e., if future development occurred of the unexploited Grizzly Deposit) waste rock dumps and would involve appropriate measures to provide the necessary environmental protection and a watertight reservoir. The EP study concluded that the following two options potentially could be economically viable only when the upper reservoir costs are shared by a mining operation (all costs in US$2015):

- **Scheme A: Faro Pit** - A 4 MW option with 9.6 GWh pumped storage (winter generation supply) with the upper reservoir located on top of the existing waste rock dump south of the Faro Pit and with the Faro Pit serving as the lower reservoir. The scheme will have a pump/turbine in the pit area that will pump stored water to the waste dump reservoir; in return, the water will drop via a penstock pipe to the pump/turbine installed on a floating barge on the pit lake (total available head of at least 300 m). The summer energy required for pumping is 11.7 GWh.

  Estimated cost of the Faro Pit scheme is US$89 million as a stand-alone project, with 50 year assumed life and annual O&M cost of approximately US$0.233 million plus an assumed summer pumping cost of US$0.351 million (assumes summer power cost of US$0.03/kWh). The study noted that if the mine picked up 50% of the reclamation costs (i.e., regarding the upper reservoir side slopes and lining the upper reservoir with an 80 mil HDPE geomembrane), then the capital cost reduces to US$48 million. Similarly, the study noted that if the mine picked up all of the upper reservoir costs, which is work that the study stated they would do anyway to close the dump, then the scheme would cost US$4.5 million.

  The EP study did an economic assessment using a different approach than that adopted for the KP and Midgard assessments of pumped storage options. Using the KP approach with the EP cost estimates and energy generation, a 50 year life, no cost for summer energy, and a WACC of 3.38% yields an LCOE of US$0.413/kWh for the stand-alone project and US$0.232/kWh if the mine picked up 50% of the reclamation costs.

- **Scheme C: Vangorda Pit** - A 40 MW option with 134 GWh of pumped storage (annual winter generation) with two reservoirs: the upper reservoir with a storage volume capacity 123 million m^3 (built on the generally flat plateau east of the Vangorda Pit, abutting the waste dump on the south side of the Vangorda Pit), and a lower reservoir with a storage capacity of 70 million m^3 (located in a very narrow region of the stream below the upper reservoir). The total available head is 390 m with a 1,780m long penstock leading to the powerhouse located next to the lower embankment. The summer energy required for pumping is 163.4 GWh.

Water from Vangorda Pit operations could be blended into the 106 million m^3 per year of natural inflow volume from the upper and lower catchments, which blending would be beneficial to the mine treatment operations currently ongoing at the pit. Just west of the upper reservoir is the Grizzly Deposit, an unexploited zinc/lead/nickel deposit previously identified as a potentially viable deposit, which if and when developed would enable the upper reservoir embankment to be created from mine waste at almost no extra cost to the mining operations.

The estimated cost of the Vangorda Pit scheme in the EP study is US$392.8 million as a stand-alone project, with a 50 year assumed life and annual O&M cost of approximately US$1.160 million plus an assumed summer pumping cost of US$4.902 million (assumes summer power cost of US$0.03/kWh). The study noted that if the Mine operation related to Grizzly Pit development picked up 50% of the cost for the dam, then the capital cost reduces to US$230.4 million (at Mine support for 75% of this cost, the capital cost overall reduces to US$176 million).

The EP study did an economic assessment using a different approach than that adopted for the KP and Midgard assessments of pumped storage options. Using the KP approach with the EP cost estimates and energy generation, a 50 year life, and a WACC of 3.38% with a cost for summer power of US$.03/kWh yields an LCOE of US$0.168/kWh (US$0.131/kWh if no cost summer power) for the stand-alone project and US$0.117/kWh (US$0.080/kWh if no cost summer power) if the Mine picked up 50% of the reclamation costs.

Both of the above options are assumed to require considerable funding of capital costs by the mine site. The Faro Pit option is also relatively small, while the Vangorda Pit option, at 40 MW, is well beyond the 20 MW cap for resource options being examined for the current Resource Plan.

Yukon Energy has requested that only the Vangorda Pit option be included in the current evaluation without assuming any related mine development. To be consistent with the other projects reviewed, cost related assumptions for the Vangorda Pit are included in Table A 4-1 based on the above EP cost estimates assuming 1$CAN equals $0.75US, as well as assuming a 50 year life with O&M cost for pumped storage energy at only $0.005/kWh.

Table A 4-1: Pumped Storage Sites Energy Production & Economics (2015$) (65-year life)

Pumped Storage Site Option	Net MW	Annual Energy Supply GWh/year	Annual Pump Energy Required GWh/year	Capital Costs ($million)	O&M Costs ($million/ year)	LCOC ($million/ MW-year)	LCOE ($/kWh)
Moon (Midgard report) (ex. trans. to grid)[1]	20.2 MW	54	48	217.6	1.893 with 0.168 BC resource fees	N/A	0.189
Racine-Moon (KP report) (ex. trans. to grid)[1]	15 MW	50	31.8	473.0	9.2	1.80	0.54
Racine-Mt. Brown (KP report) (ex. trans. to grid)[1]	15 MW 25 MW	50 100	51.8 113.6	284.0 486.0	5.8 10.1	1.1 1.1	0.33 0.29
Lindeman-Fraser (KP report) (ex. trans. to grid)[1]	15 MW	50	55.8	483.8	9.5	1.9	0.56
Squanga-Dalayee (KP report) (ex. trans. to grid)[1]	25 MW	100	119.7	613.4	12.5	1.4	0.36
Atlin-Black Mountain (KP report) (ex. trans. to grid)[1]	15 MW 25 MW	50 100	59.5 121.3	253.8 464.4	5.2 9.7	1.0 1.1	0.30 0.27
Canyon-Ittlemit (KP report)	25 MW	100	119.9	691.2	13.9	1.60	0.40
Vangorda Pit (EP Report-50 year life)[2]	40 MW	134	163.4	523.8	2.4	N/A	0.18

Notes

1. Costs exclude capital and O&M adjustments for transmission connection from the local area to the grid (see Section 5.1 of this Appendix for current cost estimates). Capital costs include interest during construction.
2. Cost, life and LCOE assumptions are not necessarily compatible for this site and other sites.

4.2 SMALL HYDRO PROJECTS

Small hydro resource options are identified from three separate sets of reports below.

Knight Piesold Report

KP provided Yukon Energy with a report on small hydro resource options ("Small Hydroelectric Projects Screening Assessment", October 7, 2016), which screened a wide range of site options and identified five preferred projects and related conclusions based on a desktop level assessment of location, project layout, site characteristics, capacity, energy and cost. The initial study as drafted in April 2016 included Surprise Lake as one of five top projects screened for more intensive assessment. The final report removed Surprise Lake from the top five and included Anvil Creek (Surprise Lake is addressed separately in the MH report summarized below).

Key conclusions from the final KP report include:

- The five most attractive or preferred projects as examined by KP are Drury Lake, Finlayson River, Anvil Creek, Tutshi-Windy Arm, and Wolf River. All of these are storage projects, except for Wolf River (which is a run-of-river project). See Tables A 4-2 and A 4-3 for summary information from the KP report on these preferred projects. Cost estimates for transmission assume that proposed new transmission corridors are in place as noted in Table A 4-2.
- Based on a stand-alone assessment of hydropower development and interconnection to the closest existing or proposed transmission line, the most attractive small hydro sites as assessed in the KP report are the Finlayson River, Wolf River, and Tutshi-Windy Arm. Drury Lake and Anvil Creek appear to be more expensive on a cost of energy basis.
- The initial installed capacities for the Finlayson River, Tutshi-Windy Arm and Wolf River projects are likely in the order of double those used in the present study (where 20 MW was the upper limit):
    - Finlayson River optimum cost to benefit scale could perhaps be in the order of 40 to 45 MW (versus 17.8 MW assumed in this study, which operates at 100% capacity factor).
    - Tutshi-Wind Arm optimum cost to benefit scale could perhaps be in the order of 15 MW (versus 7.2 MW assumed in this study, which operates at 100% capacity factor).
    - Wolf River optimum cost to benefit scale could perhaps be in the order of 40 to 45 MW (versus 20 MW cap assumed in this study). An earlier 1991 study also noted the potential opportunity for storage at Wolf Lake, which could improve winter generation and the plant capacity factor.
- The Tutshi-Windy Arm project has the additional benefit (as a result of storing water for increased winter use) of increasing the winter generation at the Yukon Whitehorse Generating Station on the Yukon River downstream of these small hydro projects:
    - An earlier KGS study estimated an increase of 6 GWh/year in Whitehorse winter generation from control of Tutshi Lake outflows.

- The initial draft KP study estimated that similar downstream benefits from the Surprise Lake project would be slightly less than 3 GWh/year.

- If the Moon Lake-Tutshi Lake pumped storage project is developed, it may have material synergies with development of the Tutshi-Windy Arm small hydro project, including provision of added downstream winter generation benefits at the Whitehorse Generating Station.

The five small hydro preferred sites in the final KP report are included in the summary information shown in Tables A 4-2 and A 4-3.

Morrison Hershfield Report

The Surprise Lake project assessed in the initial draft KP report is similar to a small hydro project (Atlin project) at this site that Morrison Hershfield (MH) recently examined in more detail ("Atlin Hydro Expansion Pre-Feasibility Study" for Atlin Tlingit Economic Limited Partnership, Revised June 23, 2016). Yukon Energy has directed that the MH study rather than the KP study be used for the current evaluation of this small hydro project.

Comparison of the MH assessment with the initial KP assessment for this site indicates the following:

- Similar design flow, but MH assumes lower gross head than KP (163.3m versus 238.0m).
- MH has lower assumed capacity (7.8 MW versus 14.2 MW with KP), as well as lower annual generation (44.6 GWh versus 58.8 GWh with KP).
- MH capital cost of $120.7 million includes $40.9 million for 100 km of 69 kV transmission; the KP capital cost of $165.7 million excludes any similar transmission connection to the Yukon grid.
- LCOE with MH is $0.144/kWh excluding transmission connection, compared with 0.18/KWh LCOE with KP.

The following MH report information is summarized for the Atlin project (see also Tables A 4-2 and A 4-3):

- The 2.1 MW Atlin Hydro Project on Pine Creek (about 4 km east of the community of Atlin) began commercial power production on April 1, 2009. It is owned by a partnership which is 100% owned by Taku River Tlingit First Nation. The community of Atlin is not connected to any external electrical power grid. Power created by this current project is sold to BC Hydro on a 25-year energy purchase agreement (which includes an obligation to provide 8.3 GWh/year by 2032). The existing project, which currently meets all of the community's electrical power needs and has additional underutilized generating capacity, only develops a portion of the hydropower potential of this site.
- The MH study provided a preliminary assessment of increasing hydropower production for export to the Yukon electrical grid. It looked at expanding the current powerhouse with two additional turbines of 1.45 MW each with related added penstock and intake structure (bringing the total powerhouse capacity to 5 MW) and developing a second lower powerhouse on Atlin Lake (with related new penstock, head pond and intake structure, to provide an additional 2.5 MW to 3 MW [2.8 MW assumed] of capacity). A new 69 kV transmission line of approximately 100 km is

assumed to connect the project with the Yukon electrical grid at Jake's Corner. Modifications were also assumed to the existing Surprise Lake control structure and weir to increase water storage range. A small diversion ditch will divert Spruce Creek into the new lower head pond just upstream up the mouth of creek into Pine Creek.

- Long-term average annual power generation from the project (including existing capacity) was estimated (assuming 2.5m storage at Surprise Lake) at 44.6 GWh/year, with 30.8 GWh (69%) of this generation in the six months from November 1 to April 30; the upper plant contributed 28.2 GWh of the estimated annual generation, and the lower plant contributed 16.3 GWh. Net of an 8.3 GWh/year obligation to BC Hydro, the project can provide long-term average generation of 36.3 GWh/year for export to Yukon. Line losses from transmission would reduce the useable electricity in Yukon: losses of 2.2% are estimated for delivery to Jake's Corner (existing 34.5 kV system in Yukon), and about 5.7% for delivery to Whitehorse (assuming current Yukon grid).[10]
- A capital cost estimate for the project of +/-30% (pre-feasibility) in 2016$ was provided of $79.7 million for the hydroelectric generation component, and $120.7 million including 69 kV transmission required to connect with the Yukon system at Jakes Corner with ability to supply power to Yukon Energy at Whitehorse (when it is not used on the ATCO portion of the southern grid).
- The MH study did not provide any estimate of annual O&M costs for the project. [An O&M cost estimate developed on a basis comparable to the KP study is included in Table A 4-3, assuming a fixed annual cost at 2.0% of capital cost excluding interest during construction (assume this approximates $1.59 million per year based on $79.7 million cost estimate for the project excluding the 100 km transmission line) plus $0.005/kWh variable cost ($0.181 million/year based on 36.3 GW.h new energy for Yukon), or a total O&M cost of $1.771 million/year].
- Assuming 65 year life, 3.38% WCC, the above capital and O&M cost estimates, and 36.3 GWh/year generation for export to Yukon, the estimated LCOE is $0.133/kWh excluding 100km transmission connection cost and $0.176/kWh including the transmission connection cost (2016$). A lower O&M cost than adopted using the KP approach would reduce the LCOE (see separate comments earlier re Moon pumped storage costs based on the Midgard study).

The current resource evaluation study will include the Atlin resource option as described in the MH report. It is noted that costs for transmission connection to the grid as developed in the MH report are not necessarily compatible with cost estimates for this portion as developed for the transmission corridor assessment of the Whitehorse-Atlin Transmission Corridor option (see Section 5.1 below of Appendix A). YEC advises that it expects to use the transmission assessment cost estimates for transmission-related cost elements related to the Atlin project.

[10] The MH study examined transmission connection options linking to a 138 kV new line from Whitehorse to Carcross, which would reduce line loss for transmission to Whitehorse. The study concluded that the option to connect at Jake's Corner, with interconnection on the existing 34.5 kV ATCO line to Yukon Energy's 138 kV grid at Whitehorse, is the most viable option available today for this project.

Earlier Studies regarding Moon Lake Small Hydro Site Option

The KP study of small hydro options excluded the Moon Lake site, which was addressed under pumped storage hydro resource options. The following information is noted from other earlier studies regarding a small hydro option at Moon Lake (this option is not examined further in the current evaluation):

- A conventional Moon Lake site option was included in the study that Midgard (Midgard recently provided for Yukon Energy on the Moon Lake project ("Moon Lake - Pumped Storage Conceptual Study Report", December 14, 2015). Based on Midgard's estimated generation (20 GWh/year), capital cost ($155 million) and related O&M costs (likely about $1.5 million/year based on Midgard's approach), the LCOE for this Moon Lake small hydro option would be very high compared to other options examined in the KP study (i.e., about $0.371/kWh) even before considering transmission connection costs for supply to the current grid.
- An earlier AECOM study[11] for Yukon Energy, using information from the 2007 KGS study, estimated annual generation of 32.9 GWh/year and a LCOE (2009$) of $0.146/kWh excluding transmission connection costs and $0.199/kWh including transmission connection costs (55 km connection).

[11] AECOM, "2009 Large Hydro Stage 1: Initial Investigation", November 2010 (Table 4.4).

Table A 4-2: Small Hydro Site Options - Physical Requirements

Project	Type	Flood Areas (km^2 of New Impoundment)	Design Flow (m^3/s)	Gross Head (m)	Location	Distance (km) to Transmission Lines	Access Road (km)
Drury (KP report)	With Storage	27.9 (new area flooded 1.9)	9.3	99.0	On Drury Creek between Drury Lk and Little Salmon Lk	0.5 to existing	5.3
Finlayson (KP report)	With Storage	10.6 (Wolverine Lk); 23.0 (Finlayson Lk) (new area flooded 5.4)	13.3	150.0	On Finlayson River upstream of Frances Lk. 300 km NE of Whitehorse (relocate 3 km of Highway due to flooding)	155.3 to existing; 5.1 to proposed (Faro-Watson L TL)	17
Atlin (Pine Creek) (MH report)	With Storage	Not applicable (no increase to FSL at Surprise Lake, increase to LSL)	6 to 7	163.1	On Pine Creek between Surprise Lk and Atlin Lk near Atlin, BC. (Upper 5.0 MW [2.9 MW new], lower 2.8 MW)	100 to existing Yukon 34.5 kV transmission	N/A
Tutshi-Windy Arm (KP report)	With Storage	55.0 (Tutshi Lk) (new area flooded 3.1)	15.0	51.0	Between Tutshi Lk and Windy Arm of Tagish Lk in northern BC. 45 km south of Carcross	24.8 to existing; 0.5 to proposed (Whitehorse-Skagway TL)	23.5
Wolf River (KP report)	Run of the River	Not applicable	37.7	60.0	On Wolf River near river mouth and 22 km NE of Teslin and Alaska Hwy	55.1 to existing; 23 to proposed (Whitehorse-Teslin TL)	23
Anvil Creek (KP report)	With Storage	5.9 (new area flooded 0.6)	8.2	13.5	On Anvil Creek approx. 4.7 km downstream of Anvil Lake outlet and upstream of Anvil Creek-Blind Creek confluence (control dam at Anvil Lake outlet)	11 to existing	3.5 new access road

Table A 4-3: Small Hydro Sites Energy Production & Economics (2015$) (65-year life)

Small Hydro Site Options	Installed Capacity (MW)	Net Annual Generation (GWh)	Capital Costs ($million)	O&M Costs ($million/ year)	LCOC ($million/MW-year)	LCOE ($/kWh)
Drury (KP report)	8.1 (8.1 firm winter)	31.7 (100% Nov.-April) (100% firm)	103.3	2.103	0.7	0.19
Finlayson (KP report) (ex. trans. to grid)[1]	17.6 (17.6 firm winter)	138.9 (about 50% Nov.-April) (100% firm)	282.5	6.015	1.0	0.12
Atlin (Pine Creek) (MH report)[1]	7.8 (5.7 new)	44.6 (36.3 available for Yukon - about 70% Nov.-April)	79.7 (excludes cost for 100 km connection)	1.771 (estimated based on KP methods)	N/A	0.133 ex. TL (estimated per KP approach)
Tutshi-Windy Arm (KP report) (ex. trans. to grid)[1]	7.2 (7.2 firm winter)	56.6 (about 50% Nov.-April) (100% firm)	133.2	2.791	1.1	0.14
Wolf River (KP report) (ex. trans. to grid)[1]	20.0 (2.2 firm winter)	95.6 (about 20% Nov.-April) (91% firm)	233.8	4.881	0.7	0.14
Anvil Creek (KP report)	9.8 (2.5 firm winter)	41.3 (about 32% Nov.-April) (75% firm)	116.0	2.391	0.7	0.17

Note:
1. Costs exclude capital and O&M adjustments for transmission connection from the local area to the grid (see Section 5.1 of this Appendix for current cost estimates). Atlin capital cost estimate is in 2016$.

4.3 GLADSTONE DIVERSION

Considerable assessment and feasibility work was done for the Gladstone Diversion project prior to the last Yukon Energy General Rate Application (GRA), including a report by AECOM ("Gladstone Diversion Concept Conceptual Design", May 2011). Based on this earlier work and Yukon Energy filings during its 2012/13 GRA before the Yukon Utilities Board, the following are noted for this project:

- The project proposes to divert water from the headwaters of Gladstone Creek into the Aishihik Lake system and would increase the amount of water available for hydroelectric generation at

the Aishihik Hydro Facility. The project is within the traditional territory of the Champagne and Aishihik First Nations. Kluane First Nation and White River First Nation also have interests in the vicinity of the project on or near Gladstone Creek near Kluane Lake.

- The project concept includes two diversion structures to divert the headwaters of Gladstone Creek into Isaac Creek, which flows into Sekulmun Lake (the primary storage reservoir of Yukon Energy's 37 MW Aishihik Hydro Facility).
- The project is forecast to provide sufficient water for up to an additional 36.6 GWh (on average) of production from the Aishihik facility, focused in the winter months. The project would not add to firm winter capacity on the grid.
- Based on feasibility studies prior to Yukon Energy's last GRA, project cost was estimated at $40 million (2010$) and LCOE over the 65 year project life estimated at 5.7 ¢/kWh (assuming full utilization of added energy generation of up to 36.6 GWh/year during the winter months at the current Aishihik plant and an assumed Yukon Energy blended capital cost averaging 6.56%/year).
- Prior work indicated concerns from the Department of Fisheries and Oceans (DFO) as well as from local First Nations.
- DFO indicated that it had a concern that the proposed Gladstone concept will result in significant effects to fish and fish habitat in the Yukon and Alsek river systems, both of which support high value fisheries. According to DFO, effects would be due particularly to transfer of pathogens and parasites from one watershed to the other. DFO suggested that Yukon Energy revise its concept to eliminate the interbasin water transfer and reduce negative effects to fish habitat. Yukon Energy advised DFO that the concept is still in the very early stages of study/planning, specifically the collection of baseline information and preliminary engineering development to gain an understanding of the feasibility of the concept. Specifically, Yukon Energy noted its intention as part of the baseline studies to gather sufficient information regarding the presence of pathogens and parasites and the risk associated with potential transfer of any pathogens and parasites after all mitigation measures are considered. Once this information is available and the preliminary assessment of risk can be completed, Yukon Energy intends to share this with DFO staff for further discussion and analysis. Yukon Energy reported that the results of a full year of baseline studies provide no evidence to date to support a concern regarding interbasin pathogen transfer.
- Yukon Energy committed as a first priority in 2012 to work with the local First Nations until they make a decision as to whether or not they will support the project.
- The Overview of the 20-year Resource Plan: 2011-2030 from July 2012 recommended that Yukon Energy plan within the next 6 to 12 months to reach a final determination regarding whether the project is feasible to pursue at this time, based on discussions with local First Nations and regulators. Yukon Energy has continued to work with the local First Nations to seek support for this project, given its potential long-term benefits for the system.

4.4 HYDRO STORAGE ENHANCEMENTS

Considerable assessment and feasibility work has been done or is ongoing separate from the current Resource Plan process to examine potential hydro storage enhancement options at Mayo Lake and the Southern Lakes. In the case of the Mayo Lake Enhanced Storage Project, a YESAB submission was filed in 2015 (information from that submission is used for the summary below of this project).

- **Mayo Lake Enhanced Storage Project** – This project would revise the existing Mayo Lake Water Licence to allow up to 1 metre lower supply level (LSL), thereby enabling added long-term average hydro generation at the Mayo hydro generating station (particularly related to enhanced retention of water that would otherwise be spilled during high run off years).

  The specific project proposed serves to increase the long-term average hydro generation potential to displace fossil fuel generation on the Yukon system by approximately 2 to 4 GWh/year[12] (the specific yearly benefit will depend on the overall load level on the Yukon grid, flow conditions throughout Yukon, the Mayo Lake LSL then allowed under the AMP, and the extent of future new renewable generation on the grid).

  The proposed Project requires no new physical works. It will utilize the Mayo Lake Control Structure facilities already in-service for the existing Mayo hydro generation, and ongoing maintenance activities of the structure and associated infrastructure from Mayo Lake to the Mayo Lake Control Dam.[13] Hydro power generation will occur at the existing Yukon Energy facilities at Mayo A and B.

  Mitigation measures proposed for the project are focused on addressing potential adverse effects on fish and fish habitat in the Mayo Lake area (whitefish and lake trout in particular). Changes to water releases would likely enhance downstream salmon spring habitat below the Mayo hydro generating facilities.

  For the first three years of project operation, the lake will be operated with an additional 0.5 m storage range (i.e., between the existing FSL of 665.84 m to a revised LSL of 662.75 m which is 0.5 m below the current LSL of 663.25 m).[14] After the first three years, the results of monitoring and the proposed Adaptive Management Plan will be used to determine if and how to proceed with up to a full metre extra storage (lowering the LSL to 3.59 m below the FSL of 665.84 m) or if the storage range should be reduced to less than 3.09 m.

[12] By way of example, at loads ranging from of 437 to 454 GWh/year, additional long-term average fossil fuel displacement due to the Project's enhancement of long-term average hydro generation ranges from 1.9 to 2.8 GWh/year with 0.5 m enhanced Mayo Lake storage and from 3.4 to 4.2 GWh/year with 1.0 m enhanced Mayo Lake storage. Within the load range of about 460 to 480 GWh/year, fossil fuel generation displacement benefits with 0.5 m enhanced Mayo Lake storage range between 2.9 and 3.2 GWh/year.

[13] Maintenance activities noted here refer to any ongoing works required to keep the control structure operational. See Mayo Outlet Channel Dredging Project.

[14] The current controlled range reflects that under certain water conditions, it is possible for the water level of Mayo Lake to be outside of the stated range due to drought or flood conditions. Under those circumstances, Yukon Energy would be required to operate its facilities at the lake so as to not further exacerbate the elevation conditions. In particular, Clause 25 of the Mayo Water Licence requires that when the lake elevation exceeds the licensed maximum range, Yukon Energy is required to have all of the gates open; a similar practice would be exercised in the event the licensed minimum range was exceeded, consistent with minimum downstream flow requirements.

The project YESAB filing has been delayed pending Yukon Energy addressing the separate maintenance requirement for dredging of sediment built up in the Mayo Outlet Channel. This sediment reduces long-term average hydro generation of the existing facility, and needs to be removed in order for the Mayo Lake project to operate (see Section 4.5 below). The Mayo Lake project in contrast enhances the economic benefit of actions to remove channel sediment and reduce the risk of added future sediment additions to this area.

- **Southern Lakes Enhanced Storage Project** – This project would revise the existing Marsh Lake Water Licence to allow 30 cm higher FSL (656.53 m asl) and 10 cm lower LSL (653.70 m asl) in order to enhance storage in the fall for increased winter use at the Whitehorse hydro generating station. No new dam or generating facilities are required – any works would be related to mitigation measures for shoreline erosion protection or other mitigation.

  The Overview of the 20-year Resource Plan: 2011-2030 in July 2012 estimated that this project would increase long-term average winter hydro generation by up to 6.4 GWh/year, and enhance reliable winter capacity by about 1 MW, at an estimated capital cost of $10.5 million (2010$).

  Marsh Lake water levels can have influence upstream on both Tagish and Bennett Lakes when its lake levels are above about 654.2 m when flows are receding in winter, and above 655.5 m when inflows are increasing in summer. Atlin Lake, along with other higher elevations lakes in the Southern Lakes region are not, and will not be affected by higher levels on Marsh Lake.

4.5 MAYO LAKE OUTLET CHANNEL DREDGING

The Mayo Lake Outlet Channel Dredging Project would remove an old cofferdam as well as sedimentation that has infilled in the Mayo Lake Outlet Channel over the past 63 years since the original Mayo hydro generation was developed and address measures to mitigate potential future sediment infill in this outlet channel.

Current sediment infill is restricting the full hydro capability of the downstream Mayo A and B hydro generation. In addition, this infill plus the cofferdam remnants are preventing any benefit from the Mayo Lake Enhanced Storage project from being realized. There is a risk that additional material sediment infill can occur in response to a major wind event, which would further reduce Mayo hydro long-term average generation capability through further erosion of the cliffs along the north shore of the lake within about 700 m of the mouth of the outlet channel.

Ongoing investigations are required to assess issues and cost effective options to remove existing sedimentation and to minimize the risks of near-term new sedimentation build up in this channel. Maintenance measures to remove sediment infill could involve dredging to move approximately 40,000 to 80,000 m^3 of sediment from the channel to an acceptable nearby land location and/or using releases from the lake at low lake levels that create velocities of flow in the channel, facilitating the occurrence of a natural process of sediment erosion. Mitigation to control future sediment infill could involve shoreline stabilization (in the nearby lake cliff areas and/or in the channel), jetties to control ingestion of sediment-laden plums into the channel or combinations of these measures. Work on this maintenance project would be required to protect fish and fish habitat and water quality. Terrestrial effects would be limited to local areas on the north side of the channel used for access and/or the deposit of sediment removed from the channel.

4.6 REFURBISH EXISTING HYDRO GENERATION

- **Mayo A Refurbishment Project** – A KGS Group draft report is available for Mayo A refurbishment ("Mayo Hydro [MHO] Future Facility Option – Concept Design Report", May 2016). This report covers a conceptual scope of work economic assessment and cost estimate for the following four options for the aged 5 MW Mayo A hydro facility. In all options, the existing dam would remain. The assessments address asset conditions that require action.
  - Option 1: Replace Mayo A hydro station, retaining the foundations and other embedded parts and providing one new turbine and generator, powerhouse, and other facilities.
  - Option 2: Refurbish Mayo A hydro station, retaining the foundations and other embedded parts of the Unit 2 turbine and providing one new generator (2.3 MW, annual energy of 10.2 GWh), turbine support systems, new turbine inlet valves (TIV), balance of plant systems, support systems, control room and surge tank. Repairs/upgrades to the existing powerhouse superstructure and cranes are required. Geotechnical work would be included to stabilize slopes, repair roads and trailrace.
  - Option 3: Remove the powerhouse (excluding the foundation) and the surge tanks, including permanently plugging the penstock upstream of the surge tank take-off and backfilling the powerhouse foundation and tailrace to return the site to near greenfield conditions.
  - Option 4: Abandon the powerhouse in place. The facility would be made safe for abandonment, the penstock would be permanently plugged upstream of the surge tank, and the tailrace would be backfilled.

  Option 2 (the refurbishment option) was found to be the most economical and is the preferred option to be included in the current resource options evaluation. Total project capital cost was estimated at $27.4 million, with an assumed 65-year life span and present value costs during operation of $2.5 million. The report estimated LCOE at $0.147/kWh.

- **Aishihik Rerunnering Project** - The KGS Group final report is available for Aishihik turbine rerunnering ("Aishihik Turbines Uprate Study," February 2016). The study examined two options, both of which would keep plant discharge within existing maximum flows and would not affect hydraulic stability during start-up and shut-down. The options are:
  - Option 1: Uprate only turbine AH2 (estimated capital cost of $3.0 million; 0.7 MW increase in capacity; 2.15 to 2.26 GWh/year benefit of increased energy, varying depending on load; payback estimated in 6 years); and
  - Option 2: Uprate both turbines AH1 and AH2 (estimated capital cost of $4.7 million; 1.3 MW increase in capacity; 2.74 to 3.04 GWh/year benefit of increased energy, varying depending on load; payback estimated in 6 to 7 years).

  Option 2 is assumed for the purpose of the current study, i.e., assumed re-runnering of units AH1 and AH2, providing increased capacity of about 1 MW and increased annual energy of about 3 GWh.

5.0 TRANSMISSION CORRIDOR OPTIONS

5.1 NEW TRANSMISSION CORRIDORS

Midgard has examined for Yukon Energy[15] the following five transmission corridor transmission options (related substation requirements are not addressed in this existing information):[16]

- **Whitehorse-Atlin Corridor** (172 km [reliable transfer capacity 97 MW], 138 kV): Route is assumed to go via Jake's Corner area existing distribution line routing). This option would provide transmission connection into northern BC for the pumped storage option at Atlin-Black Mt. and the small hydro option at Atlin (Pine Creek). Estimated capital expenditure (Capex) at $158 million, estimated operating expense (Opex) at $236k/year; includes 34.5 kV underbuild for 79 km.
- **Whitehorse-Skagway Corridor** (170 km [reliable transfer capacity 443 MW with 230 kV, 114 MW reliable transfer capacity with 138 kV): This corridor would be routed via that Carcross area. This option would provide transmission connection for pumped storage and hydro-related options in northern BC (Moon, Racine-Moon, Racine-Mt. Brown, Lindeman-Fraser, Tutshi-Windy Arm), as well as potential new summer loads (cruise ships) and other new hydro generation options at Skagway. Estimated Capex at $251 million for 230 kV and $166 million for 138 kV, estimated Opex at $285k/year; includes 34.5 kV underbuild for 68 km.
- **Whitehorse-Teslin Corridor** (174 km [reliable transfer capacity 95 MW], 138 kV): This option would provide transmission connection for the Wolf River small hydro option and the Squanga-Dalayee pumped storage option. Estimated Capex at $165 million, estimated Opex at $239k/year; includes 34.5 kV underbuild for 174 km.
- **Faro-Watson Lake Corridor** (414 km [reliable transfer capacity 190 MW], 230 kV); if developed, this option would allow Watson Lake to no longer be a diesel community, and would provide transmission connection for the Finlayson small hydro option as well as larger next generation hydro options in this region. Estimated Capex at $597 million, estimated Opex at $613k/year.
- **Aishihik-Destruction Bay Corridor** (157 km [reliable transfer capacity 484 MW with 230 kV. 122 MW reliable transfer capacity with 138 kV) – a distribution line assumed then from Burwash Landing to Destruction Bay): If developed, this option would allow Burwash Landing and Destruction Bay to no longer be diesel zone communities and would provide transmission connection for the Kluane Lake wind farm option as well as for potential future mine developments in this region. Estimated Capex at $241 million for 230 kV and $167 million for 138 kV, estimated Opex at $217k/year; includes 34.5 kV underbuild for 49 km.

Economic life for new transmission is assumed at 45 years.

[15] Midgard Consulting Inc. (Midgard), "Transmission Options Evaluation", November 8, 2016. All cost estimates in 2016$.
[16] Currently there is no grid in Yukon above 138 kV. The corridor options going south from Whitehorse include adding 138 kV to the existing distribution line voltages (25/34 kV) to Carcross and Teslin.

The Midgard study also provided the following additional assessments of transmission options to connect various project options to the Yukon grid:

- **Faro-Finlayson connection** (233 km with reliable transfer capacity 84 MW at 138 kV; estimated Capex at $221 million, estimated Opex at $351k/year.
- **Whitehorse-Squanga-Dalayee connection** (105 km with reliable transfer capacity 134 MW at 138 Kv; estimated Capex at $100 million, estimated Opex at $143k/year); includes 34.5 kV underbuild for 105 km.
- **Whitehorse-Atlin-Black Mt connection** (127 km with reliable transfer capacity 131 MW at 138 kV; estimated Capex at $119 million, estimated Opex at $174k/year); includes 34.5 kV underbuild for 79 km.
- **Whitehorse-Tutshi Windy Arm connection** (96 km with reliable transfer capacity 135 MW at 138 kV; estimated Capex at $94 million, estimated Opex at $143k/year); includes 34.5 kV underbuild for 68 km.
- **Whitehorse-Racine Mt. Brown; Moon Lake; and Tutshi-Moon Lake connections** (112 km with reliable transfer capacity 132 MW at 138 kV; estimated Capex at $108 million, estimated Opex at $168k/year); includes 34.5 kV underbuild for 68 km.
- **Whitehorse-Lindeman-Fraser connection** (129 km with reliable transfer capacity 129 MW at 138 kV; estimated Capex at $125 million, estimated Opex at $200k/year); includes 34.5 kV underbuild for 68 km.

Centreline GIS information has been provided for each transmission corridor, confirming that each would generally follow existing highway corridors. Each corridor (regardless of voltage variances) is assumed to require a 60 m right-of-way (ROW), with the cleared area constituting only about half of this ROW. The corridor for possible routing options is assumed for current study purposes at 500 m. In general, transmission routing will typically offer ample opportunity to mitigate environmental and socio-economic adverse effects specific to the terrain.

5.2 STEWART KENO CITY TRANSMISSION PROJECT

The Stewart-Keno City Transmission Project is well advanced in terms of permitting assessments. A project proposal was submitted to YESAB in the past year, and a YESAB Screening Report and Recommendation was issued on May 31, 2016.

The project involves the installation of a new 138 kV transmission line from Stewart Crossing to Keno City (about 112 km, located mainly within the existing ROW with the exception of five substantive deviations along the way), along with decommissioning of the existing 69 kV transmission line between Mayo and Keno City and accessory activities, such as the construction of new and modified sub-stations.

The project would replace end-of-life existing 69 kV transmission between Mayo and Keno City with voltage capability able to serve potential future new mine and/or renewable hydro generation connections and extend the 138 kV Yukon grid north beyond Stewart Crossing. Possible options include initial development of only the Mayo to Keno City segment at 138 kV with operation initially at 69 kV.

Yukon Energy's estimated capital cost for the full project (2015$) is approximately $86 million, with $59 million for line construction; $21 million for substation construction; and $5 million for planning, permitting and engineering. About 22% of the estimated transmission line costs is for equipment and about 50% for its installation, while about 25% of the substation costs is for materials and installation.

6.0 SUMMARY OF PROJECTS TO BE EVALUATED

The following summarizes the resource project options to be included in the current evaluation:

1. **Fossil Fuel Thermal Generation:**
    a. Diesel option at 20 MW new facility in Whitehorse, with energy generation dispatchable as required up to 166 GWh/year. Two sites are specified (Whitehorse landfill and Takhini substation). Economic life varies from 20 to 40 years, depending on average annual use of capacity.
    b. LNG option at 20 MW new facility in Whitehorse, with energy generation dispatchable as required up to 166 GWh/year. Specifies same two sites as diesel option. Economic life varies from 20 to 40 years, depending on average annual use of capacity.
2. **Non-Hydro Renewable Generation:**
    a. **Non-fossil Thermal Generation:**
        i. Waste-to-energy (WTE) at Whitehorse. 1.6 MW facility with 10 GWh annual generation, using solid MSW augmented with wood biomass during winter. It is currently premature to select site as viability is greatly enhanced by the sale of waste heat in district waste heating systems. Economic life is 25 years).
        ii. Wood Biomass at Haines Junction. 0.5 MW facility with 3.2 GWh annual net generation, located near school for waste heat use. Uses beetle-kill biomass feedstock. Economic life is 20 years).
        iii. Biogas at Whitehorse. 0.2 MW new facility, with 0.4 GWh initial annual energy. Plant located at municipal landfill next to existing composting site. Footprint is about 1800 m^2. Economic life is 20 years.
    b. **Energy Storage Facility:** (batteries) in Whitehorse (4 MW/40 MWh lead acid-based system or 8 MW/40 MWh lithium ion system). Assumed to be located at Takhini substation with some use of adjacent land. Economic life is 30 years.
    c. **Solar PV:**
        i. Whitehorse: 1 MW, 5 MW and 10 MW options (3 separate options, each at Whitehorse Copper Mine Quarry Site). Annual energy at 1.1 GWh, 5.2 GWh and 10.3 GWh, respectively. 30 year economic life.
        ii. Haines Junction; 1MW, 5 MW options (2 separate options, each located about 1 km from Haines Junction dump on site from the report). Annual energy at 1.1 GWh and 5.2 GWh, respectively. 30 year economic life.

d. **Wind Farms:**

i. Seven site options are examined, each with 25 year economic life:

- Sugarloaf: 20 MW with 32.3 GWh annual energy;
- Tehcho: 20 MW with 33.4 GWh annual energy;
- Mt. Sumanik: 20 MW with 41.5 GWh annual energy;
- Kluane: 20 MW with 47.8 GWh annual energy;
- Cyprus Mine: 20 MW with 49.6 GWh annual energy;
- Thulsoo: 20 MW with 54.4 GWh annual energy; and
- Miller's Ridge: 20 MW with 57.3 GWh annual energy.

ii. Transmission for each site to connect to grid is addressed on stand-alone basis (Kluane Lake option requires consideration of added transmission from what is in Wind report), assuming current centrelines and 60 m ROW, with 30 m cleared and corridor for selecting ROW at 500m width.

e. **Geothermal:** 2 site options, energy capacity at each is the average of potential range in first year of operation. At each site, 2% per year decline in net capacity and energy over 30 year economic life is assumed.

i. Vista Mountain near Takhini substation: Installed capacity average of 1.6 MW with average annual energy of 11.0 GWh over 30 year life.

ii. McArthur Springs south east of Stewart Crossing: Installed capacity of average 3.80 MW with average annual energy of 25.0 GWh over 30 year life.

3. **Hydro Renewable Generation:**

a. **Pumped Storage:** eight site options are examined, and two site options include two scales of development. Transmission for each site to connect to grid is addressed for the evaluation on stand-alone basis without estimating added transmission corridor costs (Canyon-Ittlemit and Vangorda sites are the only options that do not require consideration of added transmission costs according to the Midgard or KP reports), assuming current centrelines and 60 m ROW, with 30 m cleared and corridor for selecting ROW at 500m width. Specific site options are as follows (65 year economic life for each option except Vangorda Pit, where 50 to 65 years is assumed):

i. Midgard report: 1 option: Moon Lake at 20.2 MW and 54 GWh/year;

ii. KP report: 6 sites, 8 options:

- Racine-Moon (1 option): 15 MW with 50 GWh annual energy;
- Lindeman-Fraser (1 option): 15 MW with 50 GWh annual energy;
- Racine-Mt Brown (2 options): 15 MW with 50 GWh annual energy and 25 MW with 100 GWh annual energy;

- Atlin-Black Mountain (2 options): 15 MW with 50 GWh annual energy and 25 MW with 100 GWh annual energy;
- Squanga-Dalayee (1 option): 25 MW with 100 GWh annual energy; and
- Canyon-Ittlemit (1 option): 25 MW with 100 GWh annual energy.

iii. EP report: 1 option: Vangorda Pit: 40 MW with 134 GWh/year of annual energy, without any concurrent mine development.

b. **Small Hydro Projects:** five site options are examined, one of which is run of river and four of which include storage. Transmission for each site to connect to grid addressed for the evaluation on a stand-alone basis without estimating added transmission corridor costs (Drury and Anvil Creek are the only options that do not require consideration of added transmission costs according to the KP or MH reports), assuming current centrelines and 60 m ROW, with 30 m cleared and corridor for selecting ROW at 500m width. Specific site options are as follows (65 year economic life assumed for each option):

i. KP report: 5 sites (includes site added after initial report):

- Drury: 8.1 MW with 31.7 GWh annual energy;
- Tutshi-Windy Arm: 7.2 MW with 56.8 GWh annual energy;
- Wolf River: 20 MW with 95.8 GWh annual energy;
- Finlayson: 17.5 MW with 138.9 GWh annual energy and
- Anvil Creek: 9.8 MW with 41.3 GW.h annual energy (this site added after initial report).

ii. MH report: 1 site: Atlin/Pine Creek: 5.7 MW new capacity with 36.3 GWh/year annual energy for Yukon.

c. **Gladstone Diversion:** One option to enhance hydro generation at Aishihik by up to 36.6 GWh per year. Assumes 65 year economic life (generation at Aishihik generating station).

d. **Hydro Storage Enhancements:** Two options:

i. Mayo Lake Storage Enhancement through a water licence change (without new facilities) to improve winter generation at Mayo hydro on average by 2 to 4 GWh per year, depending on grid load and the outcomes of adaptive management plan activities (YESAB submission has already been prepared).

ii. Southern Lakes Storage Enhancement through a water licence change to improve winter generation at Whitehorse hydro by up to 6.4 GWh/year.

e. **Mayo Lake Outlet Channel Dredging:** one option: maintenance work to remove sediment build up and an old cofferdam in the Mayo Lake Outlet Channel and mitigation measures to inhibit future sediment infill in the channel. This option will restore Mayo B long-term average generation that is currently being restricted and enable the Mayo Lake Storage Enhancement to provide added long-term average hydro generation benefits.

f. **Refurbish Existing Hydro Generation:** Two options:

i. Mayo A Refurbishment: Refurbish Mayo A hydro station, retaining the foundations and other embedded parts of the Unit 2 turbine and providing one new generator (2.3 MW, annual energy of 10.2 GWh); and

ii. Aishihik Re-runnering: Re-runner units AH1 and AH2, providing increased capacity of about 1 MW and increased annual energy of about 3 GWh.

4. **Transmission Corridor Options:**

a. **New Transmission Corridors:** Five options are examined, including segments of a project that would enhance an existing transmission corridor. Each option assumes 60m ROW, with 30 m cleared and corridor for selecting ROW at 500m width (250 m on each side of centreline). Specific site options are as follows (assume 45 year economic life):

i. Whitehorse- Atlin at 138 kV;

ii. Whitehorse Skagway at 230 Kv;

iii. Whitehorse- Teslin at 138 kV;

iv. Faro- Watson Lake at 230 kV; and

v. Aishihik-Destruction Bay at 230 Kv.

b. **Stewart-Keno City Transmission Project:** As recommended in the YESAB Executive Committee Screening Report of May 31, 2016, a new 138 kV transmission line from Stewart Crossing to Keno City (about 112 km, located mainly within the existing ROW with the exception of five substantive deviations along the way), along with decommissioning of the existing 69 kV transmission line between Mayo and Keno City and accessory activities such as the construction of new and modified sub-stations.

When evaluating various renewable generation options, it is relevant to also note comparative scales of energy and/or capacity impacts for the grid.

- Fossil fuel thermal generation provides firm capacity and a wide range of dispatchable energy generation, i.e., up to 166 GW.h per year for 20 MW facility.
- Non-fossil thermal generation options, as well as geothermal options, are each relatively small in terms of capacity (0.2 to 4.0 MW); annual energy generation ranges from 0.4 GWh/year (biogas) to 33.4 GWh/year (geothermal option at McArthur Springs).
- Other renewable energy options show a wide range of annual energy generation:
    - Solar PV is relatively small (1.1 to 10.2 GWh/year), with energy focused from March to August;
    - Wind at 20 MW ranges from 32.8 to 59.0 GWh/year;
    - Small storage hydro ranges from 31.7 to 138.9 GWh/year;
    - Pumped storage hydro ranges from 50 to 134 GWh/year, focused in winter months (these options each need adequate non-winter surplus energy for the required pumping);

- Gladstone Diversion provides up to 36.6 GWh of winter energy; and
- Other hydro projects range from 2 to 10 GWh/year.

1.0 INTRODUCTION

An initial task in this study was to review the environmental, social and economic criteria, indicators and metrics in a Draft IRP Resource Option Evaluation Matrix and provide recommendations on removing and/or adding evaluation criteria, potentially changing criteria definitions, and on changing, adding or removing indicators and/or their associated metrics. A rating scheme was also to be developed in collaboration with Yukon Energy Corporation (Yukon Energy) for each of the three attributes in the Evaluation Matrix, and data sources identified for the evaluation.

The Resource Option Evaluation approach is reviewed below as follows:

1. RFP Draft Resource Option Evaluation Matrix;
2. Considerations for Review of Evaluation Approach;
3. Environmental Criteria and Indicators;
4. Social Criteria and Indicators;
5. Economic Criteria and Indicators; and
6. Resource Options Ratings for Each Indicator.

2.0 RFP DRAFT RESOURCE OPTIONS EVALUATION MATRIX

Yukon Energy's Request for Proposal (RFP) 2016-010 for the Resource Options Evaluation (the RFP) provided a Draft IRP Resource Option Evaluation Matrix (the Draft Evaluation Matrix) for review of the various 2016 Resource Plan resource options (see Attachment 1). The Draft Evaluation Matrix includes three separate sets of evaluation criteria:

- **Environmental Criteria:** 4 Environmental criteria, each with 1 to 4 indicators (each indicator needs 1 or more metric for a total of 21 metrics).
- **Social Criteria:** 4 Social criteria, each with 2 to 5 indicators (each indicator needs 1 or more metrics for a total of 13 metrics).
- **Economic Criteria:** 1 Economic criteria with 3 indicators and 5 metrics.

The RFP anticipated that the Draft Evaluation Matrix would be used to evaluate 40 different resource options, including thermal generation options (fossil and non-fossil fuel), solar PV options, geothermal options, wind farm options, pumped storage options, small hydro options, other hydro options, and transmission corridor options.

An initial task for the current resource options evaluation study was to review the Draft Evaluation Matrix and provide recommendations on removing and/or adding evaluation criteria, potentially changing criteria definitions, and on changing, adding or removing indicators and/or their associated metrics.

3.0 CONSIDERATIONS FOR REVIEW OF EVALUATION APPROACH

The resource options evaluation approach has been reviewed in the context of the specific requirements for the current evaluation of the broad range of 2016 Resource Plan resource options.[1]

Basic issues to address for the required study approach include the following:

- The environmental effects must often be characterized as "potential" given that the evaluation is based on secondary sources and additional baseline studies would be required to verify presence or absence of a species or habitat feature.
- The socio-economic evaluation of the priority sites can potentially focus on various forms of land tenure and dispositions, historic and archaeological resources, jobs and gross domestic product (GDP), and qualitative assessments of potential effects on local labour supply, traditional Aboriginal activities and community well-being. The evaluation can also potentially include broad indicators of potential effects, given the many opportunities that exist to mitigate adverse effects and enhance positive ones.
- The comparative ranking of different resource options will need to highlight the key advantages or disadvantages between the options, representing the positive effects that could occur and might need to be enhanced and the negative effects that will likely require attention through design and further mitigation. Initial consideration might be given to using a "Higher," "Moderate" and "Lower" rating scheme to provide a preliminary indication of the level of constraint relative to other priority sites that is likely to be associated with the proposed development:
    - **Higher** ratings in this context would mean that an option may result in negative effects and/or offers the least potential for positive effects. In some cases, this rating could also mean that the effects are of greater magnitude relative to other sites. This rating would imply requirements for a greater level of future investigation, the potential requirement for site-specific design features, and a likely need for greater effort in the design of mitigation, compensation and enhancement measures.
    - **Moderate** ratings would mean that the option has a mix of positive and negative effects.
    - **Lower** ratings in this context would mean that an option has less potential for negative effects and/or offers greater potential for positive socio-economic effects than other sites; however, this rating would not necessarily mean that a site is constraint free or will require less attention through further assessment, design and mitigation.

[1] The study team also reviewed the approach adopted in a similar prior assessment for the Yukon Development Corporation by SLR Consulting Global Environmental Solutions (SLR) of six large hydro priority site options ("Yukon Next Generation Hydro and Transmission Viability Study - Positive and Negative Environmental and Socio-economic Effects - Technical Paper", November 2015).

The resource options evaluation approach has also been reviewed in the context of the following four specific considerations, keeping in mind the requirement to review here a very broad range of resource options with varying capacity scales and characteristics:

- **Risk and Opportunity Comparative Focus** – Meaningful evaluation of diverse options at a preliminary state of assessment needs to compare distinct risks and opportunities to facilitate the selection of options meriting further work, recognizing that future work will be needed to reach more definitive assessments as to feasibility and potential effects. The highlighting of adverse effect risks for a resource option also provides a focus on the varying regulatory review challenges for the different options, recognizing that mitigation measures will be required to address these risks before a resource option can be implemented and noting that some resource options or project elements (e.g., transmission corridors or interconnections, access roads) may offer greater opportunities to mitigate (by varying site location) than other resource options or project elements dependent on the use of a specific site (e.g., pumped hydro storage reservoir options).
- **Comparative Assessments by Separate Criteria –** Comparative assessment needs to be retained for each of the separate criteria defined for each of the three attributes (i.e., environmental, social and economic attributes), recognizing the importance at this stage of displaying key differences among the resource options rather than attempting an overall ranking of these options across very different criteria. Separate evaluation matrix tables are accordingly developed for the environmental, social and economic evaluations. In each table, the key criteria are separately retained in any final assessment (showing comparative ranking of each resource option for each of these criteria).
- **Comparative Assessment of Resource Options versus Project Options –** Meaningful and easily understood comparison of very different resource options (e.g., widely varying generation options, storage options, and transmission corridor options) is required, as well as comparative assessment of project options specific to each type of resource option (e.g., different hydro sites or different wind sites, as well as different potential scales or cases for development of a specific option). In the current study, an important related consideration is clarity in showing when a generation resource project option is dependent on a specific transmission corridor project option.
- **Comparative Assessment of Resource Options with Different Technical and Financial Attributes –** Where feasible, meaningful comparison of resource options needs to consider material differences in technical attributes (e.g., capacity and energy scales, dependability, seasonal variability, timing for development) and financial attributes (e.g., capital costs and related risks, operating and maintenance costs, levelized costs of energy and capacity). Useful comparative evaluation is enhanced when resource options are sorted by similar technical and financial attributes.

The criteria were also reviewed and compared to address the following concerns:

- Avoid double counting of criteria (i.e., not use two or more criteria to measure the same thing). This is particularly important within each of the three main assessments (e.g., separate

environmental, social and economic evaluations). In some cases, information from the environmental evaluation may also be useful for the social and economic evaluations.

- Add, delete or shift criteria and/or indicators to improve or optimize assessment. Suggested additions or deletions are reviewed in greater detail for environmental, social and economic categories.
- A survey document has already been issued using the criteria developed and included in the Draft Evaluation Matrix included as Attachment 1, and it is therefore necessary that the final criteria adopted at least reflect or include the thrust points of the criteria used in the Draft Evaluation Matrix (i.e., additional criteria may be added, but the initial criteria must also be represented).

It was considered desirable to adopt a simple standard scale for the evaluation of each criteria to optimize the comparative evaluation of the various resource options separately for environmental, social and economic criteria. Initial planning looked in most cases at a Low/Medium/High or three-part numerical scale, with provision for showing whether effects are beneficial (+) or adverse (-), and with Low representing low adverse effects overall and High representing high adverse effects or concerns overall.

Based on the above considerations, the following 2016 Resource Plan Resource Option Evaluation Matrix tables have been prepared:

- Table B 4-1 - Resource Option Evaluation Matrix - Environmental Criteria & Indicators;
- Table B 5-1 - Resource Option Evaluation Matrix - Social Criteria & Indicators; and
- Table B 6-1 - Resource Option Evaluation Matrix - Economic Criteria & Indicators.

Key factors affecting each of the three attributes are reviewed below. To simplify each matrix, complex descriptions and objectives sections of the Attachment 1 Draft table are excluded and attention is directed solely at the criteria and indicators used to evaluate resource options for each attribute and the metrics used to evaluate each indicator.

4.0 ENVIRONMENTAL CRITERIA AND INDICATORS

Table B 4-1 includes the following key changes to Yukon Energy's initial list of environmental criteria and indicators (summarized in the Draft Evaluation Matrix included as Attachment 1 to this appendix):

- For **En1 (Species and Habitat)** and **En2 (Land/Resource Use Intensity and Naturalness)** as set out in Attachment 1, it is noted that many elements considered under each criteria are difficult to define as separate (e.g., footprint effects under En2 affect species and habitat under En1).

  The changes to the environmental criteria and indicators consider many of the same issues, but the presentation is simplified for the following reasons: to be consistent with the basic requirements for this evaluation as reviewed in Section 3 above and to be consistent with how these matters would be considered, addressed and understood as part of an environmental assessment (i.e., focus on effects to the aquatic environment, terrestrial environment and air quality).

  Species and Habitat and **Land Use/Resource Use Intensity and Naturalness** are still explicitly considered, but now as part of the separate consideration of the aquatic environment and the terrestrial environment.

  The criteria and indicators for the draft versions of En1 and En2 are now as follows (see Table B 4-1 for the metrics related to each indicator):

  - **En1 – Fish and Fish Habitat**: This will include consideration of the following indicators:
    - Salmon and Habitat;
    - Species at Risk and Habitat; and
    - Commercial, Recreational or Aboriginal Fishery Species and Habitat.

    For each of the above, the assessment will include consideration of the presence or absence of the species (Yes/No), as well as the relative effect (positive or negative effects and L/M/H assessments).
  - **En2 – Water Quality and Quantity**: This will include consideration of the following indicators:
    - Consumptive Water Use;
    - Relative Scale of New Impoundment/Flooding; and
    - Flow Changes.
  - **En3 – Terrestrial Species and Habitat**: This will include consideration of the following indicators:
    - Species at Risk and Habitat;
    - Protected and Conservation Areas;
    - Wildlife Key Areas; and

- Caribou Ranges.

For each of the above, where relevant the assessment will include consideration of the presence or absence of the species (Yes/No), as well as the relative effect (positive or negative effects and L/M/H assessments).

- **En4 – Terrestrial Footprint and Land Use**: This will include consideration of the following indicators:
  - Footprint Terrestrial Areas, including access and new flooding;
  - Linear Development for roads, transmission;
  - Permafrost; and
  - Wetlands.

It is also noted that **Visual Aesthetics** (considered under Land and Resource Use Intensity and Naturalness in Attachment 1) is shifted from the environmental assessment to the social assessment (aesthetics in environmental assessments typically relates to people's relationship to the environment, and is therefore included under the social matrix). This also reduces duplication between the environmental assessment and the social assessment.

- **En3 (Pollution and Contamination)** as set out in Attachment 1 is not considered as a separate criteria in the environmental assessment, but instead will be considered as follows:
  - Effects related to greenhouse gas (GHG) and other emissions will be considered as part of **En5 (Air Quality)**.
  - Other effects related to the risk of unintended release of pollutants are typically considered and addressed as part of planning for each project as part of the assessment of accidents and malfunctions (and are not intended outcomes of the proposed project). As such, there is less importance to considering these risks when evaluating different resource options at this initial planning stage. However, in the event that a specific option involves enhanced risks that merit attention, these can be addressed in the evaluation either with regard to risks to specific species and/or habitats or specific social effect concerns.
  - Other contamination risks that may arise from implementation of a project, such as mercury contamination due to impoundment, will be considered as part of the effects due to the relative scale of new impoundment/flooding (as well as social evaluations related to human and community health and traditional lifestyle activities).
- **En4 (Climate Change Adaptation/Resiliency)** as set out in Attachment 1 addresses the effects of the environment on the project (as opposed to effects of the project on the environment, which is the focus of all other environmental criteria). As such, this has been included as an economic criteria for this assessment (as opposed to being an environmental criteria) to address potential risks related to project design and operation. Overall, a project will need to be planned to address risks imposed by environmental factors such as flood, drought, wind and climate change. This requirement will affect construction and operating costs for the project.

Table B 4-1: Resource Options Evaluation Matrix - Environmental Criteria & Indicators

	ID	Criteria	Indicator	Metric ID	Metric
	Environmental Criteria				
Aquatic Environment	**En1**	**Fish and Fish Habitat**	Salmon & Habitat	En1-1	Presence or absence (Y/N) & Relative Impact (+/-)
			Species at Risk & Habitat	En1-2	Presence or absence (Y/N) & Relative Impact (+/-)
			Commercial, Recreational or Aboriginal Fishery Species & Habitat	En1-3	Presence or absence (Y/N) & Relative Impact (+/-)
	En2	**Water Quantity & Quality**	Consumptive Water Use	En2-1	Water Use Intensity (m3/day)
			Relative Scale of New Impoundment/ Flooding	En2-2	Presence or absence (Y/N) & Relative Scale (L/M/H)
			Flow changes	En2-3	Presence or absence (Y/N) & Relative Scale (Run of River; Storage; Pumped Storage)
Terrestrial Environment	**En3**	**Terrestrial Species & Habitat**	Species at Risk & Habitat	En3-1	Presence or absence (Y/N) & Relative Impact (+/-)
			Protected & Conservation Area	En3-2	Proximity to Protected & Conservation Areas (L/M/H)
			Wildlife Key Areas	En3-3	Proximity to WKAs (L/M/H)
			Caribou Ranges	En3-4	Proximity to Caribou Ranges (L/M/H)
	En4	**Terrestrial Footprint & Land Use**	Footprint Terrestrial Area including access & new flooding (Total km2)	En4-1	Area of Project Terrestrial Footprint (km2)
			Linear Development for roads, transmission (km)	En4-2	Total length of linear features (km)
			Permafrost	En4-3	Presence or absence (Y/N) & Relative Scale (L/M/H)
			Wetlands	En4-4	Presence or absence (Y/N) & Relative Scale (L/M/H)
Air	**En5**	**Air Quality**	GHG Emissions (in Yukon)	En5-1	Intensity (per kWh)
			Other Air Pollutants	En5-2	Intensity (per kWh)

5.0 SOCIAL CRITERIA AND INDICATORS

The criteria and indicators presented in Table B 5-1 maintain in most respects the original criteria provided by Yukon Energy (as summarized in Attachment 1 to this appendix) with the following key changes:

- Addition of a new criteria to address **First Nations Settlement Lands** (S1 First Nations Lands). This will consider whether there is an overlap with or effect on access to Settlement Lands or Interim Protected Lands.
- The criteria **Traditional Lifestyle** and **Heritage Resources** are maintained but are numbered separately (now S2 and S3, respectively). The indicators are refined as follows:
    - **Footprint Land Area Impact** will consider, as a point of reference, the total hectares (ha) of direct land loss (provided as part of the environment assessment Footprint Terrestrial Area [En4-1]).
    - **Land Area Loss regarding Traditional Lifestyle and Land Quality Effects on Traditional Lifestyle -** will provide a more qualitative assessment related to effects on access or direct loss of traditional areas due to impoundments or other issues related to project footprint effects. This corresponds to the **Land Quality Effects** indicator in Attachment 1.
    - **Cabins, Camps and Structures** – This addresses the **Land Tenure** indicator included in Attachment 1. It is considered that the revised title better indicates what is being examined.
    - **Country Foods** – This addresses the **Diet** indicator included in Attachment 1, but clearly shows that country foods, meat and fish are being combined into one assessment. The assessment will rely in part on information collected for the environmental assessment under Commercial, Recreational or Aboriginal Fishery Species and Habitat (En1-3).
- **Heritage Resources Potential**: The proposed criteria and indicators follow the criteria and indicators included in Attachment 1.
- **Tourism and Recreation** (S2 in Attachment 1) is maintained as a criteria but expanded in scope to include **Other Resources and Land Use**. The indicators are refined as follows:
    - **Recreational Values:** Existing and new recreational values/opportunities were considered as separate indicators in the Attachment 1 matrix. These are combined into one indicator in order to simplify the evaluation.
    - **Tourism Values:** This follows the original indicator as presented in Attachment 1.
    - **Aesthetics:** Attachment 1 considered effects on visual and auditory aesthetics as part of the environmental assessment (En2-2 in Attachment 1) or as part of Heritage Resource Potential (S3-1 in Attachment 1). This has been shifted to be considered as part of the assessment of tourism, recreation and other resources and land use.

- **Other Renewable Resources and Non-renewable Resources**: This was not included in Attachment 1, but consideration of effect on all other resources and resource use due to new access being created (or other effects of the resource option) is warranted.
- **Land Use and Renewable Resources Plans**: This was not included in Attachment 1, but consideration of land use and consistency with renewable resources plans is considered warranted.

- **Cultural and Community Well-being** is maintained with the following refinement to indicators (undertaken to be consistent with matters typically considered as part of socio-economic assessments):
  - **Infrastructure and Services**: Potential effects to infrastructure and services were considered in part under **Community value** (under the **Other Value Generation and Distribution Criteria**, Ec1-5) in Attachment 1; this is now broken into its own indicator under Cultural and Community Well-being. Effects can be positive or negative.
  - **Public Safety, Worker Interaction, Human and Community Health:** Considers issues over construction and operation (as opposed to only construction effects) and clarifies that worker interaction, as well as human and community health, are also included.
  - **Community, First Nation and Personal Development:** The key change in indicators compared to Attachment 1 is to shift consideration of employment and education opportunities from being separate indicators to being considered as part of Community and Personal Development indicator. Overall, there is concern that at this stage in project development, there will be limited information available related to employment, training and other educational opportunities. Further, such effects are typically included under economic criteria. As revised, the indicator allows for broad consideration of overall effects on local community and personal development. Effects can be positive or negative.

Table B 5-1: Resource Option Evaluation Matrix - Social Criteria & Indicators

ID	Criteria	Indicator	Metric ID	Metric	Rating Scheme
Social Criteria					
S1	**First Nation Lands**	Settlement Lands, Interim Protected Lands	S1-1	Overlap and/or access with these lands (Y/ Potential/N)	
S2	**Traditional Lifestyle**	Footprint land area impact	S2-1	Total area (ha) of direct land loss	
		Land area loss re Traditional Lifestyle	S2-2	Total area (ha) of Traditional Use land area loss	
		Land Quality Effects on Traditional Lifestyle	S2-3	Indirect effects on land or access for such pursuits (+/- and L/M/H)	
		Cabins, Camps & Structures	S2-4	Number of cabins, camps, homesteads, etc. in footprint (corridor for linear access) that may be affected (n)	
		Country Foods	S2-5	Effects to the opportunity to harvest country foods (+/- and L/M/H)	
S3	**Heritage Resources**	Heritage Resource Potential	S3-1	Density (number of discrete) known or potential archeological, palaeontological, ethnological, prehistoric, or historic resources (L/M/H)	
			S3-2	Importance/Cultural Value of heritage resources, including areas of land containing heritage resources. (L/M/H)	
S4	**Tourism, Recreation & Other Resources and Land Use**	Recreational Values	S4-1	Effect on nature and scale of existing and new Recreational Values. (+/- and L/M/H)	
		Tourism Values	S4-2	Effect on nature and Scale of Tourism Values. (+/- and L/M/H)	
		Aesthetics	S4-3	Effect on auditory or visual aesthetics. (+/- and L/M/H)	
		Non-renewable Resources	S4-4	Effect on Non-Renewable Resources. (+/- and L/M/H)	
		Other Renewable Resources	S4-5	Effect on other Renewable Resources. (+/- and L/M/H)	
		Land Use & Renewable Resources Plans	S4-6	Consistent with Land Use& Renewable Resources Plans (Y/N, NA)	
S5	**Cultural and Community Well Being**	Infrastructure & Services	S5-1	Effect on Infrastructure & Services (+/- and L/M/H)	
		Public Safety, Worker Interaction, Human and Community Health	S5-2	Risks to Community Health & Safety - construction & operation (L/M/H)	
		Community, First Nation & Personal Development	S5-3	Effects on local jobs, business, training & development (+/- and L/M/H)	

6.0 ECONOMIC CRITERIA AND INDICATORS

Economic criteria were reviewed to consider added criteria to address separate key risks and concerns related to economic effects throughout the economic life of each resource option.

The following concerns and interests are addressed in the Table B-6-1 economic criteria and indicators:

- Reliance on economic indicators such as GDP and Gross Progress Indicator (GPI) have limited use at this time based on available information and use in Yukon, duplication with other indicators/criteria and overall usefulness within the economic criteria evaluation of the different resource options to be examined at this time. Local Economic Effects can be addressed through other indicators based on information developed to date or otherwise available for the resource options.
- Effects of the environment on the resource option are relevant to economic evaluations of resource options (as such effects could affect costs and risks for specific options). In the context of the 2016 Resource Plan, this climate change risk assessment involves assessing climate change risk effects on financial attributes of resource options.

Economic evaluation for any socio-economic assessment of a resource option in Yukon would normally also include effects on ratepayers, i.e., costs of power, and any related risks and other development effects, e.g., risks of fixed costs adversely affecting ratepayers and other ratepayer risks related to potential resource underutilization. These considerations are addressed elsewhere in Yukon Energy's 2016 Resource Plan process are therefore are not included in Table B 6-1.[2]

In summary, Table B-6-1 includes the following economic criteria:

- **Ec1 – Local Economic Impacts:** Considers opportunities during construction and operation as well as community and other development opportunities (similar to **Economic Opportunity** and **Community Value** indicators included in Attachment 1).
- **Ec2 – Climate Change Risk Affecting Resource Financial Attributes:** As discussed in Section 4, each resource option will need to be planned to address risks imposed by environmental factors such as flood, drought, wind and climate change. These factors may affect construction and operating costs and economic risks for the project resource option.

[2] These considerations were not included in the Attachment 1 matrix, reflecting the fact that the 2016 Resource Plan process is currently addressing these matters separately as "Technical Attributes" and "Financial Attributes."

Table B 6-1: Resource Options Evaluation Matrix - Economic Criteria & Indicators

ID	Criteria	Indicator	Metric ID	Metric
Economic Criteria				
Ec1	**Local Economic Impacts**	Yukon Opportunities during Construction	Ec1-1	Capital Cost - Civil and Other Local Share (L/M/H)
		Yukon Opportunities during Operation	Ec1-2	Operation Costs - Yukon Labour & Business Opportunity (L/M/H)
		Community & Other Development Opportunity	Ec1-3	Community, Industry Development Opportunity (L/M/H)
Ec2	**Climate Change Risk Affecting Resource Financial Attributes**	Susceptibility to Extreme Weather Events/Conditions	Ec2-1	Susceptible to Extreme Heat/Drought (L/M/H)
			Ec2-2	Susceptible to Extreme Precipitation - flood/snow
			Ec2-3	Susceptible to Extreme Wind Events (L/M/H)
			Ec2-4	Susceptible to Ice Related Processes/Events (L/M/H)
		Conditions Susceptible to Climate Change	Ec2-5	Extent of Permafrost in project footprint (L/M/H)

7.0 RESOURCE OPTIONS RATINGS FOR EACH INDICATOR

The range of resource options to be evaluated and the groupings adopted for these options are summarized in Section 6 of Appendix A. For certain resource options, a range of sites and/or scales of potential development are also included in the evaluation.

The evaluation of each resource option is reported separately for each indicator adopted to assess environmental, social and economic criteria. This approach recognizes the importance at this stage of displaying key differences among the resource options rather than attempting any overall ranking of these options across very different key indicators.

Separate evaluation matrix tables are provided for the three main attributes (i.e., environmental, social and economic attributes) using the criteria and indicators as set out in Tables B 4-1, B 5-1 and B 6-1 of this appendix. In each evaluation matrix table, each resource option is ranked for each indicator adopted to evaluate the separate criteria.

Rating approaches for each indicator were developed separately, as appropriate, for the criteria adopted to evaluate resource options for each main attribute (see Appendix C for Environmental, Appendix D for Social and Appendix E for Economic for the technical analysis supporting each evaluation).

The overall framework for reporting on the ranking evaluation for each indicator follows the colour-coded rating system described below.

The overall objective of the evaluation approach is to identify on a common scale (low, medium, and high) which indicators are particularly relevant to each resource option. A high rating indicates that potential effects on an indicator are high for a specific resource option compared with the other resource options under review. A low rating indicates that potential effects on an indicator are low for a specific resource option compared with the other resource options under review A medium rating indicates an evaluation that falls between the high and low ratings.

The evaluation approach involves criteria that address a diverse range of risks, benefits, and potential linkages with the resource options. The following examples demonstrate this range, and highlight the need to consider in each instance the nature of the indicator when interpreting the ratings of high, medium or low for different resource options:

- **Adverse Effects Indicators -** Many of the environmental and social criteria and indicators focus on potential risks of adverse effects on specific criteria and indicators, where a high or red rating means a high relative risk of an adverse effect, e.g., effects on fish and fish habitat, effects on terrestrial species and habitat, effects on air quality, effects on First Nation lands, effects on traditional lifestyle, effects on heritage resources, and some indicators related to cultural and community well-being. When rating adverse effects for a resource option on an indicator, red means a high rating, yellow means a medium rating, and green means a low rating.
- **Positive Effects Indicators -** Some social and economic indicators focus on potential beneficial effects on specific criteria and indicators, where a high rating means a high relative level of potential benefits, e.g., effects on criteria such as Local Economic Impacts and Community, First

Nation and Personal Development. In this instance, a red colour rating as adopted for adverse effects indicators might suggest (incorrectly) that a high rating has adverse rather than positive effects - while a green colour rating to suggest "positive" outcomes could also be confusing given that green means low level effects when assessing adverse effects indicators. Accordingly, no colour rating is used for the few indicators that focus on positive effects and tables simply show the rating as high positive, medium positive or low positive.

- **Linkage/Overlap Effect Indicators -** Some environmental, social and economic criteria and indicators address overall magnitudes related to linkages or overlaps, where a high or red rating means a high level of linkage or overlap without directly addressing specific adverse or positive effects that may occur, e.g., footprint territorial area, footprints land area effect, linear development distances, flow changes, relative scale of impoundment/flooding, climate change risk affecting resource financial attributes.
- **No Linkage included as Low Rating** - For many resource options, there is no linkage with various environmental indicators (or the indicator is not applicable to the resource option). A low or green rating includes these situations (thereby highlighting no basis for special attention in the future with regard to this indicator when pursuing the resource option).

At this initial stage of the resource option review, effects on any indicator are often best characterized as "potential" given the need to rely on existing information without project specific baseline or assessment studies to verify existing conditions, as well as expected effects. For most resource options evaluated here, current information is at a preliminary level of assessment.

In assessing potential adverse or positive effects, the evaluation assumes adoption of well understood mitigation measures or best management practices to manage potential effects; however, to provide a common evaluation approach for all options, customized mitigation developed for a specific resource option is not considered (even for the few options where more detailed studies and assessments have been carried out, e.g., Stewart-Keno City Transmission, Mayo Lake and Southern Lakes hydro storage enhancement projects).

Accordingly, a high or red rating related to potential adverse effects on an environmental or social indicator does not in any way signify that the resource option is infeasible. Such a rating only shows that these effects will need to be addressed and managed/mitigated in order for the project to proceed.

In summary, the ratings for the evaluation of each indicator were classified in terms of high, medium, and low as follows (see also Figure B 7-1):

- **High (Red when non-positive - no colour when positive effect)** means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, positive or simply signify linkage and/or overlap without much additional guidance);
- **Medium (Yellow when non-positive - no colour when positive effect)** means the resource option has potential expected linkage to the indicator that falls between high and low ratings; and

- **Low (Green when non-positive - no colour when positive effect)** means the resource option likely has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, positive or simply signify no linkage/overlap with the indicator, i.e., no effects pathway).

Figure B 7-1: Rating Criteria Considerations

High	Classification of high means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, positive or simply signify linkage/overlap without much additional guidance). Red signifies a high rating for all non-positive effect indicators. A red (high) rating related to potential adverse effects does not signify that the resource option is infeasible - such a rating only shows that these effects are high and will need to be addressed and managed/mitigated in order for the project to proceed. No colour is used to signify a high rating related to potential positive effects. A high positive rating indicates that such effects for the resource option are high relative to the effects on the indicator from other options; associated with such a rating is a likely requirement to address specific benefit management or enhancement measures.
Medium	Classification of medium means the resource option has potential expected linkage to the indicator that falls between low and high ratings. Yellow signifies a medium rating for all non-positive effect indicators. A yellow (medium) rating related to potential adverse effects indicates a likely need to proceed with caution and/or special attention to the management of certain potential adverse effects (without any determination today that a high expected effects linkage exists). No colour is used to signify a medium rating related to potential positive effects. In many evaluations of adverse effects a medium rating indicates a lack of information needed for a red (high) or green (low) rating.
Low	Classification of low means the resource option has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, positive or simply signify no linkage/overlap with the indicator, i.e., no effects pathway). A green (low) rating related to potential adverse effects indicates that such effects are well understood and likely can be managed through best management practices or standard mitigation measures. No colour rating is used to signify a low rating related to potential positive effects. A low positive rating indicates that such effects for the resource option are low relative to the effects on other options and unlikely to require special benefit management or enhancement measures. A green (low) rating may also signify no linkage between the resource option and the indicator.

Resource Options Evaluation Matrix

Attachment 1: RFP 2016-010 Draft IRP Resource Options Evaluation Matrix

ID	Criteria1	Description	Objective	Indicator	Metric ID	Metric	Rating Scheme	Data Sources
Environmental Criteria								
En1	**Species and Habitats**	The greater the number of valued species that inhabit a given area the greater the species richness implying greater heterogeneity of habitat - i.e., faunal species biodiversity. Species protection and recovery/restoration. Habitats of acknowledged high ecological value (e.g., calving grounds, winter range, wetlands, spawning grounds, protected areas). Habitat conservation considerations. Influence on water quality and quantity.	Options that have the lowest negative effect on biodiversity are preferred. Options that have minimal or no effects to such areas are preferred. No significant change beyond range of natural variability and ability of ecosystem to be sustainable.	Effects Radius/Influence Relative to Fish and Wildlife Key Areas	En1-1	Key habitat areal extent affected by option (km^2)		
				Effects Radius/Influence Relative to SARA Listed Species	En1-2	Type and number of SARA-relevant species in project area (type and n)		
				Effects Radius/Influence Relative to Protected Areas	En1-3	Proximity of Project to Protected Areas (km)		
				Effects to Water Quality	En1-4	Physical or chemical changes to water quality relative to baseline (various dependent on key analyses, e.g., temp, dissolved metals, pH, total gas pressure, total suspended solids)		
				Effects to Water Quantity	En1-5	Changes to water quantity relative to baseline (m^3, m^3/s) during all times of the year		
En2	**Land/Resource Use Intensity and Naturalness**	Landscape patterns are linked to biodiversity and other ecological values of the landscapes. Measures of anthropogenic footprint and intensity as well as biodiversity and other measures of naturalness and ecosystem robustness to be used here. Stream crossings captured may include those with known fish resources or anadromous fish resources (i.e., salmon), or all substantive watercourses regardless of fish (TBD).	Projects that have smaller project footprints or otherwise minimize negative effects to biodiversity and naturalness are preferable.	Project Footprint	En2-1	Areal Extent of Project Footprint (km^2)		
					En2-2	Visual Aesthetic Effects (Naturalness) Profiles (L/M/H)		
					En2-3	Length of Project, if linear development (km)		
				Access Requirements	En2-4	Length of Access Roads (km)		
					En2-5	No. of Stream Crossings (n)		
				Consumptive Water Use	En2-6	Water Use Intensity (m^3/day)		

ID	Criteria1	Description	Objective	Indicator	Metric ID	Metric	Rating Scheme	Data Sources
En3	**Pollution and Contamination**	Waste products and pollution created by resource option. Relative risk profile of resource for environmental releases and contamination.	Lower results are favoured.	Air Pollution	En3-1	Comparative Criteria Air Contaminant Production per unit energy produced (e.g., tonnes SOx, NOx, PM per kWh)		
				GHG Profile	En3-2	Life Cycle GHG Production in Yukon (tonnes/kWh)		
					En3-3	GHG ratio with fossil fuel alternative/default (tonnes renewable GHG/tonnes default Fossil GHG per kWh or vice versa)		
				Risk of Unintended Release of Pollutants	En3-4	Relative Likelihood/Probability of spill/release (L/M/H)		
					En3-5	Consequences of Spill/Release (L/M/H)		
En4	**Climate Change Adaptation / Resiliency**	Character of the option in the context of resiliency or adaptability to predicted long-term climate change and immediate severe weather effects. (Move permafrost indicator and metrics here; develop additional indicators and metrics).	Sites with higher resiliency to forecast CC effects preferred.	Susceptibility to Extreme Weather Events/Conditions	En4-1	Resilience to Extreme Heat/Drought (L/M/H)		
					En4-2	Resilience to Extreme Precipitation - flood/snow (L/M/H)		
					En4-3	Resilience to Extreme Wind Events (L/M/H)		
					En4-4	Resilience to Ice Related Processes/Events (L/M/H)		
				Conditions Susceptible to CC	En4-5	Extent of Permafrost in project footprint (L/M/H)		
Social Criteria								
S1	**Traditional Lifestyle**	Access to country foods, medicinal plants, other subsistence pursuits.	Projects that have lower magnitude effects preferred.	Land Availability/Access Effects	S1-1	Direct Loss of Land or Land Access for such pursuits (km2)		
				Land Quality Effects	S1-2	Indirect effects on land for such pursuits (+/- and L/M/H)		
				Land Tenure	S1-3	Number of cabins, camps, homesteads, etc. in study area that may be affected (n)		
				Diet	S1-4	Predicted effects to the ability/availability of country foods (+/- and L/M/H)		
					S1-5	Effects to the opportunity to harvest fish and meat (+/- and L/M/H)		

ID	Criteria1	Description	Objective	Indicator	Metric ID	Metric	Rating Scheme	Data Sources
S2	**Tourism & Recreation**	Qualitative assessment of effect on valued tourism, leisure, and/or recreational opportunities/resources (e.g., swimming, boating, sport fishing, playgrounds, youth/community centres, campgrounds, significant water recreation, trails, etc.) Professional judgment required to assess this criteria based on local knowledge. Includes big game outfitters.	Sites with less effect to tourism and recreational resources are preferred.	Existing Recreational Values	S2-1	Effect on nature and Scale of Recreational Values. (+/- and L/M/H)		
				New Recreational Opportunities	S2-2	Number/value of new opportunities that project-related access may provide for recreation (+/- and L/M/H)		
				Tourism Value	S2-3	Potential for improved Annual Value of tourism in Regional Study Area (+/- and L/M/H)		
S3	**Heritage Resources**	Project specific effects that can damage sacred or historic areas, artifacts, and loss of use of traditional place names.	Sites that do not effect known high value or significant heritage sites are preferred.	Heritage Resource Potential	S3-1	Density (number of discrete) known or potential archeological, palaeontological, ethnological, prehistoric, historic, or aesthetic resources (L/M/H)		
					S3-2	Importance/Cultural Value of heritage resources, including areas of land containing heritage resources. (L/M/H)		
S4	**Cultural and Community Well Being**	Effects of development/operation on public and worker safety, employment and educational (skills and training) opportunities, Shifts in patterns of work availability and employment can have effects on family/community contributions and/or support of community infrastructure/culture.	Projects that have positive effects on cultural and community wellbeing are preferred.	Employment	S4-1	No. of Direct/Indirect Jobs Created during construction and operations (n)		
				Public Safety	S4-2	Public safety risks posed by project - construction period (L/M/H)		
				Educational Opportunities	S4-3	Provides opportunities for advanced education of local people (L/M/H)		

ID	Criteria1	Description	Objective	Indicator	Metric ID	Metric	Rating Scheme	Data Sources
Economic Criteria								
Ec1	**Other Value Generation and Distribution**	Value of wages, taxes, and consumer spending locally and regionally. Economic leakage. Options that provide, or leverage, the greatest long-term or durable social benefits that contribute to the community sustainability vision. Payments to capital providers and governments.	Maximize circulation of wealth locally and regionally.	Economic Growth / Financial Value	Ec1-1	Gross Domestic Product (GDP)		
					Ec1-2	Genuine Progress Indicator (GPI)		
					Ec1-3	Change in total local/regional employment (no. of FT/PT jobs for construction and operation phases)		
				Economic Opportunity	Ec1-4	% of project employment opportunities that match the skills of the locally/regionally available workforce		
				Community Value	Ec1-5	Value of infrastructure contributions/improvements in communities required for, or inevitable with, project (L/M/H)

1.0 INTRODUCTION

Environmental criteria and indicators for evaluating the resource options, as finalized in Appendix B, are copied below in Table C 1-1.

The technical environmental evaluation of each resource option is addressed in Appendix C, with separate sections for each of the five main environmental criteria in Table C 1-1.

At the start of each section of Appendix C, the distinct issues, rating criteria and data sources for each criteria are summarized. In each case, environmental indicators address non-positive effects, e.g., adverse effects as well as non-linkage cases. Accordingly, as outlined in Section 7 of Appendix B, the ratings for the evaluation of each environmental indicator are classified in terms of high (red), medium (yellow), and low (green) as follows:

- **High (red)** means the resource option has a high expected non-positive effects linkage to the indicator (depending on the indicator, the likely effects may be adverse or simply signify linkage/overlap without much additional guidance);
- **Medium (yellow)** means the resource option has potential expected non-positive linkage to the indicator that falls between green and red ratings; and
- **Low (green)** means the resource option likely has minimal, if any, expected non-positive effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse or simply signify no linkage / overlap with the indicator, i.e., no effects pathway).

“No linkage,” which is shown as green, is separated out in the environmental evaluations to identify circumstances where there is no apparent or likely link between a resource project option (including new road and/or transmission access related to the resource project) and a given environmental indicator.

As each resource project option was reviewed, it was assumed that standard best management practices (BMPs) would be applied during the construction and operation stages to mitigate adverse effects. Where standard BMPs are expected to prevent any likely effect of concern on an indicator, a green or low effect rating is adopted.

Table C 1-1: Resource Option Evaluation Matrix - Environmental Criteria & Indicators

	ID	Criteria	Indicator	Metric ID	Metric
	Environmental Criteria				
Aquatic Environment	**En1**	**Fish and Fish Habitat**	Salmon & Habitat	En1-1	Presence or absence (Y/N) & Relative Impact (+/-)
			Species at Risk & Habitat	En1-2	Presence or absence (Y/N) & Relative Impact (+/-)
			Commercial, Recreational or Aboriginal Fishery Species & Habitat	En1-3	Presence or absence (Y/N) & Relative Impact (+/-)
	En2	**Water Quantity & Quality**	Consumptive Water Use	En2-1	Water Use Intensity (m3/day)
			Relative Scale of New Impoundment/ Flooding	En2-2	Presence or absence (Y/N) & Relative Scale (L/M/H)
			Flow changes	En2-3	Presence or absence (Y/N) & Relative Scale (Run of River; Storage; Pumped Storage)
Terrestrial Environment	**En3**	**Terrestrial Species & Habitat**	Species at Risk & Habitat	En3-1	Presence or absence (Y/N) & Relative Impact (+/-)
			Protected & Conservation Area	En3-2	Proximity to Protected & Conservation Areas (L/M/H)
			Wildlife Key Areas	En3-3	Proximity to WKAs (L/M/H)
			Caribou Ranges	En3-4	Proximity to Caribou Ranges (L/M/H)
	En4	**Terrestrial Footprint & Land Use**	Footprint Terrestrial Area including access & new flooding (Total km2)	En4-1	Area of Project Terrestrial Footprint (km2)
			Linear Development for roads, transmission (km)	En4-2	Total length of linear features (km)
			Permafrost	En4-3	Presence or absence (Y/N) & Relative Scale (L/M/H)
			Wetlands	En4-4	Presence or absence (Y/N) & Relative Scale (L/M/H)
Air	**En5**	**Air Quality**	GHG Emissions (in Yukon)	En5-1	Intensity (per kWh)
			Other Air Pollutants	En5-2	Intensity (per kWh)

2.0 FISH AND FISH HABITAT

2.1 RATING CRITERIA AND DATA SOURCES FOR EN-1: FISH & FISH HABITAT

The rating system outlined in Figure C 2-1 was adopted to guide evaluations of each resource project option for each of the fish and fish habitat indicators.

Figure C 2-1: Summary of Rating Criteria for Fish & Fish Habitat

Indicator	Low	Medium	High
Salmon & Habitat (En1-1)	No salmon present, or no linkage	Potential to interact with salmon rearing habitat	Potential change to salmon migration and/or spawning areas
Species at Risk & Habitat (En1-2)	No fish Species at Risk present, or no linkage	Species of Concern present and no basis for potential major concern.	Endangered species or Species of Concern present[1] and basis for potential major concern
Commercial, Recreational or Aboriginal Fisheries Species & Habitat (En1-3)	No commercial, recreational or Aboriginal fishery present, or no linkage	Commercial, recreational or Aboriginal fishery and no basis for potential major concern	Commercial, recreational or Aboriginal fishery present and basis for potential major concern

Note:

1. Evaluation assumes if a species on Schedule 1 or 2 of *Species at Risk Act* (SARA) are present and there is a basis for potential major concern due to potential effects of the project, this would be high effect to reflect potential levels of concern.

The fish and fish habitat indicators as defined in Table C 1-1 focus on the presence or absence of each indicator (Yes/No rating) and whether the effect is positive or negative. Unless otherwise explicitly noted, the evaluations of each resource option for these indicators have identified only negative effects. Notwithstanding the presence of an indicator species, a green or low rating is applied for access roads and transmission access or corridors for a resource option based on the assumption that BMPs are applied as required for permitting. The Figure C 2-1 rating system also provides a rationale to separate medium (yellow) ratings for each indicator from high (red) ratings, rather than treating the potential for adverse effects as red (high) in each instance. A red (high) rating indicates the need for additional mitigation to be designed that adequately addresses specific concerns if the resource project was to proceed to further review.

Fish habitat indicators have been evaluated based on available fish distribution data from the BC Ministry of Environment and Fisheries and Oceans Canada (DFO). As project-specific habitat assessments have not been undertaken, potential interactions are based on known species life-history functions.

In developing and applying the rating system, the ratings are based on available information regarding resource project option descriptions, as well as known types of environmental effects that the various

types of projects can have on the aquatic environment. Ratings also reflect the preliminary status of the project information available today.

- For **En1-1 (Salmon and Salmon Habitat)**, a project in a watershed with salmon will automatically generate a yellow (medium) rating, highlighting the need to proceed with some caution; however, a red (high) rating will apply if the project includes potential change to salmon migration and/or spawning areas. For example, if the project includes a dam across the river, the rating is elevated to red (high) due to the known effects dams have on salmon migration and access to spawning areas, even if specific spawning locations have not been identified at this time.
- For **En1-2 (Species at Risk and Habitat)**, a red (high) rating applies if endangered species or species of concern are present and there is a basis for potential major concern related to potential effects of the project that are likely to require additional mitigation to be designed that adequately addresses specific concerns if the resource project was to proceed to further review.
- For **En1-3 (Commercial, Recreational or Aboriginal Fisheries Species and Habitat)**, a red (high) rating applies if any of these species/habitat are present and there is a basis for potential major concern related to potential effects of the project that are likely to require additional mitigation to be designed that adequately addresses specific concerns if the resource project was to proceed to further review. In the case of hydro storage projects, for example, habitat changes resulting from flooding can result in an increase in methylmercury production that may affect commercial, recreational or Aboriginal (CRA) fisheries.

2.2 EVALUATIONS

2.2.1 Resource Options with No Material Concerns regarding Fish and Fish Habitat

The fish and fish habitat indicators are not applicable to many resource project options due to the following factors:

- No linkage circumstances where there is no apparent or likely link between a resource project option and a given environmental indicator (e.g., waters with no salmon, no species at risk, no fisheries and settings where a resource option does not have an apparent link or effect pathway with regard to any fish or fish habitat).
- The nature of some of the project types (e.g., there would be no fish habitat in streams for wind projects situated on mountain tops), where use of BMPs would control erosion and prevent negative effects to fish habitat in down gradient areas outside of the immediate project footprint. This same situation applies for resource options where it is recognized that BMPs will address any concerns regarding effects of fish and fish habitat (e.g., transmission projects that involve river or stream crossings) and are recognized not to raise material concerns regarding fish and fish habitat so long as appropriate BMPs are implemented.
- Location of infrastructure on previously disturbed or brownfield sites that are not affecting river environments. For example, resource project options such as solar PV, energy storage, and

various thermal options addressed in this evaluation that are located within urban areas (e.g., Whitehorse or Haines Junction), require no new disturbance and are expected to use standard BMPs to control erosion would also prevent negative effects to fish habitat in down gradient areas that are outside the immediate project footprint.

Table C 2-1 provides a summary of the resource project options with either no linkage (NL) or other green (low) rating (due to assumed BMPs being applied) for any of the fish and fish habitat indicators. Brief supporting information and analysis is provided below on these resource options:

1. **Fossil Fuel Thermal (Diesel or LNG), Non-fossil Fuel Thermal (Biomass, Waste-to-Energy, Biogas), Energy Storage Facility and Solar PV:** Each of these resource options is located in either Whitehorse or Haines Junction, and in most cases, on brownfield sites (e.g., Whitehorse Landfill, Takhini Substation),[1] with no anticipated direct effect pathway on any stream, river or other water body. For projects located in Whitehorse, it is noted that the Yukon River and tributaries in this area provide habitat for salmon and other fish species. However, as noted, none of these resource options would be expected to have any direct effects on the Yukon River. The application of standard BMPs during construction and operation of these resource options are assumed to minimize the risk of sediment or other elements from the project area entering any stream down gradient from the proposed resource option site areas.
2. **Wind Farms and Geothermal:** Each of these resource options involves no anticipated direct effect pathway on any stream, river or other water body. Application of standard BMPs during construction and operation are assumed to minimize the risk of sediment or other elements from the project area entering any stream down gradient from the proposed resource option site areas. Table C 2-1 shows no linkage (NL) for specific options where there is no salmon species, species at risk, or fisheries in the vicinity; in contrast, low is shown where the species or fisheries are in the vicinity (in some cases along access routes and/or transmission routes) and BMPs are required to prevent any effects on fish and fish habitat indicators.
3. **Refurbish Existing Hydro Generation:** Each of these resource options occurs within an existing facility and does not involve any changes to water flows or levels. Application of standard BMPs during construction and operation of these resource options are assumed to minimize the risk of sediment or other elements from the project area entering any stream down gradient from the proposed resource option site areas.
4. **Transmission Corridors:** commercial, recreational or Aboriginal fisheries species and habitat are present in the areas crossed by each transmission corridor option. Salmon and salmon habitat are also likely present for some transmission corridors, e.g. Whitehorse-related corridors and Stewart-Keno City Transmission; however, transmission projects crossing of rivers or streams are recognized not to raise material concerns regarding fish and fish habitat so long as BMPs are implemented as required for any permitting of such projects.

[1] The Haines Junction sites for biomass or solar resource options are within the town in already cleared or largely open areas. The biomass resource option will use beetle-kill wood and not require harvesting green trees.

Table C 2-1: Resource Project Options with No Linkage (NL) or Low Ratings for All Fish & Fish Habitat Indicators

Project / Options	Salmon & Habitat	Species at Risk & Habitat	Commercial, Recreational or Aboriginal Fisheries Species & Habitat
Fossil Fuel Thermal (Diesel or LNG)

2.2.2 Hydro Renewable Generation

Each of the hydro resource options that affect aquatic resources is evaluated separately in the following sections.

2.2.2.1 Pumped Storage

Pumped storage hydro generation resource options each require two reservoirs with water pumped from the lower reservoir to the upper reservoir during the summer season, and the upper reservoir then used for generation during the winter. Effects on fish and fish habitat indicators are reviewed in Table C 2-2 for each of the site options, taking into consideration available information on fish and fish habitat, as well as the changes in the water regime currently assumed for each project option. This evaluation does not attempt to assess any differences in effects on fish and fish habitat due to different scales of development for some of these options, e.g., storage at 50 GWh versus 100 GWh.

Table C 2-2: Summary of Assessment for Pumped Storage

Project / Option	Indicator	Ranking	Assessment
Atlin – Black Mountain	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur within the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur or that are likely to occur in the project area are listed under *Species at Risk* Act (SARA).
	Commercial, Recreational or Aboriginal Species & Habitat	**Medium**	Fish species known to occur in Atlin Lake include: Arctic Grayling, Lake Trout Lake Whitefish, Northern Pike, Round Whitefish, Burbot, Least Cisco, Longnose Sucker, Lake Chub and Coarse (Large) Scale Sucker. Examining some of the adjacent lakes and streams, it is likely that species such as Slimy Sculpin and Burbot could also be present in the lake. There is no fisheries data available for the watershed 837-088400-28000-50000, in which the upper unnamed lake is located (Lake 00172ALL; BC MoE 2016 a, b). There is a commercial, recreational and Aboriginal fishery on Atlin Lake. There is a possibility of fish species being present in the upper reservoir lake that are of value to recreational and Aboriginal fisheries. ***The effect on these types of fisheries is considered to be Medium due to the remote location of the upper reservoir lake, uncertainty as to species in this upper reservoir lake and the minimal effects expected on Atlin Lake levels.***
Canyon – Ittlemit	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur within the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.

Project / Option	Indicator	Ranking	Assessment
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Lake Trout are known to occur in Ittlemit Lake. Lake Whitefish, Lake Trout, Northern Pike, Longnose Sucker, and Slimy Sculpin have been documented in Canyon Lake. The presence of Lake Trout in Ittlemit Lake and the diverse fish community in Canyon Lake is an indication that recreational or Aboriginal fisheries could be present. The significant increase in Canyon Lake volume (based on the presence of a >30 m high dam), could result in adverse effects to fish populations (e.g. spawning/incubation success, habitat changes). ***Therefore, effects on this indicator were considered to be High.***
Lindeman – Fraser	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Lake Trout, Arctic Grayling, and Lake Whitefish are known to occur in Lindeman Lake. There was no fish information available for Fraser Lake. Based on the known fish species present, there is likely a recreational and Aboriginal fishery in Lindeman Lake. The size of the enlargements of the upper and lower reservoir lakes is unknown at this time. The increase in impoundment size could result in adverse effects to fish populations (e.g. spawning/incubation success, habitat changes). In addition, the dam at the lake outlet could affect fish movements and access to spawning habitat. ***Therefore, effects on this indicator were considered to be High.***
Racine – Moon	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Arctic Grayling, Burbot, Lake Trout and Round Whitefish are known to occur in Racine Lake. According to local guides, there are no fish present in Moon Lake. Based on the known fish species present, there is likely a recreational and Aboriginal fishery in Racine Lake. The construction of a dam on Racine Lake would control water levels and could obstruct movements between Racine and Tagish Lake. The preliminary dam location would also make the lake smaller resulting in a loss of habitat. Based on the available information it is not possible to assess the potential significance of the changes to Tagish Lake water levels and connection. Given the species diversity in Racine Lake, the loss of habitat and potential changes to water levels and migration, ***this has been assessed as High.***

Project / Option	Indicator	Ranking	Assessment
Racine – Mt. Brown	Salmon & Habitat	No Linkage	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	No Linkage	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	High	Arctic Grayling, Burbot, Lake Trout and Round Whitefish are known to occur in Racine Lake. According to local guides, there was no fish sampling information for the unnamed lake that will be used as the upper reservoir. Based on the known fish species present, there is likely a recreational and Aboriginal fishery in Racine Lake. The construction of a dam on Racine Lake would change water levels and could obstruct movements between Racine and Tagish Lake. The preliminary dam location would also make the lake smaller resulting in a loss of habitat. Based on the available information it is not possible to assess the potential significant of the changes to Tagish Lake water levels and connection. ***Given the species diversity in Racine Lake, the loss of habitat and potential changes to water levels and migration, this has been assessed as High.***
Squanga – Dalayee	Salmon & Habitat	No Linkage	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	High	The Squanga Whitefish are a genetically distinct form of Lake Whitefish. While the speciation of the Squanga Whitefish has not yet been clarified (i.e., are they a sub-species of Lake Whitefish or a separate species), they are currently listed as a Species of Concern under Schedule 3 of SARA. There is very little known about the life-history and habitat requirements of the Squanga Whitefish; however, it is a fall spawning species that can be affected by water level management. Impoundments and water level management on the two lakes have the potential to affect spawning/incubation success as well as habitat. ***As this project has the potential to change habitat in a substantial portion of the Squanga Whitefish known range, it has been ranked as High.***
	Commercial, Recreational or Aboriginal Species & Habitat	High	Arctic Grayling, Lake Trout and Burbot are known to occur in Dalayee Lake. Arctic Grayling, Lake Whitefish, Northern Pike and Slimy Sculpin occur in the stream between Dalayee and Squanga lakes. Northern Pike and Squanga Whitefish are known to occur in Squanga Lake and it is likely that the species found upstream of Squanga Lake would also be found in Squanga Lake. The impoundments on the two lakes could affect fish species important to recreational and Aboriginal fisheries, both in the lakes and the interconnecting stream reach. The increase in impoundment

Project / Option	Indicator	Ranking	Assessment
			size on Squanga Lake and water level management on both lakes could result in adverse effects to fish populations. The preliminary dam locations will also result in a loss of existing habitat (at and behind the dam) in both lakes. ***Therefore, this has been assessed as High.***
Moon Lake (Tutshi – Moon)	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**Medium**	Arctic Grayling, Burbot, Coarse Scale Sucker, Inconnu, Lake Trout, Longnose Sucker, Northern Pike, Round Whitefish and Slimy Sculpin are known to occur in Tutshi Lake. Arctic Grayling, Lake Trout, Round Whitefish and unidentified sucker species are known to occur downstream of the project area in Tagish Lake. The importance of the downstream flows between Tutshi and Tagish lakes to local fish populations is currently unknown; however, based on its size and geomorphological characteristics visible in the satellite images, it is likely an important migration corridor and would likely provide spawning habitat to stream spawning species such as Arctic Grayling and the various sucker species. Available analysis suggests that the project will have no material effect on water levels at Tutshi Lake, implying no material effect on downstream flows to Tagish Lake. ***Given the effects on fish appear to be restricted to the river where information on fish populations and flow changes is not available, this has been assessed as Medium.***
Faro – Vangorda Pit	Salmon & Habitat	**High**	There are no salmon species in the project area of the upper reservoir; however, the lower reservoir area will flood a large portion of Blind Creek, which is a known Chinook Salmon spawning stream. ***The flooding of Chinook spawning habitat results in this being ranked as High.***
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	A waterfall on Vangorda Creek approximately 4 km upstream of Pelly River prevents fish use of the upper section of this creek near the proposed project. However, the preliminary layout of the reservoir dimensions shows the lower reservoir affecting a portion of Blind Creek, which is a known Chinook Salmon spawning stream and likely has several other fish species. ***Therefore, this has been ranked as High.***

2.2.2.2 Small Hydro Projects

With the exception of the Wolf River option (which assumes a run-of-river development at 20 MW), the Small Hydro generation resource options in this evaluation each include a dam as required to provide storage for winter generation (with resultant effects on aquatic resources related to changed water flows, lake levels and impediments to fish movement). Effects on fish and fish habitat indicators are reviewed in Table C 2-3 for each of the site options, taking into consideration available information on fish and fish habitat, as well as the changes in the water regime currently assumed for each project option.

Table C 2-3: Summary of Assessment for Small Hydro Projects

Project / Option	Indicator	Ranking	Assessment
Drury Lake	Salmon & Habitat	**Medium**	Chinook Salmon are known to occur in Drury Creek downstream of Drury Lake and the dam. Therefore, dam operation could affect downstream flows; the extent of flow changes has not been modelled; ***therefore, this has been assessed as Medium.***
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Arctic Grayling, Lake Trout and Northern Pike are known to occur in Drury Lake and Chinook Salmon have been documented in Drury Creek. Commercial, recreational and Aboriginal fisheries occur in the project area. In addition, increased lake levels and impoundment areas would flood terrestrial areas, which could have adverse effects on fish populations in the lake (e.g., spawning and incubation success and changes to habitat). Such changes could affect commercial, recreational and Aboriginal fisheries. ***Therefore, this has been assessed as High.***
Finlayson River	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**Medium**	None of the fish species known to occur in the project area are listed under SARA. Bull Trout are known to occur in the project area. The Yukon population of this species are currently listed as "Data Deficient" (COSEWIC 2012). ***Due to uncertainties associated with this species, and the fact that it has been listed as a Species of Special Concern in other parts of its Canadian range, the Species at Risk & Habitat fish species indicator has been ranked as Medium.***

Project / Option	Indicator	Ranking	Assessment
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Arctic Grayling, Bull Trout, Lake Trout, Northern Pike, and unidentified species of whitefish are known to occur in Finlayson Lake. Increases in impoundment size could result in adverse effects to fish populations. Water level management could have an effect on critical life-stages (e.g., egg incubation) and habitat quality. Specifically, changes in lake levels could affect spawning habitat for fall spawning fish species (Lake Trout and whitefish). There are potential changes in downstream flows that potentially could affect fish habitat in the lower 6 km of the Finlayson River (upstream of the Frances Lake) due to diversion of water into the penstock. The importance of this river to local fish populations is currently unknown; however, based on its size and geomorphological characteristics visible in the satellite images, it is likely an important migration corridor and would likely provide spawning habitat to stream spawning species such as Arctic Grayling and Bull Trout. ***Changes to the lake and river habitats, combined with numerous species present results in High ranking***.
Altin – Pine Creek	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**Medium**	Arctic Grayling and Slimy Sculpin are known to occur in Surprise Lake. A barrier prevents other species from accessing the middle/upper portion of the watershed. The lower watershed (~2 km) can be accessed by the several fish species found in Atlin Lake; however, in terms of commercial, recreational or Aboriginal fish species, this area appears most suitable for Arctic Grayling. The Surprise Lake Arctic Grayling population has limited spawning habitat available and a fish way was included in the current power generating facility to provide unrestricted movements between the lake and Pine Creek (outflow tributary stream). Surprise Lake is already affected by an existing hydro development with a current licence allowing water levels up to 913.85 m. The proposed project would retain the current upper level of licensed operation but utilize increased storage by drawing down the lake to 911.35 m. The project has the potential to change water levels in Pine Creek and Surprise Lake and will have to be planned to mitigate effects on fish; however, ***given there appears to be only one species of concern that is generally resilient to change, this indicator has been ranked as Medium.***

Project / Option	Indicator	Ranking	Assessment
Tutshi – Windy Arm	Salmon & Habitat	**No Linkage**	There are no salmon species known to occur in the project area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Arctic Grayling, Burbot, Inconnu, Lake Trout, Least Cisco, Longnose Sucker, Northern Pike, Round Whitefish and Slimy Sculpin are known to occur in the project area. Based on the fish species known to occur in the project area there would likely be recreational and Aboriginal fisheries. This project involves raising Tutshi Lake by 5 m, which will likely affect fish populations and habitat. There are also potential changes in downstream flows to the reach of river between Tutshi and Tagish lakes and upstream movements into Tutshi Lake due to the new dam and operation of the powerhouse. The importance of this river between Tutshi and Tagish lakes to the local fish populations is currently unknown; however, based on its size and geomorphological characteristics visible in the satellite images, it is likely an important migration corridor and would likely provide spawning habitat to stream spawning species such as Arctic Grayling and the various sucker species. ***Changes to the lake and river habitats, combined with numerous species present results in a High ranking.***
Wolf River	Salmon & Habitat	**Medium**	There are Chinook Salmon present in Wolf River and spawning has been documented as far upstream as the outlet of Wolf Lake. This project is run-of-river, which is limited to a short section of the lower Wolf River (~8 km) and should not impede fish passage. ***This has been ranked as Medium as the area affected is small and the extent of flow modifications has not been modelled.***
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**Medium**	Fish species known to occur in the Wolf River include Arctic Grayling, Burbot, Chinook Salmon, Inconnu, Lake Trout, Least Cisco, Longnose sucker, Northern Pike, Round Whitefish, and Slimy Sculpin. The fish species present would contribute to commercial, recreational and Aboriginal fisheries. ***This has been ranked as Medium due as the area affected is small and the extent of flow modifications has not been modelled.***

Project / Option	Indicator	Ranking	Assessment
Anvil Creek	Salmon & Habitat	**Medium**	Blind Creek is a known Chinook salmon spawning stream. There is also likelihood that Anvil Creek is used by Chinook (especially juveniles). Flow reductions in Anvil Creek and modifications to flow rates in Blind Creek could affect Chinook salmon. The extent of flow changes has not been modelled; ***therefore, this has been assessed as Medium.***
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**High**	Lake trout, northern pike, Arctic grayling and whitefish (unspecified species) have been documented in Anvil Creek near the outlet of Anvil Lake. Some cabins are present on the lake and recreational fishing does occur. Impoundment of the lake will result in flooding of terrestrial vegetation and this combined with fluctuating water levels could affect fish populations in the lake, especially fall spawning species such as lake trout; as such, ***this indicator has been ranked as High.***

2.2.2.3 Gladstone Diversion

The Gladstone Diversion resource option would divert water from the headwaters of Gladstone Creek into Isaac Creek, which flows into Sekulmun Lake and then Aishihik Lake. Lake trout spawning occurs in all four Gladstone Lakes, and Arctic Grayling spawning and rearing occur between the lakes and in Gladstone Creek. Lake Whitefish and other fish species occur in the Aishihik Lake area and there is an Aboriginal fishery in this area.

As reviewed in Section 4.3 of Appendix A, past work by Yukon Energy has indicated concerns from the Department of Fisheries and Oceans (DFO) as well as from local First Nations regarding interbasin pathogen transfer. YEC reported that the results of a full year of baseline studies provided no evidence to support a concern regarding interbasin pathogen transfer. Yukon Energy has continued to work with local First Nations to seek support for this project. A summary assessment for this project is provided in Table C 2-4.

Table C 2-4: Summary of Assessment for Gladstone Diversion

Project / Option	Indicator	Ranking	Assessment
Gladstone Diversion	Salmon & Habitat	**No Linkage**	No salmon or salmon habitat has been identified in this area.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.

	Commercial, Recreational or Aboriginal Species & Habitat	High	Arctic Grayling is known to occur in the area and project development would result in loss of spawning and rearing habitat between the lakes and in Gladstone Creek. Lake Trout spawn in Gladstone Lakes and project development may affect spawning/incubation success.

2.2.2.4 Hydro Storage Enhancements

Two potential hydro storage enhancement options have been under detailed review and planning by Yukon Energy for several years. Each option would enhance existing storage for existing hydro generation without developing any new dams. The evaluations in Table C 2-5 do not take into account the specific mitigation and adaptive management measures developed to date as a result of detailed environmental assessment studies (for the Mayo Lake Enhanced Storage, Yukon Energy's Yukon Environmental and Socio-economic Assessment Board [YESAB] submission set out measures to address potential adverse effects based on studies and ongoing work with the local First Nation).

Table C 2-5: Summary of Assessment for Hydro Storage Enhancements

Project / Option	Indicator	Ranking	Assessment
Mayo Lake Enhanced Storage	Salmon & Habitat	Low	No salmon or salmon habitat has been identified in this area. Project may have positive downstream effects on salmon habitat.
	Species at Risk & Habitat	No Linkage	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	High	Lake Trout and Lake Whitefish are known to occur in the area. As a result of the proposed reduction in the Mayo Lake licence lower supply level, Lake Trout and Lake Whitefish production may be lower.
Southern Lakes Enhanced Storage	Salmon & Habitat	Medium	Chinook salmon are present in the project area; however, flow changes are unlikely to have adverse effects.
	Species at Risk & Habitat	No Linkage	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	High	Lake Trout are known to occur in the area. The project may have an adverse effect on incubation success and food sources.

2.2.2.5 Mayo Lake Outlet Channel Dredging

The Mayo Lake Outlet Channel Dredging Project would remove an old cofferdam, as well as sedimentation that has infilled in the Mayo Lake Outlet Channel over the past 63 years since the original Mayo hydro generation was developed and address measures to mitigate potential future sediment infill in this outlet channel. As such, this can be viewed as a system maintenance activity that would not be anticipated to have adverse effects on fish and fish habitat assuming that BMPs are adopted as required for all of the activities. As noted for the Mayo Lake Enhanced Storage Project, there are no salmon or endangered fish species in the Mayo Lake storage area or in the outlet channel area affected by the proposed dredging.

For the purpose of this evaluation, Table C 2-6 provides a summary assessment of the Mayo Lake Outlet Channel Dredging option. This assessment does not take into account any specific mitigation and adaptive management measures developed to date as a result of detailed environmental assessment studies.

Table C 2-6: Summary of Assessment for Mayo Lake Outlet Channel Dredging

Project / Option	Indicator	Ranking	Assessment
Mayo Lake Outlet Channel Dredging	Salmon & Habitat	**No Linkage**	No salmon or salmon habitat has been identified in this area. Project may have positive downstream effects on salmon habitat.
	Species at Risk & Habitat	**No Linkage**	None of the fish species known to occur in the project area are listed under SARA.
	Commercial, Recreational or Aboriginal Species & Habitat	**Low**	Assuming BMPs for this project are implemented, no effects of concern are expected on these fisheries.

3.0 WATER QUANTITY & QUALITY

3.1 RATING CRITERIA AND DATA SOURCES FOR EN-2: WATER QUANTITY & QUALITY

The rating system outlined in Figure C 3-1 was adopted to guide evaluation of each resource project option for each of the water quantity and quality indicators.

Figure C 3-1: Summary of Rating Criteria for Water Quantity & Quality

Indicator	Low	Medium	High
Consumptive Water Use (En2-1)	<10% of instantaneous flows is not returned to the natural environment, or no linkage	10% to 20% of instantaneous flows is not returned to the natural environment	>20% of instantaneous flows is not returned to the natural environment
Relative Scale of New Impoundment / Flooding (En2-2) [relevant to water quality]	No new impoundment; water levels will be held high for longer periods of time increasing potential for erosion/sediment mobilization, or no linkage	>0% and <10% of lake surface area will be affected due to new impoundment	>10% of lake surface area will be due to new impoundment, increasing potential for erosion/sediment mobilization and mercury issues
Flow Changes (En2-3)	<10% of instantaneous flows, or no linkage	10% to 20% of instantaneous flows	>20% of instantaneous flows

The water quantity and quality indicators as defined in Figure C 3-1 each require a relative scale for comparing the different resource options. Implicit with each indicator is also an initial assessment as to whether the project is likely to have any effect on the indicator. In assessing water quantity and quality indicators, overlaps may occur with fish and fish habitat indicators, e.g., criteria for assessing high effects from new flooding may take into consideration increased potential for erosion/sediment mobilization and mercury issues that affect fish and fish habitat. Water quantity and quality effects during construction that are assumed to be addressed by BMPs (e.g., sediment disturbance) are rated green (low).

The following are noted regarding the rating scheme used for the assessment:

- **Consumptive Water Use (En2-1):** Consumptive water use is considered to be relevant to projects that consume water directly from a river, stream or lake and do not return water to the source following use (e.g., a steam plant, if it took water directly from a river and then used the water, which was evaporated and released to the atmosphere). The temporary diversion of water (e.g., run-of-river, pump storage) are included in the changes in the Flow Changes indicator (En2-3). No attempt is made for this evaluation to assess loss of water use due to reservoir evaporation or potential changes to groundwater flow regimes related to any of the resource options.

The indicator adopted focuses on the approximate assessment of changes to instantaneous flows that is not returned to the natural environment. The 10% of instantaneous flows adopted in Figure C 3-1 as the upper range of effect for low or green rating has been used in BC in recent water licence applications to indicate a low rating; 20% of instantaneous flows has been uses as an unofficial BC Ministry of Forests, Lands and Natural Resource Operations (FLNRO) guideline for run-of-river projects to indicate a high level of regulatory concern that needs to be addressed.

- **Relative Scale of New Impoundment/Flooding (En2-2):** The rating for impoundment is based on changes to water levels and the increase in lake size to reflect potential increases in erosion/sediment mobilization and methylmercury production.
    - Low rating applies if no new impoundment or increase in lake size, and includes options where existing impoundments will be used to hold water levels high for longer periods of time than is currently allowed.
    - An increase in lake surface area of less than 10% due to impoundment is rated as yellow or medium.
    - An increase in lake surface area of more than 10% due to impoundment is rated as red or high to reflect increasing potential for adverse effects related to potential increases in erosion/sediment mobilization and methylmercury production.
- **Flow Changes (En2-3):** Guidelines for small hydro and water diversions used by regulators in BC have been referenced to provide a range of rating values to develop the evaluation criteria for water quantity and flows. Unlike the En2-1 indicator, En2-3 addresses simple changes in review flows without any consumptive use of the water that removes it from the natural environment. The guidelines provide the following thresholds which have been used to evaluate effects on flows:
    - Less than 10% change in instantaneous flows has been used as a regulatory threshold for recent water licences in BC (i.e., project likely not to have a significant effect on the aquatic environment);
    - More than 20% change in instantaneous flows has been used as an unofficial FLNRO guideline for run-of-river projects to indicate a high level of regulatory concern that needs to be addressed; and
    - Projects with over 10% and less than 20% change in instantaneous flows are rated yellow (medium) to indicate the need to address potential regulatory concerns.

Some of the pumped storage projects and small hydro projects could affect lake levels in downstream reservoir lakes, as well as in the outflow streams/rivers of the downstream reservoir lakes. Detailed modelling of downstream changes for most of the hydro projects has not yet been done. In these situations, where there could be a change in flows, but the scale is unknown, the ranking has defaulted to yellow (medium). That ranking would need to be reassessed in the future, when flow modelling information becomes available. In the case of small hydro projects, a red (high) indicator has been used where relevant based on anticipated flow change effects on fish and fish habitat.

3.2 EVALUATIONS

3.2.1 Resource Options with No Material Concerns re: Water Quantity and Quality

Indicators related to the scale of new impoundments and flow changes are most applicable to the pump-storage and small hydro options, as well as upgrades or changes to existing hydroelectric facilities (i.e., Southern Lakes, Mayo Lake, and Gladstone).

A number of projects included in the resource review do not require the impoundment or diversion of water and also do not require consumptive uses of water. For these projects there is clearly no linkage to the water quantity and quality criteria or indicators.

In summary, based on currently available information, all of the resource project options shown in Table C 2-1 (for fish and fish habitat indicators) are assessed in this study to not require the impoundment or diversion of water or any consumptive uses of water. For example, none of the thermal generation projects is indicated to assume consumptive use of water from local rivers or water bodies. The Mayo Outlet Channel Dredging Project is also included in this assessment as not likely to have any effect of concern on water quantity or quality, assuming implementation of BMPs. The BMPs are assumed to address water quality impacts from sediment disturbance during construction and are therefore not specifically addressed in the water quantity and quality indicators.

3.2.2 Hydro Renewable Generation

Each of the hydro resource options that affects aquatic resources related to water quantity and quality is evaluated separately in the following sections. In many cases, flow changes have not yet been modelled and therefore a yellow or medium rating is provided (this may well change to red for many hydro options when there is further information).

3.2.2.1 Pumped Storage

Consistent summary information on each of the Pumped Storage projects is not available to summarize existing lake areas, new lake areas, area flooded and other related information. Each project involves two lake areas (upper reservoir and lower reservoir), with impoundment and flooding effects primarily being on the upper reservoir

Table C 3-1 provides the assessment on water quantity and quality of each Pumped Storage hydro generation option examined in this review. This evaluation does not attempt to assess any differences in effects on water quantity and quality due to different scales of development for some of these options, e.g., storage at 50 GWh versus 100 GWh.

Table C 3-1: Summary of Assessment for Pumped Storage

Project / Option	Indicator	Ranking	Assessment
Atlin – Black Mountain	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	High	The project consists of an unnamed upper lake/reservoir (BC Waterbody Identifier 00172ALL) south of Black Mountain and a lower reservoir (Atlin Lake). The project will involve the construction of dams (26 to 42 m) at each end of the unnamed lake to enlarge storage capacity of the unnamed lake. Water will be directed via an intake structure on the west end of the lake to a powerhouse on the shore of Atlin Lake. This will change the flows from the unnamed lake, from heading east to west. There will be some flooding associated with the dam development on the upper reservoir lake; the amount could double the size of the reservoir. Available satellite imagery shows that the lake is surrounded by alpine meadow and wetland habitat. These areas are high in organic material. Microbial degradation of flood organic materials could increase the rate of mercury methylation in the upper reservoir lake meaning that the pump and storage could be a vector for transporting methylmercury to Atlin Lake. ***Therefore, this risk is considered to be High.***
	Flow changes	Medium	The project will see flows directed from Stream 837-088400-28000-50000 and direct them to the west into Atlin Lake. The potential effects of such a flow diversion on Stream 837-088400-28000-50000 could not be assessed with the available information; ***therefore flow changes have been ranked as Medium. However, this ranking could be changed with further hydrological studies.***
Canyon – Ittlemit	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	High	The project will use Ittlemit Lake as the upper reservoir and Canyon Lake as the lower reservoir. An expansion of the existing Canyon Lake dam and a saddle dam would cause a significant increase in the surface area of Canyon Lake. A 16 m high dam would be required on the outlet of Ittlemit Lake. The proposed project would increase Canyon Lake surface area by almost 50% and increase Ittlemit Lake by 12%. The significant increase in Canyon Lake volume (based on the presence of a >30 m high dam), could result in an increase in erosion/sediment mobilization and methylmercury production. ***Therefore, effects related to the relative scale of new impoundment/flooding were considered to be High.***
	Flow changes	Medium	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***

Project / Option	Indicator	Ranking	Assessment
Lindeman – Fraser	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	**High**	This project will use Fraser Lake as the upper reservoir and Lindeman Lake as the lower reservoir. It will include a 16 km penstock to bring water from Fraser Lake to Lindeman Lake. The proposed project would increase Fraser Lake surface area by 80% and increase Lindeman Lake by 36%. ***Therefore, effects related to the relative scale of new impoundment/flooding are considered to be High.***
	Flow changes	**Medium**	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Racine – Moon	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	**High**	The project would use Moon Lake as the upper reservoir and Racine Lake as the lower reservoir. A 16 m to 21 m high dam would be constructed on Moon Lake and a control structure on Racine Lake. The construction of a dam on Racine Lake would control water levels and could obstruct movements between Racine and Tagish Lake. The proposed project would increase Moon Lake surface area by 60%, but would not change the surface area of Racine Lake. Such changes on Moon Lake could increase in erosion/sediment mobilization and methylmercury production. ***Therefore, effects related to the relative scale of new impoundment/ flooding are considered to be High.***
	Flow changes	**Medium**	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Racine – Mt. Brown	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	**High**	The project would involve the impoundment of an unnamed lake near Mt. Brown by the construction of a 29 to 43 m high dam. A dam would be constructed on the outlet of Racine Lake to control water levels. The project would increase the surface areas of the Mt. Brown lake by 500%; ***therefore, effects related to the relative scale of new impoundment/flooding are considered to be High.***
	Flow changes	**Medium**	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***

Project / Option	Indicator	Ranking	Assessment
Squanga – Dalayee	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	High	The facility is located between Johnson's Crossing and Jake's Corner. Dalayee Lake would be the upper reservoir and Squanga Lake would serve as the lower reservoir. The proposed project would not increase the surface area of Dalayee Lake, but would increase the surface area of Squanga Lake by about 12%. ***Therefore, effects related to the relative scale of new impoundment/flooding are considered to be High.***
	Flow changes	Medium	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Moon Lake (Tutshi – Moon)	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	High	This option would use Moon Lake as the Upper Reservoir. The penstock would divert water to Tutshi Lake. Project operations are not expected to have a material effect on water levels of Tutshi Lake, and inflows and outflows from Tutshi Lake will remain uncontrolled during project operations. The proposed project would increase the surface area of Moon Lake by 100%, but would not increase the surface area of Tutshi Lake. ***Therefore effects related to the relative scale of new impoundment / flooding are considered to be High.***
	Flow changes	Medium	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Faro – Vangorda Pit	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment/ Flooding	High	The project will involve the creation of new water bodies for the upper and lower reservoirs. The lower reservoir would be in the Blind Creek Valley and be 439 ha in size. The upper reservoir will be a new waterbody 520 ha in size. ***Therefore, effects related to the relative scale of new impoundment / flooding are considered to be High.***
	Flow changes	Medium	Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***

3.2.2.2 Small Hydro Projects

Table C 3-2 below summarizes some of the information available for the four small hydro projects where new impoundments are required (see also the general comments provided at outset of Section 2.2.2.2 with regard to these resource projects - Wolf River is run of river project, and the Atlin-Pine Creek project enhances power generation from storage facilities already in place).

Table C 3-2: Summary of Information Regarding Relative Scale of New Impoundment/Flooding

	Natural Lake Area (km^2)	New Lake Area (km^2)	Area Flooded (km^2)	Lake Level Increase (m)	Percentage increase of Existing Lake Surface Area	Est. Storage ($000\ m^3$)
Drury Lake	26	27.9	1.9	5	7%	134,750
Finlayson (includes Finlayson and Wolverine lakes)	28.2	33.6	5.4	5	19%	154,500
Tutshi – Windy Arm (Tutshi Lake only)	51.9	55	3.1	5	6%	267,125
Anvil Creek	5.3	5.9	0.6	5	11%	27,875

Effects on water quantity and quality indicators are reviewed in Table C 3-3 for each of the site options, taking into consideration available information on the changes in the water regime currently assumed for each project option.

Table C 3-3: Summary of Assessment for Small Hydro

Project / Option	Indicator	Ranking	Assessment
Drury Lake	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment /Flooding	Medium	The project will include an impoundment on Drury Lake, which would increase lake levels by 5 m and the lake surface area by 1.9 km^2. An increase in lake levels and impoundment areas would flood terrestrial areas and could change rate of methylmercury production. ***There is a small increase in impoundment size (7%), therefore, this has been ranked as Medium.***
	Flow changes	Medium	There will be a diversion of flows from Drury Creek. The reduction in flows from Drury Lake outlet stream by diversion into the penstock could potentially affect fish movement between Drury Lake and Little Salmon Lake (downstream of Drury Lake) and access to habitat in the stream reach between the two lakes. Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Finlayson River	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment /Flooding	High	The project would store water in Finlayson and Wolverine lakes and include a 5 m dam on each lake, which would result in an increase in surface area of 3 km^2 for Finlayson Lake and 2.4 km^2 for Wolverine Lake. Increases in impoundment size could result in increased production of methylmercury. There will be a 22% increase in Wolverine Lake and a 13% increase in Finlayson Lake. ***Therefore, this has been ranked as High.***
	Flow changes	Medium	There are potential changes in downstream flows in the lower 6 km of the Finlayson River (upstream of Frances Lake) due to the diversion of water into the penstock. Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Atlin/Pine Creek	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment	Low	The project would include an increase to power generation facilities already in place. This will include increasing the water level range on Surprise Lake from 913.85 m to 911.35 m (vs the existing operating range from 913.1 to 912.1). The existing permits allow maximum

Project / Option	Indicator	Ranking	Assessment
	/ Flooding		water levels up to 913.85 m, so no change to the permit is required. As such the project would likely just result in a higher frequency of water levels at or near the permitted full supply level; ***therefore, this has been ranked as Low.***
	Flow changes	**Medium**	There are potential changes to downstream flows in Pine Creek and changes to access because of changes in operating levels. The existing facility already modifies flows; however, incremental changes to downstream flows have not been modelled; Therefore, ***flow changes has been ranked as Medium.***
Tutshi – Windy Arm	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment / Flooding	**Medium**	The project would increase the water level in Tutshi Lake by 5 m and increase the surface area by 3.1 km^2 by constructing a dam across the outlet of the lake. Increases in impoundment size could result in increased production of methylmercury. There is a small increase in lake surface area (6%). ***This has been ranked as Medium.***
	Flow changes	**Medium**	There are potential changes in downstream flows to the reach of river between Tutshi and Tagish lakes and upstream movements into Tutshi Lake, due to the new dam and operation of the powerhouse. Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Wolf River	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment / Flooding	**No Linkage**	The project is a run-of-river development and therefore there is not anticipated to be any new impoundment/flooding.
	Flow changes	**Medium**	Wolf River is a run-of-the-river facility and does not involve impounding of water. Water intake will be constructed and water diverted through the powerhouse located approximately 8 km downstream. Due to the diversion of water, an 8 km section of river will experience changes in flows. Changes to downstream flows have not been modelled; ***therefore, this was ranked as Medium.***
Anvil Creek	Consumptive Water Use	**No Linkage**	The Project is not anticipated to have consumptive water use.

Project / Option	Indicator	Ranking	Assessment
	Relative Scale of New Impoundment /Flooding	High	The project will include an impoundment on Anvil Lake, which would increase lake levels by 5 m and the lake surface area by 0.6 km^2. An increase in lake levels and impoundment areas would flood terrestrial areas and could change rate of methylmercury production. There is a moderate increase in impoundment size (11%), ***therefore, this has been ranked as High.***
	Flow changes	Medium	There will be diversion of flow from Anvil Lake to a powerhouse located near the mouth of the stream that will result in a reduction of flow in Anvil Creek and some changes in flow rates in Blind Creek. The extent of changes to downstream flows habitat not been modelled; ***therefore, this was ranked as Medium.***

3.2.2.3 Gladstone Diversion

The Gladstone Diversion project will require flooding of area adjacent to several small lakes, creating one larger lake. The project will also result in changes in flow in Gladstone Creek of >20% and increases in flows in Isaac Creek, leading to Sekulmun Lake. Table C 3-4 provides a summary assessment of this project effects on water quantity and quality.

Table C 3-4: Summary of Assessment for Gladstone Diversion

Project / Option	Indicator	Ranking	Assessment
Gladstone Diversion	Consumptive Water Use	No Linkage	The Project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment / Flooding	High	The project requires flooding the area adjacent to several small lakes to create one larger lake. ***Therefore, this was ranked as High.***
	Flow changes	High	The project will result in changes in flow in Gladstone Creek >20% and increases in flows in Isaac Creek, leading to Sekulmun Lake. ***Therefore, this was ranked as High.***

3.2.2.4 Hydro Storage Enhancements

The Hydro Storage Enhancements projects involve changes to the use of existing storage (impoundments) without creating any new impoundment or expansion of lake surface area. Table C 3-5 outlines the expected effects of these resource options on water quantity and quality.

Table C 3-5: Summary of Assessments for Hydro Storage Enhancements

Project / Option	Indicator	Ranking	Assessment
Southern Lakes Enhanced Storage	Consumptive Water use	No Linkage	The project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment /Flooding	Low	The project includes an increase to the high supply limit where lake levels can be controlled; however, this is designed to keep water levels high in late summer and fall rather than impound/flood any land. Higher water levels for a longer period of time will increase the potential for erosion/sediment mobilization. ***Therefore, this project has been ranked as Low.***
	Flow changes	High	Changes to downstream flows are predicted to be over 20% higher in the late winter than historical flows. Reductions of flows occur during the late summer but are expected to be < 10 % lower than historical. ***Given the higher changes in late winter, diversion of flows has been ranked as High.***
Mayo Lake Enhanced Storage	Consumptive Water use	No Linkage	The project is not anticipated to have consumptive water use.
	Relative Scale of New Impoundment / Flooding	Low	The project would actually decrease the average water level in Mayo Lake and, as such, erosion from high water events should be reduced. ***Therefore, this has been ranked as Low.***
	Flow changes	High	Changes to downstream flows are predicted on average to be over 20% higher in late winter/spring than flows without the enhancement (effects will vary for different years). Reductions of flows that occur during the summer are expected to be over 10% and perhaps slightly over 20% (depending on load conditions). ***Therefore, this has been assessed as High.***

4.0 TERRESTRIAL SPECIES & HABITAT

4.1 RATING CRITERIA AND DATA SOURCES FOR EN-3: TERRESTRIAL SPECIES AND HABITAT

The rating system outlined in Figure C 4-1 was adopted to guide evaluation for each resource project option for each of the terrestrial species and habitat indicators.

Figure C 4-1: Summary of Assessment Rating Criteria for Terrestrial Species & Habitat

Indicator	No Linkage-Low	Low	Medium	High
Species at Risk & Habitat (SAR) (En3-1)	No SAR within Zone of Influence (ZoI)	Potential indirect effects; SAR occurrences within sensory disturbance ZOI	Potential direct effects; magnitude estimated to affect < a quarter of local population/habitat, effects on regional populations very limited, if any	Potential direct effects; magnitude estimated to affect > a quarter of local population/habitat, effects on regional populations may be measurable
Protected & Conservation Areas (PCA) (En3-2)	No PCA within 2 km of project	New access within 2 km of PCA, but no potential effect expected on PCA	Potential indirect effect due to proximity	Potential direct material effect within PCA
Wildlife Key Areas (WKA) (En3-3)	No WKAs within species-specific sensory disturbance ZoI	Potential indirect effects; WKAs within sensory disturbance ZOI of relevant species	Potential direct effects; magnitude estimated to affect < a quarter of WKA	Potential direct effects; magnitude estimated to affect > a quarter of WKA
Caribou Ranges (En3-4)	No caribou range within ZoI	Potential indirect effects; caribou range within sensory disturbance ZOI	Potential direct effects; magnitude limited to small proportion (< approximately 5%) of range	Potential direct effects; magnitude > approximately 5% of range

The terrestrial species and habitat indicators as defined in Table C 1-1 focus on the presence or proximity of the indicator relative to the resource project option's terrestrial footprint. Unless otherwise explicitly noted, the evaluations of each resource option for these indicators address only adverse effects. Assessments for each indicator consider the terrestrial zone of influence (ZOI)[2] for a project's footprint (e.g., noise effects can extend beyond the physical footprint), as well as the extent to which project effects are likely to affect the indicator (e.g., how much of the species habitat or WKA area would be affected). Figure C 4-1 provides separate rating criteria for No Linkage to address the degree of proximity to the indicator beyond which no linkage is assumed. As reviewed below, ratings for specific resource

[2] Zone of influence is the extent surrounding the footprint of an anthropogenic activity within which wildlife and/or habitat are affected by the activity.

options modify the criteria in Figure C 4-1 to reflect relevant factors, e.g., flexibility with transmission elements to avoid material effects (reduces ratings), caribou ranges that are very small or that are declining (increases ratings).

This subset of potential indicators for Terrestrial Species and Habitat were selected based on:

- Conservation concern (species at risk);
- Potential land use constraints (protected and conservation areas);
- High value wildlife habitat areas (wildlife key areas); and
- Regional and territorial emphasis on caribou management.

This selection of indicators is meant to provide a strategic assessment of key values of terrestrial species to identify potential showstopper issues and to facilitate a high-level comparison of relative values among projects. Assessment of additional indicators will be required for projects that advance from this strategic assessment to feasibility studies and environmental assessment stages.

Assignments of green (no linkage or low), yellow (medium) and red (high) ratings were driven by the type of project effects (i.e., mechanism of effect on the indicator) and the potential degree of overlap between the project and indicator. A list of potential effects associated with each project type on Terrestrial Species and Habitat is listed in Table C 4-1.

Table C 4-1: Summary of Potential Effects on Terrestrial Species

Project Type	Potential Effects on Terrestrial Species
Facilities (Storage, generating stations)	• Direct and indirect habitat effects of facility (generally small footprints).
Wood Biomass	• Direct and indirect habitat effects of biomass collection activities (potentially large footprints). • See also Access Roads.
Small hydro, pumped storage, enhanced storage	• Direct and indirect habitat effects of dams and associated infrastructure. • Effects to shoreline-associated birds. • Effects to littoral, shoreline and riparian vegetation and habitat.
Solar PV	• Direct and indirect habitat effects of site clearing and solar panel arrays.
Wind Farms	• Direct and indirect habitat effects of site clearing and turbines. • Collision risk to birds and bats.
Transmission Lines	• Direct and indirect habitat effects of right-of-way clearing. • Collision risk to birds. • Increased human access (disturbance and mortality effects by humans). • Facilitated predation. • Invasive plants.
Access Roads	• Direct and indirect habitat effects of roads. • Increased human access (disturbance and mortality effects by humans). • Facilitated predation. • Invasive plants.

Medium (yellow) and/or red (high) ratings were applied to situations where the project has the potential to have a direct effect on the indicator, as well as situations where data limitations prevent a clear green (low) or red (high) rating.

The list of specific criteria used to guide ratings for each indicator are described in Figure C 4-1, and reviewed below.

- For **Species at Risk** and **Wildlife Key Areas,** the primary measure used to assess magnitude of effects was proportion of local habitat potentially affected.
    - For most species this was assessed qualitatively with respect to visual estimates of broad habitat types and conceptual stage project maps. For example, for Olive-sided Flycatcher potential habitat was considered as conifer leading forest visible in satellite imagery.
    - For most projects more detailed species-specific habitat data are not available.
    - For situations where direct effects could result from a project, an approximate level of a quarter of total potential habitat was used as a threshold to define yellow (Medium) (< a quarter of total habitat) and red (High) (> a quarter of total habitat) risk ratings. That threshold was assessed qualitatively based on conceptual project design maps and written project descriptions.
    - Caribou are noted where relevant within WKA', but (to avoid doubling counting with the separate "caribou ranges" indicator) are not a key factor in determining ratings for the overall Wildlife Key Areas ratings indicator.
- For **Protected and Conservation Areas,** any projects with potential direct material effects within Protected and Conservation Areas were rated red (High). Projects with potential measureable indirect effects on Protected and Conservation Areas due to proximity were rated yellow (Medium). Projects with new access within 2 km of Protected and Conservation Areas were rated green (Low) if no indirect effects are expected, based on the potential negative effects of new human access.
- For **caribou ranges,** ratings focussed on amount of range affected, however, location of the project within the range, habitat type (e.g. calving vs general range), and population status of the herd were also considered. This indicator focuses specifically on caribou WKAs.

Ratings were modified from the general criteria outlined in Figure C 4-1 by a one class upgrade or downgrade for specific situations.

- One situation was for assumed design flexibility and mitigations. For example, where a transmission line was proposed in proximity to a rare plant occurrence, the risk rating was downgraded from red (high) to yellow (medium) to account for flexibility in pole locations to avoid occurrences of the plant.
- Another situation was consideration of the population status (size and trend) of caribou ranges. Ratings were increased by one category for caribou ranges that are very small or that are declining.
- Another situation for caribou was where proposed roads or transmission lines followed existing rights-of-way. In those circumstances, incremental effects of the new linear features were assumed to be minimal and the potential effects were rated green (low).

Assessment of Species at Risk (SAR) considered all species listed under Schedule 1 of the federal Species at Risk Act and all species listed as vulnerable (S3), imperiled (S2), or critically imperiled (S1) within

Yukon by the Yukon Conservation Data Centre (CDC). This included birds, mammals, amphibians, insects, and plants. The primary sources of information used to evaluate potential SAR occurrences near projects in this assessment were CDC species occurrence data and Wildlife Key Areas mapping. This information was supplemented with range and habitat association information from guidebooks (e.g. Birds of the Yukon), regional studies, and knowledge of local biologists. However, information about the ranges, distribution, and habitat associations of many SAR species across the project area is incomplete. Due to the large number of SAR species, incomplete knowledge of distribution and habitat associations of many SAR species, limited base habitat information available, and limited time associated with the strategic nature of this assessment, results of the assessment of Species at Risk & Habitat indicator should not be considered comprehensive. More detailed desktop reviews and field studies could find SAR occurrences not located as part of this assessment.

In the following evaluations for the resource project options, a summary of the key factors guiding the rating assignment is provided, including note of any modifying criteria. Where relevant, site specific differences among projects and indicators are noted.

Maps and data of Wildlife Key Areas and Protected and Conservation Areas were obtained from Geomatics Yukon (ftp://ftp.geomaticsyukon.ca/GeoYukon/Biological/Wildlife_Key_Areas_250k/ and ftp://ftp.geomaticsyukon.ca/GeoYukon/Base/Wetlands_50k/).

Caribou range maps were obtained from Troy Hegel (Biologist, Yukon Environment) and population estimates and trend were obtained from the Yukon State of the Environment Report (2014) (http://www.env.gov.yk.ca/publications-maps/stateenvironment.php).

4.2 EVALUATIONS

4.2.1 Resource Options with No Material Concerns re: Terrestrial Species & Habitat

The following resource project options have green (low or no linkage) ratings for each of the terrestrial species and habitat indicators:

- **Fossil Fuel Thermal Generation: Diesel and LNG**, each in Whitehorse ([landfill or Takhini substation locations]):
    - No linkage for En3-2, Wildlife Key Areas (En3-3) and Caribou Ranges (En3-4);
    - Green (low) for En3-1 (Species at Risk and Habitat) - No occurrences of SAR are known in vicinity of these sites. Species that may occur based on habitat and range are Olive-sided Flycatcher (both sites) and Short-eared Owl (Takhini substation); and
    - It is noted that other terrestrial species are valued in the Whitehorse landfill site area. McIntyre Creek and adjacent marsh and upland habitat is a known wildlife corridor (EDI 2011) that is located 1 km south of the project. Ridges along McIntyre Creek are used by raptors for migration and staging. The area, including the landfill, is used by a wintering population of Bald Eagles.

- **Non-fossil fuel thermal generation: Biogas and Waste to Energy**, each at Whitehorse locations (Biogas at Whitehorse landfill; Waste-to-energy site not known but in Whitehorse in area where other commercial/government/institutional activity to utilize waste heat):
    - No linkage for Protected and Conservation Areas (En3-2), Wildlife Key Areas (En3-3) and Caribou Ranges (En3-4);
    - Green (low) for En3-1 (Species at Risk and Habitat): No occurrences of SAR are known in vicinity of Whitehorse landfill or are expected at any likely Waste-to-Energy site in Whitehorse. Species that may occur based on habitat and range at the biogas site (Whitehorse landfill) are Olive-sided Flycatcher. No likely issue of concern for any site likely to be selected for Waste-to-energy option; and
    - It is noted that other terrestrial species are valued in the Whitehorse landfill site area (biogas site). McIntyre Creek and adjacent marsh and upland habitat is a known wildlife corridor (EDI 2011) that is located 1 km south of the project. Ridges along McIntyre Creek are used by raptors for migration and staging. The area, including the landfill, is used by a wintering population of Bald Eagles.
- **Energy Storage Facility** at Whitehorse (Takhini substation):
    - No linkage for Protected and Conservation Areas (En3-2) and Caribou Ranges (En3-4); and
    - Green (low) for En3-1 (Species at Risk and Habitat) and En3-3 (Wildlife Key Areas) The project footprint is anticipated to be within late winter moose habitat, but there is low risk based on small project footprint.
- **Solar PV** at Whitehorse (old mine quarry) and Haines Junction:
    - No linkage for Caribou Ranges (En3-4) at both sites and for Protected and Conservation Areas (En3-2) and Wildlife Key Areas (En3-3) at Whitehorse site;
    - Green (low) for En3-1 (Species at Risk and Habitat) at both sites as no occurrences of species of concern are known in the vicinity of each site (at Whitehorse site, species that may occur based on habitat and range are Common Nighthawk, which nests on exposed soil and sparsely vegetated sites);
    - Green (low) for En3-2 (Protected and Conservation Area) at Haines Junction due to possible visual effect concerns with proximity (700 m) to Kluane National Park; and
    - Green (low) for En3-3 (Wildlife Key Areas) at Haines Junction site, which is within late winter moose range WKA. Potential effects assumed to be negligible due to small footprint and location.
- **Mayo Lake Outlet Channel Dredging:**
    - No linkage for Protected and Conservation Areas (En3-2), Wildlife Key Areas (En3-3) and Caribou Ranges (En3-4); and
    - Green (low) for En3-1 (Species at Risk and Habitat). No occurrences of species of concern have been recorded within 500 m of the proposed project. Wildlife species that may occur based on habitat and range are Olive-sided Flycatcher, Barn Swallow, Bank

Swallow, and Common Nighthawk. Overall, project effects on Species at Risk and Habitat are expected to be low and mostly mitigatable via site-level BMPs.

- **Refurbishment / Maintenance: Aishihik Rerunnering, and Mayo A Refurbishment**
    - No linkage to any of the indicators, assuming BMPs and that all material work is located within each facility.

4.2.2 Non-Hydro Renewable Generation

4.2.2.1 Non-Fossil Thermal Generation - Wood Biomass

The Wood Biomass resource option assumes a 0.5 MW generating facility located in Haines Junction (near school and other existing activities for use of waste heat) and 3,000 oven dry tonnes (ODT)/year of wood biomass from local beetle kill areas (unspecified location, but assuming no change in existing harvesting areas).

For the biomass generating facility in Haines Junction, the ratings for terrestrial species and habitat indicators are all green (low or no linkage):

- No linkage for Caribou Ranges (En3-4): and
- Green (low) for Species at Risk and Habitat (En3-1), Protected and Conservation Areas (En3-2) and Wildlife Key Areas (En3-3):
    - No occurrences of SAR are known in the vicinity. Species that may occur based on habitat and range are Olive-sided Flycatcher.
    - For En3-2 (Protected and Conservation Areas), there are possible visual and air quality concerns associated with proximity of the project (700 m) to Kluane National Park.
    - For En3-3 (Wildlife Key Areas), the site is within late winter moose range WKA. Potential effects are assumed to be negligible due to small footprint and location.

Under the current instance of a 0.5 MW facility, the biomass supply is assumed primarily to be residues from existing forest harvesting and sawmill activities. If biomass supply results in incremental timber harvesting operations, that could have effects on biodiversity and individual focal species. However, a variety of coarse- and fine-filter, ecosystem-based, management strategies are available to mitigate timber harvesting effects.

Table C 4-2 presents the assessment of the harvesting operations on terrestrial species and habitat indicators.

Table C 4-2: Summary of Assessment for Wood Biomass (Timber Harvesting)

Project / Option	Indicator	Ranking	Assessment
Wood Biomass (Timber Harvesting Operations)	Species at Risk & Habitat	Low	Although harvest areas have not been spatially identified, associations of SAR with target forests are generally low. Species that may occur based on habitat and range are: Olive-sided Flycatcher, which are known to use beetle damaged forests. Potential effects to Olive-sided Flycatcher may be mitigated via stand and landscape level forest harvesting strategies.
	Protected & Conservation Areas	Low	Timber harvesting can be spatially managed to avoid PCA.
	Wildlife Key Areas	Medium	Beetle damaged stands in southwest Yukon occur within numerous WKAs, notably moose winter range. Timber harvesting and road construction could have several types of effects including habitat effects, disturbance and mortality by humans, and facilitated predation.
	Caribou Ranges	Low	Beetle damaged stands in southwest Yukon are largely outside caribou ranges. However, if harvesting does occur in caribou range, habitat effects of logging and disturbance and mortality by humans, and facilitated predation by natural predators could be High.

4.2.2.2 Wind Farms

Wind farms typically have three types of infrastructure that can affect terrestrial species and habitat: wind turbines and associated facilities, access roads, and transmission lines. The following are potential project effects associated with wind farms that were frequently noted during project evaluations. A summary of potential project-specific effects of wind farms are listed in Table C 4-3.

- Direct habitat effects associated with vegetation clearing and construction of roads, turbines, facilities, and transmission lines.
- Indirect effects that result in species avoiding project infrastructure as a result of sensory disturbance.
- Increased disturbance and mortality by humans, and facilitated predation by natural predators, associated with new linear features (roads and transmission lines).

Potential focal species vary by location but often include resident and migrating raptors (Golden Eagle, Peregrine Falcon, Short-eared Owl), migrating waterfowl, rare plants in grassland steppe habitats, and ungulate winter ranges. Although not highlighted for specific sites, other valued terrestrial species may be affected by turbines, new access and new transmission lines at most sites, e.g., alpine raptors and migrating birds passing through the area.

Table C 4-3: Summary of Assessment for Wind Farms

Project / Option	Indicator	Ranking	Assessment
Cyprus Mine Hill (central site, 10 turbines, access road and transmission line; also dependent on Faro-Watson Lake Transmission Line)	Species at Risk & Habitat	**Medium**	No occurrences of species of concern are known in vicinity. Alpine areas offer potential habitat for Short-eared Owl; turbines and transmission lines could reduce habitat effectiveness and present collision risk. Talus slopes offer potential habitat for Collared Pika; project could affect habitat.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Low**	Project occurs within early winter moose range WKA. Project would create new linear feature access onto Mount Aho that could result in increased disturbance and mortality by humans and facilitated predation by natural predators along the road and transmission line.
	Caribou Ranges	**Medium**	Project is in southwestern edge of Tay Caribou herd range. Project would create new linear feature access onto Mount Aho that could result in increased disturbance and mortality by humans and facilitated predation by natural predators. Turbines would have a small direct habitat effect and larger indirect effect via sensory disturbance.
Kluane Lake (central site, 10 turbines, access road and transmission line; also dependent on associated Transmission Lines)	Species at Risk & Habitat	**Medium**	Grizzly Bear are assumed to occur based on WKA designation (see below). Other species that may occur based on habitat and range are Olive-sided Flycatcher, Bank Swallow.
	Protected & Conservation Areas	**Medium**	Associated transmission line runs close to Kluane National Park and Kluane Wildlife Sanctuary and, under some options, might run through these protected areas. Rating may be reduced to Low depending on how project integrates with existing infrastructure.
	Wildlife Key Areas	**High**	Grizzly bear – spring, summer, fall range; project could have direct and indirect habitat effects; linear feature development could elevate risk of disturbance and mortality by humans. Moose late winter range; project could have direct and indirect habitat effects; linear feature development could affect risk of disturbance and mortality by humans, and result in facilitated predation risk.
	Caribou Ranges	**No Linkage**	
Miller's Ridge (central site, 10 turbines, access road and transmission	Species at Risk & Habitat	**Medium**	No occurrences of species of concern are known in vicinity, but risks of potential direct effects are noted. Grassland steppe ecosystems offer potential habitat for rare plants; BMP siting location mitigations to minimize effects to local plant occurrences are assumed to reduce rating to Low for such effects. Alpine areas offer suitable habitat for Short-eared Owl; turbines and transmission lines could reduce habitat effectiveness and present collision risk. Talus slopes may offer habitat for Collared Pika.

Project / Option	Indicator	Ranking	Assessment
line; also dependent on associated Transmission Lines)	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	Medium	The eastern section of transmission line intersects WKAs for Golden and Bald Eagles. Transmission line could reduce habitat effectiveness and be a collision risk. Turbines on ridge could also reduce habitat effectiveness for foraging and be a collision risk. Effects on Bald Eagle expected to be low to none.
	Caribou Ranges	Medium	Project is in southeastern edge of Klaza Caribou herd range. Project would create new linear feature access onto Miller's Ridge that could result in increased disturbance and mortality by humans and facilitated predation by natural predators along the road and transmission line. Turbines would have a small direct habitat effect and larger indirect effect via sensory disturbance.
Mt. Sumanik (central site, 10 turbines, access road and transmission line)	Species at Risk & Habitat	Medium	Collared Pika are known to occur in vicinity; project could affect habitat. Alpine areas offer suitable habitat for Short-eared Owl; turbines and transmission lines could reduce habitat effectiveness and present collision risk.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	High	Alpine raptor – summer reproduction WKA; turbines and transmission lines could reduce habitat effectiveness and present collision risk.
	Caribou Ranges	No Linkage	
Sugarloaf Mountain (central site, 10 turbines, access road and transmission line; also dependent on associated Transmission Lines)	Species at Risk & Habitat	Medium	No occurrences of species of concern are known in vicinity. Alpine areas offer potential habitat for Short-eared Owl; turbines and transmission lines could reduce habitat effectiveness and present collision risk. Talus slopes offer potential habitat for Collared Pika; project could affect habitat.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	High	Alpine raptor – summer reproduction WKA; turbines and transmission lines could reduce habitat effectiveness and present collision risk. Woodland Caribou – fall rut and winter range WKAs; project could have direct and indirect habitat effects and linear feature development could elevate risk of disturbance and mortality by humans, and facilitated predation by natural predators (however, note that roads and trails already exist in area).

Project / Option	Indicator	Ranking	Assessment
			Mountain Goat – year-round WKA; project could displace goats from cliffs north of installations (however habitat is marginal).
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd range. Project would create new linear feature access onto Montana Mountain that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators (however, note that roads and trails already exist in area). Turbines could have a small direct habitat effect and larger indirect effect via sensory disturbance.
Tehcho (Ferry Hill) (central site, 10 turbines, access road and transmission line; also dependent on associated Transmission Lines)	Species at Risk & Habitat	**Low**	No occurrences of species of concern are known in vicinity. Species that may occur based on habitat and range are: Olive-sided Flycatcher.
	Protected & Conservation Areas	**Low**	Devil's Elbow Habitat Protection Area is located 1.5 km to SE.
	Wildlife Key Areas	**Medium**	Black Bear – spring range; project could have direct and indirect habitat effects (however infrastructure avoids most high value habitat)
	Caribou Ranges	**No Linkage**	
Thulsoo Mountain (central site, 10 turbines, access road and transmission line; also dependent on associated transmission lines)	Species at Risk & Habitat	**Medium**	No occurrences of species of concern are known in vicinity. Alpine areas offer suitable habitat for Short-eared Owl; turbines and transmission lines could reduce habitat effectiveness and present collision risk. Talus slopes may offer habitat for Collared Pika.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	Bison – year-round core range; linear feature development could elevate risk of disturbance and mortality by humans, and facilitated predation by natural predators. Thin horn Sheep – winter range; turbines could have indirect habitat effects; linear feature development could elevate risk of disturbance and mortality by humans.
	Caribou Ranges	**No Linkage**	

4.2.2.3 Geothermal

The two proposed geothermal projects have three types of infrastructure that can affect Terrestrial Species and Habitat: the geothermal facilities, access roads, and transmission lines. Most potential effects were associated with the access roads and transmission lines. The following are potential project effects

associated with the geothermal projects that were noted during project evaluations. A summary of potential project-specific effects are listed in the Table C 4-4.

- Direct habitat effects associated with vegetation clearing and construction of facilities, roads, and transmission lines.
- Indirect effects that result in species avoiding project infrastructure as a result of sensory disturbance.
- Increased risk of disturbance and mortality by humans, and facilitated predation by natural predators associated with new linear features (roads and transmission lines).

Table C 4-4: Summary of Assessment for Geothermal

Project / Option	Indicator	Ranking	Assessment
McArthur Springs (facility plus 43 km access road and transmission line)	Species at Risk & Habitat	Low	No occurrences of species of concern are known in vicinity. Species that may occur based on habitat and range are: Olive-sided Flycatcher.
	Protected & Conservation Areas	High	Facility and approximately 13 km of road and transmission line occur within Ddhaw Ghro Habitat Protection Area.
	Wildlife Key Areas	Medium	Woodland Caribou - winter range; project would create 43 km of new linear feature access that could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
	Caribou Ranges	Medium	Project is within Ethel Lake Caribou herd range. Project would create 43 km of new linear feature access that could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
Vista Mountain	Species at Risk & Habitat	Low	No occurrences of species of concern are known in vicinity. Species that may occur based on habitat and range are: Olive-sided Flycatcher.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	No Linkage	
	Caribou Ranges	No Linkage	

4.2.3 Hydro Renewable Generation

Hydro renewable projects, including pumped storage, small hydro, enhanced storage and the Gladstone Diversion, typically have four types of infrastructure that can affect terrestrial species and habitat: dams and associated facilities, reservoirs that flood terrestrial habitat and affect shoreline dynamics, access roads, and transmission lines. The following are potential project effects associated with hydro renewable projects that were frequently noted during project evaluations. A summary of potential project-specific effects are listed in the following tables.

- Direct habitat effects associated with reservoirs flooding terrestrial habitats and wetlands, and affecting shoreline dynamics.
- Increased risk of disturbance and mortality by humans, and facilitated predation by natural predators, associated with new linear features (roads and transmission lines).

Potential focal species vary by location but often include resident and migrating water birds, rare plants, and moose winter ranges.

4.2.3.1 Pumped Storage

The range of pumped storage site options are reviewed below in Table C 4-5.

Table C 4-5: Summary of Assessment for Pumped Storage

Project / Option	Indicator	Ranking	Assessment
Atlin – Black Mountain (reservoir, penstock, transmission line; also dependent on associated transmission line)	Species at Risk & Habitat	Medium	No Data (BC). Wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, and Western Toad. Reservoir development could directly affect habitat of latter four species.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	Medium	Thin horn Sheep – Ungulate Winter Range (BC); project construction could displace sheep and have indirect habitat effects. *
	Caribou Ranges	Medium	Project is within Atlin and Carcross Caribou herd ranges. Project would have relatively small direct and indirect habitat effects (further study could possibly downgrade rating to Low based on small extent of footprint).
	*New access roads are not specified; if required, new roads could result in increased disturbance and mortality by humans to thin horn Sheep and, depending on location, could increase rating to high.		
Canyon –	Species at	Medium	No occurrences of species of concern are known in vicinity. Wildlife

Project / Option	Indicator	Ranking	Assessment
Ittlemit (reservoir, penstock, transmission line; also dependent on associated transmission line)	Risk & Habitat		species that may occur based on habitat and range are: Olive-sided Flycatcher, Bank Swallow, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, and Short-eared Owl. Reservoir development could directly affect habitat of latter 5 species.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	Bison – year-round core range; elevated water levels could affect foraging habitat.* Thin horn Sheep – spring lambing; project not likely to have any significant effects. * Golden Eagle – summer breeding; elevated water levels could affect prey habitat. Bald Eagle – summer breeding; elevated water levels could affect riparian nesting habitat and prey (fish). Mule Deer – year-round range; project not likely to have any significant effects.
	Caribou Ranges	**No Linkage**	
	*New access roads are not specified; if required, new roads could result in increased disturbance and mortality by humans to Bison and thin horn Sheep and, depending on location, could increase rating to high.		
Lindeman – Fraser (reservoir, penstock, transmission line; also dependent on associated transmission line)	Species at Risk & Habitat	**Medium**	No occurrences of species of concern are known in vicinity. Wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Bank Swallow, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Reservoir development could directly affect habitat of latter 6 species.
	Protected & Conservation Areas	**High**	Within Chilkoot Trail National Historic Site.
	Wildlife Key Areas	**Medium**	Carcross Caribou – fall rutting habitat. Project would create 5 km of new linear feature access that could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd range. Project would create 5 km of new linear feature access that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.

Project / Option	Indicator	Ranking	Assessment
Racine – Moon (reservoir, penstock, transmission line; also dependent on associated transmission line)	Species at Risk & Habitat	**Medium**	No data (BC). Wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Bank Swallow, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Reservoir development could directly affect habitat of latter six species.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	Carcross Caribou – fall rutting habitat and winter range. Project would create 21 km of new linear feature access that could result in increased disturbance and mortality by humans and facilitated predation by natural predators. Mountain Goat – year-round range; project construction could have disturbance effects. * Thin horn Sheep – Ungulate Winter Range (proposed, BC); project construction could have disturbance effects. *
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd range. Project would create 21 km of new linear feature access that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.
	*New access roads are not specified; if required, new roads could result in increased disturbance and mortality by humans to Mountain Goats and Thin horn Sheep and, depending on location, could increase rating to high.		
Racine – Mt. Brown (reservoir, penstock, transmission line; also dependent on associated transmission line)	Species at Risk & Habitat	**Medium**	No data (BC). Wildlife species that may occur based on habitat and range are: Banks Swallow, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Reservoir development could directly affect habitat of all species.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	Carcross Caribou – fall rutting habitat and winter range. Project would create 24 km of new linear feature access that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. Mountain Goat – year-round range; project construction could have disturbance effects. * Thin horn Sheep – Ungulate Winter Range (proposed, BC); project construction could have disturbance effects. *
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd range. Project would create 24 km of new linear feature access that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators

Project / Option	Indicator	Ranking	Assessment
	*New access roads are not specified; if required, new roads could result in increased disturbance and mortality by humans to Mountain Goats and thin horn Sheep and, depending on location, could increase rating to high.		
Squanga – Dalayee (reservoir, penstock, transmission line)	Species at Risk & Habitat	**Medium**	No occurrences of terrestrial species of concern are known in vicinity. Terrestrial wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Bank Swallow, Horned Grebe, Red-necked Phalarope, and Rusty Blackbird. Reservoir development could directly affect habitat of latter four species.
	Protected & Conservation Areas	**Medium**	Elevated water level in Dalayee Lake would affect Agay Mene Natural Environment Park. Rating downgraded from high due to limited effect on edge of Park.
	Wildlife Key Areas	**High**	Carcross Caribou - fall rutting habitat and winter range. Project would create 8 km of new linear features (penstock) that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. Waterfowl – summer breeding and fall staging; changes in water levels could affect breeding and staging habitat. Bald Eagle – summer breeding; changes in water levels could affect riparian nesting habitat and prey (fish). High (red) rating reflects direct mechanism of potential effects and extent of effects on WKAs for three species.
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd fall rutting habitat and winter range. Project would create 8 km of new linear features (penstock) that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.
Tutshi – Moon	Species at Risk & Habitat	**Medium**	No data (BC). Species that may occur based on habitat and range are: Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Reservoir development could directly affect habitat of latter six species.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	Carcross Caribou - fall rutting habitat and winter range. Project would create linear features that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. Mountain Goat – year-round range; project construction could have disturbance effects; new roads could result in increased disturbance and mortality by humans. Thin horn Sheep – Ungulate Winter Range (proposed, BC); project construction could have disturbance effects; new roads could result in increased disturbance and mortality by humans.
	Caribou	**Medium**	Project is within Carcross Caribou herd fall rutting habitat and winter

Project / Option	Indicator	Ranking	Assessment
	Ranges		range. Project would create linear features that could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
Faro – Vangorda Pit	Species at Risk & Habitat	Low	No occurrences of terrestrial species of concern are known within project ZOI. An occurrence of Mount Sheldon Ragwort is recorded 6 km north of the reservoir and Canada Darner has been recorded 2 km east. Other species that may occur based on habitat and range are: Olive-sided Flycatcher. Grass steppe areas in the vicinity are candidates for rare plant species.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	Medium	Thin horn Sheep – movement corridor; project could directly affect movement corridor.
	Caribou Ranges	Medium	Project is in southwestern edge of Tay Caribou herd range. Project would have limited direct habitat effects.

4.2.3.2 Small Hydro

The range of small hydro site options are reviewed below in Table C 4-6.

Table C 4-6: Summary of Assessment for Small Hydro

Project / Option	Indicator	Ranking	Assessment
Drury Lake	Species at Risk & Habitat	Medium	No occurrences of species of concern are known in vicinity. Wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Short-eared Owl, Horned Grebe, Red-necked Phalarope, and Rusty Blackbird. Reservoir development could directly affect habitat of latter three species.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	No Linkage	
	Caribou Ranges	Low	Southeast edge of Tatchun Caribou Herd range; project is expected to have minimal incremental effects to existing development.
Finlayson River	Species at Risk & Habitat	Medium	Rusty Blackbird and Barn Swallow have been documented in area. Other species that may occur based on habitat and range are: Olive-sided Flycatcher, Short-eared Owl, Horned Grebe, and Red-necked Phalarope. Changes in water levels in reservoir lakes and Finlayson River could directly affect habitat of latter two species and Rusty Blackbird.

Project / Option	Indicator	Ranking	Assessment
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	Medium	Finlayson Caribou – fall rutting habitat and winter range. Project would create new linear feature access that could result in increased disturbance and mortality by humans and facilitated predation by natural predators. Moose – late winter range; project could directly affect habitat by flooding habitat; new linear feature access could result in increased disturbance and mortality by humans and facilitated predation by natural predators. Thin horn Sheep – winter, rutting and lambing range; new roads could result in increased disturbance and mortality by humans.
	Caribou Ranges	Medium	Within Finlayson Caribou Herd range; project would create new linear feature access could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
Atlin/Pine Creek	Species at Risk & Habitat	Medium	No occurrences of species of concern are known in vicinity. Wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Bank Swallow, Barn Swallow, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, and Short-eared Owl. Reservoir development could directly affect habitat of latter six species.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	No Linkage	
	Caribou Ranges	Low	Within Atlin Caribou Herd range; based on existing development in area, project would have minimal incremental effects to existing development.
Tutshi – Windy Arm	Species at Risk & Habitat	Medium	No data (BC). Species that may occur based on habitat and range are: Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Reservoir development could directly affect habitat of all six species.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	Medium	Carcross Caribou - fall rutting habitat and winter range. Project would create new linear feature access that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. Mountain Goat – year-round range; project construction could have disturbance effects; new roads could result in increased disturbance

Project / Option	Indicator	Ranking	Assessment
			and mortality by humans. Thin horn Sheep – Ungulate Winter Range (proposed, BC); project construction could have disturbance effects; new roads could result in increased disturbance and mortality by humans.
	Caribou Ranges	**Medium**	Project is within Carcross Caribou herd fall rutting habitat and winter range. Project would create linear features that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.
Wolf River	Species at Risk & Habitat	**Medium**	Northern Mudwort occurrence within Nisutlin National Wildlife Area (NWA). Other species that may occur based on habitat and range are: Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Transmission line may present collision risk to birds in area.
	Protected & Conservation Areas	**Medium**	Access road and transmission line run along edge of Nisutlin River Delta NWA; road access may increase disturbance and mortality by humans to wildlife in NWA; transmission line may present collision risk to water birds in NWA.
	Wildlife Key Areas	**Medium**	Moose – late winter range; new linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. Muskrat – year-round all functions; changes to water flows could affect species (low risk). Bald Eagle – summer breeding; transmission lines could present collision risk. Waterfowl – summer breeding; transmission lines could present collision risk. Swan – summer breeding; transmission lines could present collision risk.
	Caribou Ranges	**Low**	On edge of Wold Lake Caribou Herd range; new linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators; effects likely to be low due to limited overlap with range.
Anvil Creek	Species at Risk & Habitat	**Medium**	One species of conservation concern has been documented in the area, Canada Darner, a dragonfly. Other wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Short-eared Owl, Horned Grebe, Red-necked Phalarope, Rusty Blackbird. Changes in water levels in Anvil Lake and the outlet stream could directly affect habitat of latter 3 species and Canada Darner.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Low**	The transmission line intersects a Thin horn Sheep movement corridor across Blind Creek; project could result in incremental disturbance and mortality by humans along the transmission line.

Project / Option	Indicator	Ranking	Assessment
	Caribou Ranges	**Medium**	Project is in southwestern edge of Tay Caribou herd range. Project would have limited direct habitat effects and create 19 km of new linear features that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.

4.2.3.3 Gladstone Diversion

The Gladstone Diversion involves dams to raise water levels in or to divert flows into the Aishihik Lake existing hydro generation. Table C 4-7 summarizes the assessment of terrestrial species and habitat effects.

Table C 4-7: Summary of Assessment for Gladstone Diversion

Project / Option	Indicator	Ranking	Assessment
Gladstone Diversion	Species at Risk & Habitat	High	Three occurrences of species of concern have been recorded within 500 m of the proposed project: Dawson Wallflower, Rock Wormwood, and Pale Comandra. Other wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Peregrine Falcon, Short-eared Owl, Common Nighthawk, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Sharp-tailed Grouse, Grizzly Bear, and Collared Pika. Reservoir development could flood two occurrences of rare plants and affect habitat for Horned Grebe, Red-necked Phalarope, Rusty Blackbird, Short-eared Owl, and Common Nighthawk.
	Protected & Conservation Areas	No Linkage	
	Wildlife Key Areas	High	The project overlaps with 16 Wildlife Key Areas: • Woodland Caribou – fall rutting and winter range (6). • Moose – late winter range (1). • Thin horn Sheep – winter range (2). • Bison – annual core range (1). • Ungulate miner lick (2). • Golden Eagle, Gyrfalcon, Peregrine Falcon – summer breeding (5). Potential project effects include: • New linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators, on ungulates. • Disturbance effects on nesting raptors. • Disturbance and indirect habitat effects on thin horn Sheep. o Effects may be partially mitigated by route selection. • Disturbance and habitat effects on ungulate mineral licks. o Effects may be partially mitigated by infrastructure siting locations.
	Caribou Ranges	Medium	The project occurs within the Aishihik Caribou Herd range. New linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.

4.2.3.4 Hydro Storage Enhancements

Hydro storage enhancement projects will utilize existing road and transmission corridors and generally not involve new structures or any increase in flooded areas. Therefore, project effects are primarily related to changes in water levels during different seasons or years. Table C 4-8 provides a summary of the assessment of effects on terrestrial species and habitat for the two hydro storage enhancement projects.

Table C 4-8: Summary of Assessment for Hydro Storage Enhancements

Project / Option	Indicator	Ranking	Assessment
Mayo Lake Enhanced Storage	Species at Risk & Habitat	**Medium**	No occurrences of species of concern are known in vicinity. Wildlife species that may occur based on habitat and range with habitat that could be affected by changes in water levels include Common Nighthawk, Horned Grebe, Red-necked Phalarope, and Rusty Blackbird.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Low**	Bald Eagle – summer breeding; changes in water levels could affect riparian nesting habitat and foraging habitat in lake.
	Caribou Ranges	**No Linkage**	
Southern Lakes Enhanced Storage	Species at Risk & Habitat	**High**	Twelve occurrences of species of concern have been recorded within 500 m of the proposed project: Barn Swallow, Buff-breasted Sandpiper, Collared Pika, Columbia Spotted Frog, Dune Tachnid Fly, Muskeg Emerald, Baikal Sedge, Water Awlwort, Water Pygmyweed, and Slim-leaved Goosefoot. Other wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Peregrine Falcon, Bank Swallow, Short-eared Owl, Common Nighthawk, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, and Western Toad. Changes in water levels could affect habitat and/or forage for most of the known and potential species of concern.
	Protected & Conservation Areas	**High**	The project overlaps the Lewes Marsh and Tagish Narrows Habitat Protection Areas (HPAs). Changes in water levels associated with the project could affect wetland habitats within the HPAs.
	Wildlife Key Areas	**High**	The project overlaps with 72 Wildlife Key Areas: • Woodland Caribou: fall rutting and winter range (25). • Moose: late winter range (1). • Thin horn Sheep: winter range and spring lambing (3). • Mountain Goat: annual range (20). • Muskrat: annual habitat (2). • Bald Eagle: summer nesting (4). • Golden Eagle, Gyrfalcon, alpine Raptor: summer breeding (8). • Waterfowl, Swan, Duck – spring and fall staging, summer

Project / Option	Indicator	Ranking	Assessment
			breeding (12, 8 noted as national / international significance). Potential project effects include: • Changes in water level that could affect. o Staging and breeding habitat for water birds; o Habitat and overwintering conditions for muskrats; and o Riparian nesting habitat and prey (fish) for Bald Eagle and Osprey. • Effects to riparian and wetland vegetation in moose winter range. • Changes in distribution and abundance of water birds as prey for raptors. • Minimal project effects expected on caribou, sheep, goats.
	Caribou Ranges	Low	The project overlaps with the Carcross Caribou Herd range and, peripherally, with the Idex Caribou Herd range. The project would have minimal incremental effects to existing development.

4.2.4 Transmission Corridors

Due to the long, linear nature of transmission corridors these projects tend to have the highest degree of overlap with terrestrial species and habitat indicators. However, the mechanism and magnitude of effects on terrestrial species and habitats is relatively low in most circumstances, in part due to best management practices (including routing to avoid specific concerns) and in part due to the nature of the disturbance caused by a transmission line.

The primary factors associated with transmission line development on terrestrial species and habitat are removal of tree and shrub cover within the right-of-way and installation of power poles and transmission lines. A small area of site disturbance (clearing down to mineral soil) is also associated with power pole installation and construction access. The long (10s to 100s of km), narrow (<100 m) shape of transmission line corridors has specific effects associated with terrestrial species. For most mid- to large-wildlife species, at the individual territory or home range level, the right-of-way represents a narrow break in natural vegetation that most species will simply travel across. Prey species, especially smaller species, may be reluctant to cross the right-of-way, similar to how they avoid natural areas that lack cover. At larger scales, the transmission corridors may function as new access corridors. This includes human access, which could result in increased disturbance and direct mortality by humans on certain wildlife (notably ungulates). Transmission corridors may also be used by wolves for enhanced travel and hunting resulting in facilitated predation. Transmission corridors may also facilitate the spread of invasive species.

Often, potential site-specific effects of transmission line development on terrestrial species, such as effects on ungulates using a mineral lick or a rare plant occurrence, can be avoided by route selection, power pole location, and site-level BMPs. Where new transmission lines are located along existing highway or utility rights-of-way the incremental effects of the new lines are much reduced compared to completely new lines.

The following are potential project effects associated with transmission corridors that were frequently noted during project evaluations. A summary of potential project-specific effects are listed in the Table C 4-9.

- Transmission corridors may result in new human access that could result in disturbance and mortality (i.e., hunting) to certain wildlife species. This effect is most likely to occur where the transmission corridors occur in proximity to high use wildlife areas, such as ungulate winter ranges or escape terrain for mountain goats and tinhorn sheep. Information sources that identified potential areas where this effect is more likely to occur include WKAs and caribou ranges.
- Transmission corridors may provide travel corridors that elevate natural predation by wolves by allowing them to hunt more effectively under certain circumstances.[3] Information sources that identified potential areas where this effect is more likely to occur include WKAs and caribou ranges.
- Transmission corridors may directly affect high value terrestrial species habitat or provide new access that could result in disturbance effects to wildlife concentration areas. Information sources that identified where this effect is more likely to occur include Parks and Conservation Areas, species occurrence locations from the Conservation Data Centre, and wildlife key areas.
- Power lines can be a source of avian mortality as a result of collisions and electrocution. This effect is elevated where birds with large wing spans congregate. Information sources that identified where this effect is more likely to occur include Parks and Conservation Areas and WKAs.

[3] This situation is often referred to as facilitated predation.

Table C 4-9: Summary of Assessment for Transmission Corridors

Project / Option	Indicator	Ranking	Assessment
Aishihik – Destruction Bay	Species at Risk & Habitat	Low	Fourteen occurrences of species of concern have been recorded within 500 m of the proposed project. These include Rusty Blackbird, Yukon Grasshopper, Yukon Draba, Narrow-leaved Moonwort, Rock Wormwood, Yukon Aster, Pale Comandra, Many-headed Sedge, and Winterfat. Other wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Peregrine Falcon, Short-eared Owl, Common Nighthawk, and Sharp-tailed Grouse. Overall, project effects on Species at Risk are expected to be low and mostly mitigatable via route selection and site-level BMPs.
	Protected & Conservation Areas	High	A portion of the project is assumed to run through Kluane National Park and Kluane Wildlife Sanctuary. Options are noted for a route to avoid the park.
	Wildlife Key Areas	Medium	The project overlaps with 43 Wildlife Key Areas: • Grizzly Bear – spring, summer and fall range (7). • Moose – late winter range (7). • Mountain Goat – annual range (2); project is on edge of WKA, no escape terrain is affected. • Mule Deer – annual range (2). • Thin horn Sheep – winter range (3). • Swan – fall staging (2). • Bald Eagle, Osprey – summer breeding (1). • Peregrine Falcon – summer breeding (1). • Sharp tailed Grouse – year-round habitat (6). Potential project effects include: • Transmission line right-of-way (ROW) may provide suitable forage for grizzly bears that could result in elevated risk of human interactions and vehicle collisions. • New linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators, on ungulates. o Effects can be partially mitigated by overlapping route with existing highway and utility ROW. • Collision risk for nesting and migrating raptors and swans. o Effects can be partially mitigated by route selection and visual deterrents • Indirect habitat effects on Sharp-tailed Grouse. o Effects may be partially mitigated by route selection.
	Caribou Ranges	Low	The project has very limited overlap with the Kluane Caribou Herd range. Potential project would have minimal incremental effects to existing development.

Project / Option	Indicator	Ranking	Assessment
Faro – Watson Lake	Species at Risk & Habitat	**Low**	Twenty one occurrences of species of concern have been recorded within 500 m of the proposed project. These include Rusty Blackbird, Barn Swallow, Woodchuck, Raups's Willow, Yukon Goldenweed, Shadow Darner, Siberian Polypod Additional species that may occur based on habitat and range are: Olive-sided Flycatcher, Peregrine Falcon, Short-eared Owl, Common Nighthawk, and Western Toad (southern extent only). Overall, project effects on SAR are expected to be low and mostly mitigatable via route selection and site-level BMPs.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	The project overlaps with 23 WKAs: • Moose – late winter range and mineral licks. • Thin horn Sheep – winter range, mineral licks, migration corridor. • Caribou – fall rutting, winter range, and mineral licks. • Bald Eagle, Osprey, Golden Eagle, Peregrine Falcon – summer breeding. Potential project effects include: • Linear features that could result in increased disturbance and mortality by humans and facilitated predation by natural predators on ungulates. o Effects can be partially mitigated by overlapping route with existing highway ROW. • Habitat and disturbance effects at mineral licks. o Effects can be largely mitigated by route selection. • Collision risk for nesting raptors. o Effects can be partially mitigated by route selection and visual deterrents.
	Caribou Ranges	**High**	The project overlaps with five Caribou Herd ranges: Tay, Pelly (limited overlap), Finlayson, Horseranch and Little Rancheria. Development of the transmission line would create a new linear feature that could result in increased disturbance and mortality by humans, and facilitated predation by natural predators. The High rating is based on the large linear extent of the project. Potential effects could potentially be reduced to Medium or Low if the project as finally planned followed the nearby highway ROW to a greater extent (the footprint as provided is offset from the highway ROW for most of its length).
Whitehorse – Atlin	Species at Risk & Habitat	**Low**	Four occurrences of species of concern have been recorded within 500 m of the proposed project. These include Common Nighthawk, Barn Swallow, Dune Tachnid Fly, and Dryland Sedge. Other wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Rusty Blackbird, Short-eared Owl, and Western Toad. Overall, project effects on Species at Risk are expected to be low and mostly mitigatable via route selection and site-level BMPs.

Project / Option	Indicator	Ranking	Assessment
	Protected & Conservation Areas	**Medium**	The project runs just inside Agay Mene Natural Environment Park and outside Lewes Marsh Habitat Protection Area, along existing highway ROW. New transmission lines may pose a collision risk to concentrations of birds at Lewes Marsh.
	Wildlife Key Areas	**Medium**	The project overlaps with 37 Wildlife Key Areas: • Moose – late winter range (3). • Woodland Caribou – fall rutting and winter range (16). • Mountain Goat – year-round (2); project is on edge of WKA, no escape terrain is affected. • Muskrat – year-round (2). • Bald Eagle, Osprey, Riparian Raptor– summer breeding (3). • Golden Eagle – summer breeding (2). • Waterfowl, Swan– spring and fall staging, summer breeding (9, 4 noted as national/international significance). Potential project effects include: • New linear features could result in increased disturbance and mortality by humans, and facilitated predation by natural predators, on ungulates. o Effects expected to be minimal because route follows existing highway and utility ROW. • Collision risk for nesting and migrating raptors and waterfowl. o Effects can be partially mitigated by route selection and visual deterrents. • No effects expected for Muskrat.
	Caribou Ranges	**Low**	The project overlaps with three Caribou Herd ranges: Carcross, Atlin, and Laberge (peripheral). Most of the project utilizes existing highway and utility ROW, and would have minimal incremental effects to existing development. Small sections of new linear feature development could result in increased disturbance and mortality by humans and facilitated predation by natural predators.
Whitehorse – Skagway	Species at Risk & Habitat	**Low**	Eight occurrences of species of concern have been recorded within 500 m of the proposed project. These include Common Nighthawk, Collared Pika, Dune Tachnid Fly, Muskeg Emerald, Baikal Sedge, and Water Pygmyweed. Species that may occur based on habitat and range are: Olive-sided Flycatcher, Rusty Blackbird, Short-eared Owl, Common Nighthawk, and Western Toad. Overall, project effects on Species at Risk are expected to be low and mostly mitigatable via route selection and site-level BMPs.
	Protected & Conservation Areas	**No Linkage**	
	Wildlife Key Areas	**Medium**	The project overlaps with 30 Wildlife Key Areas: • Moose – late winter range (1). • Mountain Goat – annual range (4); project is on edge of WKAs, no escape terrain is affected.

Project / Option	Indicator	Ranking	Assessment
			• Thin horn Sheep – spring lambing (1). • Woodland Caribou – fall rutting and winter range (19). • Swan and waterfowl– spring staging (2). • Bald Eagle and Osprey– summer breeding (2). • Alpine Raptor – summer breeding (1). Potential project effects include: • New linear features could result in increased disturbance and mortality by humans and facilitated predation by natural predators on ungulates. o Effects can be substantially mitigated by overlapping route with existing highway and utility ROW. • Collision risk for nesting and migrating raptors and waterfowl. o Effects can be partially mitigated by route selection and visual deterrents.
	Caribou Ranges	**Low**	The project overlaps with one Caribou Herd range, the Carcross Caribou Herd. Most of the project utilizes existing highway and utility ROW, and would have minimal incremental effects to existing development. Small sections of new linear feature development could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.
Whitehorse – Teslin	Species at Risk & Habitat	**Low**	Five occurrences of species of concern have been recorded within 500m of the proposed project. These include Common Nighthawk, Barn Swallow, and Elko Paintbrush. Additional wildlife species that may occur based on habitat and range are Olive-sided Flycatcher, Rusty Blackbird, and Short-eared Owl. Overall, project effects on SAR are expected to be low and mostly mitigatable via route selection and site-level BMPs.
	Protected & Conservation Areas	**Low**	The project runs just outside Agay Mene Natural Environment Park and Lewes Marsh Habitat Protection Area, along existing highway ROW. New transmission lines may pose a collision risk to concentrations of birds at Lewes Marsh.
	Wildlife Key Areas	**Medium**	The project overlaps with 42 Wildlife Key Areas: • Moose – late winter range (2). • Woodland Caribou – fall rutting and winter range (16). • Ungulate – mineral lick (1). • Muskrat – year-round (4). • Beaver – year-round (2). • Bald Eagle, Osprey, Riparian Raptor– summer breeding (5). • Golden Eagle – summer breeding (1). • Waterfowl, Swan– spring and fall staging, summer breeding (11, 4 noted as national/international significance). Potential project effects include: • New linear features could result in increased disturbance and mortality by humans and facilitated predation by natural predators on ungulates.

Project / Option	Indicator	Ranking	Assessment
			o Effects expected to be minimal because route follows existing highway and utility ROW. • Potential habitat and disturbance effects at mineral licks. o Effects expected to be largely mitigated by route selection. • Collision risk for nesting and migrating raptors and waterfowl. o Effects can be partially mitigated by route selection and visual deterrents. No effects expected for Muskrat and Beaver.
	Caribou Ranges	**Low**	The project overlaps with three Caribou Herd ranges: Carcross, Atlin (peripheral), and Laberge (peripheral). Most of the project utilizes existing highway and utility ROW, and would have minimal incremental effects to existing development. Small sections of new linear feature development could result in increased disturbance and mortality by humans, and facilitated predation by natural predators.
Stewart River – Keno	Species at Risk & Habitat	**Low**	Three occurrences of species of concern have been recorded within 500 m of the proposed project. These include Collared Pika, Slack Sedge, and Hudson Bay Sedge. Additional wildlife species that may occur based on habitat and range are: Olive-sided Flycatcher, Horned Grebe, Red-necked Phalarope, Rusty Blackbird, and Short-eared Owl. Overall, project effects on SAR are expected to be low and mostly mitigatable via route selection and site-level BMPs.
	Protected & Conservation Areas	**Low**	The project runs just outside Devil's Elbow Habitat Protection Area, along existing road ROW. New transmission lines may pose a collision risk to concentrations of birds using the HPA.
	Wildlife Key Areas	**Medium**	The project overlaps with 6 Wildlife Key Areas: • Black Bear – spring range (1). • Bald Eagle raptor– summer breeding (2). • Golden Eagle – summer breeding (1). • Waterfowl – summer breeding and moult (3). Potential project effects include: • New linear features could result in increased disturbance and mortality by humans to black bears. o Effects expected to be minimal because route follows existing highway and utility ROW. • Collision risk for nesting and migrating raptors and waterfowl. o Effects can be partially mitigated by route selection and visual deterrents.
	Caribou Ranges	**No Linkage**	

5.0 TERRESTRIAL FOOTPRINT & LAND USE

5.1 RATING CRITERIA AND DATA SOURCES FOR EN-4: TERRESTRIAL FOOTPRINT AND LAND USE

The rating system outlined in Figure C 5-1 was adopted to guide evaluations of each resource project option for each of the Terrestrial Footprint & Land Use indicators.

Figure C 5-1: Summary of Assessment Rating Criteria for Terrestrial Footprint & Land Use

Indicator	Low	Medium	High
Footprint Terrestrial Area including access & new flooding (Total km2) (En4-1)	< 0.5 km^2	0.5-1.0 km^2	> 1.0 km^2
Linear Development for roads, transmission (km) (En4-2)	< 10 km	10 – 100 km	> 100 km
Permafrost (En4-3)	< 2 km^2 affected by project, or no linkage to permafrost	>2 km^2 affected by project	Permafrost potential to be a material constraint to project
Wetlands (En4-4)	< 0.1 km^2 affected by project or no linkage to wetlands	0.1– 1.0 km^2 affected by project	> 1.0 km^2 affected by project or other potential for major concern

Indicators for Terrestrial Footprint and Land Use were selected to highlight the range of two terrestrial footprint indicators (Footprint Terrestrial Area and Linear Development distance) for the various project resource options, and to quantify the extent of potential project effects and overlap with two types of potentially sensitive environmental areas: Permafrost and Wetlands.

The following are noted regarding the rating scheme and thresholds used for the assessment:

- **Terrestrial Area Footprint (En4-1):** Estimates of terrestrial area footprints include all project components including facilities, access roads, transmission corridors, and, for hydro-related projects, new flooding (i.e., existing water areas were not included). Where the sizes of certain project components were not specified in the project description, industry standard right-of-way widths and buffer sizes were used (Table CA 2-1). For flooded areas, the estimated area from the project description was used. No new hydrological modelling was conducted to estimate the footprints associated with water level changes. Footprint areas were summed for all components within projects (e.g. area of facilities plus area of new roads plus area of transmission corridors).[4] These footprint assessments do not provide any information as to which valued terrestrial

[4] Estimated footprint areas for Terrestrial Area Footprint (En4-1) do not correspond to the areas estimated for Footprint Land Area Impact (S2-1), reflecting differences in assumptions and methods used to develop each estimate.

components may be affected by each project or resource option. The rating criteria were selected simply to help assign resource projects to clearly separate groups based on this indicator.

- **Linear Development for Roads and Transmission (En4-2):** Linear developments primarily consist of access roads and transmission corridors. Lengths of all linear developments were summed for all components within projects (e.g. length of roads plus length of transmission corridors). These linear footprint assessments do not provide any information as to which valued terrestrial components may be affected by each project or resource option. The rating criteria were selected simply to help assign resource projects to clearly separate groups based on this indicator.

- **Permafrost (En4-3):** Potential project effects associated with permafrost were estimated by assessing the extent of overlap between the Terrestrial Area Footprint and modelled permafrost occurrence. The permafrost model that was used was the Yukon Permafrost Probability Map (Bonnaventure et al. 2012). The permafrost area was calculated by weighting the Terrestrial Area Footprint (En4-1) by the modelled probability of permafrost occurring. This method may dilute the extent by which a specific permafrost effect area may be concentrated in a material portion of the project footprint area. The dominant permafrost class (isolated patches [<10%], sporadic discontinuous [10-50%], extensive discontinuous [50-90%], or continuous [>90%) was also noted for each project.

  This evaluation was from the perspective of potential environmental effects associated with permafrost degradation affected by the projects. Construction and engineering factors associated with project development and permafrost were not considered as part of this assessment. Also, the effects of permafrost change associated with climate change were not considered in this assessment due to the complexity and uncertainty of those patterns of permafrost change. However, planners should be aware that widespread changes to permafrost are occurring across the planning area. Those changes have effects from site-level to regional scales, and could have significant effects for each project, depending on the local distribution of permafrost.

  Notwithstanding the uncertainty associated with regional changes in permafrost, no red (high) ratings were applied, reflecting the lack of evidence that permafrost related issues would pose a material constraint to any project, in terms of potential environmental effects. A threshold of 200 ha (2 km^2) was selected to classify projects as green (low) or yellow (medium) ratings, based on the observed distribution of values across projects.

- **Wetlands (En4-4):** Potential project effects associated with wetlands were estimated primarily by assessing the extent of overlap between the Terrestrial Area Footprint and 1:50,000 scale wetland mapping available from Geomatics Yukon. Ratings also considered whether the project overlapped any wetland complexes that had been identified at the territory level (e.g., Yukon Environment 2008). A green rating is applied for projects with less than 10 ha (0.1 km^2) of estimated wetland area affected, and a yellow rating is applied for projects with estimated wetland area affected between 10 and 100 ha (between 0.1 and 1.0 km^2). No resource projects are rated red with affected wetland area in excess of 100 ha (1.0 km^2).

  Wetland area estimates appear to be most significant for hydro renewable projects. Waterbodies associated with hydro renewable projects may contain unmapped wetlands that would be affected by changes in water levels, including small wetlands, long thin wetlands, and wetlands

fringing ponds and lakes. This potential issue is not reflected in the current ratings, and more work would be needed to map such areas where appropriate should a hydro project go forward to more detailed review.

For indicators within the Terrestrial Footprint and Land Use criteria, ratings were based primarily on the aerial extent of the indicator measure. The break points used to differentiate between green (low), yellow (medium), and red (high) ratings were selected based on the range of extents that occurred across the proposed projects. In this context, ratings represent more of a relative comparison across projects, than references to specific benchmarks.

Footprint indicators for overall area and linear distances for access are applicable to all resource options other than those that involve no new land areas, e.g., hydro storage enhancements and existing hydro generation refurbishment or maintenance. Assessments were based on geospatial GIS files without adjustment for potential spatial configuration of components.

Table C 5-1 presents the resource project option information for two indicators (Footprint Terrestrial Area [En4-1] and Linear Development [En4-2]). These indicators provide an overview of the relative terrestrial footprint requirements of each resource option without addressing which valued terrestrial elements are being affected. Table C A2-2 in Attachment 2 provides each of the four indicator results for each resource option.

Table C 5-1: Terrestrial Footprint & Land Use: Footprint Terrestrial Area & Linear Development

Resource Option	Project / Site	Footprint Terrestrial Area (En4-1) (km^2)	Linear Development (roads, trans.) (En4-2) (km)
Fossil Thermal	Whitehorse Landfill	0.20	N/A
	Takhini Substation	0.20	0.31
Non-Fossil Thermal Generation	Biogas - Whitehorse	0.20	0.31
	Waste to Energy (Whitehorse)	0.20	N/A
	Wood Biomass (Haines Junction Facility, Timber Harvesting)	0.20 facility Unknown harvesting[1]	N/A
Energy Storage Facilities	Takhini Energy Storage	0.20	N/A
Solar PV	Haines Junction	0.25	N/A
	Whitehorse	0.50	N/A
Wind Farms	Cyprus Mine Hill	1.13	20.1
	Kluane Lake	1.00	11.2
	Miller's Ridge	2.23	41.0
	Mt. Sumanik	1.13	22.8
	Sugarloaf Mountain	1.21	13.9
	Tehcho (Ferry Hill)	1.18	14.0
	Thulsoo Mountain	2.28	64.3
Geothermal	McArthur Springs	2.61	87.0
	Vista Mountain	0.28	6.3
Hydro - Pumped Storage	Atlin-Black Mountain	2.43	4.7
	Canyon-Ittlemit	6.92	15.4
	Lindeman – Fraser	4.65	22.6
	Racine – Moon	5.66	31.0
	Racine – Mt. Brown	6.64	30.0
	Squanga – Dalayee	3.01	13.1
	Faro – Vangorda Pit	10.87	22.9
	Moon Lake (Tutshi – Moon)	4.99	8.5
Small Hydro	Drury Lake	2.33	15.5
	Finlayson River	19.36	33.2
	Atlin/Pine Creek	3.09	15.0
	Tutshi-Windy Arm	3.78	30.2
	Wolf River	3.25	60.4
	Anvil Creek	2.27	19.2
Other Hydro	Gladstone Diversion	3.61	54.5
	Hydro Storage Enhancements (Southern Lakes, Mayo Lake)	N/A	0
	Mayo Lake Outlet Channel Dredging	0.20	0

Resource Option	Project/Site	Footprint Terrestrial Area (En4-1) (km^2)	Linear Development (roads, trans.) (En4-2) (km)
	Refurbish/enhance existing hydro (Mayo A, Aishihik re-runnering)	N/A	0
Transmission Corridors	Aishihik – Destruction Bay	10.41	173.6
	Faro – Watson Lake	25.63	427.2
	Whitehorse – Atlin	10.33	171.7
	Whitehorse – Skagway	10.27	170.8
	Whitehorse – Teslin	10.48	174.4
	Stewart River – Keno	11.42	190.0

Notes:
1. Area associated with timber harvesting unknown but expected to be thousands of hectares.
2. Footprints associated with hydro renewable projects are driven by reservoirs; estimates of those extents are preliminary.

5.2 EVALUATIONS

The following terrestrial evaluations regarding concerns focuses mainly on the Terrestrial Footprint and Land Use indicators related to permafrost and wetlands (as these indicators address potential specific effect concerns).

5.2.1 Resource Options with No Material Concerns regarding Terrestrial Footprint and Land Use

The following resource project options are rated green (low or not applicable) for each of the terrestrial footprint and land use indicators:

- **Fossil Thermal: Diesel and LNG** (Whitehorse Landfill and Takhini Substation location options);
- **Non-fossil Thermal: Biogas, Waste-to-Energy, Wood Biomass** (Whitehorse and Haines Junction location options);
- **Energy Storage Facilities** (Takhini Substation);
- **Solar PV** (Haines Junction site);
- **Geothermal** (Vista Mountain);
- **Hydro Storage Enhancements** (Mayo Lake);
- **Mayo Lake Outlet Channel Dredging;** and
- **Existing Hydro Refurbishments / Maintenance** (Mayo A, Aishihik Re-runnering).

If the basic footprint indicators Footprint Terrestrial Area (En4-1) and Linear Development (En4-2) as provided in Table C 5-1 are excluded, the following additional resource options are rated green (low or not applicable) for each of the two remaining footprint and land use indicators (Permafrost [En4-3] and Wetlands [En4-4]):

- **Solar PV** (Whitehorse quarry site);
- **Wind Farms** (all site options);
- **Geothermal** (McArthur Springs);
- **Pumped Storage** (Atlin-Black Mountain, Lindeman-Fraser);
- **Small Hydro** (Drury Lake,[5] Atlin-Pine Creek [Surprise Lake], Tutshi-Windy Arm, Anvil Creek); and
- **Transmission Corridors** (Whitehorse-Atlin, Whitehorse-Skagway, Whitehorse-Teslin).

[5] See Appendix E, Table E 3-1, which rated Drury Creek red with regard to extent of permafrost in the project footprint, based on geotechnical risks and presence of permafrost noted in previous KGS reports on this small hydro site.

5.2.2 Hydro Renewable Generation

5.2.2.1 Pumped Storage

As reviewed in Attachment 2, Table C A 2-2, the following pumped storage projects have yellow ratings:

- Canyon-Ittlemit: rated yellow for Permafrost (En4-3) with an expected area of 3.89 km^2;
- Racine-Moon: rated yellow for Wetlands (En4-4) with an expected area of 0.96 km^2;
- Racine-Mt. Brown: rated yellow for Permafrost (En4-3) with an expected area of 3.07 km^2;
- Squanga-Dalayee: rated yellow for Wetlands (En4-4) with an expected area of 0.12 km^2;
- Faro-Vangorda Pit: rated yellow for Permafrost (En4-3) with an expected area of 7.18 km^2 and rated yellow for Wetlands (En4-4) with an expected area of 0.40 km^2; and
- Moon Lake (Tutshi-Moon): rated yellow for Wetlands (En4-4) with an expected area of 0.94 km^2.

5.2.2.2 Small Hydro

As reviewed in Attachment 2, Table C A 2-2, the following small hydro projects have yellow ratings:

- Finlayson River: rated yellow for Permafrost (En4-3) with an expected area of 16.15 km^2; and
- Wolf River: rated yellow for Wetlands (En4-4) with an expected area of 0.19 km^2.

5.2.2.3 Hydro Storage Enhancements – Southern Lakes

As reviewed in Attachment 2, Table C A 2-2, Southern Lakes Storage Enhancement has a red rating for Wetlands (En4-4), based on the quality rather than the quantity of wetlands potentially affected by changes in water levels at different seasons, including wetlands at M'Clintock Bay, Lewes Marsh and Nares Lake.

5.2.2.4 Other Hydro - Gladstone Diversion

As reviewed in Attachment 2, Table C A 2-2, Gladstone Diversion has a yellow rating for Permafrost (En4-3) with an expected area of 2.57 km^2.

5.2.3 Transmission Corridors

As reviewed in Attachment 2, Table C A 2-2, the following transmission corridor projects have yellow ratings for Permafrost (En4-3):

- Aishihik-Destruction Bay (Burwash): rated yellow for Permafrost (En4-3) with an expected area of 3.83 km^2; this expected or average estimate may well understate the significance of permafrost challenges for a material segment of this corridor (see Appendix E, Table E 3-1, which highlights permafrost as a material challenge for segments of this corridor based on the Midgard report's estimate of 14,789 ha of extensive discontinuous as well as 6078 ha of sporadic discontinuous permafrost in the 500 m corridor examined for that study).

- Faro-Watson Lake: rated yellow for Permafrost (En4-3) with an expected area of 14.94 km^2.
- Stewart-Keno City: rated yellow for Permafrost (En4-3) with an expected area of 7.89 km^2; planning for this specific corridor has advance to complete YESAB assessment for a preferred route that improves the existing line's location through these challenging areas.

6.0 AIR QUALITY

6.1 RATING CRITERIA AND DATA SOURCES FOR EN-5: AIR QUALITY

The rating system outlined in Figure C 6-1 was adopted to guide evaluations of each resource project option for each of the Air Quality indicators.

Figure C 6-1: Summary of Assessment Rating Criteria for Air Quality

Indicator	Low	Medium	High
GHG Emissions En5-1	Total GHG <50 kg CO_2e.MWh [20 & 100 year GWP]	Total GHG >50 and <500 kg CO_2e.MWh [20 & 100 year GWP]	Total GHG >500 kg CO_2e.MWh [20 & 100 year GWP]
Other Air Emissions En5-2	Non-thermal option, or no linkage	Thermal generation	N/A

Indicators for Air Quality as defined in Table C 6-1 focus on the intensity of emissions per unit of energy generated or transmitted, e.g., kg of emissions per kWh or per MWh. The ratings and evaluation are based on information as provided by Yukon Energy's studies, as reviewed below:

- **Information Sources**: The scope for the resource studies carried out for Yukon Energy, as referenced in Appendix A, did not address air emission intensity for any of the options. The only Yukon Energy study on Air Emissions is provided by ArticCan Energy Services (ACES), "Lifecycle Assessment for Energy Resource Options in Yukon Territory – Final Report", September 6, 2016 (the "ACES Report"). A summary of the results of the ACES Report is provided in Table C 6-1.
- **Non-GHG Air Emissions**: All non-thermal resource options assessed in this study will have no air emission effects as an integral element of operation, and therefore are rated green for Other Air Emissions (En5-2). In contrast, thermal generation resource options (e.g., fossil fuel thermal generation [diesel or LNG] or non-fossil fuel generation [municipal solid waste, biomass, biogas]) will each have air emissions. It is assumed for these thermal generation options (as well as for any other option where air emissions may occur during construction or operation) that all air emissions will be required to comply with regulations such that no material adverse effects are expected, i.e., no red ratings are applicable. In the absence of detailed assessments of potential non-GHG air emissions for each thermal generation option, each thermal generation resource option is rated yellow under non-GHG emissions (Other Air Emissions [En5-2]).
- **GHG Emissions** – The ACES Report as summarized in Table C 6-1 addresses, per MW.h equivalent of useful net energy delivered (including heat as well as electricity) over a technology option life, total GHG emissions (kg CO_2e [carbon dioxide equivalent]) from all sources (including greenhouse gas [GHG] emissions related to construction of facilities, operation in Yukon, and operation activities required outside of Yukon, but excluding "downstream" emissions from plant decommissioning and related activities). GHG emissions are estimated using the Global Warming

Potential (GWP) for both the 20 year and 100 year time horizons, using GWP factors taken from the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report (ARS).[6]

The ACES Report notes that the most widely accepted time scale for reporting GWP values is 100 years, which adequately represents most GHGs due to their significantly long lifetime and was used under the Kyoto Protocol. The shorter 20 year GWP value is included in the ACES Report to examine global warming potential effects over shorter timeframes in order to address the immediate effects of short-lived methane on global temperatures.[7]

The ACES Report reports GWP values with and without biogenic CO_2 emissions. Biogenic CO_2 emissions in biogas and biomass pathways originate from biogas combustion and biomass gasification life cycle stages, and without these biogenic CO_2 emissions the overall CO_2 emissions for these options fall significantly. Material CO_2 emission reduction estimates also occur for hydro options when biogenic CO_2 emissions are excluded.[8]

Table C 6-1 shows the following GHG emissions estimates for each technology, with and without biogenic CO2 emissions and for both 100 year and 20 year GWP values:

- Fixed GHG intensity (kg CO_2e/MWh) is calculated based on the total plant fixed emissions[9] divided by the total energy delivered by the plant over its expected life. Table C 6-1 shows this estimate calculated per the assumptions provided and as reported in the ACES Report. Reductions in actual energy delivered over the plant life result in an increase in GHG intensity for "fixed emissions", i.e., these emissions are locked prior to plant operation. Variances can occur in fixed emissions within a technology or resource option depending on the source of materials, the specific technology method selected, etc.[10]
- Variable GHG emissions (kg CO_2e/MWh) as shown in Table C 6-1 are as reported in the ACES Report, and reflect GHG emissions for plant operation (including production and transportation to the plant of any fuel source used). Variable emissions per year typically vary annually depending on actual plant operation; however, for some technologies (e.g., hydro plants) the variable emissions relate to land inundated and may therefore not be affected as directly by actual hydro generation (and may decline over time as land inundation impacts on GHG emissions decline).
- Variable emissions per MWh will also vary depending on operation practices and on total energy delivered per MWh of power generation, i.e., if heat is also delivered the GHG intensity per unit of delivered energy will decline.

---

[6] For more information and full discussion on the issues, see: ArticCan Energy Services (ACES), “Lifecycle Assessment for Energy Resource Options in Yukon Territory – Final Report”, September 6, 2016 (the "ACES Report").
[7] Ibid. for full discussion of 100 Year and 20 Year GWP.
[8] Ibid. for full discussion of issues related to inclusion and exclusion of biogenic CO2 emissions. Burning of biomass, or flooding of organic areas, releases CO2 emissions that can be recaptured by planting and growing new vegetation - issues arise related to the time scales of these two activities.
[9] Fixed plant emissions as estimated in the ACES Report (kg CO2e per plant) reflect GHG emissions for plant construction or manufacture, transmission line construction, materials acquisition and transportation, site preparation, and resource extraction (diesel and LNG). These GHG emissions occur from activities conducted prior to operation of the generation or transmission resource option.
[10] The ACES Report notes, by way of example, significant fixed GHG emission variances for different wind and storage battery technologies.

The ACES Report provides estimated GHG intensity for a specific scope design for different resource options examined (see Table C 6-1). The ACES report does not address the enhanced hydro storage resource options, the Mayo Lake Outlet Channel Dredging option, or options to refurbish existing hydro generation at Mayo and Aishihik.

Ratings in Figure C 6-1 for resource option GHG emissions (En5-1) are based on a simple scale to highlight the extent by which the Yukon Energy resource options differ for this indicator.

- **Including biogenic CO_2 emissions:** When assessed on a relative basis as per Table C 6-1 with biogenic CO_2 emissions, the resource options typically fall into either green (low) rating at <50 kg CO_2e/MWh lifecycle emissions, or red (high) rating at >500 kg CO_2e/MWh lifecycle emissions, regardless as to whether evaluated on the 20 year or 100 year GWP. None of the technology options evaluated in Table C 6-1 with biogenic VO_2 emissions fall into the yellow [medium] rating for GHG emissions.
- **Excluding biogenic CO_2 emissions:** When assessed on a relative basis as per Table C 6-1 without biogenic CO_2 emissions, the only changes that occur are reductions in GHG emissions for the following resource options (ratings are the same for both 20 year and 100 year GWP):
    - Waste-to-energy and Biogas resource options - ratings for these options change from red to yellow.
    - Biomass - ratings for this option change from red to green.
    - Pumped Storage, Small Hydro and Other Hydro (Gladstone Diversion) - ratings for these options remain unchanged (green ratings).

The GHG ratings applicable to a technology option per Table C 6-1 are assumed to apply for all other Yukon Energy resource options of that same technology, e.g., the wind rating for Mt. Sumanik is assumed to apply for all other wind options, the small hydro rating for Drury Lake is assumed to apply for all other small hydro options.

The ACES Report identifies the following factors that can vary the GHG emission estimates from the Table C 6-1 intensities:

1. **Modify Heat Energy Assumed to be consumed:** Table C 6-1 highlights assumed heat energy for biomass and municipal solid waste (MSW) waste-to-energy resource options, i.e., heat energy assumed to be used is 2.4 times the assumed equivalent electricity generation for MSW options and 3.1 times for the biomass option. Reductions in assumed heat energy use for the biomass and MSW waste-to-energy options would result in a material increase in GHG emission intensity. Conversely, assuming similar heat energy use for diesel and LNG options would result in a material decrease in GHG emission intensity. In summary, potential use of heat waste energy from thermal generation is desirable, where feasible, regardless of the resource option – and it can be argued that these resource options should be assessed based on comparable assumptions as regards use of available heat energy.
2. **LNG Combustion Emissions:** The ACES Report notes that emission factors selected for the baseline scenario for LNG combustion (as shown in Table C 6-1) are in the upper range of emissions and are therefore conservative. The ACES Report notes that actual natural gas GHG

emissions would likely be lower based on actual operating conditions of each unit. The ACES Report notes that GHG combustion operation emissions assuming 2016/217 B.C. Best Practices Methodology for Qualifying Greenhouse Gas Emissions (Ministry of Environment, May 2016) would be only 46% of the baseline scenario operation emissions for 20 year GWP (reduction of 456.4 kg CO_2e/MWh to 390.49 kg CO_2e/MWh) and 68% of the baseline scenario operation emissions for 100 year GWP (reduction of 184.2 kg CO2e/MWh, to 390.08 kg CO2e/MWh). Such reductions as a single measure would still leave LNG rated red (high) based on Figure C 6-1 when non-operation emissions are included.

3. **Transmission Line Capacity Utilization:** Table C 6-1 indicates the very high level of electricity transmission capacity utilization assumed for estimates of GHG emissions intensity for transmission corridor options. The ACES Report notes that reduction of the assumed use to 40% of transmission capacity (230 kV) would more than double the estimated GHG intensity per MWh for this option. Even at much lower levels of use, kg CO_2e/MWh for transmission continue to be rated green or low based on Figure C 6-1.

Table C 6-1: Summary of GHG Emissions from Resource Options (20 and 100 Year GWP)

Technology	Annual Power Energy (net) GWh/yr.	Annual Heat Energy (net) GW.hth/yr.	Operating Years	GHG Emissions with Biogenic CO2						Excluding Biogenic CO2	
				20 Year GWP			100 Year GWP			20 Year GWP	100 Year GWP
				Fixed GHG (kg CO2e/MWh)	Variable GHG (kg CO_2e/MWh)	Total GHG (kg CO_2e/MWh)	Fixed GHG (kg CO_2e/MWh)	Variable GHG (kg CO_2e/MWh)	Total GHG (kg CO_2e/MWh)	Total GHG (kg CO_2e/MWh)	Total GHG (kg CO_2e/MWh)
Diesel, 5 MW	39.4	-	20.0	0.4	1058.5	**1058.9**	0.4	950.7	**951.1**	**1058.9**	**951.1**
LNG, 5 MW	39.4	-	20.0	0.7	1050.1	**1050.8**	0.6	727.0	**727.7**	**1050.8**	**727.7**
Waste to energy: MSW & Biomass	10.0	23.70	25.0	9.2	666.0	**675.2**	8.9	654.1	**663.0**	**319.3**	**307.1**
Waste to energy: MSW	10.0	23.70	25.0	9.2	699.8	**709.1**	8.9	687.9	**696.8**	**453.7**	**441.4**

6.2 EVALUATIONS

6.2.1 Resource Options with No Material Concerns re: Air Quality

All non-thermal generation resource options are assumed to have no material concerns (green rating) for non-GHG air emissions (En5-2).

The following non-thermal generation resource options are also rated green or low for GHG emissions based on the Figure C 6-1 criteria for En5-1 and the estimated GHG emissions intensity as estimated in Table C 6-1 with and without biogenic CO2 emissions for both 20 year and 100 year GWP:

- Storage Battery options examined in the current resource planning;
- All Solar PVs examined in the current resource planning;
- All Wind site options at 6 MW to 20 MW examined in the current resource planning;
- All Geothermal site options examined in the current resource planning;
- All Pumped Storage site options examined in the current resource planning;
- All Small Hydro site options examined in the current resource planning;
- All Other Hydro options examined in the current resource planning (including Gladstone Diversion, Hydro Storage Enhancements, Mayo Lake Outlet Channel Dredging, Refurbish/enhance existing hydro facilities); and
- All transmission corridor options examined in the current resource planning.

In the case of hydro generation options (e.g., pumped storage, small hydro, diversion project), the level of GHG emissions is reduced if biogenic CO_2 emissions are excluded rather than included. However, with or without CO_2 emissions, green (low) ratings continue to apply for each hydro resource option.

6.2.2 Thermal Generation Resource Options

The remaining resource options that are not rated green (low) are thermal generation resource options.

Each thermal generation resource option is rated yellow for Other Air Emissions (En5-2).

Each of the fossil fuel thermal generation options is rated red (high) for GHG Emissions (En5-1), based on the Figure C 6-1 criteria and the estimated GHG emissions intensity as estimated in Table C 6-1. The 100 year GWP total GHG [CO_2/MWh] are shown below for each option with no use of heat energy as assumed in Table C 6-1, i.e., material use of available heat energy will materially reduce total GHG intensity per MWh for each option:

- **Fossil Thermal**
    - Diesel generation (951.1 kg CO_2/MWh).
    - LNG generation (727.7 kg CO_2/MWh).

Each of the non-fossil thermal generation options is rated red or high for GHG emission (En5-1) when biogenic CO2 emissions are included, based on the Figure C 6-1 criteria and the estimated GHG emissions intensity as estimated in Table C 6-1. If biogenic CO2 emissions are excluded, ratings for these options are reduced to yellow (medium) (waste-to-energy and biogas) or green (low) (biomass). The 100 year GWP total GHG (CO_2/MWh) are shown below for each option, with and without biogenic CO_2 emissions, with full use of heat energy as assumed in Table C 6-1, i.e., materially lower levels of heat energy use will materially increase total GHG intensity per MWh:

- **Non-Fossil Thermal (Renewable Thermal Generation)**
  - Waste to-energy
    - Including biogenic CO_2 emissions: 663.0 kg CO_2/MWh for MSW & Biomass, 696.8 kg CO_2/MWh for only MSW.
    - Excluding biogenic CO_2 emissions: 307.1 kg CO_2/MWh for MSW and Biomass, 441.4 kg CO_2/MWh for only MSW.
  - Biogas
    - Including biogenic CO_2 emissions: 1,005.8 kg CO_2/MWh.
    - Excluding biogenic CO_2 emissions: 113.8 kg CO_2/MWh.
  - Biomass
    - Including biogenic CO_2 emissions: 772.0 kg CO_2/MWh.
    - Excluding biogenic CO_2 emissions: 17.2 kg CO_2/MWh.

Fisheries Information

Table C A1-1: Summary of Common and Scientific Names of Fish Species that occur in the Yukon Energy Power Review Study Area

Common Name	Scientific Name	BC/Yukon Species Codes
Longnose Sucker	*Catostomus catostomus*	LSU
Largescale Sucker	*C. macrocheilus*	CSU
Lake Whitefish	*Coregonus clupeaformis*	LW
Least Cisco	*C. sardinella*	CS
Squanga Whitefish	*C. sp*[1]	SQ
Slimy Sculpin	*Cottus cognatus*	CCG
Lake Chub	*Couesius plumbeus*	LKC
Northern Pike	*Esox lucius*	NP
Arctic Lamprey	*Lethenteron camtschaticum*	AL
Burbot	*Lota lota*	BB
Round Whitefish	*Prosopium cylindraceum*	RW
Pygmy Whitefish	*P. coulteri*	PW
Bull Trout	*Salvelinus confluentus*	BT
Dolly Varden	*S. malma*	DV
Lake Trout	*S. namaycush*	LT
Inconnu	*Inconnu*	IN
Arctic Grayling	*Thymallus arcticus*	GR

[1]Not officially designated as a species or subspecies; however, they appear to be genetically distinct from sympatric populations of Lake Whitefish (Government of Canada 2016).

Table C A1-2: Summary of Fish Species Information

Project	Fish Species	Comments	Type of Fisheries*	References
Waste-to-energy generation		No major creek on access road or actual site.		
Wood biomass generation (Haines Junction)		No major creek on access road or actual site.		
Biogas generation		No site specifications.		
Fossil thermal generation – Takhini Substation		No major creek on access road or actual site.		
Solar - Whitehorse Quarry site (120 acres)		No major creek on access road or actual site.		
Solar - Haines Junction site north of dump (65 acres)		No major creek on access road or actual site.		
Geothermal - Vista Mountain		No major creek on site or near access road. The only water body close to site is a small pond to the south.		
Geothermal - McArthur Springs	N/A	The potential road would cross several creeks close to Summit Lake, Woodburn Lake and the head waters of Little Kalzas River area. No fish information is available for the area.		
Pumped storage - Tutshi-Moon (Midgard report)	BB, CCG, CS, GR, IN, LSU, LT, NP, RW.	All fish listed are from Tutshi Lake. No game fish in Moon Lake according to Gerd at Alpine Aviation.	Recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.

Project	Fish Species	Comments	Type of Fisheries*	References
Pumped storage – Tutshi-Moon (KP report)	BB, CCG, CS, GR, IN, LSU, LT, NP, RW.	All fish listed are from Tutshi Lake. No game fish in Moon Lake according to Gerd at Alpine Aviation.	Recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.
Pumped storage – Racine-Moon	BB, RW, GR, LT.	All fish listed are from Racine Lake. No game fish in Moon Lake according to Gerd at Alpine Aviation.	Recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.
Pumped storage – Racine-Mt. Brown	BB, RW, GR, LT.	All fish listed are from Racine Lake.	Recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.
Pumped storage – Lindeman-Fraser	LT, GR, LW.	All fish listed are from Lindeman Lake. More species are suspected to be found in Lindeman, no information was available for Fraser.	Recreational and traditional fisheries.	Environment Canada – Catalogue of Aquatic Resources of the Upper Yukon River Drainage (Whitehorse Area).
Pumped storage – Squanga-Dalayee	LT, GR, BB in Dalayee Lake (Taiga Journeys) LW, NP, CCG were also found in a creek between Dalayee Lake and Squanga Lake (FISS 2003) SQ, NP are also known to be in Squanga Lake.	Likely to find more species in Dalayee Lake, a change in water levels could affect lake trout and other species that might be living in the lake. Squanga Whitefish are genetically unique species of Lake Whitefish that have a restricted distribution in northern BC and southern Yukon. They are currently listed on SARA Schedule 3 as species of Special Concern.	Recreational and traditional fisheries.	FISS 2003 Taiga Journeys (pers. Comm.). Environment Yukon – Burbot Population Assessment Squanga Lake 2013 (Barker et al. 2014b).

Project	Fish Species	Comments	Type of Fisheries*	References
Pumped storage – Atlin-Black Mountain	GR, LT, LW, NP, RW, BB, CS, LSU, LKC, CSU.	All species listed are from Atlin Lake.	Commercial, recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.
Pumped storage – Canyon-Ittlemit	LT (Ittlemit) LT, NP, RW, LW, BB LSU and CCG in Canyon Lake.	Lake trout living in Ittlemit lake could be affected.	Recreational and traditional fisheries.	EDI fish and fish habitat report for Champagne and Aishihik.
Pumped storage – Faro-Vangorda Pit (With storage)	GR, BB, CH (juveniles), LKC, LSU, CCG, RW (in lower 4 km of Vangorda only). RW, BB, CH in Blind Creek.	Blind Creek is a known Chinook spawning stream with returns that are counted annually at a weir.	Possible CH commercial fishery, Recreational and traditional fisheries.	EDI – Faro Mine Fish and Fish Habitat Literature Review (Vangorda). FISS Database (Blind Creek).
Small hydro – Drury Lake(With storage)	CH (in Creek), LT, GR, NP.	Juvenile CH may use the creek as natal habitat depending on the extent of spawning. LT, GR, NP are found in Drury Lake.	Possible CH commercial fishery. Recreational and traditional fisheries.	EDI - Little Salmon Carmacks First Nation Salmon Knowledge Study. Drury Lake Fishing Lodge.
Small hydro – Finlayson (With storage)	LT, GR, NP, WF, BT.	All the species listed other than BT are found in the lake, while BT is found in the river just below the lake.	Recreational and traditional fisheries.	Environment Yukon.
Small hydro – Atlin-Pine Creek (Surprise Lake) (With storage)	GR, CCG.	All the species listed are found in Surprise Lake or in the upper section of Pine Creek.	Recreational and traditional fisheries.	Biological Assessment of the Atlin Hydroelectric Project.
Small hydro – Tutshi-Windy Arm (With storage)	BB, CCG, GR, LT, NP, RW, IN, LSU, CS.	All the species listed are found in Tutshi Lake.	Recreational and traditional fisheries.	Single Waterbody Query – BC Ministry of Environment.
Small hydro – Wolf river (Run of river)	GR, LT, RW, CCG, BB, LW, NP, LSU, WSU, CH.	Chinook salmon have been identified spawning as far upstream as the outlet of Wolf Lake.	Possible CH commercial fishery. Recreational and traditional fisheries.	EDI – Compilation and mapping of fisheries information within the Teslin Tlingit Traditional Territory.

Project	Fish Species	Comments	Type of Fisheries*	References
Small Hydro – Anvil Creek	LT, NP, GR, WF	Documented near the outlet of Anvil Lake. Species are likely present in lake as well.	Recreational fishery is documented – some locals from Faros have cabins on lake. Species that are targeted by traditional fisheries are present	FISS Database (Blind Creek)
Southern Lakes Enhanced Project	LW, CS, RW, GR, LT, CH, NP, LSU, BB, CCG.	All fish listed are found in the southern lakes and would need to be considered for any water level changes.	Commercial, recreational and traditional fisheries	AECOM – Fish species presence in the Yukon River Drainage.
Mayo Lake Enhanced Project	GR, LW, NP, LT, BB, RW, CCG, LSU.	All fish listed were found in Mayo River and would need to be considered for any water level changes.	Recreational and traditional fisheries.	EDI – Mayo Lake Aquatic Baseline Studies 2009.
Mayo A possible changes	GR, LW, NP, LT, BB, RW, CCG, LSU, PW.	All fish listed were found in Mayo and would need to be considered for any water level changes.	Recreational and traditional fisheries	EDI – Mayo Lake Aquatic Baseline Studies 2009.
Transmission - Whitehorse-Atlin corridor	LW, CS, RW, GR, LT, CH, NP, LSU, BB, CCG.	Transmission line would follow existing road. It would cross the McClintock River which is salmon habitat.	Commercial, recreational and traditional fisheries.	EDI Ta'an Salmon Information Gathering/Workshop Summary Report. AECOM – Fish species presence in the Yukon River Drainage.
Transmission – Whitehorse – Skagway corridor	LW, CS, RW, GR, LT, CH, NP, LSU, BB, CCG (Yukon River).	Transmission line would follow existing road. So it will cross many streams, including the Yukon River in Carcross.	Commercial, recreational and traditional fisheries.	AECOM – Fish species presence in the Yukon River Drainage.

Project	Fish Species	Comments	Type of Fisheries*	References
Transmission – Whitehorse – Teslin corridor	LW, CS, RW, GR, LT, CH, NP, LSU, BB, CCG, IN, CM, DV, PW, LKC, SQ.	Transmission line would follow existing road. It would cross the McClintock River and Teslin River. The McLintock River has Chinook Salmon spawning habitat, while the Teslin river has both Chinook and Chum salmon spawning habitat.	Commercial, recreational and traditional fisheries.	AECOM – Fish species presence in the Yukon River Drainage. EDI Ta'an Salmon Information Gathering/Workshop Summary Report.
Transmission – Faro – Watson Lake corridor (More info needed from YE)	LW, CS, RW, GR, LT, CH, NP LSU, BB, CCG, BT, PW, LKC all likely to occur.	Transmission line would follow existing road. Crosses Pelly River and tributaries as well as many streams in the Liard River watershed.	Commercial, recreational and traditional fisheries.	DFO – FISS Yukon.
Transmission – Aishihik – Burwash Landing corridor	LW, RW, GR, LT, NP, LSU, CCG, BB, RB, DV.	Transmission line would follow existing road. Most fish found on the different crossings along this road are noted.	Commercial, recreational and traditional fisheries.	EDI – Overview fish and fish habitat for the Champagne and Aishihik Traditional Territory.
Wind farm – Cyprus Mine		The turbines would be located at high elevation, away from creeks or other water bodies. The access road passes close to a small creek flowing into Rose Creek, but no fish have been found in area.		DFO – FISS Yukon.
Wind farm - Kluane	LT, RW, CCG, GR, LW, NP, LSU, BB, IN.	All the turbines and access road would be very close to existing Alaska Highway and would not cross any streams.		Barker et al. 2014a.

Project	Fish Species	Comments	Type of Fisheries*	References
Wind farm – Miller's Ridge	In Nordenskiold River: CH, CM, LT, GR, RW, LW, LSU, NP, BB, AL, CCG.	Access road and turbines would not cross any streams. The transmission line would cross the Nordenskiold River South of Carmacks.	Possible commercial fisheries for CH and CM. Recreational and traditional fisheries.	Tsawnjik Chu Nordenskiold – Habitat Protection Area Management Plan.
Wind farm - Sugarloaf	In Yukon River: LW, CS, RW, GR, LT, CH, NP, LSU, BB, CCG.	Access road and turbines don't cross any major streams, but the proposed transmission likely would cross the Yukon River.	Commercial, recreational and traditional fisheries.	AECOM – Fish Species presence in Yukon River Drainage (Lindsey et al. 1981).
Wind farm - Sumanik		Access road follows a small creek which has been sampled downstream from the proposed road and no fish were found. (DFO) Turbines are not close to any streams.		DFO – FISS Yukon ID: 80093044.
Wind farm – Tehcho		Access road already established, turbines up high with no streams in proximity.		
Wind farm – Thulsoo		Access road does not cross any streams, all turbines have no streams in proximity.		

*Type of fisheries is inferred by the fish species present.

Terrestrial Information

Table C A2-1: Summary of Disturbance Footprints Associated with Project Feature Types

Feature	Disturbance Footprint
Access Road	10 m each side of centreline (20 m ROW total footprint)
Canal	70 m (140 m total footprint)
Control Dam	10 m radius
Dam Crest	15 m radius
Forebay	15 m radius
Heat Transfer Line	15 m (30 m total footprint)
Intake	15 m radius
Interconnection Line	15 m (30 m total footprint)
Low Pressure Pipe	15 m (30 m total footprint)
Penstock	100 m ROW footprint
Powerhouse	15 m radius (circular footprint)
Saddle Dam	15 m radius
Transmission Line	30 m each side of centreline (100 m ROW footprint)
Weir	15 m radius
Wind Turbine	50 m radius

A summary of ratings for Terrestrial Footprint and Land Area indicators is provided below.

Table C A2-2: Terrestrial Footprint and Land Area Indicators by Resource Option

Resource Option / Project	Terrestrial Development (km^2)	Linear Development (roads, trans., km)	Permafrost (mean probability and weighted area km^2)	Wetlands (km^2)
Fossil Thermal				
Whitehorse Landfill	0.20	N/A	**Sporadic Discontinuous, Mean=0.20, Area=0.01**	**0**

Resource Option / Project	Terrestrial Development (km^2)	Linear Development (roads, trans., km)	Permafrost (mean probability and weighted area km^2)	Wetlands (km^2)
Transmission Lines				
Aishihik – Destruction Bay	10.41	173.6	**Sporadic Discontinuous, Mean=0.44, Area=3.83**	**0.02 Swede Johnson Wetland; Kloo and Sulpur Lakes**
Faro – Watson Lake	25.63	427.2	**Extensive Discontinuous, Mean=0.58, Area=14.94**	**0.40 Frances Lake**
Whitehorse – Atlin	10.33	171.7	**Isolated Patches, Mean=0.13, Area=1.13**	**0.07 M'Clintock Bay Lewes Marsh**
Whitehorse – Skagway	10.27	170.8	**Isolated Patches, Mean=0.12, Area=0.95**	**0.14 Nares Lake**
Whitehorse – Teslin	10.48	174.4	**Isolated Patches, Mean=0.13, Area=1.27**	**0.02 M'Clintock Bay Lewes Marsh; Teslin Lake Outlet**
Stewart – Keno City	11.42	190.0	**Extensive Discontinuous, Mean=0.69, Area=7.89**	**0.04 McQuesten and Devil's Elbow**

Notes:
1. Area associated with timber harvesting unknown but expected to be thousands of hectares.
2. Footprints associated with hydro renewable projects are driven by reservoirs; estimates of those extents are preliminary.

1.0 INTRODUCTION

Social criteria and indicators for evaluating resource options as finalized in Appendix B, are copied below in Table D 1-1.

The technical social evaluation of each resource option is addressed in Appendix D, with separate sections for each of the social criteria in Table D 1-1.

At the start of each section of Appendix D, the distinct issues, rating criteria and data sources for each criteria are summarized. As outlined in Section 7 of Appendix B, the ratings for the evaluation of each indicator are classified in terms of high, medium, and low as follows:

- **High (Red when non-positive - no colour when positive effect)** means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, beneficial or simply signify linkage/overlap without much additional guidance);
- **Medium (Yellow when non-positive - no colour when positive effect)** means the resource option has potential expected linkage to the indicator that falls between low and high ratings; and
- **Low (Green when non-positive - no colour when positive effect)** means the resource option likely has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, beneficial or simply signify no linkage / overlap with the indicator, i.e., no effects pathway).

No linkage or Not Applicable, which is shown as green, is separated out in the social evaluations to identify circumstances where there is no apparent or likely link between a resource project option and a given social indicator.

As each resource project option was reviewed, it was assumed that standard best management practices (BMPs) would be applied during the construction and operation stages to mitigate adverse effects and enhance positive effects. Where standard BMPs are expected to prevent any likely effect of concern on an indicator, a green or low effect rating was adopted.

Table D 1-1: Resource Options Evaluation Matrix – Social Criteria & Indicators

ID	Criteria	Indicator	Metric ID	Metric
Social Criteria				
S1	**First Nation Lands**	Settlement Lands, Interim Protected Lands	S1-1	Overlap and/or access with these lands (Y/ Potential/N)
S2	**Traditional Lifestyle**	Footprint land area impact	S2-1	Total area (ha) of direct land loss
		Land area loss re Traditional Lifestyle	S2-2	Total area (ha) of Traditional Use land area loss
		Land Quality Effects on Traditional Lifestyle	S2-3	Indirect effects on land or access for such pursuits (+/- and L/M/H)
		Cabins, Camps & Structures	S2-4	Number of cabins, camps, homesteads, etc. in footprint (corridor for linear access) that may be affected (n)
		Country Foods	S2-5	Effects to the opportunity to harvest country foods (+/- and L/M/H)
S3	**Heritage Resources**	Heritage Resource Potential	S3-1	Density (number of discrete) known or potential archeological, palaeontological, ethnological, prehistoric, or historic resources (L/M/H)
			S3-2	Importance/Cultural Value of heritage resources, including areas of land containing heritage resources. (L/M/H)
S4	**Tourism, Recreation & Other Resources and Land Use**	Recreational Values	S4-1	Effect on nature and scale of existing and new Recreational Values. (+/- and L/M/H)
		Tourism Values	S4-2	Effect on nature and Scale of Tourism Values. (+/- and L/M/H)
		Aesthetics	S4-3	Effect on auditory or visual aesthetics. (+/- and L/M/H)
		Non-renewable Resources	S4-4	Effect on Non-Renewable Resources. (+/- and L/M/H)
		Other Renewable Resources	S4-5	Effect on other Renewable Resources. (+/- and L/M/H)
		Land Use & Renewable Resources Plans	S4-6	Consistent with Land Use& Renewable Resources Plans (Y/N, NA)
S5	**Cultural and Community Well Being**	Infrastructure & Services	S5-1	Effect on Infrastructure & Services (+/- and L/M/H)
		Public Safety, Worker Interaction, Human and Community Health	S5-2	Risks to Community Health & Safety - construction & operation (L/M/H)
		Community, First Nation & Personal Development	S5-3	Effects on local jobs, business, training & development (+/- and L/M/H)

2.0 FIRST NATION LANDS

2.1 RATING CRITERIA AND DATA SOURCES FOR S1: FIRST NATION LANDS

The rating system outlined in Figure D 2-1 below was adopted to guide evaluations of each resource project option for the First Nation Lands indicator.

Figure D 2-1: Summary of Rating Criteria for First Nation Lands

Indicator	Low	Medium	High
Settlement Lands, Interim Protected Lands (S1-1)	No overlap with Settlement Lands or Interim Protected Lands	Potential overlap with Settlement Lands or Interim Protected Lands	Expected overlap with Settlement Lands or Interim Protected Lands

The Settlement Lands and Interim Protected Lands indicator as defined in Table D 1-1 focuses on the presence or absence of an overlap (Yes/No rating), with the option of a potential effect (if there is uncertainty). "Overlap" in this context references the footprint required for the resource option lands, access rights-of-way (ROW) (road and transmission), any required buffer lands, and whether any of the footprint requires use of any settlement lands or interim protected lands in Yukon (or any known reserve blocks in British Columbia).

An initial question is whether a generation resource site footprint is expected to overlap (red), or might potentially overlap (yellow), with First Nation lands as defined. Separately, a related question is whether new road and/or transmission access required for a resource option is expected to overlap, or might potentially overlap, with First Nation lands as defined. In this case, it becomes relevant to assess if the overlap is expected/required (a red [high] rating) or merely a potential option within the 500m area assumed for selecting a final 60m ROW (a yellow [medium] rating).

The approach and assumptions used in evaluating potential effects on the First Nation Lands indicator are:

- In applying the rating system, available information was considered regarding resource project options description.
- The evaluations of each resource option for this indicator identify resource project option overlaps with Settlement or Interim Protected Lands that must be addressed (and reserve blocks for projects in BC). It is noted that such overlaps are not necessarily adverse and could have positive effects as well as adverse effects (i.e., in certain cases the affected First Nation may not be opposed to the development, recognizing that there may be the potential for positive effects due to projects being located on settlement land, such as benefits to the First Nation through project agreements).
- Existing information is not likely, without consultation with the First Nation, to provide any useful basis for assessing the extent that there may be material concerns in this regard that are not

likely to be mitigated. Accordingly, the assessment focuses only on the extent to which an overlap is expected versus may only potentially occur (without being a likely requirement).

- This indicator focuses only on First Nation lands where a project must obtain some form of permit for actual use. Consultation with First Nations with regard to project effects on traditional lands is a separate requirement that continues to apply in connection with almost all resource options.

2.2 EVALUATION

Table D 2-1 provides a summary of all resource options indicating for each option whether it has no overlap with Settlement or Interim Protected Lands (green [low] rating) or is expected to have an overlap with Settlement or Interim Protected Lands (red [high] rating). A yellow (medium) rating is provided for situations where there is uncertainty with the potential for the resource option to have an overlap that cannot be avoided with Settlement or Interim Protected Lands. This rating reflects the existence of First Nation lands within the area potentially affected by a project's footprint, including access roads and/or transmission where it is not clear in the available information that there are options for final routing and/or project location that may avoid overlap with such lands.[1]

Table D 2-1 indicates that the largest group of projects is rated green (low) because there is no overlap.

The next largest groups of project sites is rated yellow, highlighting the potential overlap with settlement lands or interim settlement lands without a separate report confirming that an overlap is in fact required for the resource option. The specific assessments of future projects will determine the exact issues to be addressed in each instance, potentially in the manner adopted for the Stewart-Keno City Transmission project (as noted in Table D 2-1).

The following 13 resource options are rated red (high) in Table D 2-1, and the components leading to this rating are noted below where feasible:

- Two wind farm projects (Kluane Lake and Sugarloaf Mountain) are rated red (high), based on information supported by the specific resource option report indicating that each option requires overlap with Settlement Lands for the generation site component.
- The three potential new transmission corridors rated red (high) have segments where First Nation Settlement Lands are adjacent to both sides of the proposed corridor located along an existing highway, e.g., this situation has been identified for multiple points along corridors from Whitehorse to Carcross and from Whitehorse to Jake's Corner or Teslin.
- Southern Lakes Enhanced Storage project is rated red to reflect affected water bodies adjacent to various Settlement Lands, where potential edge effects have been highlighted for the project.
- Gladstone Diversion is rated red to reflect the linear features' potential overlap with Settlement Lands.

[1] Existing information for a potential resource project option typically does not allow for a clear conclusion that flexibility exists to avoid First Nation lands. First Nation lands may create constraints for even transmission line routing that must be addressed, and that cannot be avoided by BMPs in the same way as many environmentally sensitive areas.

- Canyon-Ittlemit is rated red to note that potential overlaps with Settlement Land would occur in the context of existing issues with local First Nations with regard to current Aishihik generation.
- Anvil Creek small hydro is rated red to reflect that the transmission connection to the grid would overlap with Interim Protected Lands (without any apparent practical routing option to avoid this overlap).
- Four other hydro generation options are rated red to reflect potential segments of Settlement Lands that may affect routing options and discussions for new transmission connections needed to connect with the existing grid, plus specific potential Settlement Land overlaps that may affect the Vangorda Pit pumped storage development on currently undeveloped lands.

Table D 2-1: Resource Project Options Assessment for First Nation Lands Indicator

	ResourceOptions	No Overlap with Settlement or Interim Protected Lands	Potential Overlap with Settlement or Interim Protected Lands	Expected Overlap with Settlement or Interim Protected Lands
		Low	**Medium**	**High**
Fossil Fuel Thermal (Diesel or LNG)	Whitehorse Landfill	No Overlap		
	Takhini Substation		Yes	
Non-Fossil Thermal	Biomass (Haines Junction)	No Overlap		
	Waste-to-Energy (Whitehorse)	No Overlap Expected		
	Biogas (Whitehorse)	No Overlap		
Energy Storage Facility (Takhini)		No Overlap		
Solar PV	Whitehorse	No Overlap		
	Haines Junction	No Overlap		
Wind Farms	Cyprus Mine Hill	No Overlap		
	Kluane Lake			Yes[2]
	Millers Ridge		Yes	
	Mt. Sumanik	No Overlap		
	Sugarloaf Mountain			Yes[2]
	Tehcho (Ferry Hill)	No Overlap		
	Thulsoo Mountain	No Overlap		
Geothermal	McArthur		Yes	
	Vista Mountain		Yes	
Pumped Storage	Moon Lake (Tutshi-Moon)	No Overlap		
	Racine - Moon	No Overlap		
	Lindeman – Fraser	No Overlap		
	Racine – Mt. Brown		Yes	
	Atlin – Black Mountain		Yes	
	Squanga - Dalayee			Yes[2]
	Canyon - Ittlemit			Yes[2]
	Faro – Vangorda Pit			Yes[2]
Small Hydro	Drury Lake		Yes	
	Tutshi – Windy Arm	No Overlap		
	Wolf River			Yes[2]
	Finlayson River			Yes[2]
	Anvil Creek			Yes[2]
	Atlin/Pine Creek		Yes	
Other Hydro	Gladstone Diversion			Yes[2]
	Southern Lakes			Yes[2]
	Mayo Lake	No Overlap		
	Mayo Lake Dredging	No Overlap		
Refurbish Existing Hydro Generation	Mayo A	No Overlap		
	Aishihik re-runnering	No Overlap		
Transmission Corridors	Aishihik-Burwash		Yes	
	Faro – Watson Lake		Yes	
	Whitehorse – Atlin			Yes[2]
	Whitehorse – Skagway			Yes[2]
	Whitehorse – Teslin			Yes[2]
	Stewart - Keno City		Yes[1]	

Notes:

1. Reference to one parcel where the existing line has an existing right of way, and no objection to having a new line also use this area (options existed for routing if the First Nation settlement land use not acceptable).
2. See text for discussion of components and information that lead to each red rating.

3.0 TRADITIONAL LIFESTYLE

3.1 RATING CRITERIA AND DATA SOURCES FOR S2: TRADITIONAL LIFESTYLE

The rating system outlined in Figure D 3-1 was adopted to guide evaluations of each resource project option for each of the Traditional Lifestyle indicators.

Figure D 3-1: Summary of Rating Criteria for Traditional Lifestyle

Indicator	Low	Medium	High
Footprint Land Area Impact (S2-1)[1]	<10 ha of land area affected, or not applicable	Between 10 and 100 ha of land area affected	>100 ha of land area affected
Land Area Loss re: Traditional Lifestyle[2] (S2-2)	< 500 ha of potential traditional lifestyle land area loss, or not applicable	Between 500 and 2500 ha of potential traditional lifestyle land area loss	Over 2500 ha of traditional lifestyle land area loss
Land Quality Effects on Traditional Lifestyle (S2-3)	No known or only minor concerns, or not applicable	Known minor concerns that require further work	Known significant concerns that may be very difficult to mitigate[3]
Cabins, Camps, & Structures (S2-4)[4]	Less than 26 Cabins, Camps or other Structures within the right-of-way or buffer area[5], or not applicable	Between 26 and 50 Cabins, Camps or other Structures within the right-of-way or buffer area[5]	Over 50 Cabins, Camps or other Structures within the right-of-way or buffer area[5]
Country Foods (S2-5)	No known concerns or only minor concerns, or not applicable	Known minor concerns that require some further work	Known significant concerns that may be difficult to mitigate[6]

Notes:
1. This indicator is similar to, but not the same as, the environmental indicator En4-1. See text for discussion of the differences.
2. This indicator considers total area (ha) of access loss (i.e., amount of land lost to use and lost to access). The assessment assumes that roads to facilities are gated in order to restrict access to each facility.
3. Examples: adverse impacts on known sacred places, burial grounds, graves.
4. May include indirect impacts on quality of life.
5. For smaller projects, only consider footprint. For larger projects such as pumped storage or small hydro, a buffer of 100 m has been included. A low rating for the larger projects would apply where there are no known sites or low potential for sites within the 100 m buffer.
6. Examples: adverse impacts on known special species, habitat or land; known special spawning grounds or collection areas.

The Traditional Lifestyle indicators as defined in Table D 1-1 focus on the scale of impact (L/M/H), including total area or number of structures impacted, and (for Land Quality Effects on Traditional Lifestyle [S2-3] and Country Foods [S2-5]) whether the effect is positive or negative. Unless otherwise explicitly noted, the evaluations of each resource option for these indicators address only negative effects. Figure D 3-1 provides ratings for assessing relative magnitude of the effect(s) of a resource option on each indicator.

In applying the rating system, available information regarding resource project option descriptions was considered, as well as known types of effects that the various types of projects can have on the social environment.

Traditional Lifestyle indictors have been evaluated based on information available from:

- A combination of known heritage resources and Yukon Historic Sites Inventory (YHSI) resources; cabins, camps, and structures; and high value natural resources; and
- Known traditional lifestyle valued components for other project studies.

In addition, as outlined in Table D 3-1, other environmental and/or social criteria assessments were considered where relevant for each of the S2 indicators.

Table D 3-1: Other Criteria Considered in Evaluation of Traditional Lifestyle

S2 Criteria - Indicators	Other Criteria Considered
Footprint Land Area Impact	En4-1: Footprint Terrestrial Area, including Access and New Flooding
Land Area Loss re: Traditional Lifestyle	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3: Wildlife Key Areas En3-4: Caribou Ranges
Land Quality Effects on Traditional Lifestyle	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3: Wildlife Key Areas En3-4: Caribou Ranges
Cabins, Camps, & Structures	N/A
Country Foods	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3: Wildlife Key Areas En3-4: Caribou Ranges

The following are noted with regard to the assessment approach adopted for each indicator:

- **Footprint Land Area Impact (S2-1)** – Footprint Land Area Impact is a quantitative metric that considers only direct land loss. The total footprint or land area affected may not be permanently lost for the purposes of traditional lifestyle activities (assessed separately below). Accordingly, this indicator is used only as background information and is not directly adopted for the assessment of effects on the Land Quality Effects on Traditional Lifestyle indicator.[2] The rating criteria were selected simply to help assign resource project options to clearly separate groups based on the indicator.
