- **Land Area Loss regarding Traditional Lifestyle** – This metric assesses the amount of the footprint or land area that is permanently lost or that can no longer be accessed for traditional lifestyle activities (e.g., an access road or site area that is gated or closed off).

[2] Estimated footprint areas for S2-1 do not correspond to the areas estimated for En4-1, reflecting differences in assumptions and methods used to develop each estimate.

- **For projects located within Whitehorse or Haines Junction** (i.e., fossil thermal, non-fossil thermal [biomass, biogas and waste-to-energy] and other renewable, including solar and storage battery), the total access lost is expected to equal the total area of direct land lost due to the project. This assumes that the areas for the project are gated and access to the site is controlled. However, for each of these sites there are less than 50 ha of total land area affected and consequently effects are expected to be low.
- **Wind projects or geothermal projects located outside of urban centres** – The total area of land loss for these projects ranges between 28 ha (Vista Mountain) and 261 ha (McArthur Springs). The assessment assumes that access roads and the project site are gated with restricted access. Adverse effects are expected, but are anticipated to be low.
- **Small hydro and pumped storage projects -** These projects have higher total area of land affected by the project when reservoir or surface area of affected lakes are considered. Consequently, while the total area of the project may be high, the effects on traditional lifestyle activities, including access to lakes or shoreline areas may not be as large or significant. The assessment considers only the incremental effect on land area due to the project and does not consider the existing surface area of the lake or reservoir.
- **Transmission projects -** The total area loss relating to traditional lifestyle activities will likely be much smaller. The project may create new access into previously inaccessible areas and could have both positive and negative effects on traditional activities.

- **Land Quality Effects on Traditional Lifestyle** – This indicator considers indirect effects on traditional areas or traditional lifestyle activities due to the loss of access or other concerns related to the project. This considers the effects related to footprint and land area effects, as well as land area loss related to traditional lifestyle.
- **Cabins, Camps and Structures** – This is a quantitative indicator that considers the number of dwellings (e.g., cabins, camps) that are either within a project ROW or within a 100m buffer of a project ROW for hydro and pumped storage projects.
- **Country Foods** – This considers the effects on the ability to harvest available country foods (including hunting, trapping, fishing and plant collection activities).

Table D 3-2 summarizes the assessment of the resource options with regard to the indicators for the Traditional Lifestyle criteria.

Table D 3-2: Traditional Lifestyle: All Indicators

Resource Options	Footprint Land Area Impact (S2-1) (ha)	Land Area Loss re: Traditional Lifestyle (S2-2) (ha)	Land Quality Effects on Traditional Lifestyle (S2-3) (L,M,H)	Cabins, Camps, & Structures (S2-4)	Country Foods (S2-5) (L,M,H)
Fossil Thermal (Diesel or LNG)					
Whitehorse Landfill	7	7	L	0	N/A

Transmission: Aishihik - Destruction Bay (230 kV)	1042	0-500	L	9	L
Transmission: Stewart-Keno City (138 kV & substations)	1143	0-500	L	9	L

3.2 EVALUATION

3.2.1 Resource Options with No Material Concerns re: Traditional Lifestyle

The first indicator in Table D 3-2 (Footprint Land Area Impact [S2-1]) does not directly address effects on traditional lifestyle, and is therefore not considered in this assessment beyond providing background information. The following resource project options have a green (low) rating for each of the four remaining indicators assessed in Table D 3-2, indicating no material basis for concerns regarding the Traditional Lifestyle criteria:

- Fossil fuel thermal generation (diesel and LNG, each in Whitehorse);
- Non fossil thermal generation (biomass at Haines Junction, biogas and waste-to-energy in Whitehorse);
- Energy storage facility (batteries) at Takhini Substation;
- Solar PV at Whitehorse and Haines Junction;
- Wind farms at each of the 7 sites included in this evaluation;
- Geothermal generation at McArthur Springs and Vista Mountain (near Takhini Substation) – it is assumed that any sensitive areas may be avoided with moveable footprint access and transmission line;
- Pumped storage hydro generation options, except for Squanga-Delayee, Canyon-Ittlemit and Vangorda Pit;
- Small hydro options, except for Finlayson River;
- Other hydro options, except for Gladstone Diversion and Southern Lakes Storage Enhancement;
- Hydro refurbishment/maintenance (Mayo A and Aishihik); and
- Transmission corridors (each of the project options included in this evaluation, except for the Whitehorse-Skagway Transmission Corridor).

3.2.2 Hydro Generation

3.2.2.1 Pumped Storage

The following yellow (medium) ratings are assessed for three pumped storage project options:

- Squanga-Dalayee - a yellow (medium) rating for potential effects on Country Foods (S2-5) related to effects to game outfitting[3] and perceived high game habitat;

[3] Outfitting is also discussed in the evaluations for Land Use and Renewable Resource Plans and Tourism.

- Canyon-Ittlemit - a yellow (medium) rating for potential effects of Land Quality Effects on Traditional Lifestyle (S2-3) related to high food values and perceived high game habitat, and game outfitting concerns; and
- Vangorda Pit - a yellow (medium) rating for Land Area Loss regarding Traditional Lifestyle (S2-2) – although this area is adjacent to the disturbed ground of the Vangorda Pit area, this footprint is basically undisturbed and would affect a relatively large amount of land and stream basin.

3.2.2.2 Small Hydro

The Finlayson River option is rated yellow (medium) for Land Area Loss regarding Traditional Lifestyle (S2-2), Land Quality Effects on Traditional Lifestyle (S2-3), and potential effects on Country Foods (S2-5). This option would overlap with a moderate amount of land area (in the yellow/medium category), and has known significant values for wetlands, game and fisheries.

3.2.2.3 Other Hydro

Red (high) ratings are provided for the following indicators and projects (assessments are made prior to consideration of potential mitigation that may be developed for each project):

- Gladstone Diversion - a red (high) rating for potential effects on Country Foods (S2-5). A significant concern here is based on the federal fisheries concerns of potential risk of disease (due to potential interbasin pathogen transfer) and perceived high values of indirect effects similar to previous concerns at the Aishihik Generating Station, such as changes in water levels and related possible effects.
- Southern Lakes Enhanced Storage - a red (high) rating for potential effects on Cabins, Camps and Structures (S2-4). The cabins, camps and structures values are the highest of all the resource options and reflect a high level of private and First Nations concerns, possible effects to graves and perceived concerns of ground water effects and erosion.

The same two resource options also have a yellow (medium) rating for potential effects on Land Quality Effects on Traditional Lifestyle (S2-3).

3.2.2.4 Transmission Corridors

The Whitehorse-Skagway transmission corridor resource option has yellow (medium) rating for potential effects on Cabins, Camps and Structures (S2-4). It is likely that the project routing would be selected to address any such potential effects.

4.0 HERITAGE RESOURCES

4.1 RATING CRITERIA AND DATA SOURCES FOR S3: HERITAGE RESOURCES

The rating system outlined in Figure D 4-1 was adopted to guide evaluations of each resource project option for each of the Heritage indicators.

Figure D 4-1: Summary of Rating Criteria for Heritage Resources

Indicator	Low	Medium	High
Density of Heritage Resources (S3-1)	Few known or expected heritage sites[1] (approximately <2) within or near project right-of-way or buffer area[2]	Small number of known heritage sites within or near ROW or buffer (approximately>2 and <25); high potential for archeological sites	High number of heritage sites within or near ROW or buffer (approximately >25)
Importance/ Cultural Value of Heritage Resources (S3-2)	No known sites of cultural value (or only minor concerns) within or near project right-of-way or buffer area[2]	Presence of known minor sites with concerns that require further work	Presence of known sites or potential sites with known significant concerns[3]

Notes:
1. Heritage site or heritage resources includes YHSI sites, paleontological sites, and archeological sites or other sites of cultural value.
2. For smaller projects, the evaluation only considers footprint. For larger projects, such as pumped storage or small hydro, a buffer of 100 m has been included. A low rating for the larger projects would apply where there are no known heritage sites or low potential for heritage sites within the 100m buffer. Transmission projects are rated low if route selection is likely to avoid any effects on heritage sites.
3. Examples: known significant sites and resources, sacred places, burial grounds, graves. This indicator does not include parks, as parks are included in the environmental indicator Protected and Conservation Areas (En3-2).

The Heritage Resources indicators as defined in Table D 1-1 focus on the scale of effect (L/M/H), including total area or number of heritage resources (and important heritage resources) affected. Unless otherwise explicitly noted, the evaluations of each resource option for these indicators address only negative effects. Figure D 4-1 provides ratings for assessing relative magnitude of effect of a resource activity on each indicator. “Heritage resources” include known archeological sites, known YHSI sites, known paleontological sites, known areas of archeological potential and areas of ethnographical potential.

In applying the rating system, available information was considered regarding resource project option descriptions, as well as known types of effects that the various types of projects can have on the social environment.

Heritage Resources indicators have been evaluated based on information available from:

- Previously recorded archeological, paleontological and historic sites in Yukon and British Columbia and YHSI records.

The approach and assumptions used in evaluating potential effects on Heritage Resources indicators are:

- Looked for overlap between resource project option sites and the following:
    - Known archeological sites;
    - Known YHSI sites;
    - Known paleontological sites;
    - Known areas of archeological potential; and
    - Areas of ethnographical potential.
- Combined number of sites and resources by total hectares (ha).
- Considered whether there were sites of specific cultural value or importance.

Table D 4-1 summarizes the assessment of the resource options with regard to the indicators for the Heritage Resource criteria. Resource options rated yellow or red for any indicator are highlighted with the colour rating. The considerations in each evaluation are reviewed in Section 4.2 below.

Table D 4-1: Heritage Resource: All Indicators

	Density of Heritage Resources (S3-1 - combined number of sites & resources by area)	Importance / Cultural Value (S3-2 - Summary of Overall Concerns)
Fossil Thermal (Diesel or LNG)		
Whitehorse Landfill		
Takhini Substation		
Non-Fossil Thermal		
Waste to Energy (Whitehorse)		
Biogas (CHP) (Whitehorse Landfill)		
Biomass (Haines Junction)		
Other Non-Hydro Renewable		
Storage Battery (Takhini Substation)		
Solar PV: Whitehorse Fixed Tilt: 10 MW		
Solar PV: Haines Junction Fixed Tilt: 5 MW		
Wind: Cyprus Mine Hill, 20 MW		
Wind: Kluane Lake, 20 MW		
Wind: Millers Ridge, 20 MW		
Wind: Mt. Sumanik , 20 MW		
Wind: Sugarloaf Mountain, 20 MW		
Wind: Tehcho (Ferry Hill), 20 MW		
Wind: Thulsoo Mountain, 20 MW		
Geothermal: McArthur Springs		
Geothermal: Vista Mountain		
Hydro Generation		
Pumped Storage: Moon Lake (Tutshi-Moon)		
Pumped Storage: Racine - Moon		
Pumped Storage: Lindeman-Fraser		
Pumped Storage: Racine - Mt. Brown (15 MW)		
Pumped Storage: Racine - Mt. Brown (25 MW)		
Pumped Storage: Atlin - Black Mountain (15 MW)		
Pumped Storage: Atlin - Black Mountain (25 MW)		
Pumped Storage: Squanga - Dalayee		
Pumped Storage: Canyon - Ittlemit		
Pumped Storage: Vangorda Pit		
Small Hydro: Drury Lake		
Small Hydro: Tutshi - Windy Arm		
Small Hydro: Wolf River		
Small Hydro: Finlayson River		
Small Hydro: Anvil Creek		
Small Hydro: Atlin/Pine Creek		
Other Hydro: Gladstone Diversion		
Other Hydro: Southern Lakes Storage		
Other Hydro: Mayo Lake Storage		
Other Hydro: Mayo Dredging		
Aishihik Re-runnering		
Mayo A Refurbishment		
Transmission Corridors		
Transmission: Whitehorse - Atlin (138 kV)		
Transmission: Whitehorse - Skagway (230 kV)		
Transmission: Whitehorse - Teslin (138 kV)		
Transmission: Faro - Watson Lake (230 kV)		
Transmission: Aishihik - Destruction Bay (230 kV)		
Transmission: Stewart-Keno City (138 kV & substations)		

4.2 EVALUATION

4.2.1 Resource Options with No Material Concerns re: Heritage Resources

The following resource project options have a green (low) rating for each of the heritage resources indicators reviewed in Table D 4-1, indicating no material basis for concerns regarding the Heritage Resources criteria:

- Fossil fuel thermal generation (diesel and LNG, each in Whitehorse);
- Non fossil thermal generation (biomass in Haines Junction, biogas and waste-to-energy in Whitehorse);
- Energy storage facility (batteries) at Takhini Substation;
- Solar PV in Whitehorse and Haines Junction;
- Wind farms at Cyprus Mine Hill and Kluane Lake;
- Geothermal generation at Vista Mountain (near Takhini Substation);
- Pumped storage hydro generation options at Moon Lake (Tutshi-Moon), Racine-Moon, Racine-Mt. Brown, and Vangorda Pit;
- Small hydro options at Drury Lake and Wolf River;
- Other hydro options – Mayo Lake Storage Enhancement and Mayo Dredging;
- Hydro refurbishment/maintenance (Mayo A and Aishihik); and
- Transmission corridors – Faro-Watson Lake.

4.2.2 Non-Hydro Renewables

4.2.2.1 Wind Farms

All of the wind farm options are rated green (low) for Density of Heritage Resources (S3-1). Although there are no heritage sites known today in these footprints, the following five wind farm options are rated yellow (medium) for Importance/Cultural Value of Heritage Resources (S3-2) due to the predicted high potential areas that the footprints overlap:

- Miller's Ridge;
- Mt. Sumanik;
- Sugarloaf Mountain;
- Tehcho (Ferry Hill); and
- Thulsoo Mountain.

4.2.2.2 Geothermal – McArthur Springs

McArthur Springs geothermal is rated green (low) for Density of Heritage Resources (S3-1) and rated yellow (medium) for Importance/Cultural Value of Heritage Resources (S3-2). A medium rating is based on expected level of sites and resources.

4.2.3 Hydro Generation

4.2.3.1 Pumped Storage

The following three pumped storage sites are rated yellow (medium) for Density of Heritage Resources (S3-1) and for Importance/Cultural Value of Heritage Resources (S3-2):

- Lindeman-Fraser – Chilkoot Trail National Historic Site and related resources and areas of potential;
- Squanga-Dalayee - structures close to footprint on Dalayee Lake and structures near footprint on Squaqnga Lake, significant heritage potential; and
- Canyon-Ittlemit - reference to previous Champagne and Aishihik First Nations (CAFN) concerns regarding Aishihik Generating Station.

The Atlin-Black Mountain pumped storage site is rated red (high) for Density of Heritage Resources (S3-1) and green (low) for Importance/Cultural Value of Heritage Resources (S3-2).

4.2.3.2 Small Hydro

The Finlayson River and Anvil Creek small hydro sites are each rated yellow (medium) for Density of Heritage Resources (S3-1) and for Importance/Cultural Value of Heritage Resources (S3-2) due to significant heritage and paleontological potential. The Anvil Creek site ratings reflect high archaeological potential along Anvil Lake shore, along Anvil and Blind Creek, and Pelly River valley.

The Tutshi-Windy Arm and Atlin-Pine Creek small hydro sites are each rated yellow (medium) for Density of Heritage Resources (S3-1) and green (low) for Importance/Cultural Value of Heritage Resources (S3-2).

4.2.3.3 Other Hydro - Gladstone Diversion and Southern Lakes Storage Enhancement

Gladstone Diversion is rated yellow (medium) for Density of Heritage Resources (S3-1) and for Importance/Cultural Value of Heritage Resources (S3-2) due to moderate amount of sites and CAFN concerns.

Southern Lakes Storage Enhancement is rated red (high) for Density of Heritage Resources (S3-1) and for Importance/Cultural Value of Heritage Resources (S3-2), due to high number of sites and Carcross/Tagish First Nation (CTFN) concerns.

4.2.3.4 Transmission Corridors – Other Than Faro-Watson Lake

Each of the transmission corridors other than Faro-Watson Lake is rated yellow (medium) for Density of Heritage Resources (S3-1), reflecting the potential for a notable number of heritage resource sites along such corridors.

The Whitehorse-Skagway Transmission Corridor is also rated yellow (medium) for Importance/Cultural Value of Heritage Resources (S3-2), reflecting the Chilkoot Trail National Historic Park of Canada and Klondike Gold Rush National Historic Site (USA) and related resources, as well as BC and Alaska Historic Site concerns.

5.0 TOURISM, RECREATION AND OTHER RESOURCES AND LAND USE

5.1 RATING CRITERIA AND DATA SOURCES FOR S4: TOURISM, RECREATION, AND OTHER RESOURCES AND LAND USE

The rating system outlined in Figure D 5-1 was adopted to guide evaluations of each resource project option for each of the tourism, recreation, and other resources and land use indicators.

Figure D 5-1: Summary of Rating Criteria for Tourism, Recreation, and Other Resources and Land Use

Indicator	Low	Medium	High
Recreational Values (S4-1)	No nearby/ affected recreational sites, or not applicable[1]	Project visible or audible – do not expect major change in recreational activities	Project overlaps with site(s)/ may necessitate a major change in recreational activities
Tourism Values (S4-2)	No nearby/ affected tourism opportunities, or not applicable[1]	Project overlaps with site – do not expect major change in activities	Project overlaps with site(s)/ may necessitate a major change in tourist activities
Aesthetics (S4-3)	Project not visible/audible from known valued viewpoints/ communities, or not applicable	Project visible or audible from known valued viewpoints/ communities - not expect major aesthetic value change	Project location may disrupt/ disturb valued viewpoint/ community-noted aesthetic value of area
Non-renewable Resources (S4-4)	No overlap with claims and current extraction activities, or not applicable[1]	Project overlaps with known claims - not expect major change in ability to undertake activity	Project overlaps and may affect ability to undertake resource extraction activity
Other Renewable Resources (S4-5)	No overlap with known renewable resource activities, or not applicable	Project overlaps with known renewable resource activity - not expect major change in the activity	Project overlaps and may affect the ability to undertake renewable resource activity
Land Use and Renewable Resource Plans (S4-6)	Project does not overlap with such plans, or not applicable	Project overlaps with such plans – not in conflict nor a cause a major change in activity	Project is located in zone with conflicting usage designation

Note:
1. Projects may also have a positive effect on recreational values, tourism values, and non-renewable resources (e.g., access enabled by transmission lines or access roads). These indicators do not include parks per se, as parks are included in the environmental indicator Protected and Conservation Areas (En3-2). Activities in and tourism associated with parks are discussed in evaluations where relevant.

The Tourism, Recreation, and Other Resources and Land Use indicators as defined in Table D 1-1 focus generally on whether the effect of the resource option on the indicator is positive or negative, and the relative magnitude of the effect (L/M/H). Unless otherwise explicitly noted, the evaluations of each resource option for these indicators have identified only negative effects. Figure D 5-1 provides ratings for assessing relative magnitude of effect from a resource option on each indicator, including provision

for a possible yellow (medium) magnitude effect that differs from red (high) magnitude (even for S4-6, where the indicator assumes a Yes/No or Not Applicable rating). Overall, the social evaluations tend to treat "not applicable" in the same manner as the environmental evaluations treat "no linkage."

Tourism, Recreation, and Other Resources and Land Use indicators have been evaluated based on information available from:

- **Yukon Environment:** Community-based Work Plans (for Renewable Resource Council), wildlife management plans, trapping concessions, campground locations, forestry plans;
- **Department of Tourism and Culture:** tourism information;
- **Community Websites:** Official Community Plans, Zoning by-laws, tourism and recreation information, infrastructure and services;
- **Yukon Department of Energy, Mines and Resources:** Claims information;
- **Geomatics Yukon:** Spatial data; and
- **DataBC:** Spatial data.

Summary baseline information for population centres near resource options are included in Attachment 1. Information includes population counts, applicable land use plans, infrastructure and services.

In addition to outside sources, results from other evaluations were considered. Table D 5-1 presents the other environmental, social, and economic criteria inform the evaluations in this section.

Table D 5-1: Other Criteria Considered in Evaluation of Tourism, Recreation, and Other Resource and Land Use

S4 Criteria - Indicators	Other Criteria Considered
Recreational Values (S4-1)	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3 Wildlife Key Areas En3-4 Caribou Ranges
Tourism Values (S4-2)	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3 Wildlife Key Areas En3-4 Caribou Ranges
Aesthetics (S4-3)	N/A
Non-renewable Resources (S4-4)	N/A
Other Renewable Resources (S4-5)	N/A
Land Use and Renewable Resource Plans (S4-6)	En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat En3-2: Protected and Conservation Areas En3-3 Wildlife Key Areas En3-4 Caribou Ranges

The approach and assumptions used in evaluating potential effects on Tourism, Recreation, and Other Resources and Land Use indicators are:

- Looked for geographic overlap between resource project option sites and known recreational sites, tourist sites, mineral and oil and gas claims, designated areas in planning and resource management documents.
- Direct spatial overlap would result in at least a medium ranking because it is assumed that it could potentially result in some change in activity or desirability of engaging in the activity at that site. A red rating results if there is a potential for major change in the indicator.
- There is not necessarily a linkage related to aesthetics solely because a site is a greenfield site. The site must be visible and infrastructure must have an effect on a landscape that someone values (e.g., be visible from a viewpoint popular for wildlife viewing).
- In light of the remote location of most of the projects, the focus for recreation and tourism is on outdoor activities (e.g., hiking, fishing, camping) and it assumed that individuals engaging in these activities value undisturbed landscapes.

Limitations to the evaluation include:

- Recreational and tourism values are personal and subjective. Changes to a recreational or tourist experience because of project development may adversely affect the experience for one individual but not have an effect on another individual's experience. For evaluating changes in recreational and tourism experiences, the evaluation focuses primarily on physical proximity as assessable with desktop research, i.e., no interviews or field work was feasible.
- All projects fall within an area overseen by a Renewable Resource Council (RRC). The status of community-based fish and wildlife work plans were at different stages at the time of these evaluations and some RRCs do not complete multi-year work plans. The evaluations for Land use and Renewable Resource Plans (S4-6), therefore, incorporate plans where they are known. It is assumed that the appropriate RRC will be engaged should a given project be advanced.

5.2 EVALUATION

5.2.1 Resource Options with No Material Concerns re: Tourism, Recreation and Other Resources and Land Use

Table D 5-2 provides a summary of the resource project options with green (low) ratings for each of the tourism, recreation and other resources and land use indicators. Brief supporting information and analysis is provided in the table on the application of the Tourism, Recreation, and Other Resources and Land Use indicators to these resource options.[4]

[4] Detailed review of mapping or local plan information has not been done for these resource options. If and when a resource option is subject to more detailed feasibility and planning review, it is possible that specific issues may arise that will need to be addressed in order to proceed.

Table D 5-2: Resource Project Options with Green Ratings for All Tourism, Recreation and Other Resources & Land Use Indicators

Resource Project Options	Comments re: All Indicators being Green
Fossil Fuel Thermal (Diesel or LNG)	
Whitehorse Landfill	Brownfield site with current industrial use; zoned for public utilities.
Takhini Substation	Adjacent to brownfield site (substation). No apparent conflicts; however, planning issues must be addressed.[1]
Non-Fossil Thermal	
Waste-to-Energy (Whitehorse)	Assumed brownfield site without any conflicts.
Biogas (Whitehorse)	Brownfield site; zoned for public utilities.
Energy Storage Facility	
Takhini Substation	Adjacent to brownfield site (substation). No apparent conflicts; however, planning issues must be addressed.[1]
Solar PV	
Whitehorse	Brownfield site (abandoned mine site); zoned for heavy utilities and future planning.
Haines Junction	Semi-open site near landfill, no apparent conflict.
Wind Farms	
Cyprus Mine Hill	Brownfield site, no apparent conflicts.
Mt. Sumanik	Proximity to Whitehorse; no apparent conflicts. However, planning issues must be addressed.[2]
Tehcho (Ferry Hill)	No apparent conflicts.
Geothermal	
Vista Mountain	Near brownfield site (Takhini Substation); No apparent conflicts; however, planning issues must be addressed.[1]
Pumped Storage	
Vangorda Pit	Faro mine site (brownfield site); No apparent conflicts; however, planning issues must be addressed.[3]
Hydro Storage Enhancements	
Mayo Lake	No apparent conflicts with any indicator.
Southern Lakes	No apparent conflicts with any indicator; borders multiple development zones.[4]
Mayo Outlet Channel Dredging	No apparent conflicts with any indicator.[4]
Refurbish/ Enhance Existing Hydro	Existing generating station site; no conflicts.
Mayo A	
Aishihik re-runnering	
Transmission Corridors	BMPs/routing by highway/assume can avoid conflicts with any indicator, e.g., assume avoid potential conflict with Caribou Hotel in Carcross which is near proposed centerlines for Whitehorse-Skagway corridor.
Aishihik-Burwash[5]	
Faro – Watson Lake	
Whitehorse – Atlin	
Whitehorse – Skagway[6]	
Whitehorse – Teslin	
Stewart- Keno	

Notes:

1. Infrastructure would be located in zones of the Mayo Road Development Area Regulation (Public Use and Institutional); First Nations Land Use; and Hinterland. 2005/I75.
2. Located in Whitehorse Periphery Development Regulation (Rural Residential 2013/207).
3. Infrastructure would be located in Hinterland zoning for Town of Faro 96-06.
4. Each of these projects may result in some visible changes when mitigation or dredging is being undertaken; BMPs are assumed to address any short-term disruptions, e.g., sustained boat access to Mayo Lake during dredging activities.
5. A section of the centreline for this transmission corridor as shown in the Midgard [2016], (see Appendix A) runs through Kluane National Park; Midgard notes that there is an option between Hwy 1 and Kluane Lake, which would have at least a medium effect on Land Use and Renewable Resource Plans and/or Aesthetics. The Kluane Lake wind farm resource option (and related transmission) is assumed to be in the area between Hwy 1 and Kluane Lake.
6. The Klondike Hwy from Skagway to Whitehorse is a popular drive for its scenery and historical significance, which is the proposed route for the Whitehorse to Skagway transmission line. The highway also abuts the Tsongas National Forest in Alaska (not the Klondike Gold Rush National Historical Park as suggested in Midgard [2016]), which may have an effect on the Aesthetics.

5.2.2 Non-Hydro Renewable Generation

The following non-hydro renewable generation options have at least one of the Tourism, Recreation, and Other Resources and Land Use indicators rated yellow or red, and therefore the resource option is not included in Table D 5-2.

5.2.2.1 Non-Fossil Thermal Generation - Biomass at Haines Junction

For the purpose of this evaluation, the biomass thermal generation resource option plant at Haines Junction is assumed to be located within city limits and likely near the school to take advantage of captured school waste heating load. It would require 400m buffer zones around buildings and potentially 500m to 1,000m buffers for sensitive receptors.

The potential concern regarding this site location for the biomass plant is that it is adjacent to undeveloped land zoned for residential use and on land zoned for community use/commercial.

Table D 5-3: Summary of Assessment for Non-Fossil Thermal Generation - Biomass

Project / Option	Indicator	Ranking	Assessment
Biomass (Haines Junction)	Recreational Values	**Low**	Assuming use of location recommended in Stantec report, which is zoned community use/commercial, the project is not anticipated to overlap with recreational sites/activities. Recreational values are rated low.
	Tourism Values	**Low**	Tourism activities in Haines Junction are assumed to be focused on servicing visitors to the Kluane National Park and Reserve of Canada. While the project may be audible and visible in town, it is not anticipated to change tourist activities nor is it anticipated to overlap with any known tourist sites within town limits.
	Aesthetics	**Medium**	Assumes siting near school, which is downtown and near residential and commercial areas, therefore aesthetics is rated medium.
	Non-renewable Resources	**Low**	No overlap with mineral, placer, or quartz claims.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Medium**	The location recommended in the Stantec report is adjacent to undeveloped land zoned for residential use and on land zoned for community use or commercial. It is anticipated that there will need to be some zoning variance for the project and adjacent residential development will need to be altered. Located in area for Alsek Renewable Resource Council Plan but no overlap with concerns is apparent.

5.2.2.2 Wind Farms

The following wind farm options have at least one of the Tourism, Recreation, and Other Resources and Land Use criteria indicators rated yellow or red, and therefore the resource option is not included in Table D 5-2.[5] The wind farm resource option assumes a 20 MW development on each site, with 10 turbines each of which has a 90-metre rotor diameter and 80-metre height. Ratings for Tourism, Recreation, and Other Resources and Land Use criteria take into consideration potential for concerns about wind farm effects on aesthetics and recreational or tourism values related to visual and auditory effects.

[5] Wind farms at Cyprus Mine Hill, Mt. Sumanik, Tehcho (Ferry Hill) and Thulsoo Mountain are included in Table D 5-2.

Table D 5-4: Summary of Assessment for Wind Farms

Project / Option	Indicator	Ranking	Assessment
Kluane Lake (west shore)	Recreational Values	**Medium**	Changes to landscape may change enjoyment of fishing on Kluane Lake.
	Tourism Values	**Medium**	Changes to landscape may change tourism value of fishing on Kluane Lake.
	Aesthetics	**Medium**	Anticipated to be visible from Alaska Hwy and Kluane Lake. May be visible from Kluane National Park. Potential noise disturbance.
	Non-renewable Resources	**Low**	No overlap with mineral, quartz, or placer claims.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Low**	Located in the Beaver Creek/Burwash/Destruction Bay Annual Limit Region but does not overlap with timber harvest plans or harvest licences. Located in area for Alsek Renewable Resource Council Plan but no overlap with areas of concern is apparent.
Miller's Ridge (west of, & close to, Carmacks)	Recreational Values	**Medium**	Miller's Ridge features a hiking trail that may potentially be affected. However, the Nansen Mine Road routes immediately under and south of the ridge for the wind farm.
	Tourism Values	**Medium**	Potentially precludes part of the hiking trail on Miller's Ridge but overall tourism in and around Carmacks should not be materially altered outside of Miller's Ridge trail.
	Aesthetics	**Medium**	Visible from Hwy 2 and due to elevated position, potentially visible from Carmacks. Potential noise disturbance.
	Non-renewable Resources	**Low**	Overlaps with 12 expired quartz claims.

Project / Option	Indicator	Ranking	Assessment
	Other Renewable Resources	Low	No known conflicts.
	Land Use and Renewable Resource Plans	Medium	Located in Carmacks West Moose Management Unit, but no activity cited in RRC Work Plan. Located in the Carmacks Annual Limit Region and overlaps with two cutting permits – one for the Village of Carmacks and one for Yukon Government, Department of Highways and Public Works.
Sugarloaf Mountain (southeast of Carcross)	Recreational Values	Low	Potentially affects value of Brute Mountain as hiking destination because infrastructure is anticipated to be visible from top. Do not expect major change in recreational activities.
	Tourism Values	Low	Potentially affects value of Brute Mountain as hiking destination because infrastructure is anticipated to be visible from top. Do not expect major change in tourism activities.
	Aesthetics	Medium	Infrastructure anticipated to be visible from Brute Mountain, which is endpoint for hike valued for its view. Potential noise disturbance.
	Non-renewable Resources	Low	Does not overlap with any leases or claims.
	Other Renewable Resources	Low	No known conflicts.
	Land Use and Renewable Resource Plans	Medium	Project is located in the Carcross Local Area Plan and Carcross Development Area Regulation, with the transmission line as it approaches Carcross from the south currently overlapping with the largest variety of zones: Mixed Residential Commercial, Residential, Tourist Commercial, and Commercial (1976/231). South of Carcross, the transmission line and the northern turbines are in areas zoned as Hinterland, which is a "'catch-all' open space designation that has been applied liberally to lands with no pre-determined purpose, most Settlement Lands, as well as environmentally sensitive lands" (Inukshuk Planning and Development Ltd. 2013). Located in the Whitehorse Annual Limit Region and Whitehorse-Southern Lakes Forest Management Planning Area but does not overlap with any cutting permits or Timber Harvest Plans.
Thulsoo Mountain	Recreational Values	Medium	Current location of project infrastructure may make camping at Otter Falls Campground less desirable, although it may not necessarily necessitate change in activities.

Project / Option	Indicator	Ranking	Assessment
	Tourism Values	Low	Potentially affects Otter Falls Campground and is located in outfitting concession 13 but is not anticipated to materially affect tourist activities.
	Aesthetics	Medium	Project is located in relatively close proximity to Otter Falls Campground and may be visible/audible from site.
	Non-renewable Resources	Medium	Project overlaps with multiple quartz claims, although is not anticipated to require a change in activities.
	Other Renewable Resources	Low	No apparent conflicts.
	Land Use and Renewable Resource Plans	Medium	Project infrastructure overlaps with two fuel wood licences, outfitting concession 13, which is discussed in tourism, and multiple trapping concessions.

5.2.2.3 Geothermal - McArthur Springs

The McArthur Springs project is located in the Ddhaw Ghro Habitat Protection Area. While the management plan for this area is still under development, protection areas are typically created to preserve culturally or environmentally important features (Environment Yukon 2016). According to planning documents the Ddhaw Ghro mountain range has multiple regionally significant features, including unglaciated alpine areas and plant communities, a culturally important hot spring, fannin sheep population, an intact mountain ecosystem, and cultural importance to the Northern Tutchone People (ScienceBase 2006).

Table D 5-5: Summary of Assessment for Geothermal - McArthur Springs

Project / Option	Indicator	Ranking	Assessment
McArthur Springs	Recreational Values	**Medium**	Changes in aesthetics anticipated to reduce attractiveness of area for recreational activities but a new access road in difficult terrain may open up area. New access may be seen as positive (e.g., increased camping, hiking, fishing) or negative (increased hunting in an area where the local RRC is trying to protect wildlife).
	Tourism Values	**Medium**	Changes in aesthetics anticipated to reduce attractiveness of area as a tourist destination but a new access road in difficult terrain may open up area.
	Aesthetics	**High**	Located in a protected area, which has cultural significance to the Northern Tutchone People and is valued for several environmental elements. In light of this, project infrastructure (plant site, production wells, induction well, access road) and operations would alter valued visual and auditory environment.
	Non-renewable Resources	**Medium**	Location designated as mining interest for Selkirk First Nation (SFN). While a new access road in difficult terrain my open up area to new opportunities, it is unlikely that parties will be able to take advantage of opportunities in light of area's status as a protected area.
	Other Renewable Resources	**Medium**	While a new access road in difficult terrain my open up area to new opportunities, it is unlikely that parties will be able to take advantage of opportunities in light of area's status as a protected area.
	Land Use and Renewable Resource Plans	**High**	Located in Mayo District Renewable Resource Council, the Project overlaps with two areas subject to high priority activities: managing the Ethel Lake Caribou Herd and monitoring sheep populations. Located in the Pelly Crossing Annual Limit Region but does not overlap with currently active Timber Harvest Plans or Cutting Permits. Overlaps with three trapping concessions, since project is located in a proposed protected area (Ddhaw Ghro Habitat Protection Area), project is not anticipated to interfere with trapping activities.

5.2.3 Hydro Renewable Generation

The following hydro renewable generation options have at least one of the Tourism, Recreation, and Other Resources and Land Use criteria indicators rated yellow or red, and therefore the resource option is not included in Table D 5-2.

5.2.3.1 Pumped Storage

The only pumped storage option included in Table D 5-2 is Vangorda Pit. Assessment of the remaining pumped storage resource options is provided in Table D 5-6. No attempt is made to assess any variances for specific sites developed at 50 GWh versus 100 GWh storage.

Table D 5-6: Summary of Assessment for Pumped Storage (excluding Vangorda Pit)

Project / Option	Indicator	Ranking	Assessment
Atlin – Black Mountain	Recreational Values	**Low**	According to the Wóoshtin wudidaa Atlin Taku Land Use Plan), the area has high recreational value for local community, including resource gathering and recreation; however, activities are centred on Indian/Porter Lake, Steamboat Mountain, and Fourth of July Creek, which are southeast of the upper reservoir lake. Associated linear infrastructure may make the upper reservoir lake, which may contain burbot, more accessible for recreational fishing.
	Tourism Values	**Low**	Project is located in a new/proposed protected area (Indian Lk – Hitchcock Ck At Ch' according to the Wóoshtin wudidaa Atlin Taku Land Use Plan). While site is located in area, it does not appear to overlap directly with known or currently planned tourism sites/activities.
	Aesthetics	**Low**	Locations noted as valued in the At Ch'ini Sha Protected Area are not in the vicinity of the project location. The project is not anticipated to be visible/audible from known viewpoints and nearby communities. Project infrastructure, however, will cross area with a visual quality objective of preservation, but this primarily applies to forestry practices.
	Non-renewable Resources	**Medium**	Project overlaps with eight mineral claims and one placer claim.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**High**	Project is located in a proposed protected area (Indian Lk – Hitchcock Ck according to the Wóoshtin wudidaa Atlin Taku Land Use Plan). Focus of the protected area is Indian Lake and Hitchcock Creek, not the lake being used for upper reservoir. Objectives for protected area are to protect high-value caribou winter habitat, ensure management contributes to health of caribou and sheep populations, maintain high recreational values of area. According to the environmental evaluation, the project occurs within the Atlin and Carcross Caribou herd ranges and in a Wildlife Key Area for thin horn sheep. The evaluation for commercial, recreational, and Aboriginal (CRA) fishery notes that burbot may be present in the upper reservoir lake, which is valued by recreational and aboriginal fisheries. In addition, major hydroelectric development other than local run-of-the-river projects that "supply power to approved uses in the protected areas" are prohibited. The Yukon portion of the Project is located in the Tagish Local Advisory Area, which is represented by a local advisory council. Local advisory councils advise the Minister of Community Services but do not create bylaws or collect taxes.

Project / Option	Indicator	Ranking	Assessment
Canyon – Ittlemit	Recreational Values	**High**	The project does not overlap with known/currently planned recreational activities, although the presence of lake trout in Ittlemit Lake suggests that recreational fishery may be present and Canyon Lake is included in Environment Yukon material on recreational fishing with lake trout and whitefish present. The increase of methylmercury production as a result of the volume increase in Canyon Lake may alter recreational fishing activities as consumption patterns of lake trout may need to be altered.
	Tourism Values	**Medium**	The project is located in Outfitting Concession 13, which advertises hunts for moose, wolverine, wild wood bison, black and grizzly bears, dall sheep, wolf, mountain caribou, and fishing. If outfitter uses Canyon or Ittlemit lakes for fishing activities, they may be required to temporarily use other lakes due to an increase in methylmercury production. Independent tourists may also need to temporarily use other fishing lakes for the same reason. In addition, potential changes to aesthetics along Aishihik Road (route to Otter Falls) may make area less attractive as a tourist site.
	Aesthetics	**Medium**	Project infrastructure may be visible from Aishihik Road, which leads from Canyon to Otter Falls and Aishihik Village.
	Non-renewable Resources	**Low**	No overlap with mineral, placer, or quartz claims or leases.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Medium**	Overlaps with two trapping concessions, although it is not anticipated to require a change in trapping activities. Project is located in the Champagne and Aishihik Traditional Territory Strategic Forest Management Plan in an area that is low priority for planning and merchantable timber (Alsek Renewable Resource Council 2004) and two fuel wood licence areas.
Lindeman – Fraser	Recreational Values	**Medium**	The Chilkoot Trail runs along the west side of Lake Lindeman. The trail is a Historic Site and is likely valued by hikers for its hiking terrain and its place in Canadian history. A limited number of permits are issued. The presence of project infrastructure may not change activities but the change in aesthetics may change the desirability of using the northern part of the trail and the campgrounds next to Lindeman Lake.
	Tourism Values	**Medium**	The Chilkoot Trail runs along the west side of Lake Lindeman and is a tourist destination. The presence of project infrastructure may not

Project / Option	Indicator	Ranking	Assessment
			change activities but the change of in aesthetics may change the desirability of using the northern part of the trail and the campgrounds next to Lindeman Lake.
	Aesthetics	**Medium**	Project infrastructure (powerhouse, transmission line, potentially penstock) would likely be visible from trail and/or two campgrounds on the west side of Lindeman Lake but is not anticipated to disrupt known views.
	Non-renewable Resources	**Low**	No overlap with mineral, placer, and coal claims and leases.
	Other Renewable Resources	**Low**	The project is not anticipated to have any effect on other renewable resources.
	Land Use and Renewable Resource Plans	**Medium**	Project is located within the Atlin Taku Land Use Plan, although there appears to be no overlap with designated zones so project neither conflicts with nor causes substantive change in activity. Project is located in Chilkoot Trail National Historic Site of Canada. While project may not alter activities, National Historic Sites are regulated by some of the subsections of the *Canada National Parks Act* regarding usage. Since protected areas are included in the environmental evaluation, this has been rated as a medium.
Racine – Moon	Recreational Values	**High**	According to the evaluation of CRA fishery, multiple species are present in Racine Lake, while no fish are present in Moon Lake. Impoundment may increase methylmercury production, which could alter fishing patters as consumption patterns may need to be changed. The dam may obstruct flows between Racine Lake and Tagish Lake may also change flows at Racine Falls, which is a recreational site.
	Tourism Values	**Medium**	In addition to being used for recreational activities, the general area is used by an outfitter for hunting and fishing, but the project is not anticipated to materially alter activities.
	Aesthetics	**Low**	Since Racine Lake and Moon Lake are removed from major waterways and not near communities, it is anticipated that the presence of the project will not be visible or audible from known viewpoints and communities.
	Non-renewable Resources	**Medium**	Project overlaps with two mineral claims.
	Other Renewable Resources	**Low**	No known conflicts.

Project / Option	Indicator	Ranking	Assessment
	Land Use and Renewable Resource Plans	High	The eastern part of Racine Lake, Racine Creek, and Racine Falls are part of the Racine Falls Resource Management Area, which falls within the Atlin Land Use Plan. Racine Falls is a Goal 2 area by BC's Protected Areas Strategy, which is for special features and means that it is "set aside primarily to protect rare or vulnerable features." The dam may obstruct flows between Racine Lake and Tagish Lake may also change flows at Racine Falls, which is a recreational site.
Racine – Mt. Brown	Recreational Values	High	According to the evaluation of CRA fishery, multiple species are present in Racine Lake, while there is no fish sampling information for the unnamed lake that would be the upper reservoir. Impoundment may increase methylmercury production, which could alter fishing patters as consumption patterns may need to be changed. The dam may obstruct flows between Racine Lake and Tagish Lake and may also change flows at Racine Falls, which is a recreational site.
	Tourism Values	Medium	In addition to being used for recreational activities, the general area is used by an outfitter for hunting and fishing, but the project is not anticipated to materially alter activities.
	Aesthetics	Low	Since Racine Lake and Mt. Brown Lake are removed from major waterways and not near communities, it is anticipated that the presence of the project will not be visible or audible from known viewpoints and communities.
	Non-renewable Resources	Medium	Overlaps with two mineral claims.
	Other Renewable Resources	Low	No known conflicts.
	Land Use and Renewable Resource Plans	High	The eastern part of Racine Lake, Racine Creek, and Racine Falls are part of the Racine Falls Resource Management Area, which falls within the Atlin Land Use Plan. Racine Falls is a Goal 2 area by BC's Protected Areas Strategy, which is for special features. These areas are "set aside primarily to protect rare or vulnerable features." The dam may obstruct flows between Racine Lake and Tagish Lake and may also change flows at Racine Falls, which is a recreational site.
Squanga – Dalayee	Recreational Values	High	Campground with boat launch is located at Squanga Lake. Fish species present in Squanga and Dalayee lakes and the stream reach between them are important to CRA fisheries. Since impoundment of both lakes could increase the production of methylmercury, the project may alter fishing practices on both lakes.
	Tourism Values	Medium	The presence of project infrastructure may make the area less attractive for tourism; however, the project is not likely to alter activities.

Project / Option	Indicator	Ranking	Assessment
	Aesthetics	**Medium**	Project infrastructure may be visible or audible from the Squanga Lake campgrounds, making it less attractive as a camping ground; however, the project should not alter activities.
	Non-renewable Resources	**Medium**	Overlaps with 9 expired and 27 active quartz claims.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Medium**	Located in the Carcross/Tagish Renewable Resource Council. Overlaps with five trapping concessions.
Moon Lake (Tutshi – Moon)	Recreational Values	**Low**	Tutshi and Tagish lakes both contain multiple fish species that are important to the CRA fisheries. According to the environmental analysis, water levels are not anticipated to change at Tutshi Lake and are therefore not expected to change at Tagish Lake. Therefore, changes in fishing practices are not anticipated to be affected.
	Tourism Values	**Low**	The general area is used by an outfitter that has infrastructure on and near Tagish Lake. The presence of the project, though, is not currently anticipated to alter outfitting activities.
	Aesthetics	**Medium**	Project infrastructure is located in an area with a Visual Quality Objective of Retention. While these guidelines apply primarily to forestry practices, the provide context for areas that are deemed "scenic." However, the project does not require a dam on Tutshi Lake.
	Non-renewable Resources	**Medium**	The Midgard report indicates mineral claims in downstream portion of project area. Project overlaps with nine claims.
	Other Renewable Resources	**Low**	The Midgard report did not indicate any other renewable resource interests that might affect the project. Tenure of a Commercial Licence to Occupy for Guide Outfitters does not preclude other licenses on the project area.
	Land Use and Renewable Resource Plans	**Medium**	The eastern arm of Tutshi Lake is in the Tutshi Lake Protected Area, which is a culturally significant area for Carcross/Tagish First Nation and is used by members. Review would likely be needed to address any interests or concerns related to the project effects in this area of Tutshi Lake.

Project / Option	Indicator	Ranking	Assessment
			The western part of Tutshi Lake is part of a Use, Recreation and Enjoyment of the Public (UREP) map reserve. A UREP is on Crown land outside of Provincial Forests to guard against unwarranted disposition or unplanned use, which (in this area) would compromise current or potential recreation values or uses. The Midgard report notes that this map reserve exists on the downstream portion of the project, but does not suggest that the project would be compromised by this map reserve. The Midgard report notes that a protected area tenure exists on the downstream portion of Tutshi Lake, which explicitly precludes development of any hydroelectric projects or any water control facility. The Midgard report notes that this protected area is outside the project area.

5.2.3.2 Small Hydro Projects

Assessment of the all small hydro resource options is provided in Table D 5-7.

Table D 5-7: Summary of Assessment for Small Hydro Projects

Project / Option	Indicator	Ranking	Assessment
Drury Lake	Recreational Values	**High**	According to environmental evaluation, project area is a known site of CRA fisheries. Any changes required to fishing activities due to increase in methylmercury production may affect recreational value of area as activities will need to change.
	Tourism Values	**High**	Drury Lake is used by a fishing outfitter for trout, northern pike, and arctic grayling fishing. If changes to fishing activities are required as a result of increased methylmercury production, the outfitter may need to temporarily halt usage of Drury Lake or limit usage to hunting expeditions. Drury Lake falls within Outfitting Concession 14, which is advertised for hunting the following animals: stone sheep, moose and caribou, and bear and wolf.
	Aesthetics	**Low**	It is not anticipated that project infrastructure will be visible from known viewpoints.
	Non-renewable Resources	**Low**	Project overlaps with four expired quartz claims.
	Other Renewable Resources	**Low**	No known conflicts.

Project / Option	Indicator	Ranking	Assessment
	Land Use and Renewable Resource Plans	**Medium**	Project is located in single trapping concession and outfitter concession. The latter is discussed under tourism values. Project is located in the Southeast Yukon Forest Management Area (draft), but not within cutting permits and timber harvest plans.
Tutshi-Windy Arm	Recreational Values	**High**	Tutshi Lake is used for fishing, boating, and camping. Impoundment may lead to an increase in methylmercury production, which could temporarily change the use of Tutshi Lake as a recreational fishing location. Changes in the water level may also affect the boating on the lake and the boat launch at the southern end of the lake.
	Tourism Values	**Low**	Tutshi Lake has several known tourism sites, including the Yukon Suspension Bridge and campgrounds; however, project infrastructure is not anticipated to overlap with sites or alter activities.
	Aesthetics	**Medium**	Project infrastructure may be visible to individuals using the lake for boating and/or fishing but is not anticipated to cause major aesthetic changes.
	Non-renewable Resources	**Low**	No overlap with mineral tenures.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Medium**	The eastern arm of Tutshi Lake is in the Tutshi Lake Protected Area, which is a culturally significant area for Carcross/Tagish First Nation and is used by members. Review would likely be needed to address any interests or concerns related to the project effects in this area of Tutshi Lake as control dam is currently proposed at eastern end of lake and an access road would run along the northern side of the lake. The western part of Tutshi Lake is part of Use, Recreation and Enjoyment of the Public (UREP) map reserve. A UREP is on Crown land outside of Provincial Forests to guard against unwarranted disposition or unplanned use, which (in this area) would compromise current or potential recreation values or uses. The Midgard report notes that this map reserve exists on the downstream portion of the project, but does not suggest that the project would be compromised by this map reserve.
Wolf River	Recreational Values	**Medium**	Known fish species occurring in the Wolf River (see environmental evaluation) are important to recreational fishery and the river was cited as a high-value recreation area (Teslin Strategic Forest Management Plan). Project infrastructure is not anticipated to alter recreational activities on the river.

Project / Option	Indicator	Ranking	Assessment
	Tourism Values	**Medium**	Located in Outfitter Concession 19, although according to the Yukon Outfitters Association website, no outfitter is currently associated with the concession. The Wolf River is important for river trip outfitters but project infrastructure is not anticipated to disrupt activities.
	Aesthetics	**Low**	Project infrastructure is not anticipated to be visible/audible from known viewpoints.
	Non-renewable Resources	**Low**	Project does not overlap with known mineral tenure.
	Other Renewable Resources	**Low**	No known conflicts.
	Land Use and Renewable Resource Plans	**Medium**	Located in Teslin Renewable Resource Council area. Overlaps with three single holder traplines but is not expected to alter activities. Located in the Teslin Traditional Territory Forest Resource Management Area and within two cutting permits (held by the Teslin Tlingit Council and Village of Teslin), and the Sawmill Road Demonstration Forest Timber Harvest Plan, but is not anticipated to interfere with forestry activities.
Finlayson River	Recreational Values	**High**	Finlayson Lake is a recreational fishery site with Lake Trout, Artic Grayling, Northern Pike, and Whitefish present. Since impoundment could increase methylmercury production, recreational fishing activities may also need to change. In addition, changes to downstream flows could affect fish populations, making the lake a less attractive recreational site.
	Tourism Values	**High**	The Finlayson Lake Wildlife Viewpoint is not anticipated to be affected by project infrastructure on Finlayson Lake. There is a wilderness lodge located on Frances Lake. Depending on its location, project infrastructure may be visible and have an adverse effect on its ability to attract tourists. Project is located in Outfitting Concession 20, which is used for large game hunting. In light of the proximity of project infrastructure to the highway, project is not anticipated to alter outfitting activities.
	Aesthetics	**Low**	Finlayson Lake has a wildlife viewpoint at the northern end. Project infrastructure is anticipated to be at the southern end of the lake and therefore should not alter or detract from the view.

Project / Option	Indicator	Ranking	Assessment
	Non-renewable Resources	Medium	Project overlaps with one active and two expired placer claims and 18 expired and 82 active quartz claims, but project is not anticipated to affect activities.
	Other Renewable Resources	Low	No known conflicts.
	Land Use and Renewable Resource Plans	Medium	Project overlaps with outfitting concession 20, which is discussed under tourism. Project overlaps with one group trapping concession and seven individual concessions. Project overlaps with an active fuel wood licence and timber resources licence, and two issued fuel wood licences. Project is located in multiple annual limit regions (Watson Lake, Carmacks, Ross River-Faro) and the Southeast Yukon Forest Management Plan (draft) but is not anticipated to affect activities.
Anvil Creek	Recreational Values	High	Anvil Lake is the site of a known recreational fishery and there are cabins present on the lake. Since impoundment could increase methylmercury production, recreational fishing activities may also need to change.
	Tourism Values	Medium	Project is located in outfitting concession 9, which is known for big game hunting at remote, fly-in locations. Project infrastructure is not anticipated to overlap with activities.
	Aesthetics	Medium	There are cabins present on Anvil Lake. Depending on location, project infrastructure may be visible.
	Non-renewable Resources	Medium	Project overlaps with 22 quartz claims, but project is not anticipated to affect activities.
	Other Renewable Resources	Low	No known conflicts.
	Land Use and Renewable Resources	Medium	Project overlaps with outfitting concession 9, which is discussed under tourism. Project overlaps with one group trapping concession. Project is located in Ross River-Faro annual limit region and the Draft Faro Area of Interest and the Southeast Yukon Forest Management Plan (draft) but is not anticipated to affect activities.

Project / Option	Indicator	Ranking	Assessment
Atlin-Pine Creek (Surprise Lake)	Recreational Values	**High**	At the southwest end of Surprise Lake is a maintained recreation site, including campsites and boat launch. Project infrastructure, depending on the placement of the powerhouse, may affect the use of the campsite and boat launch and may affect the desirability of using the site. There are several trails/recreation sites along Pine Creek, which infrastructure may affect as well.
	Tourism Values	**High**	Changes to recreational values may have an adverse effect on tourism values at the same site, changing the desirability of visiting these sites and activities in the area.
	Aesthetics	**High**	Project infrastructure could be visible and/or audible.
	Non-renewable Resources	**High**	Project overlaps with 10 placer leases, and 109 claims (placer and mineral combined).
	Other Renewable Resources	**Low**	No overlaps anticipated.
	Land Use and Renewable Resource Plans	**Low**	Project located in the Atlin Taku Land Use Plan but does not appear to overlap with any designated zones.

5.2.3.3 Gladstone Diversion

The Gladstone Diversion resource option would divert water from the headwaters of Gladstone Creek into Isaac Creek, which flows into Sekulmun Lake and then Aishihik Lake.

Past studies by Yukon Energy of this resource option identified potential adverse effects to fish and fish habitat related to potential pathogen transfer (from diversion of waters from one watershed into another) as well as loss of Arctic Grayling spawning and rearing habitat in streams between the lakes and in Gladstone Creek.

As reviewed in Section 4.3 of Appendix A, past work by YEC has indicated concerns from the Department of Fisheries and Oceans (DFO) as well as from local First Nations. YEC reported that the results of a full year of baseline studies provided no evidence to support a concern regarding interbasin pathogen transfer. YEC has continued to work with local First Nations to seek support for this project.

Table D 5-8 provides a summary assessment of the project effects Tourism, Recreation and Other Resources and Land Use:

Table D 5-8: Summary of Assessment for Gladstone Diversion

Project / Option	Indicator	Ranking	Assessment
Gladstone Diversion	Recreational Values	**Medium**	Known fish species occurring in the project area (see environmental evaluation) are important to recreational fishery and could be affected by project development.
	Tourism Values	**Low**	Project is predominantly in outfitting concession 12, which is relatively small, with the eastern most reach of the project in outfitting concession 13. Project development is not anticipated to change outfitting activities or affect other tourist activities.
	Aesthetics	**Medium**	The project occurs within the traditional territory of three First Nations: Champagne and Aishihik First Nations, Kluane First Nation, and White River First Nation. There is a potential for project to be visible and/or audible from viewpoints valued by First Nations.
	Non-renewable Resources	**Medium**	Project overlaps with placer leases, placer claims, and quartz claims.
	Other Renewable Resources	**Low**	No overlaps anticipated.
	Land Use and Renewable Resource Plans	**Medium**	Project overlaps with Champagne and Aishihik FRMP but does not appear to overlap with areas of concern. Overlaps with two timber harvest licences. Overlaps with four single trapping concessions. Project's overlap with outfitting concessions discussed in tourism.

6.0 CULTURAL AND COMMUNITY WELL-BEING

6.1 RATING CRITERIA AND DATA SOURCES FOR S5: CULTURAL AND COMMUNITY WELL-BEING

The rating system outlined in Figure D 6-1 was adopted to guide evaluations of each resource project evaluation for each of the cultural and community well-being indicators.

Figure D 6-1: Summary of Rating Criteria for Cultural and Community Well-Being

Indicator	Low	Medium	High
Infrastructure and Services (S5-1)	Minimal stress to infrastructure and services[1]	Moderate stress to infrastructure and services (Does not require added management)	Material stress to infrastructure and services (Requires added management)
Public Safety, Worker Interaction, Human and Community Health (S5-2)	Minimal risk re: human and community health	Moderate risk re: human and community health	Material risk re: human and community health
Community, First Nation, and Personal Development (S5-3) [Positive effects - no colour]	Minimal development opportunity [Low Positive]	Moderate development opportunity [Medium Positive]	Material development opportunity [High Positive]

Note:
1. Projects may also have a positive effect on cultural and community well-being.

The cultural and community well-being indicators as defined in Table D 1-1 focus generally on whether the effect of the resource option on the indicator is positive or negative (Public Safety, Worker Interaction and Community Health [S5-2] only looks at the risk of negative effects) and the relative magnitude of the effect (L/M/H). Unless otherwise explicitly noted (e.g., S5-3 evaluates positive effects), the evaluations of each resource option for these indicators have identified only negative effects. Table D 6-1 provides ratings for assessing relative magnitude of effect from a resource option on each indicator, including the provision for a possible medium magnitude effect that differs from high magnitude. Each resource option tends to have some effect on each of these indicators.

Summary baseline information for population centres near resource options is included in Attachment 1. Information includes population counts, applicable land use plans, infrastructure and services.

In addition to outside sources, results from other evaluations were considered. Table D 6-1 presents the issues and other criteria considered for the S5 criteria evaluations in this section. Based on the rating system, assessments focused on risks, rather than benefits, related to the magnitude of project effects (i.e., larger and longer absolute effects in this instance receive higher ratings) relative to local community infrastructure, services, workforces, lifestyle, culture and values.

Table D 6-1: Issues and Other Criteria Considered in Evaluation of Cultural and Community Well-Being

S5 Criteria – Indicators	Considerations
Infrastructure & Services	Stress on infrastructure and services in existing communities from project and project workforce during construction and operation, including roads/highways, police, health, waste facilities, water supply, accommodations (overlap with public safety and worker interaction). A proxy metric for evaluating resource option effects on this indicator is capital spending and activities in Yukon estimates and operation work force and activities. There is also a potential also for positive effects (if project provides new infrastructure, access, services). Other indicators considered include: • En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat; • En2-1: Consumptive Water Use; • Ec1-1: Yukon Opportunities During Construction; and • Ec1-2: Yukon Opportunities during Operation.
Public Safety, Worker Interaction, Human and Community Health	The evaluation of this indicator considers risks to public safety and worker interaction during construction and operation can be affected by size of project workforces, composition of workforce (i.e., local/non-local), size of near-by communities (There is overlap with the same metrics needed for infrastructure and services). Risks to human and community health include: direct effects during construction and operation on country foods, quality of air and/or water, and community safety. Other indicators considered include: • En1-3: Commercial, Recreational or Aboriginal Fishery Species and Habitat; • En5-2: Other Air Pollutants; • S2-5: Country Foods; • Ec1-1: Yukon Opportunities During Construction; and • Ec1-2: Yukon Opportunities during Operation.
Community, First Nation and Personal Development	The evaluation of this indicator focuses on potential for positive effects (if project provides opportunities for training, development, First Nation development agreements, etc.). It also considers risks to traditional lifestyle, values, culture (including traditional lifestyle), as well as effects on local jobs, business, training and development. Other indicators considered in this evaluation include: • S1-1: Settlement Lands, Interim Protected Lands; • S2-2: Land area loss re Traditional Lifestyle; • S2-5: Country Foods; • S3: Heritage Resource Potential; • S4-3: Aesthetics; • Ec1-1: Yukon Opportunities During Construction; and • Ec1-2: Yukon Opportunities during Operation.

Assessments focused on the risks related to the magnitude of project effects, including the amount of management likely needed to address stresses and risks, as well as specific development opportunities to be managed. Smaller projects and projects in certain locations (e.g., major centres and/or remote locations) tended to be of no material concern for the cultural and community well-being indicators, given the scale of the project construction[6] relative to the scale of potentially affected community infrastructure and services, worker interaction, and overall public safety. Projects with potentially large labour requirements near smaller and/or remote communities, especially those with multi-year construction periods, are expected to present more risks to local community infrastructure and services, lifestyle, culture and values. In contrast, projects near Whitehorse are anticipated to present no material concerns regarding cultural and community well-being indicators because Whitehorse is large enough to absorb a temporary, non-local workforce up to a certain size in terms of infrastructure, services and amenities.

In contrast to construction phase activities, operation phase activities are expected in all instances to have minimal effects on infrastructure and services, worker interaction and public safety.[7] Table D 6-2 summarizes the assessment with regard to indicator S5-1.

With regard to human and community health effects, the evaluation also focused on direct effects during operation on country foods, quality of air and/or water, and (if any issue) community safety. Overall, air and water related effects on health are expected to be minimal from construction and operation of resource options due to BMPs requirements and restrictions. In contrast, human and community health effects from limitations on use of country food (due to methylmercury effects on fish or other factors) are a specific concern that could require added management activity. Table D 6-3 summarizes the assessment with regard to indicator S5-2.

Community, First Nation and Personal Development effects consider all of the available information. Table D 6-4 summarizes the assessment with regard to Community, First Nation and Personal Development (S5-3), relying on Table E 2-3 from Appendix E, which summarizes community and other development opportunities for each resource option and provides the same evaluations for each resource option.

[6] Determination of resource options scale relied on the economic evaluations in Appendix E, and in particular Table E 2-1, Local Economic Impact: Yukon Opportunities during Construction. The larger a project's capital cost and impact on Yukon's gross domestic product (GDP), the larger in scale it is assumed to be.
[7] Table E 2-2 in Appendix E reviews information on expected non-fuel operating costs and jobs related to each resource option.

Table D 6-2: Cultural and Community Well-Being: Infrastructure and Services

	Magnitude of Project (Capex $million)	Percent of Capex ex. Major Equipment	Proximity to Communities	Duration of Construction	GDP impacts in Yukon - Jobs	Comments	Low	Medium	High
Fossil Thermal									
Diesel: 20 MW - Whitehorse	62	71%	Whitehorse	1-2 years	192	Minimal risks	■		
Diesel: 20 MW - Takhini	62	71%	Whitehorse	1-2 years	192	Minimal risks	■

Notes:

1. Methods and sources for Construction Costs excluding major equipment and jobs are discussed in Appendix E.

Table D 6-4: Cultural & Community Well-Being: Community, First Nation & Personal Development

	Project Size (Capex $million)	Notes re Community & Economic Development Opportunity (from Appendix E, Table E2-3)	Low Positive	Medium Positive	High Positive
Fossil Thermal					
Diesel: 20 MW - Whitehorse	62	No specific local development opportunties.	Low positive		
LNG: 20 MW - Whitehorse	100	Local opportunity to facilitate LNG use to displace other fossil fuel use in Whitehorse/Yukon.		Medium positive	
Non-Fossil Thermal					
Waste to Energy	35	Local opportunity to use renewable and (except for biogas) to supply waste heat to displace fossil fuel use. High operating jobs for Waste to Energy.		Medium positive	
Biogas (CHP)	7			Medium positive	
Biomass 0.5 MW Boiler / Steam Turbine	11			Medium positive	
Other Non-Hydro Renewable					
Storage Battery: 8 MW/40 MWh (lithium ion, 5hrs)	49	Minimal direct local development impact. Might facilitate solar or wind.	Low positive		
Solar PV: Whitehorse Fixed Tilt: 10 MW	36	Minimal direct local development impact.	Low positive		
Solar PV: Haines Junction Fixed Tilt: 5 MW	13		Low positive		
Wind: Cyprus Mine Hill, 20 MW	69	Moderate local economic development impacts from operations (ex. Mt Sumanik). Proposed Kluane & Sugarloaf Mountain sites are on aboriginal traditional land and assume land lease payments to the local FN; Kluane Lake option also facilitates development of an Aishihik-Destruction Bay Transmission Corridor.		Medium positive	
Wind: Kluane Lake, 20 MW	62				High positive
Wind: Millers Ridge, 20 MW	73			Medium positive	
Wind: Mt. Sumanik , 20 MW	64		Low positive		
Wind: Sugarloaf Mountain, 20 MW	62				High positive
Wind: Tehcho (Ferry Hill), 20 MW	64			Medium positive	
Wind: Thulsoo Mountain, 20 MW	72			Medium positive	
Geothermal: McArthur Springs (3.8 MW Av.)	121	Moderate local economic development impacts from operations (new access road).		Medium positive	
Geothermal: Vista Mountain (1.6 MW Av.)	42	Minimal local economic development impact	Low positive		
Hydro Generation					
Pumped Storage: Moon Lake (Tutshi-Moon)	218	Moderate local economic development impact based on Opex levels. In addition, options other than Squana Delayee, Canyon Ittlemit & Vangorda Pit each facilitate development of a portion of a Transmission Corridor resource option. The Vangorda Pit option may facilitate development of the Grizzly Pit mine deposit.			High positive
Pumped Storage: Racine - Moon	473				High positive
Pumped Storage: Lindeman-Fraser	484				High positive
Pumped Storage: Racine - Mt. Brown	284				High positive
Pumped Storage: Atlin - Black Mountain	254				High positive
Pumped Storage: Squanga - Dalayee	613			Medium positive	
Pumped Storage: Canyon - Ittlemit	691			Medium positive	
Pumped Storage: Vangorda Pit	524			Medium positive	
Small Hydro: Drury Lake	103	Moderate local economic development impact based on Opex level. All options other than Drury Lake and Anvil Creek also facilitate development of a Transmission Corridor (Tutshi-Windy Arm requires portion of Whitehorse-Skagway line, Wolf River and Atlin/Pine Creek facilitate Whitehorse-Atlin line, and Finlayson needs line extending from Faro toward Watson Lake).		Medium positive	
Small Hydro: Tutshi - Windy Arm	133				High positive
Small Hydro: Wolf River	234				High positive
Small Hydro: Finlayson River	283				High positive
Small Hydro: Anvil Creek	116			Medium positive	
Small Hydro: Atlin/Pine Creek	80				High positive
Other Hydro: Gladstone Diversion	40	Minimal local economic development impact; facilitate local First Nation income benefits.			High positive
Other Hydro: Southern Lakes Storage	11	Minimal local economic development impact	Low positive		
Other Hydro: Mayo Lake Storage	approx 5		Low positive		
Other Hydro: Mayo Dredging	approx 15		Low positive		
Aishihik Re-runnering	5	Minimal local economic development impact	Low positive		
Mayo A Refurbishment	27		Low positive		
Transmission Corridors					
Transmission: Whitehorse - Atlin (138 kV)	158	Moderate potential local economic development impact if stimulates small hydro (in Atlin and Teslin areas, or in Moon-Tutshi area); and if (for Whitehorse-Skagway corridor) stimulates sales of summer hydro or wind generation (to cruise ships).		Medium positive	
Transmission: Whitehorse - Skagway (230 kV)	251			Medium positive	
Transmission: Whitehorse - Teslin (138 kV)	165			Medium positive	
Transmission: Faro - Watson Lake (230 kV)	597	Material potential local economic development impacts (displace diesel generation in local communities with hydro, benefits to local businesses and population, opportunity to facilitate new mining and hydro or wind developments).			High positive
Transmission: Aishihik - Destruction Bay (230 kV)	241				High positive
Transmission: Stewart-Keno City (138 kV & substations)	80	Material local economic development impact by replacing end of life line, retains access to hydro generation, facilitates expanded capability for new mine developments in this region.			High positive

1. Capex from Appendix E, Table E2-1.

6.2 EVALUATION

6.2.1 Resource Options with No Material Concerns re: Cultural and Community Well-Being

Table D 6-5 provides a summary of the resource project options with low ratings for each of the cultural and community well-being indicators. Brief supporting information and analysis is provided in the table on the application of the S5 criteria indicators to these resource options.[8]

Table D 6-5: Resource Project Options with No Material Concerns

Resource Project Options	Comments re: All Indicators being Low
Fossil Fuel Thermal (Diesel)	
Whitehorse Landfill	In Whitehorse at a brownfield site with current industrial use; relative magnitude of project is anticipated to be low to medium.
Takhini Substation	Near Whitehorse and adjacent to brownfield site (substation); relative magnitude of project is anticipated to be low.
Energy Storage Facility	
Takhini Substation	Near Whitehorse and adjacent to brownfield site (substation); relative magnitude of project is anticipated to be low.
Solar PV	
Whitehorse	Brownfield site (abandoned mine site); zoned for heavy utilities and future planning. Construction anticipated to last less than a year (low).
Haines Junction	Near Haines Junction landfill. Construction anticipated to last less than a year (low).
Wind Farms	
Mt. Sumanik	Proximity to Whitehorse; no apparent conflicts.
Geothermal	
Vista Mountain	Proximity to Whitehorse; no apparent conflicts.
Hydro Storage Enhancements	
Mayo Lake	No apparent conflicts with any indicator.
Southern Lakes	No apparent conflicts with any indicator.
Mayo Outlet Channel Dredging	No apparent conflicts with any indicator.
Refurbish / Enhance Existing Hydro	
Mayo A	Existing generating station site; no conflicts.
Aishihik re-runnering	Existing generating station site; no conflicts.

6.2.2 Fossil Thermal - LNG

The LNG fossil thermal resource option is rated low (green) with regard to Infrastructure and Services, as well as Public Safety, Worker Interaction, Human and Community Health.

[8] Detailed review of mapping or local plan information has not been done for these resource options. If and when a resource option is subject to more detailed feasibility and planning review, it is possible that specific issues may arise that will need to be addressed in order to proceed.

The LNG fossil thermal resource option is rated medium positive with regard to Community, First Nation and Personal Development to reflect local opportunity to facilitate LNG use to displace other fossil fuel use in Whitehorse/Yukon.

6.2.3 Non-Hydro Renewable Generation

6.2.3.1 Non-Fossil Thermal

Waste-to-energy, biogas and biomass resource options are each rated green (low) with regard to Infrastructure and Services, as well as Public Safety, Worker Interaction, Human and Community Health. Waste-to-energy would provide relatively high level of operating jobs.

These three non-fossil thermal resource options are each rated medium positive with regard to Community, First Nation and Personal Development to reflect local opportunity to use renewable and (except for biogas) to supply waste heat to displace fossil fuel use. Waste-to-energy would provide a relatively high level of operating jobs.

6.2.3.2 Wind Farms

Wind projects located near communities other than Whitehorse, which is all of them excluding Mt. Sumanik, are categorized as either medium or high for the Cultural and Community Health and Well-being indicators because of their relative scale compared to neighbouring communities and the amount of management likely required to minimize potential adverse effects and, in the case of Community, First Nation and Personal Development, enhance positive effects.

The Kluane Lake and Sugarloaf Mountain wind farm resource options are rated high positive for Community, First Nation and Personal Development to reflect opportunities for First Nation lease revenues for two sites (Kluane Lake and Sugarloaf Mountain) and the opportunity to develop the new transmission corridor for the Kluane Lake site, which would allow Destruction Bay and likely Burwash Landing to stop relying on diesel generation.

6.2.3.3 Geothermal - McArthur Springs

The McArthur Springs geothermal resource option has a medium rating for each of the three Cultural and Community Health and Well-being indicators, reflecting the magnitude of its capital expenditures (Capex) and operating expenditures (Opex) costs, as well as any local development opportunities (positive effects) facilitated by the new access road that this option provides to the area.

6.2.4 Hydro Renewable Generation

6.2.4.1 Pumped Storage

Each of the pumped storage resource options has a red (high) rating for Infrastructure and Services effects during construction, reflecting the Capex cost levels (which are generally higher than the levels for all other resource options considered in the current Yukon Energy resource planning). Table D6-2 does not include the Capex costs needed to connect most of these sites (i.e., all sites other than Canyon-

Ittlemit and Vangorda Pit) to the existing grid, and therefore understates the actual construction requirements needed for development of most sites.

Each of the pumped storage resource options has a red (high) rating for Public Safety, Worker Interaction, Human and Community Health, reflecting material risks during construction and (for all options other than Moon Lake [Tutshi-Moon] and Vangorda Pit) the risk of methylmercury effects on fisheries during operation that could require added management.

The Squanga-Dalayee, Canyon-Ittlemit and Vangorda Pit pumped storage options each has a medium positive rating for Community, First Nation and Personal Development, reflecting the expectation that these options will provide moderate local or community development opportunities based on Opex levels. Each of the other pumped storage options has a high positive rating for this indicator, reflecting the opportunity to develop one of the transmission corridor resource options (e.g., Whitehorse-Skagway or Whitehorse-Atlin), and in the case of Tushi-Moon option, to facilitate other small hydro development at Tutshi-Windy Arm.

6.2.4.2 Small Hydro Projects

Each of the small hydro resource options other than Drury Lake and Anvil Creek has a high rating for each of the three Cultural and Community Health and Well-being indicators, reflecting material risks during construction, the risk of methylmercury effects on fisheries during operation that could require added management (this risk does not apply to Atlin/Pine Creek option), and the positive effects opportunity (except for the Drury Lake and Anvil Creek options) to develop one of the transmission corridor resource options (e.g., Whitehorse-Skagway, Whitehorse-Atlin, or Faro-Watson Lake).

Drury Lake and Anvil Creek small hydro have a high (red) rating for each of these indicators other than for Community, First Nation and Personal Development. For this last indicator, Drury Lake and Anvil Creek have a medium positive rating to reflect the moderate level of local development based on the level of Opex spending.

6.2.4.3 Other Hydro - Gladstone Diversion

The Gladstone Diversion resource option has a yellow (medium) rating for Infrastructure and Services, as well as for Public Safety, Worker Interaction, Human and Community Health to reflect moderate risk during construction.

The Gladstone Diversion resource option has a high positive rating for Community, First Nation and Personal Development, reflecting the opportunity to facilitate local First Nation income benefits.

6.2.5 Transmission Corridor Options

Each of the transmission corridor options has a low (green) rating for Infrastructure and Services, as well as for Public Safety, Worker Interaction, Human and Community Health to reflect moderate risk during construction. This reflects minimal risks during construction and operation.

Faro-Watson Lake, Aishihik-Destruction Bay and Stewart-Keno City transmission corridor options are each rated high positive for Community, First Nation and Personal Development, reflecting opportunities to

displace local diesel (or sustain existing transmission capability to do this, as in the case of the Stewart-Keno City option), as well as to facilitate new mining and renewable generation (hydro or wind) development. The three remaining transmission corridor options (Whitehorse-Atlin, Whitehorse-Skagway, and Whitehorse-Teslin) are each rated medium positive for Community, First Nation and Personal Development, reflecting potential local development effects if they facilitate renewable generation (pumped storage or small hydro) and, in the case of the Skagway connection, the sale of summer renewable generation (hydro or wind) to cruise ships.

ATTACHMENT 1:

Baseline Information for S4 and S5 Indicators

Table D A1-1: Baseline Information for Whitehorse, Yukon

Projects	Waste-to-energy, biogas, solar generation, Vista Mountain Geothermal, Sumanik Wind Farm, Diesel Plant, LNG Facility, energy storage facility.
Population	29,057
Traditional Territory	Kwanlin Dun and Ta'an Kwach'an traditional territories.
Available Recreation Activities	Standard suite of recreational activities available, outdoor activities include skiing at Mt. Sima. Facilities include Canada Games Centre, arena, recreation centre, multiple parks, trail network.
Tourist Activities	Standard suite of tourist activities.
Applicable Land Use Plans	Whitehorse Official Community Plan; Whitehorse and Southern Lakes Forest Resources Management Plan; Mayo Street Development Area; Whitehorse Periphery Development Area; Laberge Renewable Resource Council.
Community Infrastructure and Services	Multiple primary and secondary schools, Yukon College, library services, daycare, RCMP detachment, professional fire department, emergency medical services, hospital, health centre, both First Nations offer health and social services, dental services, hearing services, landfill, water and wastewater services.

Table D A1-2: Baseline Information for Haines Junction, Yukon

Projects	Biomass, solar generation, Kluane Lake Wind Farm[1], Thulsoo Mountain Wind Farm, Canyon-Ittlemit Pumped Storage.
Population	896
Traditional Territory	Champagne-Aishihik.
Available Recreation Activities	Hiking, camping, and fishing, trail network, recreation complex with indoor ice arena, summer pool, curling link, community hall.
Tourist Activities	Hiking, camping, and fishing; Kluane National Park.
Applicable Land Use Plans	Beaver Creek/Burwash/Destruction Bay FRMPA, Haines Junction Official Community Plan.
Community Infrastructure and Services	K-12 school, Yukon College campus, library services, RCMP detachment, volunteer fire service, emergency medical services, health centre, dental services, Champagne and Aishishik First Nations Health and Social Services, landfill, water and wastewater services, recycling.

Note:
1. Kluane Lake Wind Farm is located in Kluane First Nation traditional territory.

Table D A1-3: Baseline Information for Carmacks, Yukon

Projects	Miller's Ridge Wind Farm.
Population (includes surrounding area, including Marsh Creek)	548
Traditional Territory	Little Salmon/Carmacks First Nation.
Available Recreation Activities	Community recreation complex (with pool), mountain biking, cross-country skiing, snowmobile hiking.
Tourist Activities	Museum, interpretive centre, hiking.
Applicable Land Use Plans	Community-based Fish and Wildlife Work Plan Little Salmon Carmacks First Nation Traditional Territory, 2012-2017; Carmacks Annual Limit Region.
Community Infrastructure and Services	K-12 school, Yukon College campus, library services, RCMP detachment, volunteer fire services, emergency medical services, health services, Little Carmacks/Salmon First Nation health and family services, dental services, daycare, municipal landfill site, water and wastewater services.

Table D A1-4: Baseline Information for Faro, Yukon

Project	Cyprus Hill Wind Farm, Faro Pit Pumped Storage, Vangorda Pit Pumped Storage, Finlayson and Anvil Creek Small Hydro.
Population	388
Traditional Territory	Kaska Dena, Ross River Dena Council.
Available Recreation Activities	Summer pool, indoor ice arena, trail network, hiking, wildlife viewing, camping, fishing, and hunting.
Tourist Activities	Hiking, wildlife viewing, camping, fishing, and hunting.
Applicable Land Use Plans	Ross River – Faro Annual Limit Region; Draft Southeast Yukon Forest Management.
Community Infrastructure and Services	K-12 school, Yukon College campus, library services, RCMP detachment, volunteer fire service, emergency medical services, health centre, youth dental services, waste and wastewater services, landfill, gymnasium.

Table D A1-5: Baseline Information for Carcross, Yukon

Projects	Sugarloaf Mountain Wind Farm, Tutshi-Windy Lake Small Hydro, Racine-Mt. Brown Pumped Storage, Lindemann-Fraser Pumped Storage, Tutshi-Moon Pumped Storage, Racine-Moon Pumped Storage, Squanga-Dalayee Pumped Storage.
Population	771
Traditional Territory	Carcross/Tagish First Nation.
Available Recreation Activities	Hiking, mountain biking, camping, skiing, snowmobiling, ice fishing.
Tourist Activities	Same as recreational activities, wildlife viewing, heritage buildings, on Southern Lakes Circuit Drive.
Community Infrastructure and Services	K-9 school, Yukon College campus, RCMP detachment, volunteer fire service, health centre, social services, youth dental services, childcare services, landfill, water and wastewater services, summer community pool, drop-in at school gymnasium.

Table D A1-6: Baseline Information for Stewart Crossing, Yukon

Projects	Tehcho (Ferry Hill) Wind Farm.
Population	25
Traditional Territory	NND Traditional Territory.
Community Infrastructure and Services	Closest health centre is in Pelly Crossing, gas station, emergency services located in Mayo.

Table D A1-7: Baseline Information for Teslin, Yukon

Projects	Wolf River
Population	499
Traditional Territory	Teslin Tlingit Council.
Available Recreation Activities	Recreation complex and programming, including indoor ice arena, baseball diamond, skateboard park; trail network, skiing, boating, fishing, hiking.
Tourist Activities	Museum, on Southern Lakes Circuit Drive, Teslin Tlingit Heritage Centre, museum, fishing, hunting, Nisutlin River Delta National Wildlife Area.
Applicable Land Use Plans	Teslin Tlingit Council has a Department of Lands and Resources that oversees land and resource use.
Community Infrastructure and Services	Pre-K to Grade 9 school, Yukon College campus, Health Centre, RCMP detachment, volunteer fire service, emergency medical services, gravel airport, water and wastewater services, landfill.

Table D A1-8: Baseline Information for Atlin, British Columbia

Projects	Atlin-Black Mountain Pumped Storage, Atlin (Pine Creek) Small Hydro, Surprise Small Hydro.
2011 Population	402 (Stikine Region Regional District Electoral Area).
Traditional Territory	Taku River Tlingit First Nation.
Available Recreation Activities	Camping, boating (motorized, canoes, kayaks), fishing, hunting.
Tourist Activities	Camping, boating (motorized, canoes, kayaks), fishing, hunting, annual music festival.
Applicable Land Use Plans	Atlin Taku Land Use Plans Use, Recreation and Enjoyment of the Public Reserves (UREP) – Tutshi Lake and River.
Community Infrastructure and Services	Health clinic, RCMP, fire department, BCEHS, school, college campus.
Local Business	Grocery stores, hardware store, gas station, restaurants, laundromat, air transportation, and construction services.

1.0 INTRODUCTION

Economic criteria and indicators for evaluating resource options as finalized in Appendix B are copied below in Table E 1-1.

The technical economic evaluation of each resource option is addressed in Appendix E, with separate sections for each of the economic criteria in Table E 1-1.

At the start of each section of Appendix E, the distinct issues, rating criteria and data sources for each criteria are summarized. As outlined in Section 7 of Appendix B, the ratings for the evaluation of each indicator are classified in terms of high, medium, and low as follows:

- **High (red when non-positive - no colour when positive effect)** means the resource option has a high expected effects linkage to the indicator (depending on the indicator, the likely effects may be adverse, beneficial or simply signify linkage/overlap without much additional guidance);
- **Medium (yellow when non-positive - no colour when positive effect)** means the resource option has potential expected linkage to the indicator that falls between low and high ratings; and
- **Low (green when non-positive - no colour when positive effect)** means the resource option likely has minimal, if any, expected effects linkage to the indicator (again, depending on the indicator, any potential minimal effects may be adverse, beneficial or simply signify no linkage/overlap with the indicator, i.e., no effects pathway).

No linkage or Not Applicable, which is shown as green, is separated out in the economic evaluations to identify circumstances where there is no apparent or likely link between a resource project option and a given economic indicator.

As each resource project option was reviewed, it was assumed that standard best management practices (BMPs) would be applied during the construction and operation stages to mitigate adverse effects and enhance positive effects. Where standard BMPs are expected to prevent any likely impact of concern on an indicator, a green or low impact rating was adopted.

Table E 1-1: Resource Options Evaluation Matrix – Economic Criteria & Indicators

ID	Criteria	Indicator	Metric ID	Metric
Economic Criteria				
Ec1	**Local Economic Impacts**	Yukon Opportunities during Construction	Ec1-1	Capital Cost - Civil and Other Local Share (L/M/H)
		Yukon Opportunities during Operation	Ec1-2	Operation Costs - Yukon Labour & Business Opportunity (L/M/H)
		Community & Other Development Opportunity	Ec1-3	Community, Industry Development Opportunity (L/M/H)
Ec2	**Climate Change Risk Affecting Resource Financial Attributes**	Susceptibility to Extreme Weather Events/Conditions	Ec2-1	Susceptible to Extreme Heat/Drought (L/M/H)
			Ec2-2	Susceptible to Extreme Precipitation - flood/snow
			Ec2-3	Susceptible to Extreme Wind Events (L/M/H)
			Ec2-4	Susceptible to Ice Related Processes/Events (L/M/H)
		Conditions Susceptible to Climate Change	Ec2-5	Extent of Permafrost in project footprint (L/M/H)

2.0 LOCAL ECONOMIC IMPACTS

2.1 RATING CRITERIA AND DATA SOURCES FOR EC1: LOCAL ECONOMIC IMPACTS

The rating system outlined in Figure E 2-1 was adopted to guide evaluations of each resource project option for each of the local economic impacts indicators. The rating system was selected in each instance based on the range of resource options under review and the objective to highlight clear differences in relative economic effects based on differences in capital expenditure (Capex), operating expenditure (Opex) or other specific community and development economic effect factors. Effects are positive for each indicator, and therefore no colours are used for rating of these indicators.

Figure E 2-1: Summary of Rating Criteria for Local Economic Impacts

Indicator	Low Positive	Medium Positive	High Positive
Yukon Opportunities during Construction (Ec1-1)	Capex <$100M, Yukon GDP <$50M (approximate range)	Capex $100 -$200M, Yukon GDP $50-$100M (approximate range)	Capex >$200M, Yukon GDP >$100M (approximate range)
Yukon Opportunities during Operation (Ec1-2)	Non-fuel Opex <$1.0M/yr.	Non-fuel Opex $1 to $2M/yr.	Non-fuel Opex >$2.0M/yr.
Community & Other Development Opportunity (Ec1-3)	Minimal development opportunity	Moderate development opportunity	Material development opportunity

The local economic impacts indicators as defined in Table E 1-1 focus on the relative magnitude of the local economic impact (L/M/H) for each resource project option. The evaluation examines the relative magnitude of absolute positive effect for each resource option (e.g., total dollars per project rather than dollars per kWh or percentages of overall project Capex or Opex going to local effects), assuming that this will be the most important basis for comparative evaluation. Where relevant, other factors may also be noted, e.g., development of new access for a region, use of local feedstocks for fuel.

Local Economic Impact criteria indicators have been evaluated based on the following:

- Yukon Energy project studies for the resource options (as reviewed in Appendix A). This assessment generally adopted costs as provided by others without attempting to address possible inconsistencies.
- Yukon input-output model based on 2010 Statistics Canada multipliers. The industry selected may not always be the proper industry that matches to the construction of the resource option.
- Results from other evaluations, including Social Criteria S4-4 (Non-renewable Resources) and S5-3 (Community, First Nation and Personal Development).

- Summary background Yukon economy information (see Attachment 1 to this appendix).

The following approach and assumptions were used in the evaluation process:

- **Yukon Opportunities during Construction** (see Table E 2-1 for the detailed information used):
    - The total capital construction cost (Capex), usually in 2016$, was identified for each resource project option based on the available Yukon Energy resource options studies.
        - In the few cases where no estimate was readily available (e.g., Mayo Lake Storage and Mayo Lake Outlet Channel Dredging), Table E 2-1 shows that approximate amounts were adopted for the evaluation.
        - These estimates were used as one key metric of construction-phase local economic impacts (separating all projects into three groups, i.e., less than $100 million Capex (low), between $100 and $200 million Capex (medium) and over $200 million Capex (high).
    - Separately, the local portion of the Capex and related gross domestic product (GDP) impacts in Yukon was estimated for each resource project option based on the available Yukon Energy resource studies and the Yukon input-output model based on Statistics Canada multipliers:
        - Where feasible from the available Yukon Energy resource options studies, the portion of the Capex identified for major equipment was removed (assuming that such equipment costs will be spent outside Yukon) in order to provide an indicator of the civil and other costs that local businesses and population can participate in by carrying out activities such as clearing, roads, building and structures (unless brought from outside of Yukon).[1] This indicator may understate economic leakage from Yukon for construction costs, e.g., installation of major equipment may often involve a specialized work force and management brought into Yukon only for the duration of time needed for this specific work.[2]
        - In cases where no estimate was readily available of the major equipment portion of Capex, Table E 2-1 shows the assumed percentages that were adopted for the evaluation.
        - After the above initial identification of the construction costs that facilitate local business and population participation, the Yukon input-output model was used to

[1] It was recognized that looking only at major equipment was a crude indicator of non-local Capex spending. However, review of available information indicated that information on civil or other "local" spending was much less consistently available.
[2] The Stewart-Keno City transmission project, for example, indicates the major equipment costs are 20 to 25% of substation and transmission line Capex cost estimates. However, these costs plus costs for installation equal to 64% of overall transmission line Capex costs.

estimate the impact to Yukon GDP, employment income within Yukon and jobs that construction activities can create.[3]

- These estimates were used as a separate key metric of local economic impacts during construction (separating all projects into three groups, i.e., less than $50 million Yukon GDP impact (low), between $50 and $100 million Yukon GDP impact (medium), and over $100 million Yukon GDP impact (high).

- The results of the GDP assessment rating were compared with the total Capex rating and were found to generally yield consistent results. In the few cases where there was some variance, judgement was used to provide a final rating of the resource option for economic opportunity impacts during construction in Yukon.

- **Yukon Opportunities during Operation** (see Table E 2-2 for the detailed information used):
  - After review of available information in the Yukon Energy studies, the analysis focused on non-fuel operations and maintenance (O&M) cost estimates (Opex) for each option as the best available overall indicator of potential resource option operating spending impacts on the Yukon economy.[4] Where relevant and feasible, other operation features were also noted, e.g., use or local feedstocks for fuel, numbers of jobs.
  - Table E 2-2 identifies where assumptions were required to assess non-fuel Opex for an option.
  - The O&M estimates were used as a key metric of operation local economic impacts (separating all projects into three groups, i.e., less than $1 million per year Opex (low), between $1 and $2 million per year Opex (medium), and over $2 million per year Opex (high).

- **Community and Other Development Opportunity** (see Table E 2-3 for the detailed assessment):
  - Consideration was given to any specific new opportunities that each resource option would provide to community and other developments. This includes effects from new roads, transmission lines and business opportunities during operation of the resource option. Projects with notable specific new opportunities to be addressed and managed were rated high.
  - Rating of resource options for Community and Other Development Opportunity (Ec1-3 economic indicator) yields a similar assessment in practice to the rating of resource options for Community, First Nation, and Personal Development (S5-3).

---

[3] Direct and indirect, based on the Yukon input-output model (2010 Statistics Canada multipliers) http://economics.gov.yk.ca/impact.aspx [detailed industry multipliers: "electric power engineering construction" for hydro, thermal and transmission options, "other engineering construction" for all other options]. There would also be a construction GDP employment impact for the cost of major equipment based on the local wholesale margin and multipliers; however, it is not practical at this stage to estimate these values and, even though it would indicate a slightly higher multiplier impacts in Yukon, such a change would not appear to affect the overall evaluation ranking of the resource options.

[4] Annual operating spending changes over time for some resource options: a) to reflect inflation and b) other factors such as reduced annual generation, etc. To avoid inconsistency the first year annual operating cost was used for the ranking purposes.

The economic evaluation of resource options does not show any useful basis for separate assessment of many sub-options for specific resource options, including Whitehorse landfill versus Takhini substation locations for fossil fuel thermal options, different technologies for the storage battery option, and various smaller scale options of the solar options in Whitehorse and Haines Junction.

Table E 2-1: Local Economic Impact: Yukon Opportunities during Construction

	Installed Capacity, MW	Annual Average Energy GW.h	Construction cost[4] ($ million)			Construction GDP impact ($ million, excl. jobs) - direct plus indirect within Yukon				Evaluation				
			Total Construction cost[4]	Major Equipment costs	% of Major Equipment costs	Construction cost excl. 1. Yukon GDP impact analysis are based on Yukon input-output model available at http://economics.gov.yk.ca/impact.aspx [2010 Statistics Canada multipliers, simple multipliers (direct plus indirect) within Yukon applied to estimated construction cost excluding major equipment; detailed aggregation for industry "Electric power engineering construction" for thermal, hydro & transmission options; "Other engineering construction" for all other options].

2. The construction cost estimates for some options do not provide breakdown of the costs to identify amount related to major equipment, and even when estimates are provided they may not provide reliable or consistent numbers for the GDP analysis. For example, the major equipment cost for Waste to Energy option shown in the table above is the cost for "complete facility installed and commissioned", which may include other construction related costs. For Storage Battery options the major equipment cost includes "Capital cost" plus "replacement cost" [this assumes replacement of all batteries after 15 years for lead acid batteries and after 20 years for lithium ion batteries]. No breakout of equipment costs is provided for transmission corridor options, or certain other projects as noted. The capital cost for these options would require further breakdown in order to estimate major equipment related costs to be excluded for the GDP analysis.

3. Most of the pumped storage hydro options (as well as the Atlin/Pine Creek small hydro option) are located in the northern BC close to the Yukon border. The locations are very close to Yukon compared to any other major population centres in BC and access to the construction site would be from Yukon. Therefore, all capital spending and employment opportunities are assumed to be within Yukon resources.

4. Kluane Lake Wind and Atlin/Pine Creek Small Hydro ratings reflect need for material transmission Capex not included in this table (see Appendix A, section 5.1). No capital costs are yet included for most of the transmission needed to connect certain options to grid: Kluane wind farm ($241 million Aishihik-Destruction Bay transmission corridor); all pumped storage options other Vangorda Pit and Canyon-Ittlemit (estimated capex ranges from $100 to $125 million); all small hydro other than Drury Lake and Anvil Creek (estimated capex ranges from $94 to $221 million).

Table E 2-2: Local Economic Impact: Yukon Opportunities during Operation

	Installed Capacity, MW	Annual Average Energy GW.h	Operation cost ($ million, excludes feedstock/fuel costs)		Notes	Evaluation			
			Annual Operation Cost	Jobs		Nonfuel Opex $M/yr	Low Positive Non-fuel Opex <$1M/yr	Medium Positive Non-fuel Opex $1 to 2 M/yr	High Positive Non-fuel Opex >$2M/yr
Fossil Thermal									
Diesel: 20 MW - Whitehorse	20.0	up to >166	up to 1.19	N/A	Non-fuel O&M likely to be well under $1 million/yr with actual usage. Fuel sourced from outside Yukon, and used when required.	up to 1.19	Low Positive		
LNG: 20 MW - Whitehorse	20.0	up to >166	up to 1.19	N/A		up to 1.19	Low Positive		
Non-Fossil Thermal									
Waste to Energy	1.6	10	3.36	18	Fuel feedstocks from local sources (cost excluded here). Economics assume year-round operation. Except for biogas, assumes sale of waste heat.	3.36			High Positive
Biogas (CHP)	0.2	0.4	0.26	N/A		0.26	Low Positive		
Biomass 0.5 MW Boiler / Steam Turbine	0.5	3	0.62	5		0.62	Low Positive		
Other Non-Hydro Renewable									
Storage Battery: 8 MW/40 MWh (lithium ion, 5hrs)	8.0	0.04	0.26	N/A		0.26	Low Positive		
Solar PV: Whitehorse Fixed Tilt: 10 MW	10.0	10	0.37	N/A		0.37	Low Positive		
Solar PV: Haines Junction Fixed Tilt: 5 MW	5.0	5	0.14	N/A		0.14	Low Positive		
Wind: Cyprus Mine Hill, 20 MW	20.0	50	1.36	2	Wind farm options earn medium positive rating, except for the two options with FN land lease payments. Assumes employ two technicians working out of an office near any of wind farm. About 20% of O&M costs are fixed; variable costs include maintenance costs and royalties. Two site options [Kluane Lake & Sugarloaf Mountain] are on aboriginal traditional land and assume land lease payments to the local FN (reflected in high positive rating). Kluane Lake required new transmission to Haines Junction or Aishihik area.	1.36		Medium Positive	
Wind: Kluane Lake, 20 MW	20.0	48	1.31	2		1.31			High Positive
Wind: Millers Ridge, 20 MW	20.0	57	1.44	2		1.44		Medium Positive	
Wind: Mt. Sumanik , 20 MW	20.0	42	1.12	2		1.12		Medium Positive	
Wind: Sugarloaf Mountain, 20 MW	20.0	32	0.98	2		0.98			High Positive
Wind: Tehcho (Ferry Hill), 20 MW	20.0	33	0.97	2		0.97		Medium Positive	
Wind: Thulsoo Mountain, 20 MW	20.0	54	1.39	2		1.39		Medium Positive	
Geothermal: McArthur Springs (3.8 MW Av.)	3.8	25	1.30	N/A		1.30		Medium Positive	
Geothermal: Vista Mountain (1.6 MW Av.)	1.6	11	0.58	NA		0.58	Low Positive		
Hydro Generation									
Pumped Storage: Moon Lake (Tutshi-Moon)	20.2	54	1.90	N/A	All sites (except Moon and Vangorda Pit) annual O&M cost estimated at 2.0% of capital cost before IDC plus $0.005/kW.h for generation and pumped energy. Moon option O&M cost as per Midgard report, with provision specifically for BC resource fees. Vangorda Pitt O&M cost adjusted from EMC[2] Picacho report to provide $0.005/kW.h cost for pumped storage.	1.90		Medium Positive	
Pumped Storage: Racine - Moon	15.0	50	9.20	N/A		9.20			High Positive
Pumped Storage: Lindeman-Fraser	15.0	50	9.50	N/A		9.50			High Positive
Pumped Storage: Racine - Mt. Brown	15.0	50	5.80	N/A		5.80			High Positive
Pumped Storage: Atlin - Black Mountain	15.0	50	5.20	N/A		5.20			High Positive
Pumped Storage: Squanga - Dalayee	25.0	100	12.50	N/A		12.50			High Positive
Pumped Storage: Canyon - Ittlemit	25.0	100	13.90	N/A		13.90			High Positive
Pumped Storage: Vangorda Pit	40.0	134	2.40	N/A		2.40			High Positive
Small Hydro: Drury Lake	8.1	32	2.10	N/A	Small hydro option annual O&M cost estimated at 2.0% of capital cost before IDC plus $0.005/kW.h variable cost for generation. Atlin/Pine Creek rated High Positive after considering need for added O&M on transmission required to connect to Yukon grid.	2.10			High Positive
Small Hydro: Tutshi - Windy Arm	7.2	57	2.79	N/A		2.79			High Positive
Small Hydro: Wolf River	20.0	96	4.88	N/A		4.88			High Positive
Small Hydro: Finlayson River	17.6	139	6.02	N/A		6.02			High Positive
Small Hydro: Anvil Creek	9.8	41	2.39	N/A		2.39			High Positive
Small Hydro: Atlin/Pine Creek	5.7	36.3 avail to Yukon	1.77	N/A		1.77			High Positive
Other Hydro: Gladstone Diversion	N/A	37	likely<1.0	N/A		likely<1.0	Low Positive		
Other Hydro: Southern Lakes Storage	1.0	6	likely<1.0	N/A		likely<1.0	Low Positive		
Other Hydro: Mayo Lake Storage	N/A	2 to 4	likely<1.0	N/A		likely<1.0	Low Positive		
Other Hydro: Mayo Dredging	N/A	1 to 2	likely<1.0	N/A		likely<1.0	Low Positive		
Aishihik Re-runnering	1.00	3	likely<0.5	N/A		likely<0.5	Low Positive		
Mayo A Refurbishment	2.30	10	likely<0.5	N/A		likely<0.5	Low Positive		
Transmission Corridors	Transfer Capacity								
Transmission: Whitehorse - Atlin (138 kV)	97.0	N/A	0.24	N/A	Ongoing O&M includes labour costs, brushing costs, and other non-labour costs, adjusted for corridor length and difficulty factors.	0.24	Low Positive		
Transmission: Whitehorse - Skagway (230 kV)	443.0	N/A	0.29	N/A		0.29	Low Positive		
Transmission: Whitehorse - Teslin (138 kV)	95.0	N/A	0.24	N/A		0.24	Low Positive		
Transmission: Faro - Watson Lake (230 kV)	190.0	N/A	0.61	N/A		0.61	Low Positive		
Transmission: Aishihik - Destruction Bay (230 kV)	484.0	N/A	0.22	N/A		0.22	Low Positive		
Transmission: Stewart-Keno City (138 kV & substations)	N/A	N/A	likely<0.2	N/A		likely<0.2	Low Positive		

Table E 2-3: Local Economic Impact: Community and Other Development Opportunity

	Evaluation			
	Notes	**Low Positive**	**Medium Positive**	**High Positive**
Fossil Thermal				
Diesel: 20 MW - Whitehorse	No specific local development opportunities.	**Low Positive**		
LNG: 20 MW - Whitehorse	Local opportunity to facilitate LNG use to displace other fossil fuel use in Whitehorse/Yukon.		**Medium Positive**	
Non-Fossil Thermal				
Waste to Energy	Local opportunity to use renewable and (except for biogas) to supply waste heat to displace fossil fuel use. High operating jobs for Waste to Energy.		**Medium Positive**	
Biogas (CHP)			**Medium Positive**	
Biomass 0.5 MW Boiler / Steam Turbine			**Medium Positive**	
Other Non-Hydro Renewable				
Storage Battery: 8 MW/40 MWh (lithium ion, 5hrs)	Minimal direct local development impact. Might facilitate solar or wind.	**Low Positive**		
Solar PV: Whitehorse Fixed Tilt: 10 MW	Minimal direct local development impact.	**Low Positive**		
Solar PV: Haines Junction Fixed Tilt: 5 MW		**Low Positive**		
Wind: Cyprus Mine Hill, 20 MW	Moderate local economic development impacts from operations (ex. Mt Sumanik). Proposed Kluane & Sugarloaf Mountain sites are on aboriginal traditional land and assume land lease payments to the local FN; Kluane Lake option also facilitates development of an Aishihik-Destruction Bay Transmission Corridor.		**Medium Positive**	
Wind: Kluane Lake, 20 MW				**High Positive**
Wind: Millers Ridge, 20 MW			**Medium Positive**	
Wind: Mt. Sumanik , 20 MW		**Low Positive**		
Wind: Sugarloaf Mountain, 20 MW				**High Positive**
Wind: Tehcho (Ferry Hill), 20 MW			**Medium Positive**	
Wind: Thulsoo Mountain, 20 MW			**Medium Positive**	
Geothermal: McArthur Springs (3.8 MW Av.)	Moderate local economic development impacts from operations (new access road).		**Medium Positive**	
Geothermal: Vista Mountain (1.6 MW Av.)	Minimal local economic development impact.	**Low Positive**		
Hydro Generation				
Pumped Storage: Moon Lake (Tutshi-Moon)	Moderate local economic development impact based on Opex levels. In addition, options other than Squanga Dalayee, Canyon Ittlemit & Vangorda Pit each facilitate development of a portion of a Transmission Corridor resource option. The Vangorda Pit option may facilitate development of the Grizzly Pit mine deposit.			**High Positive**
Pumped Storage: Racine - Moon				**High Positive**
Pumped Storage: Lindeman-Fraser				**High Positive**
Pumped Storage: Racine - Mt. Brown				**High Positive**
Pumped Storage: Atlin - Black Mountain				**High Positive**
Pumped Storage: Squanga - Dalayee			**Medium Positive**	
Pumped Storage: Canyon - Ittlemit			**Medium Positive**	
Pumped Storage: Vangorda Pit			**Medium Positive**	
Small Hydro: Drury Lake	Moderate local economic development impact based on Opex level. All options other than Drury Lake and Anvil Creek also facilitate development of a Transmission Corridor (Tutshi-Windy Arm requires portion of Whitehorse-Skagway line, Wolf River and Atlin/Pine Creek facilitate Whitehorse-Atlin line, Finlayson needs line extending from Faro toward Watson Lake).		**Medium Positive**	
Small Hydro: Tutshi - Windy Arm				**High Positive**
Small Hydro: Wolf River				**High Positive**
Small Hydro: Finlayson River				**High Positive**
Small Hydro: Anvil Creek			**Medium Positive**	
Small Hydro: Atlin/Pine Creek				**High Positive**
Other Hydro: Gladstone Diversion	Minimal local economic development impact; facilitate local First Nation income benefits.			**High Positive**
Other Hydro: Southern Lakes Storage	Minimal local economic development impact.	**Low Positive**		
Other Hydro: Mayo Lake Storage		**Low Positive**		
Other Hydro: Mayo Dredging		**Low Positive**		
Aishihik Re-runnering	Minimal local economic development impact.	**Low Positive**		
Mayo A Refurbishment		**Low Positive**		
Transmission Corridors				
Transmission: Whitehorse - Atlin (138 kV)	Moderate potential local economic development impact if stimulates small hydro (in Atlin and Teslin areas, or in Moon-Tutshi area); and if (for Whitehorse-Skagway corridor) stimulates sales of summer hydro or wind generation (to cruise ships).		**Medium Positive**	
Transmission: Whitehorse - Skagway (230 kV)			**Medium Positive**	
Transmission: Whitehorse - Teslin (138 kV)			**Medium Positive**	
Transmission: Faro - Watson Lake (230 kV)	Material potential local economic development impacts (displace diesel generation in local communities with hydro, benefits to local businesses and population, opportunity to facilitate new mining and hydro or wind developments).			**High Positive**
Transmission: Aishihik - Destruction Bay (230 kV)				**High Positive**
Transmission: Stewart-Keno City (138 kV & substations)	Material local economic development impact by replacing end of life line, retains access to hydro generation, facilitates expanded capability for new mine developments.			**High Positive**

2.2 EVALUATIONS

2.2.1 Resource Options with No Material Concerns re: Local Economic Impacts

Tables E 2-1 to E 2-3 show a low positive rating for each of the local economic impact indicators for the following resource project options:

- Fossil fuel thermal - diesel generation options.
- Non-hydro renewable:
    - Storage Battery;
    - Solar PV; and
    - Geothermal - Vista Mountain.
- Hydro Generation:
    - Other Hydro – Southern Lakes Enhanced Storage, Mayo Lake Enhanced Storage, and Mayo Lake Outlet Channel Dredging; and
    - Refurbishment/Maintenance – Aishihik Rerunnering, Mayo A Refurbishment.

2.2.2 Fossil Fuel Thermal Generation

2.2.2.1 LNG Thermal Generation

Liquefied natural gas (LNG) thermal generation in Whitehorse has a low positive rating for both construction and operation Yukon opportunities.

This resource option has a medium positive rating for community and other development opportunities, reflecting local opportunities facilitated by this option (through its development of an LNG supply chain) to use LNG to displace other fossil fuel use in Whitehorse/Yukon.

2.2.3 Non-Hydro Renewable Generation

2.2.3.1 Non-Fossil Thermal Generation

Each of the non-fossil thermal generation resource options has a low positive rating for Yukon opportunities during construction, and each option other than Waste to Energy also has a low positive rating for Yukon opportunities during operation. Waste to Energy has a high positive rating for Yukon opportunities during operation, reflecting its high annual Opex cost level and the level of operation jobs.

Each of the non-fossil thermal generation resource options has a medium positive rating for community and other development opportunities, reflecting local opportunities to use renewable energy resources, as well as local opportunities (except for biogas) to use waste heat to displace fossil fuel use.

2.2.3.2 Wind Farms

Each of the wind farm resource options other than Kluane Lake has a low positive rating for Yukon opportunities during construction. Kluane Lake has a medium positive rating for Yukon opportunities during construction, reflecting the additional development (not reflected in the Kluane Lake costs as estimated in the Table E 2-1) for the new transmission line required to connect the Kluane Lake wind far to the existing grid at Haines Junction or the WAF 138 kV grid near Aishihik.

Each of the wind farm options other than Kluane Lake and Sugarloaf Mountain have a medium positive rating for Yukon opportunities during operation and (except for Mt. Sumanik) for community and other development opportunity. The medium positive ratings reflect the level of annual Opex costs and the expectation that these costs will provide some local opportunities. Mt. Sumanik has a low positive rating for community and other development opportunity to reflect its proximity to Whitehorse and the extent to which this proximity will reduce the overall effect on local community development.

The high positive ratings for Kluane Lake and Sugarloaf Mountain for Yukon opportunities during operation and for community and other development opportunity reflect opportunities for First Nation lease revenues for the two sites (Kluane Lake and Sugarloaf Mountain) and the opportunity to develop the new transmission corridor for the Kluane Lake site, which will allow Destruction Bay and likely Burwash Landing to stop relying on diesel generation.

2.2.3.3 Geothermal - McArthur Springs

The McArthur Springs geothermal resource option has a medium positive rating for each of the three Local Economic Impact indicators, reflecting the magnitude of its Capex and Opex costs, as well as any local development opportunities facilitated by the new access road that this option provides to the area.

2.2.4 Hydro Generation

2.2.4.1 Pumped Storage

Each of the pumped storage resource options has a high positive rating for Yukon opportunities during construction, reflecting the Capex cost levels (which are generally higher than the levels for all other resource options considered in this Resource Plan). Table E 2-1 does not include Capex costs needed to connect most of these sites (i.e., all sites other than Canyon-Ittlemit and Vangorda Pit) to the existing grid, and therefore understates the actual Capex cost requirements needed for development of most sites.

Each of the pumped storage resource options other than Tutshi-Moon has a high positive rating for Yukon opportunities during operation, reflecting the Opex cost levels, which are generally higher than the levels for all other resource options considered in this Resource Plan. The Tutshi-Moon site has a medium positive rating for Yukon opportunities during operation. These operation opportunities are expected to be focused inside the facility and the utility.

The Squanga-Dalayee, Canyon-Ittlemit and Vangorda Pit pumped storage options each has a medium positive rating for community and other development opportunity, reflecting the expectation that these

options will provide moderate local or community development opportunities based on Opex levels. Each of the other pumped storage options has a high positive rating for this indicator reflecting opportunity to develop one of the Transmission Corridor resource options (e.g., Whitehorse-Skagway or Whitehorse-Atlin), and (in the case of Tutshi-Moon option) to facilitate other small hydro development at Tutshi-Windy Arm.

2.2.4.2 Small Hydro

Based on Capex cost levels and estimates of Yukon GDP effects, the following small hydro resource ratings occur for Yukon opportunities during construction:

- Wolf River and Finlayson River have a high positive rating;
- Tutshi-Windy Arm, Anvil Creek and Atlin/Pine Creek options have a medium positive rating (the Atlin/Pine Creek medium rating reflects the additional development [not reflected in the Kluane Lake costs as estimated in the Table E 2-1] for the new transmission line needed to connect the project to the Yukon grid at Jakes Corner); and
- Drury Lake has a low positive rating.

Each of the small hydro resource options has a high positive rating for Yukon opportunities during operation, reflecting the Opex cost levels (the Atlin/Pine Creek rating reflects Opex expected for required new transmission connection as well as the hydro facility expansion). These operation opportunities are expected to be focused inside the facility and the utility.

Drury Lake and Anvil Creek small hydro has a medium positive rating for community and other development opportunity to reflect the level of Opex spending. Each of the other small hydro options has a high positive rating to reflect that it facilitates the development of a specific transmission corridor.

2.2.4.3 Other Hydro - Gladstone Diversion

The Gladstone Diversion resource option has a low positive rating for Yukon opportunities during construction and operation, and a high positive rating for community and other development opportunity. The high positive rating reflects the opportunity to facilitate local First Nation income benefits.

2.2.5 Transmission Corridors

Based on Capex cost levels and estimates of Yukon GDP effects, the following transmission corridor resource ratings occur for Yukon opportunities during construction:

- Whitehorse-Skagway and Faro-Watson Lake each have a high positive rating;
- Whitehorse-Atlin, Whitehorse-Teslin, and Aishihik-Destruction Bay each have a medium positive rating; and
- Stewart-Keno City has a low positive rating.

Based on Opex cost levels, each of the transmission corridor options has a low positive rating for Yukon opportunities during operation.

Faro-Watson Lake, Aishihik-Destruction Bay and Stewart-Keno City transmission corridor options are each rated high positive for local community and other development opportunities, reflecting opportunities to displace local diesel (or sustain existing transmission capability to do this, as in the case of the Stewart-Keno City option), as well as to facilitate new mining and renewable generation (hydro or wind) development. The three remaining transmission corridor options (Whitehorse-Atlin, Whitehorse-Skagway, and Whitehorse-Teslin) are each rated medium positive, reflecting potential local development impacts if they facilitate renewable generation (pumped storage or small hydro) and, in the case of the Skagway connection, the sale of summer renewable generation (hydro or wind) to cruise ships.

3.0 CLIMATE CHANGE RISK

3.1 RATING CRITERIA AND DATA SOURCES FOR EC2: CLIMATE CHANGE RISK AFFECTING RESOURCE FINANCIAL ATTRIBUTES

The rating system outlined in Figure E 3-1 was adopted to guide evaluations of each resource project option for each of the climate change risk indicators. These assessments address the extent to which financial attributes of the resource options are potentially affected by various climate change risk factors.

Figure E 3-1: Summary of Rating Criteria for Climate Change Risk

Indicator	Low	Medium	High
Susceptible to Extreme Weather/Events Conditions (Ec2-1) Extreme Heat/Drought (Ec2-2) Extreme Precipitation (Ec2-3) Extreme Wind Events (Ec2-4) Ice Related Processes	Not Specifically Susceptible, or Not Applicable	Potentially Susceptible	Specifically Susceptible
Conditions Susceptible to Climate Change - Extent of Permafrost in Project Footprint (Ec2-5)	Not Specifically Susceptible, or Not Applicable	Potentially Susceptible	Specifically Susceptible

The climate change risk indicators as defined in Table E 1-1 focus on the relative magnitude of the risk (L/M/H) for each resource project option. Green (low) shows minimal concerns, meaning that the resource option is not specifically susceptible to the specified risk or the risk is not applicable to the resource option. In contrast, red (high) identifies resource options that are known to be specifically susceptible to the risk (and thus at risk for relatively high adverse economic effects, either in design, construction or operation). Yellow (medium) addresses resource options where there is uncertainty as to the relative magnitude of the risk, based on current information.

Climate Change Risk criteria indicators have been evaluated based on information available from:

- Yukon Energy project studies for the resource options (as reviewed in Appendix A); and
- Results from other evaluations, including environmental criteria En4-3 (Permafrost).

Many resource options are not specifically susceptible to climate change risks beyond what might be called "normal" susceptibility, i.e., exposures to risks of extreme weather events similar to the exposure of other community activities. The evaluation is directed at identifying resource options where the specified risk is clearly of direct and special importance relative to the risk exposure for the other resource options relevant to the current Resource Plan evaluation. See Table E 3-1 for the detailed evaluation.

Table E 3-1: Climate Change Risk: Indicator Evaluation of Resource Options

	Susceptibility to Extreme Weather Events/Conditions (L/M/H)				Conditions Susceptible to Climate Change
	Notes	Extreme Heat/Drought	Extreme Precipitation - flood/snow	Extreme Wind Events	Ice Related Processes/Events	Extent of Permafrost in Project Footprint
Fossil Thermal						
Diesel: 20 MW - Whitehorse		Low	Low	Low	Low	Low
LNG: 20 MW - Whitehorse		Low	Low	Low	Low	Low
Non-Fossil Thermal						
Waste to Energy		Low	Low	Low	Low	Low
Biogas (CHP)		Low	Low	Low	Low	Low
Biomass 0.5 MW Boiler / Steam Turbine		Medium	Low	Low	Low	Low
Other Non-Hydro Renewable						
Storage Battery: 8 MW/40 MWh (lithium ion, 5hrs)		Low	Low	Low	Low	Low
Solar PV: Whitehorse Fixed Tilt: 10 MW	When working in cold climates, the voltage changes as a function of temperature becomes a critical design component.	Low	Low	Low	Low	Low
Solar PV: Haines Junction Fixed Tilt: 5 MW		Low	Low	Low	Low	Low
Wind: Cyprus Mine Hill, 20 MW	Turbine output will decrease below -30°C (all sites other than Kluane Lake) and wind turbines generally stop working below 40°C. For all sites other than Kluane Lake, 10% loss assumed for icing impacts. Kluane Lake transmission access also likely affected by permafrost conditions. Assume wind resource potentially susceptible to extreme wind events.	Low	Low	Medium	High	Low
Wind: Kluane Lake, 20 MW		Low	Low	Medium	Low	High
Wind: Millers Ridge, 20 MW		Low	Low	Medium	High	Low
Wind: Mt. Sumanik , 20 MW		Low	Low	Medium	High	Low
Wind: Sugarloaf Mountain, 20 MW		Low	Low	Medium	High	Low
Wind: Tehcho (Ferry Hill), 20 MW		Low	Low	Medium	High	Low
Wind: Thulsoo Mountain, 20 MW		Low	Low	Medium	High	Low
Geothermal: McArthur Springs (3.8 MW Av.)	Potential permafrost conditions affecting road / transmission access.	Low	Low	Low	Low	Medium
Geothermal: Vista Mountain (1.6 MW Av.)		Low	Low	Low	Low	Low
Hydro Generation						
Pumped Storage: Moon Lake (Tutshi-Moon)	Hydro resource options are specifically susceptible to drought, and therefore each of these options is rated on this basis. There is inadequate information to rate any material differences among these projects - however, storage can assist resiliency, along with capacity being set well below maximum potential. Potential permafrost conditions are assumed for options requiring material new transmission development.	High	Low	Low	Low	Medium
Pumped Storage: Racine - Moon		High	Low	Low	Low	Medium
Pumped Storage: Lindeman-Fraser		High	Low	Low	Low	Medium
Pumped Storage: Racine - Mt. Brown		High	Low	Low	Low	Medium
Pumped Storage: Racine - Mt. Brown		High	Low	Low	Low	Medium
Pumped Storage: Atlin - Black Mountain		High	Low	Low	Low	Medium
Pumped Storage: Atlin - Black Mountain		High	Low	Low	Low	Medium
Pumped Storage: Squanga - Dalayee		High	Low	Low	Low	Medium
Pumped Storage: Canyon - Ittlemit		High	Low	Low	Low	Low
Pumped Storage: Vangorda Pit		High	Low	Low	Low	Low
Small Hydro: Drury Lake	Hydro resource options are specifically susceptible to drought. Storage can assist resiliency, along with capacity for some options being set well below maximum potential. Geotechnical risk and the presence of permafrost noted for Drury Lake option. Permafrost risk assumed for new transmission.	High	Low	Low	Low	High
Small Hydro: Tutshi - Windy Arm		High	Low	Low	Low	Medium
Small Hydro: Wolf River		High	Low	Low	Low	Medium
Small Hydro: Finlayson River		High	Low	Low	Low	Medium
Small Hydro: Anvil Creek		High	Low	Low	Low	Medium
Small Hydro: Atlin/Pine Creek		High	Low	Low	Low	Medium
Other Hydro: Gladstone Diversion	Gladstone Diversion assumed to be susceptible to drought risk (red rating). It is assumed that drought related risks are only moderate for the storage enhancement options.	High	Low	Low	Low	Low
Other Hydro: Southern Lakes Storage		Medium	Low	Low	Low	Low
Other Hydro: Mayo Lake Storage		Medium	Low	Low	Low	Low
Other Hydro: Mayo Dredging		Low	Low	Low	Low	Low
Aishihik Re-runnering	The viability or design of these options is assumed not to be susceptible to these risks.	Low	Low	Low	Low	Low
Mayo A Refurbishment		Low	Low	Low	Low	Low
Transmission Corridors						
Transmission: Whitehorse - Atlin (138 kV)	Potential risks include additional snow clearing costs from heavy snow, structure & conductor damage, contact between phases and transmission structure or guys, phase contact with trees or buildings, trees falling into line (wind event related risks), forest fire ignition (extended heat/drought risk). Permafrost in project footprint would increase capital costs (specific risk for Aishihik-Destruction Bay option).	Low	Medium	Medium	Medium	Medium
Transmission: Whitehorse - Skagway (230 kV)		Low	Medium	Medium	Medium	Medium
Transmission: Whitehorse - Teslin (138 kV)		Low	Medium	Medium	Medium	Medium
Transmission: Faro - Watson Lake (230 kV)		Medium	Medium	Medium	Medium	Medium
Transmission: Aishihik - Destruction Bay (230 kV)		Medium	Medium	Medium	Medium	High
Transmission: Stewart-Keno City (138 kV & sub.)		Medium	Medium	Medium	Medium	Medium

3.2 EVALUATIONS

3.2.1 Resource Options with No Material Concerns re: Climate Change Risk

Tables E 3-1 shows a green rating for each of the climate change risk indicators for the following resource project options:

- Fossil fuel thermal options (diesel and LNG).
- Non-hydro renewable:
    - Non-fuel thermal options (waste to energy, biogas and biomass);
    - Storage Battery;
    - Solar PV;
    - Geothermal - Vista Mountain;
    - Other Hydro - Mayo Outlet Channel Dredging; and
    - Refurbishment/Maintenance - Aishihik Rerunnering, Mayo A Refurbishment).

3.2.2 Non-Hydro Renewable Generation

3.2.2.1 Biomass

The biomass generation option has a yellow (medium) rating for susceptibility to extreme heat/drought (e.g., forest fires). Biomass generation has a green (low) rating for all other Climate Change Risk indicators.

3.2.2.2 Wind Farms

Each of the wind farm site options has a green (low) rating for susceptibility to extreme heat/drought, as well as extreme precipitation (flood/snow). All wind farm sites other than Kluane Lake have a green rating as well for the extent of permafrost in project footprint (Kluane Lake has a red [high] rating based on extensive discontinuous permafrost affecting the new transmission routing needed for this option).

Each of the wind farm site options has a yellow (medium) rating for susceptibility to extreme wind events.

Each of the wind farm site options other than Kluane Lake has a red (high) rating for susceptibility to ice-related processes/events (Kluane Lake has a green [low] rating).

3.2.2.3 Geothermal - McArthur Springs

McArthur Springs has a green (low) rating for all four indicators regarding susceptibility to extreme weather events/conditions.

McArthur Springs has a yellow (medium) rating for the extent of permafrost in project footprint, reflecting potential permafrost conditions affecting new road and transmission access to this site.

3.2.3 Hydro Renewable Generation

3.2.3.1 Pumped Storage

With regard to susceptibility to extreme water events/conditions, each of the pumped storage resource options has the following ratings:

- Extreme heat/drought - red (high) rating, reflecting specific susceptibility to drought; and
- Extreme precipitation (flood/snow), extreme wind events, and ice-related processes/events - green (low) rating.

With regard to the extent of permafrost in project footprint, each option other than Canyon-Ittlemit and Vangorda Pit has a medium rating reflecting potential permafrost conditions affecting material new transmission access development requirements. Canyon-Ittlemit and Vangorda Pit have a green rating, reflecting proximity to existing transmission.

3.2.3.2 Small Hydro

With regard to susceptibility to extreme water events/conditions, each of the small hydro resource options has the following ratings:

- Extreme heat/drought - red (high) rating, reflecting specific susceptibility to drought; and
- Extreme precipitation (flood/snow), extreme wind events, and ice-related processes/events - green (low) rating.

With regard to the extent of permafrost in project footprint, each option other than Drury Lake has a medium rating reflecting potential permafrost conditions affecting material new transmission access development requirements. Drury Lake has a red (high) rating based on geotechnical risks and presence of permafrost noted in previous KGS reports.

3.2.3.3 Other Hydro (excluding Mayo Outlet Channel Dredging)

Each of these resource options has a green (low) rating regarding susceptibility to extreme precipitation (flood/snow), extreme wind events, ice-related process/events, and the extent of permafrost in the project footprint.

Regarding susceptibility to extreme heat/drought conditions, Gladstone Diversion has a red (high) rating, and each of the enhanced storage options (Mayo Lake and Southern Lakes) has a yellow (moderate) rating (reflecting the modest nature of these enhancements within the overall existing hydro generation regime).

3.2.4 Transmission Corridors

The transmission corridor options tend (by their linear nature) to be susceptible to extreme weather events and/or permafrost condition risks. Accordingly, each of these resource options has a yellow (medium) rating for all of the climate risk indicators, with the following exceptions:

- Regarding susceptibility to extreme heat/drought, which increases forest fire risks, the Whitehorse-Atlin, Whitehorse-Teslin, and Whitehorse-Skagway transmission corridor options are rated green (low) reflecting the extent that each route covers well developed areas and/or mountain areas.
- Regarding susceptibility to the extent of permafrost in project footprint, the Aishihik-Destruction Bay transmission corridor option has a red (high) rating, reflecting the extensive discontinuous permafrost affecting the new transmission routing needed for this option.

ATTACHMENT 1:

Baseline Information

In 2015, Yukon's population grew for the 12th consecutive year,[1] and as of June 2015, Yukon's population was estimated at 37,343,[2] (an approximate 20% increase over the last ten years, representing an annual average increase of 1.8%). Notably, the City of Whitehorse accounted for over 77% of the total population in Yukon at 28,872, and Whitehorse's population gains accounted for the majority of overall population growth in Yukon in 2015 over 2014 (about 85% of the annual change).

As of November 2015, the Yukon labour force averaged 21,200,[3] up 700 from 2014 level. The unemployment rate was 4.2%, the lowest unemployment rate amongst Canadian provinces and territories, and lower than the national unemployment rate of 7.1%. For the same period in the prior year the territorial unemployment rate was at 4.4%.

The service-producing sector accounted for about 84% of total employment, while 16.0% were employed in the goods-producing sector. Approximately 39.5% of working Yukoners were employed by one of the levels of government in the territory, while the remaining 60.5% were employed in the private sector with about 26.2% as self-employed.

In 2014, Yukon's real gross domestic product (GDP) contracted for a second consecutive year (after nine consecutive year over year increases), decreasing by approximately 0.8% to $2.264 billion. An annual decline in mineral production as a result of weak mineral prices and an ongoing slowdown in the global mining industry was the primary contributor to the reduction in GDP.[4] In summary:

- GDP from mining, quarrying and oil and gas extraction was a significant contributor to Yukon's economy at 19% of total GDP in 2014 (at $2007); however, it was down from an estimated contribution of over 21% in 2012 and 2013;
- GDP related to Public Administration contributed about 21% to 22% to Yukon's GDP over the last five years (2010-2014), highlighting the important role the public sector plays in Yukon's economy; and
- The construction sector also provides notable impact to GDP with about 7% to 7.5% contribution to Yukon's GDP over the last three years (2012-2014), declining from 10%-11% in 2010 and 2011.

Whitehorse is the largest electricity load centre[5] and accounts for largest portion of Yukon businesses. In 2013, Whitehorse businesses accounted for about 77% of all territorial businesses surveyed and about 82% of employees.[6] Government activity provides considerable economic stability to the Whitehorse area, with Whitehorse serving as the headquarters for territorial and federal government offices. The

[1] Review of the impact of Faro Mine in the 1980s and 1990s shows that closure of a large mine development may impact the overall Yukon population. The 2013 Yukon Economic Outlook also notes that following the final closure of the Faro mine in 1998, Yukon experienced six consecutive years of declining population, which saw the population fall just below 30,000 in 2003.

[5] In 2015, Whitehorse residential and commercial energy sales accounted for about 67% of total Yukon-wide retail electricity sales including both AEY and Yukon Energy sales (source for Whitehorse and AEY sales is AEY 2016-17 GRA, Table 3 on page 2-4).
[6] Source: Government of Yukon Socio-Economic Web Portal http://www.sewp.gov.yk.ca/subject (accessed on June 24, 2016).

public sector was the largest source of employment in 2011, employing about 27% of the total population aged 15 years and over.[7] Tourism has also become a major source of economic growth for the city. Outside of the public sector, the following sectors were the largest sources of employment in 2011: 12.8% of the population aged 15 years and over were employed in the retail trade, 9.0% employed in construction, 7.1% in accommodation and food services, and 6.9% in health care and social assistance.

Appendix 5.3
Southern Lakes Enhanced Storage Concept Studies

2017 INTEGRATED RESOURCE PLAN

SOUTHERN LAKES ENHANCED STORAGE CONCEPT

PLANNING OVERVIEW

FEBRUARY 2017

YUKON ENERGY

EXECUTIVE SUMMARY

PROJECT OVERVIEW & BACKGROUND

The Southern Lakes Enhanced Storage Concept (SLESC or the Concept) envisions increasing the licenced water storage range on the Southern Lakes (SL) in order to increase the production of winter energy at the Whitehorse Rapids Generating Station (WRGS).

No new infrastructure needs to be built to realize the Concept benefits, only a change to the allowable winter storage limits on the SL and the implementation/construction of mitigation measures.

BENEFITS

- The Concept represents a low cost source of winter renewable energy introduced by enhancing YEC's existing infrastructure. As such, the Concept is complementary to YEC's prior commitments and disclosures to the YUB and the Yukon Public – both of which emphasize maximizing the generation from YEC's existing assets.
- The Concept:
  - Provides a low cost source of firm winter energy of up to 9.9 GWh/year at a levelized cost of 9 cents/kWh;
  - Displaces nearly 5,100 tonnes of GHG emissions each year under average water conditions, assuming a split of 75% natural gas and 25% diesel generation;[1]
  - Maximizes production from existing assets and natural resources;
  - Can be implemented in near term (winter 2019 or 2020);
  - Provides a lasting benefit to some landowners who are already impacted by the effects of rising water levels in the Southern Lakes. Project mitigation would address existing problems with shoreline erosion and high groundwater; and,
  - Has a lower environmental impact than a greenfield hydroelectric project.

[1] Thermal equivalent of 9.9 GWh project power benefit at 75% natural gas (451 tonnes/GWh CO_2e) and 25% diesel (700 tonnes/GWh of GHGs) equates to nearly 5,100 tonnes CO_2e.

FEASIBILITY STUDY KEY FINDINGS/CONSIDERATIONS

- There are high human and environmental values contained in the Concept study area (Southern Lakes system). Some residents have concerns about, or have voiced opposition to the Concept. Others have indicated an interest in proceeding with a project.
- Baseline environmental and socio-economic studies, preliminary effects assessments, and conceptual mitigation designs for the Concept are complete.
- After 6+ years of study the character of the potential Concept effects is well understood. The likely effects are subtle, and are mostly additive to pre-existing effects of seasonal erosion and groundwater effects to low-lying properties that result from water levels on the system during the unregulated period (spring – fall). Technically and economically feasible mitigation options exist for identified adverse effects.
- No significant effects are predicted to accrue to valued aquatic or terrestrial habitats or species.

PROJECT STATUS

At this time baseline studies have been completed and a preliminary effects assessment has been conducted. Remaining work is mostly technical and involves the completion of a field level heritage resources impact assessment, the finalization of a detailed monitoring and adaptive management plan, with the associated stakeholder consultations. Discussions are ongoing with both Carcross/Tagish First Nation (C/TFN) and the Kwanlin Dun First Nation (KDFN) as potential YESAA decision bodies and with Ta'an Kwach'an Council (TKC) as the Concept study area includes their traditional territory as well. Yukon Energy is interested to know the perspectives of these first nations on the technical merits of the Concept before proceeding with further planning and assessment in 2017. Following these activities, YEC will have sufficient information to prepare a project proposal for assessment under the Yukon Environmental and Socio-economic Assessment Act (YESAA).

1.0 INTRODUCTION

1.1 PROJECT OVERVIEW

In 2009, Yukon Energy restarted its examination of the Southern Lakes Enhanced Storage Project (the Project). The Project would increase winter generation at the existing Whitehorse Rapids Generating Station (WRGS) by increasing the amount of water available for power production in winter. The additional winter flow in the river will come from the proposed increase in the volume of water stored upstream in the southern lakes. This extra storage will then be available to augment flow in the Yukon River during the winter when the demand for electricity is greatest.

To achieve this, the Concept envisions expanding the storage range on the Southern Lakes by decreasing the licenced low supply level (LSL) by up to 10 cm, and by increasing the licenced full supply level (FSL) by up to 30 cm. No other operational changes are necessary to achieve the increased storage.

The only observable changes to lake levels during the regulated period (August to May) would be a slightly higher fall and early winter water level in the lakes, but no higher than what is often seen in the unregulated summer period. By winter there would be little difference in water levels as compared to present levels.

The expansion of the low supply level would mean that water levels in Marsh Lake in the spring would be up to 10 cm lower than historical/present. This difference would only be observed for a few weeks in late April and early May, and only observed on Marsh Lake, with little observable influence on Tagish Lake or Bennett Lake.

Figure 1 demonstrates how the change in the operational range can provide additional power generation at the Whitehorse station.

Figure 1 Limitations of Existing Water Storage Range

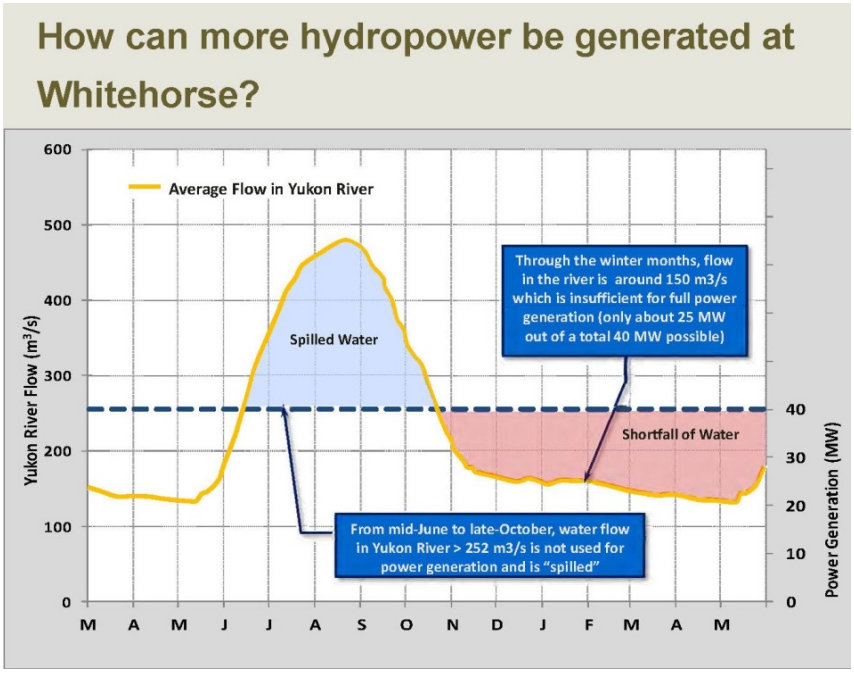

Figure 2 Effect of Increased Storage Range on Winter Energy Production

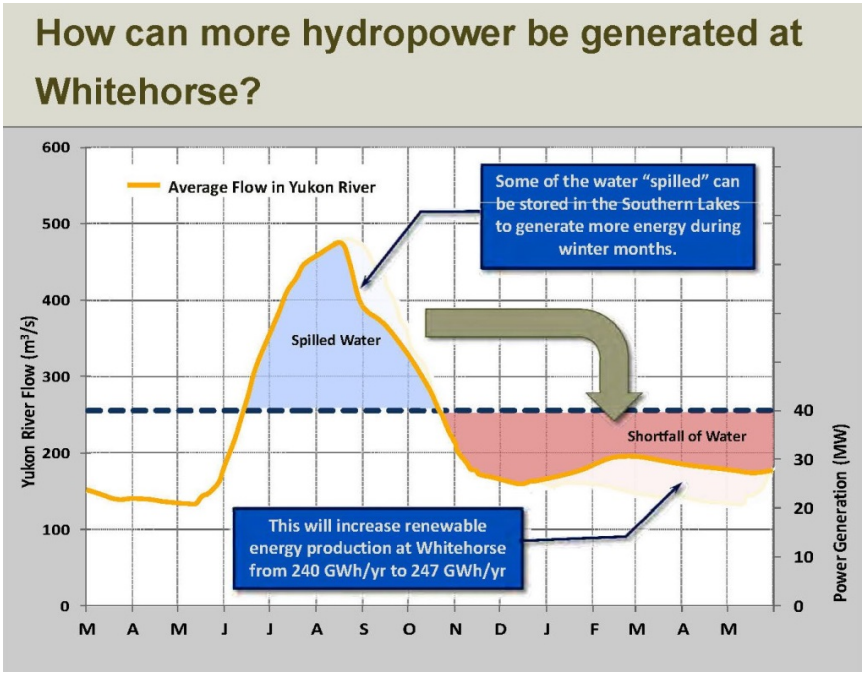


2.0 PLANNING ACTIVITY DETAILS

2.1 OVERVIEW OF RECENT PLANNING ACTIVITIES/OBJECTIVES

Work in recent years has been focused on narrowing down any remaining uncertainties regarding potential project effects, views/interests of potentially affected stakeholders, likely mitigation requirements and methods, and monitoring adaptive management plan requirements. Estimation of costs to implement mitigation and provide monitoring and adaptive management was also undertaken.

Key tasks included:

- *Erosion Program*
  - Complete erosion modelling.
  - Landowner contact and engagement for mitigation design.
  - Finalize mitigation options and forecast costs.
- *Groundwater Program*
  - Confirm specific properties potentially affected.
  - Land owner engagement for mitigation design.
  - Finalize mitigation options and forecast costs.
- *Monitoring and Adaptive Management Planning*
  - Determine key areas requiring pre-project effects prediction and post-project mitigation success confirmation.
  - Develop broad program requirements, frequency, and costs.
  - Develop draft cooperative/collaborative monitoring plan execution and reporting components (e.g., work with C/TFN, KDFN, TKC, regulators to draft plan tasks and review plan results).
- *Information Adequacy Program*
  - Update gap analysis and fill key info gaps.
  - Engage Regulators to confirm assessment approach and preliminary findings.
  - Discus draft mitigation, monitoring, and adaptive management plans.
- *Communications Program*
  - Targeted outreach to all stakeholders and Yukoners to relay key messages and develop better project understanding via house mailings.

- *FN Engagement & Consultation Program*
  - Consultation and engagement to develop common understating of potential project effects and mitigation.
  - Explore compensation requirements and benefit opportunities.
  - Seek to lever mutually beneficial renewable energy or other outcomes from engagement vis-à-vis the project Concept and other interests of Yukon Energy and/or FNs.
  - Seek acceptance of Concept 'in principle' and green light to proceed to the YESAA review stage.

2.2 PLANNING ACTIVITY RESULTS AND STATUS

All program activities, except for the First Nations engagement program, have been completed as of Q1 2017. Additional time is needed conclude the technical reviews with C/TFN, KDFN, and TKC for the Concept and the plan to proceed to assessment and permitting. It is expected that this work will be concluded by end of Q2 2017.

3.0 MITIGATION DESIGN & UPDATED COSTS

3.1 EROSION

The erosion program involved an intensive engagement and technical effort to identify, explore, and narrow down the optimal mitigation options for shoreline erosion protection in the areas potentially impacted by the Concept. A range of options are available for mitigation of erosion-related project effects, and 9 mitigation options were explored individually and with shoreline groups of potentially affected property owners.

The process of review and selection of an appropriate/acceptable mitigation solution was conducted in 2 rounds using a Structure Decision Making (SDM) process. In Round 1 Yukon Energy met with individual property owners to review the Concept and its potential effects, and to review various options to mitigate erosion effects. Round 2 included bringing together individuals from each discrete shoreline neighborhood together as a shoreline unit group to review and work toward consensus on a preferred mitigation option(s). Over 40 round-one meetings were held, with over 75% of landowners participating. Five round-two meetings were held with groups of residents from each potentially affected shoreline area. Over 85% of potentially affected property owners were engaged in at least one meeting to explore the Concept and potential mitigation options.

Mitigation in the form of engineered rip rap (hard, angular rock) was the dominant choice of homeowners who indicated a strong preference toward a solution that would be effective against erosion, durable, and low maintenance. One neighborhood indicated a preference for groins as a mitigation solution, although

the feasibility and acceptability of such a solution is not considered optimal and requires further discussions with subject area residents. A sample of mitigation options used in Round 1 consultations is presented in Appendix A.

Plate 1 Example of Shoreline Protection Using Rip Rap

YEC also instructed the project consultants (Hemmera) to review the work completed by the previous planning consultant (AECOM) regarding the assessment of areas recommended for erosion protection. All previously identified areas were confirmed, with some expansion to the overall length of required shoreline erosion protection in some areas (refer to the discussion below).

Updated erosion mitigation costs are estimated at $6.0M (feasibility or Conceptual-level estimate, with an associated accuracy of +/- 15% to 30%). This updated estimate is increased from the previous estimate of approximately $3.1M. The budget increase for erosion mitigation was a result of a number of changes:

Increase in construction costs: Updated engineering design work completed by Northwest Hydraulic Consultants (NHC) in 2015 has increased the length of shoreline requiring protection, and more conservative unit cost estimates for the shoreline mitigation have been used. The previous mitigation cost estimates completed by AECOM in 2012 utilized a value of $790 per metre of shoreline protected with rip rap. Northwest Hydraulic Consultants concluded that AECOM's cost estimates for construction were low, and revised the unit cost to $1,300 per metre. This updated unit cost was thought to be more realistic and was based on NHC's recent experience with similar projects. In addition, NHC's estimate of shoreline needing mitigation is 3,457 metres, an increase of 1,187 metres from the AECOM estimate of 2,270 m. The increase in shoreline length is partly related to the inclusion of beach features at the ends of each mitigation area, as opposed to prior calculations of required mitigation length based on property boundaries at the end of each beach section. In addition, NHC included a number of gaps in what is otherwise continuous shoreline armouring of Army Beach (e.g., mitigation will be needed at several sections of Army Beach with public access easements that adjacent property owners have not addressed).

Increase in in contingency: The previous estimate of $3.1M included a 20% contingency. However, NHC has increased the contingency allowance to 30% to more appropriately account for the current level of engineering definition of the mitigation designs.

The cost and design definition will be updated at the preliminary design phase, which in scheduled for 2018 as part of preparations for permitting. A further round of detailed design will be completed in 2019 following permitting, and will consider any regulatory requirements coming out of the assessment and permitting processes. Detailed design will generate design specifications to be used as inputs for the construction tendering stage.

3.2 GROUNDWATER

Preliminary groundwater surveying work completed in 2010-2014 estimated that somewhere between 75 and 100 properties might be affected by the Concept. Intensive survey work completed in 2015 confirmed that only 53 properties would need mitigation for project-related groundwater effects.

Required mitigation will take the form of raised septic fields, septic tank replacement and/or anchoring, installation or enhancement of basement/crawlspace sump pumps. A single property will require some foundation insulation. In many cases the effects of unregulated high summer water levels already impact these properties. With the Concept the duration of such impacts would increase and therefore Yukon Energy would address these effects. In addition to construction and installation of physical mitigation infrastructure as outlined above, one time compensation payments will be calculated and paid to some affected land owners for costs associated with increased wear and tear on equipment and increased electricity costs associated with some installations (e.g., increased annual duration of sump pump operation). These costs are factored into the mitigation cost estimate below.

Estimated groundwater mitigation costs are approximately $1.2M, reduced from an earlier estimate of $1.35M. The decrease in the estimated costs was caused by the decrease in the number of properties that would be impacted. These cost estimates are considered to have an expected precision variance of +/- 15% to 30%.

4.0 COMMUNITY ENGAGEMENT AND HOME-OWNER SUPPORT

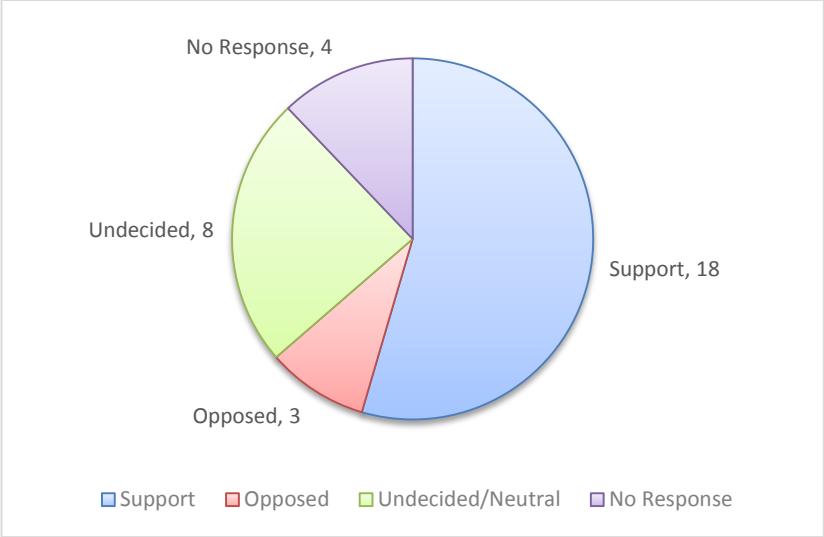
YEC has completed an extensive program of community engagement on the Southern Lakes ESP since 2010, including numerous public meetings, workshops, and an outreach and public education program.

4.1 EROSION

General attitudes towards the project Concept were surveyed as part of the engagement on erosion mitigation designs with property owners potentially impacted by the Concept. The results of this survey

are presented in Figure 3. Of those property owners who participated in the group mitigation evaluation meetings 55% (18 individuals) indicated support for the mitigation and the project. Of the remaining participants, 9% (3 individuals) were not in favor of the project, with 24% (8 individuals) indicated they were undecided, and 12% (4 individuals) did not respond. Only 1 respondent indicated they couldn't accept the mitigation if the project were to proceed (i.e., of the 3 respondents opposed to the project, only one was opposed to the mitigation if the project did in fact proceed). In most cases the mitigation would be installed on Crown Land (i.e. below the ordinary high-water mark, which is owned by the Crown in most cases).

Figure 3 General Attitudes of Erosion Landowners Who Attended Group Engagement (Round 2) Meetings (n = 33)



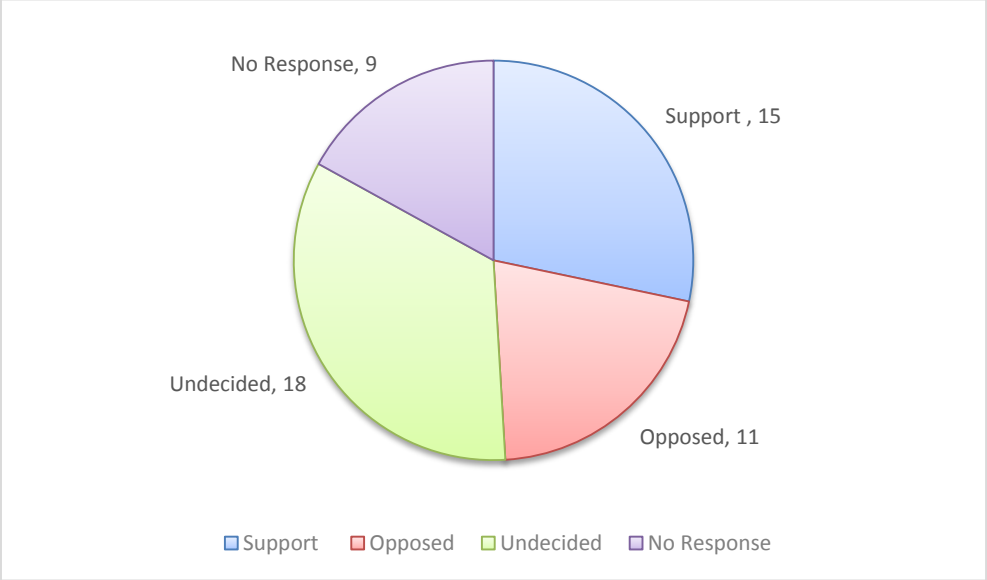
4.2 GROUNDWATER

General attitudes towards the project Concept were also surveyed as part of the engagement on groundwater mitigation designs with property owners potentially impacted by the Concept. The results of this survey are presented in Figure 4. The groundwater program involved engagement with 153 properties that were assessed to be within the zone of influence of the Concept. Of those, 53 properties were confirmed to be likely to need mitigation if the Concept were to proceed.

- In all, 157 telephone conversations and formal meetings were held with potentially affected property owners regarding groundwater.
- 71 properties were physically surveyed to confirm infrastructure elevations and 12 "complex" properties were evaluated by an engineer for geotechnical/structural potential effects.
- At only one of the 12 complex properties assessed was it determined that mitigation would be required to address the potential effects of the project.

Of those property owners who participated in the initial assessment and follow-up mitigation meetings, 28% (15 individuals) explicitly indicated support for the mitigation and the project. Of the remaining participants, 21% (11 individuals) were not in favor of the project, with 34% (18 individuals) indicated they were undecided, and 17% (9 individuals) either did not respond or could not be contacted. Some property owners in the 'undecided' category stated that they would reserve their final acceptance or refusal of Yukon Energy's offer to provide mitigation to a point in time where they would be engaged for discussions regarding the detailed mitigation work/construction plan following the YESAA assessment. Other stakeholders in the 'undecided' or 'neutral' category were otherwise indifferent to the project and/or the proposed mitigation.

Figure 4 Groundwater Impacted Landowner Project Acceptance (n=53)



All stakeholders will have an opportunity to provide input and information to the regulators during both the YESAA assessment process and the water board licencing process.

5.0 MONITORING & ADAPTIVE MANAGEMENT PLAN

5.1 OVERVIEW

A detailed monitoring and adaptive management program will form an integral part of the implementation of the Southern Lakes ESP, and the mitigation of risk post-implementation. While draft components have been prepared, a final detailed monitoring and adaptive management program requires input from stakeholders and as yet has not been completed. Work is planned in 2017 to complete a plan

suitable for assessment under YESAA in collaboration from key stakeholders. An overview of the scope of this plan, and the general principles that will be applied in the development of the plan are outlined in sections 5.1 and 5.2, below.

5.2 MONITORING PROGRAM

The monitoring program will include elements that allow Yukon Energy to assess two things:

1. The observed effects on fish, wildlife and wetland environments, compared to the predicted effects made during the assessment.
2. The effectiveness of implemented erosion and groundwater mitigation measures.

Consequently, monitoring is proposed in the following key areas:

- Heritage Resources
- Erosion Mitigation Effectiveness (incl. sites with mitigation and unmitigated control sites)
- Groundwater Mitigation Effectiveness (incl. sites with mitigation and unmitigated control sites)
- Fish and Wildlife
- Wetlands

The following principles will be followed in the development of a detailed monitoring program:

a) The monitoring program will be sensitive and provide timely results for decision-making. YEC will collaborate directly with affected first nations and others to carry out the monitoring plan and to jointly review the results of the annual reporting.
b) Monitoring will also include the use of control sites to ensure Yukon Energy and others are able to discern effects that may be caused by the project or effects that are caused by factors other than those influenced by the project (e.g., erosion caused by peak summer water levels above the Concept full supply level).

The estimated monitoring program costs are as follows:

- Years 1-3 = $167,000/year
- Years 4-5 = $120,000/year
- Years 6-10 = $70,000/year
- Years 10+ = $40,000/year

5.3 ADAPTIVE MANAGEMENT PROGRAM

The adaptive management program will define the steps or measures that YEC will take in response to unexpected negative outcomes in the key areas covered by the monitoring program (e.g., if the actual effects predictions on fish/wildlife/wetland environments are worse than predicted, or if the erosion and groundwater mitigation measures are not fully effective).

The adaptive management program will define both the specific actions (to the extent possible) and the financial commitment that YEC will make in response to any negative impacts, up to an including reversal of the project (i.e., reversion to the current storage range on the Southern Lakes system).

The following general principles will be followed in the development of the detailed adaptive management plan:

a) YEC will consult with key stakeholders (FN's, Environmental NGO's, homeowners) on the development of the adaptive management plan. It is important that these stakeholders have a clear understanding of the way the monitoring will be undertaken and what the results will direct Yukon Energy to do in response.
b) The adaptive management plan will be as specific as possible, defining clear responses to specific outcomes. As such, the plan will attempt to limit YEC's financial risk by defining the scope and value of additional actions, and associated expenditures, that the corporation will incur in response to defined negative outcomes.
c) In addition, the total (cumulative) financial commitment to cover potential adaptive management responses will be capped at a fixed amount, where after a reversion to the previous storage range, or something in between, would be the remaining option to address any unexpected impacts (i.e., reverse the effects).
d) YEC will consider creating a multi-stakeholder committee, or use some form of independent oversight mechanism to evaluate unsolicited complaints from the public regarding perceived project impacts. It will be critical that the process to evaluate such complaints and administer any resulting mitigation be transparent, fact-based, and unbiased.

For the purposes of financial modeling of the overall project, Yukon Energy has assumed a worst case financial commitment of $3.3M ($2016) to cover potential adaptive management responses. A break-down of the $3.3M budget allocation for adaptive management is provided in Table 1:

Table 1 Estimated costs for Adaptive Management Program (2016$)

Item	Estimated Costs (2016$)	Assumptions
Adaptive management costs for groundwater mitigation	$0.05M	Percentage of installed systems require replacement/maintenance (5%-25% depending on the type of mitigation installed)
Adaptive management responses for erosion	$2.67M	10% of initial costs to repair installed mitigation after a 1 in 50+ year storm event Up to one third of the non-mitigated erosion sites being monitored to require mitigation within a few years post-implementation
Lake trout and/or other wildlife species habitat enhancements and studies	$0.60M	
	$3.32M	

The forecast cost of the adaptive management responses will be reviewed as part of the development of the detailed adaptive management program and as part of Yukon Energy's stagegate project review process.

6.0 PROJECT ECONOMICS

6.1 PROJECT COSTS

A summary of the total upfront costs of the project are presented below in Table 2.

Table 2 Southern Lakes ESP Project Development Costs

Item	Total Costs (2016$)	Notes
Planning, Assessment & Permitting – Committed to date	$6.50M	
Planning, Assessment, Permitting & Preliminary/Detailed Engineering– Future	$1.75M	
Project Implementation – Erosion Mitigation	$6.00M	1, 2
Project Implementation – Groundwater Mitigation	$1.00M	1, 2

Subtotal – Capital Cost	$15.25M	
Post-Implementation Adaptive Management	$3.32M	3, 4
Total	$18.57 M	

Notes:
1. Compensation to FN's for increased duration of inundation of settlement land included.
2. Cost areas will be for design and construction of erosion and groundwater effect mitigation.
3. These costs for cover potential adaptive management responses will be incurred over time, but are expressed as 2016$.
4. Post-Implementation adaptive management responses have been estimated based on professional judgement of potential unexpected effects and/or rates of mitigation failure. While erosion, fish and wildlife, heritage resources, and groundwater adaptive management responses are included in the estimates, the erosion component represents over 75% of the dollars assigned here.

6.2 OPERATING COSTS

Operating costs include monitoring, land use fees associated with FN land inundation, and any other project costs such as benefit payments. These costs are estimated to range from $50,000 per year in later years and up to $270,000 in the early years post-implementation.

6.3 CONCEPT RENEWABLE ENERGY VALUE & LEVELIZED COST OF ENERGY

The Concept delivers incremental winter renewable energy, which displaces more costly thermal energy. Power benefit calculations estimate that 9.9 GWh per year of thermal energy under the High Industrial Activity Scenario from the 20-Year Load and Peak Demand Forecast presented in the 2016 Resource Plan be displaced by the project under average water conditions.

Estimates of the costs and benefits, and the resulting levelized cost of energy of the Concept are presented in Table 4.

Table 3 Summary of Economic Analysis - Southern Lakes ESP

Present Value of Costs 2016 $000's	$23,126
Present Value of Benefits 2016 $000's	$30,020
Project Real LCOE at $2016 /kW.h	$0.09
Benefit/Cost Ratio	1.3

Notes:
1. Values are real LCOE numbers (inflation free).
2. Assumes 2% inflation rate
3. Economic life of the project set to 34 years
4. Assumes real discount rate of 3.38%, nominal 5.45%,
5. Assumes 8.25% nominal return rate and Debt/Equity ratio of 60%/40%
6. Energy benefit assumed constant at 9.9 GWh/yr fully utilized

7. Based on 20-yr load forecast for the High Industrial Activity Scenario. This load forecast was also used for Mayo Lake Enhanced Storage Project.

In the case modelled, the levelized cost of energy represents the lowest costs renewable energy option currently available to Yukon Energy, and compares favourably to LNG at 17.4 c/kW.h. The Concept also has the added benefit of avoiding nearly 5,100 tonnes of thermal GHG emissions each year, which would otherwise be emitted with equivalent thermal energy.[2]

7.0 FN ENGAGEMENT

All first nations whose traditional territory and/or settlement lands fall within the regional study area have been engaged periodically since the studies began in 2009. This includes the Kwanlin Dun First Nation, (KDFN), Carcross/Tagish First Nation (C/TFN), Ta'an Kwach'an Council (TKC), and the Taku River Tlingit (TRT). Efforts have been made to share information regarding the purpose and need for the project, the baseline studies and preliminary impact assessments, proposed mitigation, monitoring, and adaptive management commitments, and to identify and understand interests and concerns of the FNs.

First Nations engagement has been focused primarily with C/TFN and KDFN, as no significant adverse effects have been identified to the interests of the TKC or the TRT. C/TFN and KDFN will also likely be Decision Bodies under the YESAA assessment, along with other governments (e.g., YG, DFO).

Engagement activities to date have identified several key issues for FNs related to the Concept including:

- Shoreline erosion and related effects on private property and settlement lands, water quality, riparian and nearshore aquatic habitats for such valued components as moose, caribou, and aquatic furbearers.
- Shoreline heritage resources located in zone of influence of existing/potential erosion.
- Inundation of low lying shoreline areas on settlement land or otherwise:
    - A draft compensation framework based on a 'land rental value' has been shared with C/TFN and KDFN, but more work is needed to negotiate an agreement in this regard.
    - Approximately 7 hectares of additional KDFN settlement land would see an increased duration of wetting in the fall of each year.
    - Approximately 45 hectares of additional C/TFN settlement land would see an increased duration of wetting in the fall of each year.

[2] Thermal equivalent of 9.9 GWh project power benefit at 75% natural gas (451 tonnes/GWh CO_2e) and 25% diesel (700 tonnes/GWh of GHGs) equates to nearly 5,081 tonnes CO_2e.

- No new/additional settlement land parcels would be wetted, i.e., only parcels wetted under the existing FSL would be wetted longer under the Concept FSL.
- The additional period of wetting of settlement lands is on average about 93 days per year and occurring in the late summer and fall.
- Inundated areas have only been mapped for Marsh Lake as the steep topography of the shorelines at Tagish Lake and Bennett Lake indicates that only very minimal increases in shoreline inundation will occur there.

At this point in the planning Yukon Energy has been able to provide technical responses to previously identified interests and concerns with the Concept. The key steps now are to respond to follow up questions and concerns and seek feedback from the FNs on whether they would consider Yukon Energy has exercised sufficient due diligence and has done enough work to move to the YESAA assessment stage.

8.0 PROJECT TIMELINE

If a decision were made to proceed with the Project at the next stagegate (tentatively scheduled for Q2 2017), a submission could be made to the YESAAA Whitehorse Designated Office by the end 2017. Following a 6-8-month assessment process an application to the Yukon Water Board would be made with the potential to have an amended licence by the end of 2018. Work could then begin to tender and undertake the physical mitigation construction in 2018 and 2019. Construction of shoreline protection would need to be undertaken in the later winter and early spring so that the work could be done during dry conditions from the lake side of the shore as opposed to the land side. This will minimize disturbance to the shoreline and private property. Use of the additional storage would then be feasible for the fall of 2019 or 2020.

APPENDIX A

EROSION & GROUNDWATER ENGAGEMENT INFORMATION PACKAGES

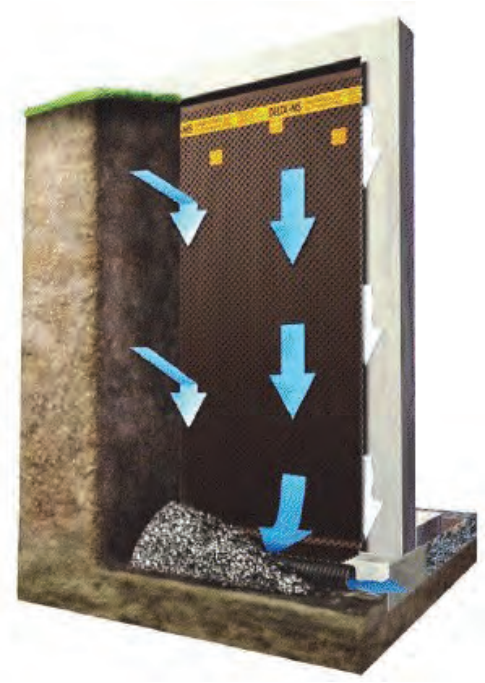
YUKON ENERGY

Basement/Crawlspace Waterproofing

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • FACT SHEET 5

How could groundwater rise affect my home?

The proposed concept would involve holding back (storing) more water in the Southern Lakes during the fall, which may result in a slightly longer duration of seasonal high groundwater levels in some areas around the lakes. On some properties this could exacerbate flooding or dampness already experienced in some basements/crawlspaces during seasonal high water levels, or it could cause flooding or dampness in a few basements/crawlspaces that have not previously experienced such groundwater effects.



Typical basement/crawlspace waterproofing installation

Mitigation Solution – Basement/Crawlspace Waterproofing

Basement and crawlspace waterproofing is a mitigation option to manage the potential impacts of groundwater rise, such as flooding and dampness. A typical waterproofing installation involves excavating down to the foundation around the perimeter of the home, cleaning and repairing cracks in the foundation walls, and installing a waterproofing membrane, a weeping tile and drainage gravel.

Benefits

Increased property value though improvements (up to $21,000)

Reduces damage to property (e.g. flood damage)

Discourages mold in basements/crawlspaces

Drawback

Requires access around building foundation (e.g., tree removal)

Significant temporary modification to property during installation

Will basement/crawlspace waterproofing work for you and your property?

Can it be installed around your basement/ crawlspace?

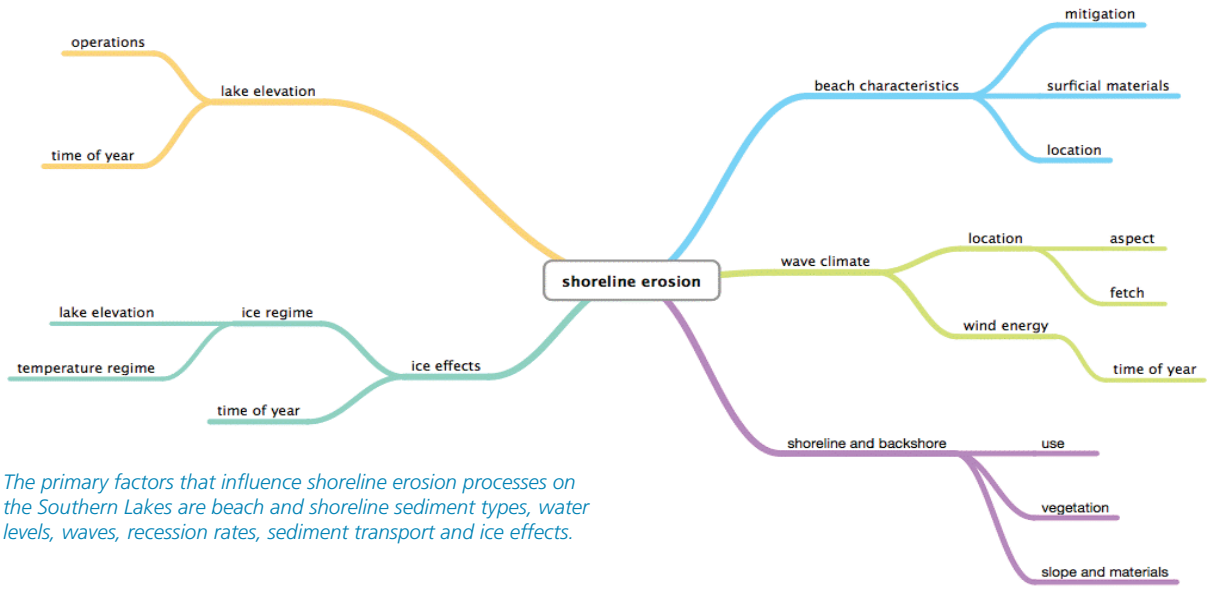
Is there good access?

Is the site accessible with conventional excavation equipment?

Basement/crawlspace waterproofing examples

Erosion Program

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 1



The primary factors that influence shoreline erosion processes on the Southern Lakes are beach and shoreline sediment types, water levels, waves, recession rates, sediment transport and ice effects.

Introduction

Over the last several years, Yukon Energy has engaged regularly with Yukoners and done significant research on the idea of increased water storage in the lakes south of Whitehorse. The Corporation has worked hard to understand the potential environmental and socio-economic impacts that could occur as a result of the concept.

Over the next few months, this research will be reviewed and used to decide whether to move the concept forward to the YESAA environmental and socio-economic assessment phase.

Wave-induced currents along the shoreline transport beach sediment in and out of, or along the shoreline causing sand deposits and erosion.

Summary of the Concept

Electricity demand in Yukon is highest during the cold, dark winter months, which is also the time of year when water levels in our lakes and rivers are naturally low. In order for Yukon Energy to produce enough hydroelectricity for Yukoners during the winter the Corporation must hold back (or store) water in Marsh, Tagish and Bennett Lakes during the fall, when water levels are higher.

Right now, the amount of water Yukon Energy is allowed to store (Full Supply Level) is not always enough to meet energy demands in winter, so fossil fuels are burned to make up the difference.

The Southern Lakes Enhanced Storage Concept would involve changing Yukon Energy's water license so the Corporation could store up to 30 centimeters more water in the fall and early winter and use up to an additional 10 cm of water below the current level in the spring.

This water would be available for winter energy production when it's needed the most, and would provide cost-effective and environmentally responsible energy. The concept would not increase naturally-occurring high water levels that occur in the Southern Lakes and the additional water storage would not be carried over year-to-year.

YUKON ENERGY

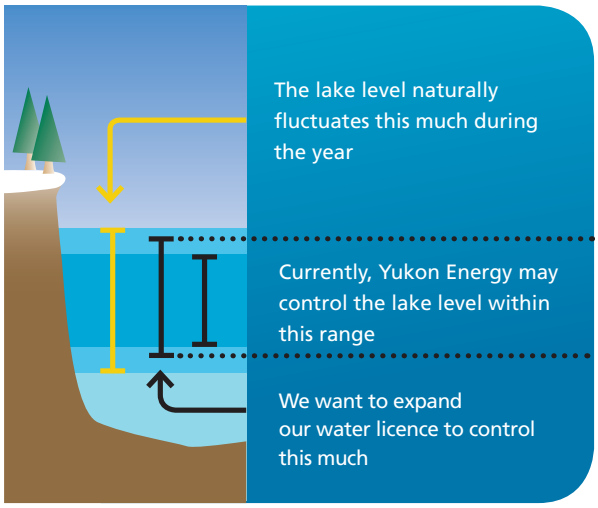
Erosion Program

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 2

Potential Impacts to Properties Related to Erosion

There are already naturally-occurring erosion issues in some areas of the Southern Lakes. The Corporation's previous erosion studies identified six shoreline areas containing multiple properties that are currently experiencing erosion and may experience additional erosion as a result of the concept.

The proposed increase to the Full Supply Level will result in additional shoreline areas of up to 30 vertical centimeters being inundated for a longer period of time each year. This additional period of higher lake levels may result in additional shoreline erosion due to wave action. It is important to note that the proposed increase is well below the natural high water level that occurs each year in late summer.



Shoreline erosion along the Southern Lakes is site-specific and depends on the location and aspect of the property, as well as the characteristics of the shoreline. Such natural characteristics include the slope of the foreshore and bluffs, and the type of material in these areas such as sand and gravel. The presence of vegetation also affects the rate of erosion.

Initial Meeting (one-on-one)
- Discuss shoreline erosion on property
- Discuss YEC shoreline erosion mitigations
- Get your feedback

Design a preliminary shoreline-unit specific erosion mitigation plan

Follow-up meeting (one-on-one or groups)
- Review prepared preliminary shore-line-unit specific erosion mitigation plan
- Incorporate com-ments and feedback for final design

Final mitigation plans and landowner feedback are reported to Yukon Energy and used in decision making on whether to proceed with a project assessment and permitting

Landowner Engagement Process

An important part of this next step is engaging with landowners who may experience erosion on their properties as a result of the concept.

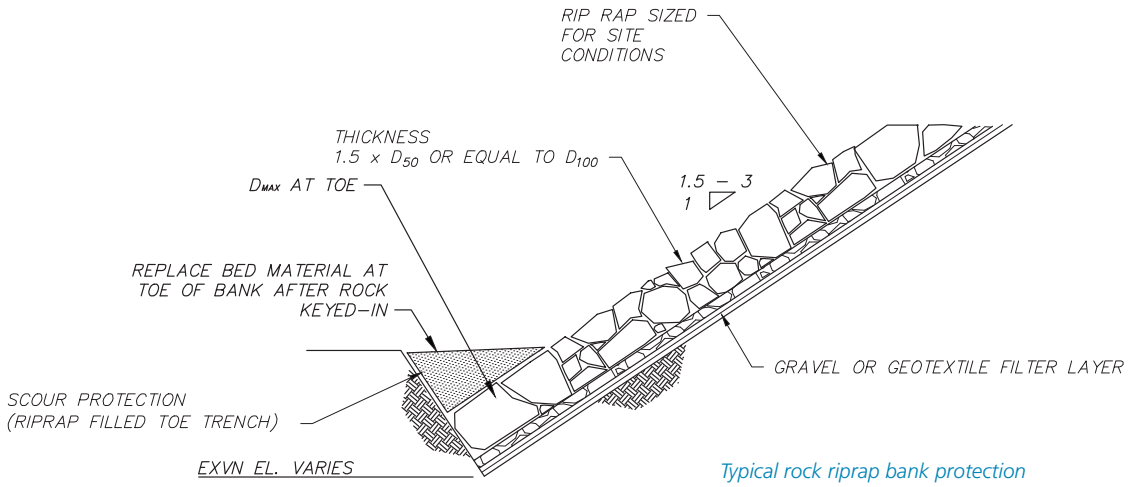
Yukon Energy will use your input as well as the input of your neighbours to help develop one consistent erosion mitigation plan for your shoreline unit. If implemented, this plan would combat existing erosion as well as any potential concept-related erosion and would provide a long-term benefit should the concept move forward.

Please note that it is not necessary for you to support the Southern Lakes Enhanced Storage Concept to participate in this engagement process. This process allows us to fully understand the issues and costs related to potential mitigation of shoreline erosion, which will provide Yukon Energy with a more accurate estimate of the costs and benefits of the project for the assessment process and Yukon ratepayers.

YUKON ENERGY

RipRap

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 3



Typical rock riprap bank protection

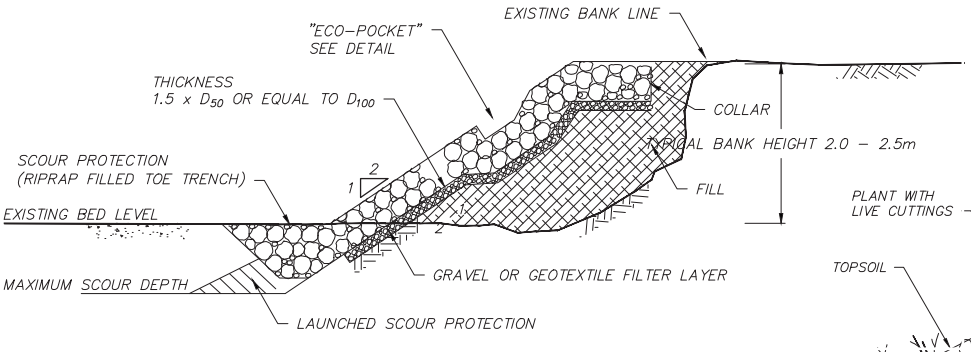
Typical riprap involves using quarried angular rock to protect eroding slopes. The size of the rock and the thickness of the armour layer depend on the extent of the erosive forces on the slope. An underlayer is used between the rock and eroding slope to keep fine sediments from eroding away between the spaces in the rocks. The toe of the riprap can either be excavated into the bottom of the slope or an apron can be constructed to avoid excavation. Riprap is typically used where erosion is extensive or in proximity to infrastructure, and construction requires access for large and heavy machinery (e.g., excavators and dump trucks). In order to make this option feasible a good source of quality rock needs to be available in reasonable proximity to the site.

Advantages	Disadvantages
Highly effective protection	Artificial and unnatural appearance
Very low maintenance	Does not provide valuable habitat
Effective on high and steep slopes with significant erosion	Access required for large and heavy equipment
Requires minimal manual labour	High initial cost

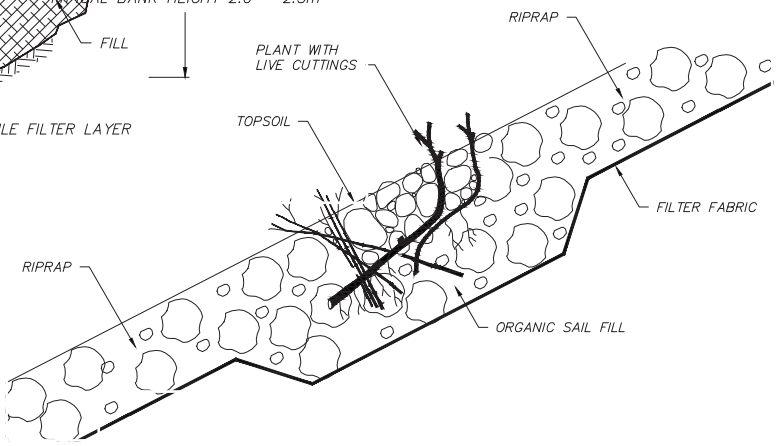
YUKON ENERGY

Vegetated RipRap

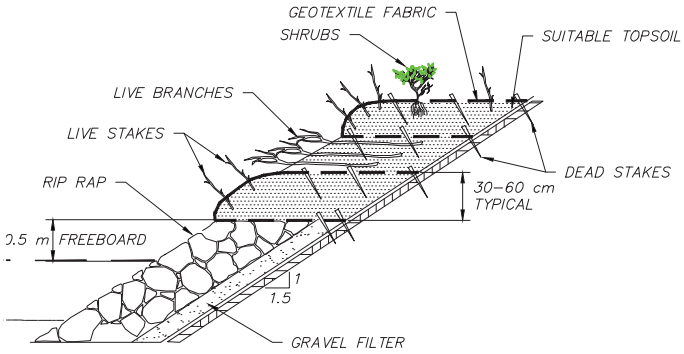
SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 4



Typical riprap with vegetated ecopocket



Vegetated riprap is the same as typical riprap with the addition of vegetation within and or above the riprap slope. Vegetation can be in the form of "eco-pockets" which are small pockets of soil and vegetation in various locations on the surface of the rock slope. The planting of stakes or live cuttings in the spaces between the rocks are also an effective planting option. The top of the riprap slope can be planted with grass seed, brush, stakes or live cuttings or trees.



Typical riprap with vegetated soil wrap

Advantages	Disadvantage
Highly effective protection	Somewhat artificial and unnatural appearance
Low maintenance	Access required for large and heavy equipment
Effective on high and steep slopes with significant erosion	Requires more manual labour than typical riprap
More natural appearance and provides better habitat than typical riprap	Some maintenance required for vegetation

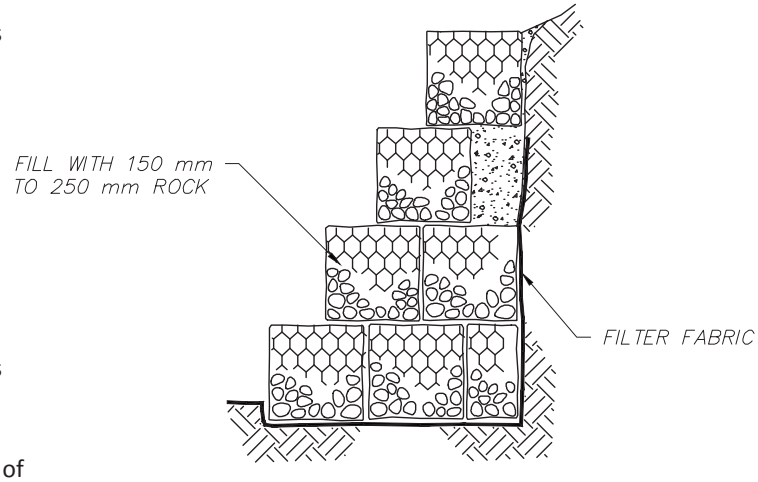
Revised July 2015

YUKON ENERGY

Gabion Baskets (Standard & Vegetated)

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 5

Gabion baskets are box shaped wire mesh containers that are filled with rock and stacked on top of each other to a desired height to provide protection on steep slopes. The baskets arrive from the manufacturer flattened and are assembled on site using manual labour. Small or medium sized machinery is used to fill each basket with rocks approximately 15 cm in diameter. Quarried angular rock is preferred but rounded rock can be used. The bottom row of baskets are buried into the toe of the slope and the baskets can be stacked numerous rows high. For the vegetated option stakes or live cuttings are placed between or within the baskets. Gabion baskets are typically used in areas where a high level of protection is needed but where large quality rock is not available for riprap.



Typical gabion bank protection

Advantages

Highly effective protection

Low maintenance on non-vegetated option

Effective on high and steep slopes with significant erosion

Good option where large rock is not available

Large and heavy equipment not required

Disadvantages

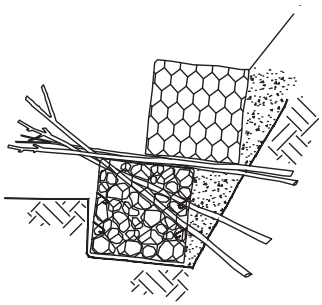
Gabion wire will corrode over time depending on conditions

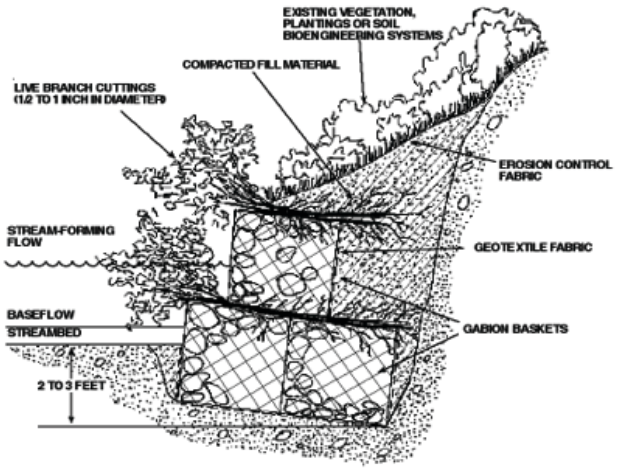
Artificial and unnatural appearance (non-vegetated option)

Does not provide valuable habitat (non-vegetated option)

Requires machinery

Requires manual labour, especially for vegetated option



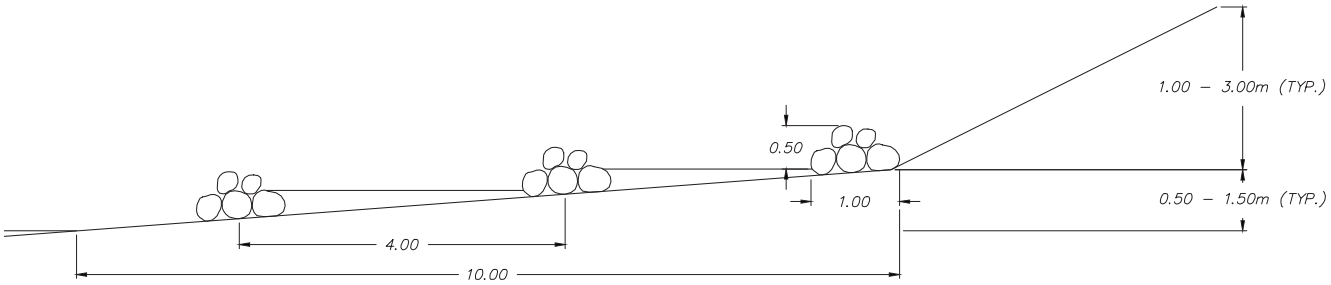


Typical vegetated gabion bank protection

YUKON ENERGY

Groynes (Perpendicular & Parallel)

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 6



Parallel groynes

Groynes are structures that extend into the water to protect the shoreline from erosion by disrupting the flow of water, wave action or longshore transport of sediment. Groynes can be walls made of timber or logs but are typically made of large rock similar to that used for riprap. Perpendicular groynes are only effective where beaches or bluffs are degrading due to waves and currents running parallel or near parallel to the shoreline resulting in longshore transport of sediment. Parellel groynes are only effective where onshore and offshore processes dominate.

Advantages

Highly effective protection depending on transport scenario

Very low maintenance

Requires minimal manual labour

Disadvantages

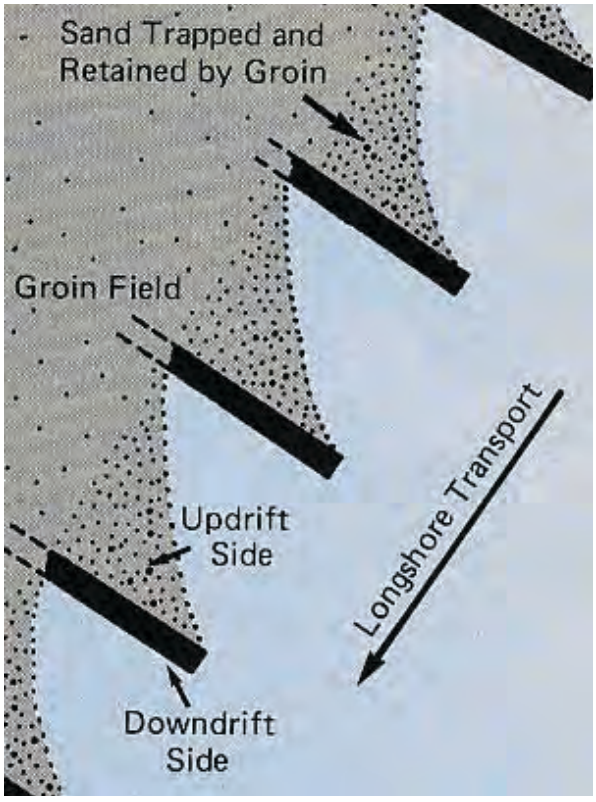
Only effective under specific transport scenarios

High initial cost

Artificial and unnatural appearance

Does not provide valuable habitat

Access required for large and heavy equipment

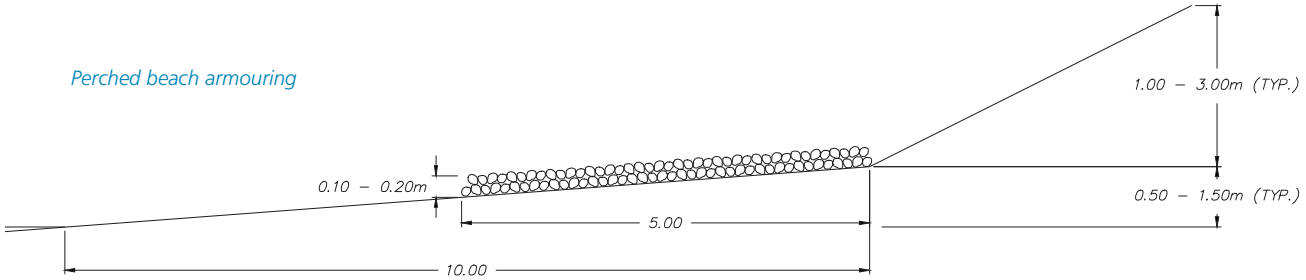


YUKON ENERGY

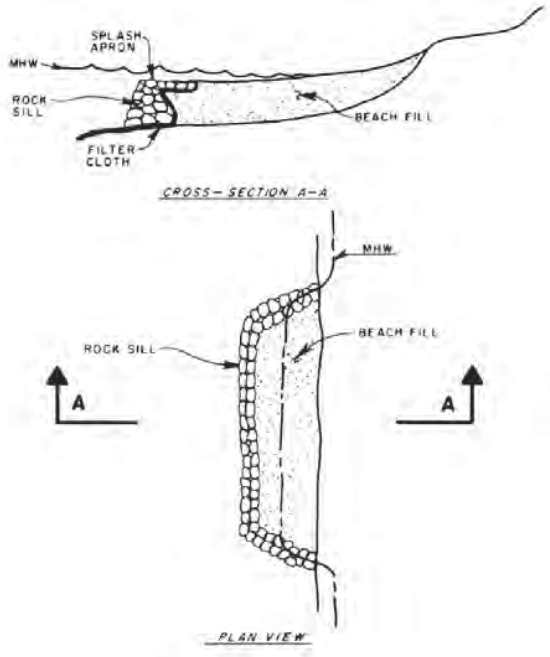
Perched Beach

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 7

Perched beach armouring



A perched beach involves protecting an eroding beach by armouring the shoreline with a rock sill along with beach fill on the landward side of the armour. An alternate method involves laying a thin layer of armour protection on the surface of the beach to prevent additional degradation from occurring. With the beach fill option an armoured berm is constructed with large rock and the beach fill can either be backfilled beach material or left empty to gradually fill with natural beach material. With the alternate method the entire beach or portions of the beach along the shoreline can be covered with rock.



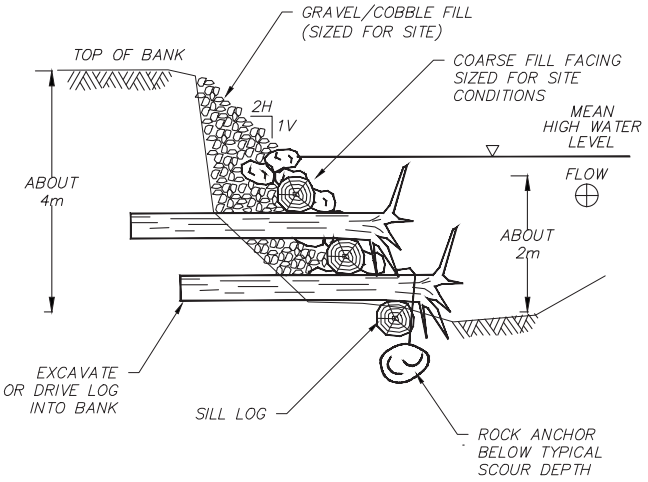
Advantages	Disadvantages
Reduces wave effects	Impacts existing beach and foreshore area
Installed on existing foreshore	Does not directly protect backshore slopes
Does not impact backshore slopes	Somewhat artificial and unnatural appearance
Highly effective protection under longshore or onshore/ offshore transport scenarios	Does not provide valuable habitat
Low maintenance	Access required for large and heavy equipment
Requires minimal manual labour	

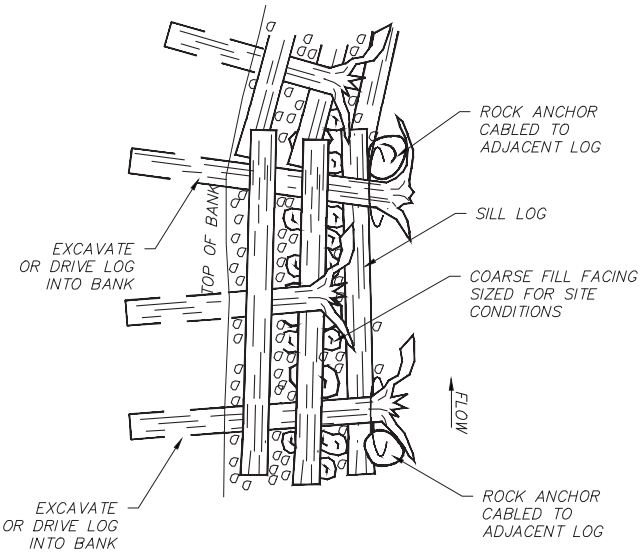
Cribwall

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 8

A cribwall is a wall made of logs or timber to protect a vertical or near vertical eroding slope. For a high level of protection the wall can be built vertically with alternating logs parallel and perpendicular to the slope and backfilled with rock. See drawings below for an example of this method.

The toe of the wall can be buried into the ground for additional protection. For a less engineered option a series of logs can be laid beside each other or stacked to provide a moderate level of protection as shown in the photo below. The logs can also be cabled together or anchored into the ground to provide more durable protection.





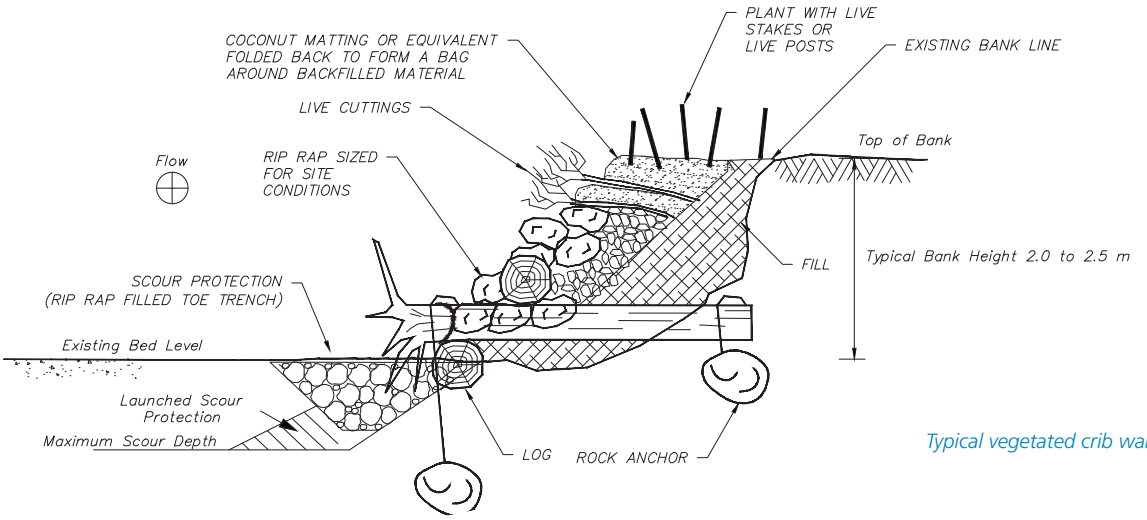
Typical crib wall

Advantages	Disadvantages
Good for poor or limited machine access	Not ideal option if available logs are small and deciduous
Provides habitat	Moderate level of protection
Can be built with manual labour	

YUKON ENERGY

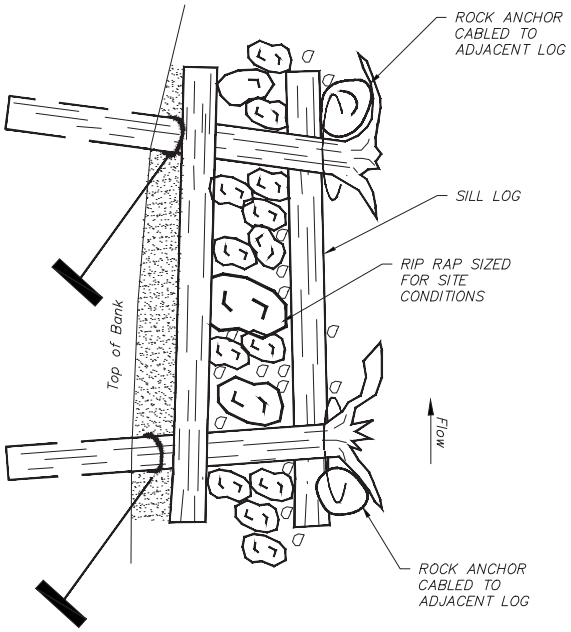
Vegetated Cribwall

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 9



Typical vegetated crib wall

Vegetated cribwalls are similar to standard cribwalls but with the addition of vegetation incorporated into the wall. The vegetation can be stakes or live cuttings incorporated into the spaces between the logs. The top of the cribwall can be planted with grass seed, brush, stakes or live cuttings or trees. If not naturally occurring, a growing medium (soil or bags filled with soil would need to be added for the planting at the top of the cribwall.



Advantages

- Good for poor or limited machine access
- Provides valuable habitat
- Can be built with manual labour
- Uses natural materials
- Ideal for log-based foreshores
- Effective slope protection
- Effective on high and steep slopes with significant erosion
- More natural appearance and provides better habitat than typical cribwalls

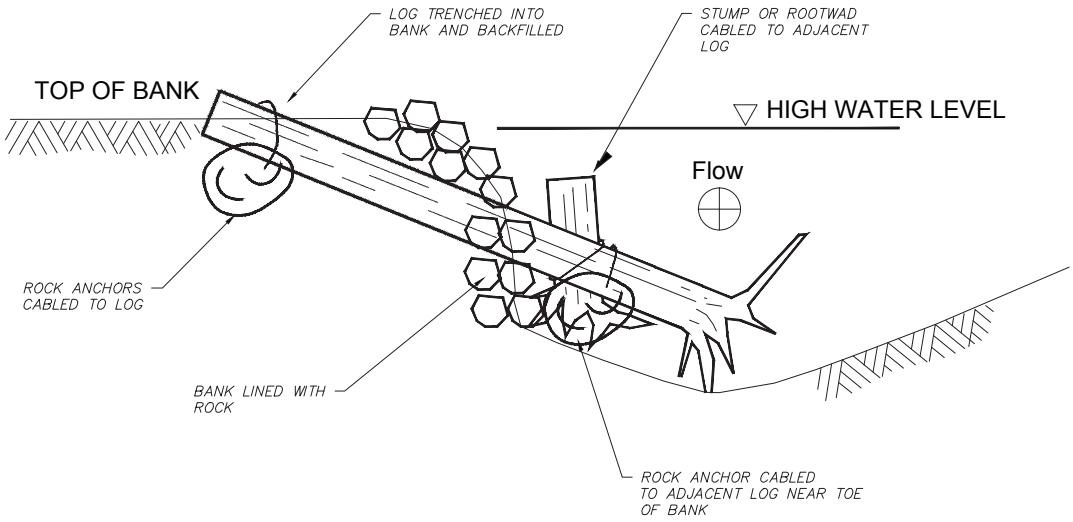
Disadvantages

- Not ideal option if available logs are small and deciduous
- Moderate level of protection
- Limited design life in harsh environments
- Limited structure strength
- Requires excavation to embed/fill/build
- Will require maintenance to replace vegetation that does not survive
- Requires more manual labour than typical cribwalls

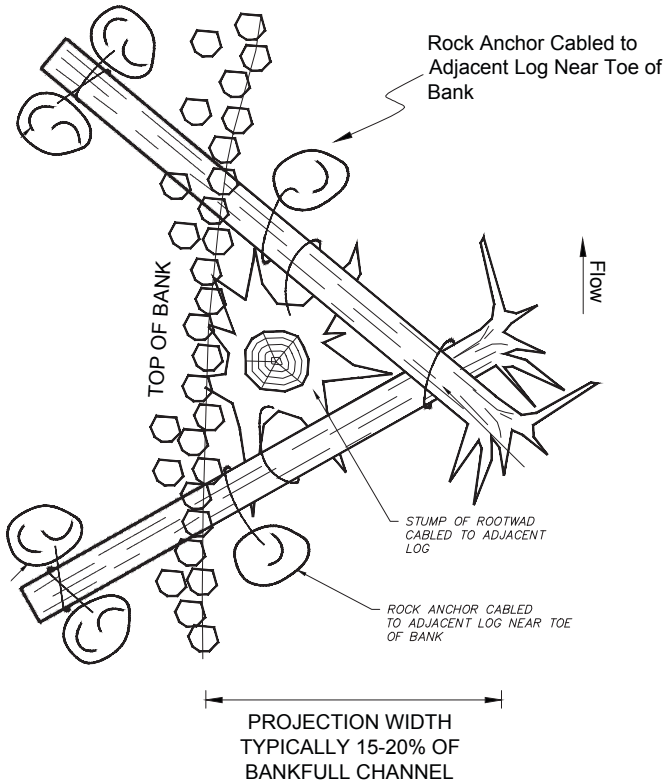
YUKON ENERGY

Large Woody Debris Structures

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 10



Large Woody Debris (LWD) structures are a collection of logs that are clustered together to provide protection for eroding slopes. The logs may have the root wad attached and they are typically cabled together and or anchored into the slope or anchored to large boulders. They can be quite natural in appearance and provide habitat for fish and wildlife. They do not provide a high level of protection but are inexpensive to construct and are low maintenance. This option is not appropriate when the eroding slope is high and steep or the erosive forces are significant.

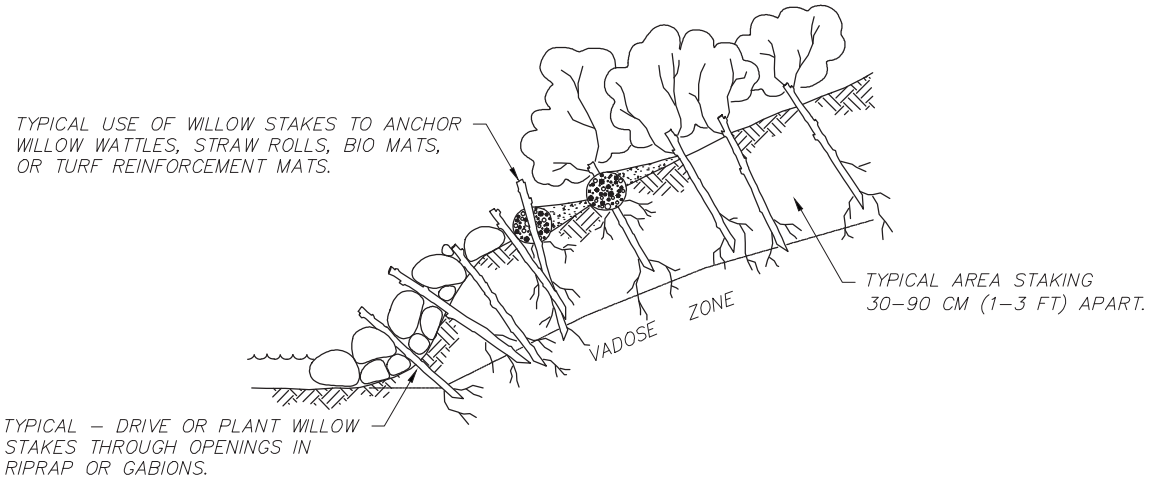


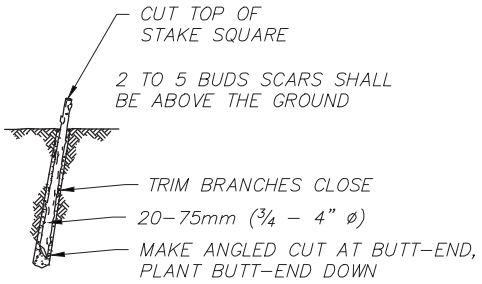
Advantages	Disadvantages
Good for poor or limited machine access	Not ideal option if available logs are small and deciduous
Natural appearance and provides valuable habitat	Minimal level of protection

YUKON ENERGY

Live Staking

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 11





Live Staking involves cutting vegetation from a nearby source and planting the cuttings on the eroding slope or beach to decrease the rate of erosion. This method is only effective where the extent of erosion is not significant. Ideal growing conditions are required for this option. The stakes are only effective after they have established which can take several years depending on the growing conditions. This option is very natural looking when the stakes are established and can be constructed with manual labour. This option is ideal where access is difficult for large and heavy machinery.

Advantages

Provides additional protection over time as vegetation establishes

High ecological value

Low cost

No large or heavy machinery required

Natural appearance and provides valuable habitat

Disadvantages

High failure rate in initial years

Limited installation period

High initial maintenance for replanting

Requires suitable soil for growing

Requires moisture in the soil for growing

Brush Layering

SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 12

Brush layering involves cutting vegetation from a nearby source and planting the brush cuttings in dense layers on the eroding slope and then backfilling with soil. This method is only effective where the extent of erosion is not significant. Ideal growing conditions are required for this option. The brush layers are only effective after they have established which can take several years depending on the growing conditions. This option is very natural looking when the brush layers are established and can be constructed manually. This option is ideal where access is difficult for large and heavy machinery.

Advantages

Provides additional protection over time as vegetation establishes

High ecological value

Low cost

No large or heavy machinery required

Natural appearance and provides valuable habitat

Disadvantages

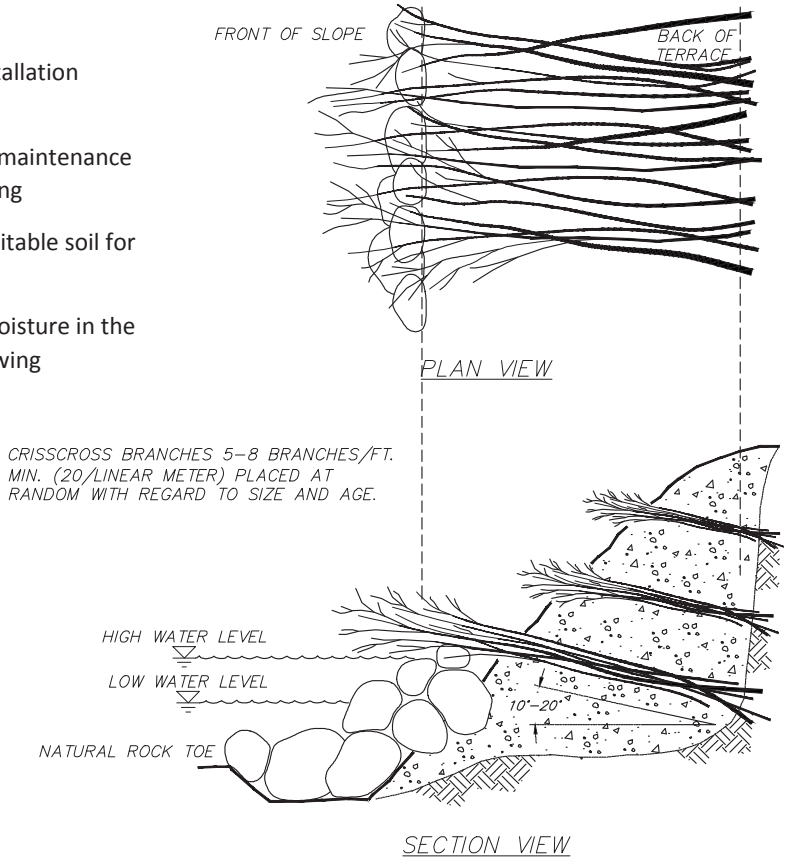
High failure rate in initial years

Limited installation period

High initial maintenance for replanting

Requires suitable soil for growing

Requires moisture in the soil for growing



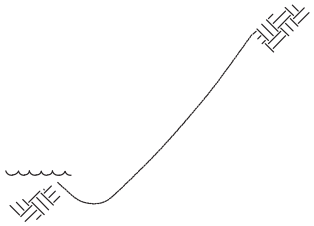
YUKON ENERGY

Brush Matting

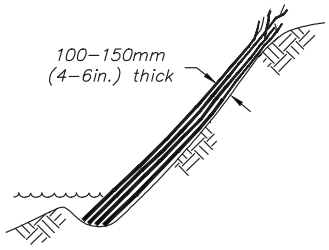
SOUTHERN LAKES ENHANCED STORAGE CONCEPT • EROSION 13

Brush matting involves cutting vegetation from a nearby source and planting the brush cuttings in dense layers on the eroding slope. The cuttings are densely placed side by side and secured together with twine or rope to create a mattress like structure. This method is only effective where the extent of erosion is not significant. Ideal growing conditions are required for this option. The brush matting is only effective after the vegetation has established which can take several years depending on the growing conditions. This option is very natural looking when the brush matting is established and can be constructed with manual labour. This option is ideal where access is difficult for large and heavy machinery.

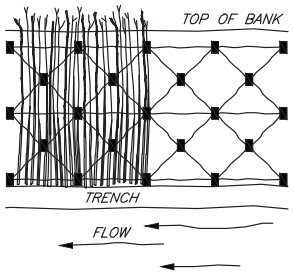
Advantages	Disadvantages
Provides additional protection over time as vegetation establishes	High failure rate in initial years
High ecological value	Limited installation period
Low cost	High initial maintenance for replanting
No large or heavy machinery required	Requires suitable soil for growing
Natural appearance and provides valuable habitat	Requires moisture in the soil for growing



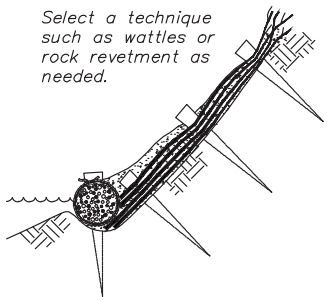
Step 1: Excavate trench and grade bank.



Step 2: Place willow branches making sure that the butt ends reach the bottom.



Step 3: Place stake (notched) on 1.0m (3ft.) centers and secure the mattress with twine, rope or wire.



Step 4: Drive the stakes deeply into the bank to tightly compress the branches against the soil. Cover and partially bury the mattress to encourage rooting.

1.0 PROJECT INTRODUCTION AND OVERVIEW

1.1 OVERVIEW

The Mayo Lake Enhanced Storage Project (the Project) is located in the Yukon interior, at Mayo Lake and lies within the Traditional Territory of the First Nation of Na-Cho Nyak Dun (NND). The Project proposes to reduce reliance on fossil fuel generation by increasing bottom storage in Mayo Lake through reducing the licenced Low Supply Level subject to a reservoir Monitoring and Adaptive Management Plan to guide water management decisions.

In February 2009, Yukon Energy initially proposed the Project as part of the Mayo Hydro Enhancement Project (Mayo B) Project Proposal to the Yukon Environmental and Socio-Economic Assessment Board (YESAB); however, the Mayo Lake Project was withdrawn in July 2009 in response to YESAB's determination of the need for additional fisheries and wetlands baseline studies (see Appendix 1A for the July 2009 YESAB Adequacy Review Report). Yukon Energy has undertaken additional fieldwork between 2009 and 2014 and has now fully addressed YESAB's July 2009 information requests (see Appendix 1B for a concordance table).

Yukon Energy undertook a public involvement program in order to incorporate community input in the Project design and environmental assessment, as well as to meet requirements for public consultation in an effective and meaningful manner, and as a standing corporate principle for good planning. This included involvement with NND, the Village of Mayo, the Mayo District Renewable Resources Council (MDRRC), residents of Mayo and the surrounding area, various territorial and federal government departments, and other interested parties. Yukon Energy shared information about the Project, including ongoing studies to assist in the assessment of effects, and sought to address concerns and interests of individuals and organizations. Yukon Energy intends to continue its engagement with stakeholders, particularly NND and others in the Mayo area throughout the Yukon Environmental and Socio-Economic Assessment Act (YESAA) process and Project implementation.

Yukon Energy focused the assessment of effects of the Project from a Valued Components perspective. Valued Components (VCs) are elements of the Project's Local and Regional Study Areas that are valued for environmental, scientific, social, aesthetic, or cultural reasons. Final VCs were determined in part based on results of consultation activities with stakeholders. Consideration was also given to whether there was an existing pathway of effect from the Project to the VC or environmental value. The following environmental and socio-economic VCs were included in the effects assessment:

- Environmental VCs
    - Aquatic and Terrestrial Environment
        - Lake Trout
        - Lake Whitefish
        - Fish Community Productivity
        - Roop Lakes
        - Shallow Water Littoral Areas at the ends of Roop and Nelson Arms

        - Ducks, Geese and Migratory Birds
    - Aquatic Mammals
        - Aquatic Furbearers – beaver/muskrat
    - Mammals
        - Moose
- Socio-Economic VCs
    - Traditional and Domestic Resource Use
        - Hunting
        - Fishing
        - Harvest Success
        - Trapping
    - Other Resource Use
        - Placer Mining
        - Tourism, Outfitting, and Outdoor Recreation
        - Private and Commercial Land Use
    - Regional Economy
        - Government Fiscal Flows
        - Utility Ratepayers

Cumulative effects have been fully considered as an integral part of the effects assessment process. The assessment process was completed based on data previously available, as well as Project-specific studies, existing literature, and available local and traditional knowledge collected during the study process.

The Project, including mitigation measures set out in the Project proposal, is not expected to cause any likely significant adverse environmental or socio-economic effects. This conclusion reflects careful consideration of the Project design as well as the consideration of mitigation measures that reduce or eliminate potential adverse effects and the development of a robust monitoring plan and adaptive management plan.

The Project will also have positive environmental and socio-economic effects in a variety of areas. Notably, the Project is expected to provide for reduced greenhouse gas and particulate emissions in the Territory resulting from the displacement of fossil fuel generation emissions. This is consistent with the Energy Strategy for Yukon (Yukon Government 2009a) and the Yukon Government Climate Change Action Plan (Yukon Government 2009b). Both the plan and strategy set reduction of greenhouse gas emissions as a priority.

1.2 PROPONENT INFORMATION

Yukon Energy is the Project Proponent.

Yukon Energy, a public utility, is owned by the Yukon Government through the Yukon Development Corporation (a Crown Corporation), and is subject to rate regulation by the Yukon Utilities Board under the Public Utilities Act (Yukon Government YUB 2002b). Yukon Energy owns and operates the Yukon's integrated transmission system (consisting of a 138 kV line between Whitehorse, Aishihik, Carmacks, Faro and Stewart Crossing and a 69 kV line between Dawson, Stewart Crossing, Mayo and Keno) and generates almost 100% of the power on this isolated grid. It is also the electric utility with primary responsibility for planning and development of new generation and transmission facilities in Yukon.

Yukon Energy has an installed generation capacity of approximately 129 MW. Of this, 92 MW is installed capacity at three hydro facilities: Whitehorse, Aishihik and Mayo. A further 0.8 MW is installed wind generation. The remaining 36 MW is installed fossil fuel thermal generating capacity of which 25 MW is installed in the Whitehorse Thermal Generating Station. Yukon Energy's wholesale customer, Yukon Electrical Company Limited, distributes power to 89% of Yukon retail customers, while Yukon Energy distributes power to the other 11% (approximately 1,900 customers) located primarily in Dawson City, Mayo and Faro.

Yukon Energy management reports to a Board of Directors through the President. Final approval to proceed with the Mayo Lake Project is subject to the approval of the Board of Directors as well as required territorial regulatory approvals.

Yukon Energy is incorporated under, and regulated by, the Business Corporations Act (Yukon Government 2002a), the Public Utilities Act (Yukon Government YUB 2002b) and the Yukon Waters Act (Yukon Government 2003).

The designated contact for the YESAA assessment and subsequent licensing of the Project is Travis Ritchie, Yukon Energy's Manager of Environment, Assessment, and Licensing.

1.3 PROJECT PURPOSE AND BACKGROUND

The Mayo Lake Enhanced Storage Project is proposed to enhance the renewable power generation capability of the existing hydro generating units installed on the Mayo River (see Appendix 6A for a description of existing facilities). The proposed Project is designed to improve energy generation to help displace fossil fuel that would otherwise be required during winter/spring to meet the overall power loads throughout the Integrated Yukon grid. The Project is consistent with Yukon Government policy, as set out in the Energy Strategy for Yukon (Yukon Government 2009a), which includes the goal of increasing

renewable energy supply by 20% by 2020. It also is in alignment with Yukon Government's 2009 Climate Change Action Plan (Yukon Government 2009b), which includes the reduction of carbon emissions.

The Project comprises a revision to the existing licensed range within which Yukon Energy is permitted to operate Mayo Lake, along with a reservoir management framework to guide water management decisions. The Project requires no physical works for water storage beyond those already in-service for the existing Mayo generation, including ongoing maintenance activities of the structure and outlet channel.

The proposed Project is consistent with Yukon Energy's efforts to minimize fossil fuel generation requirements, and to maximize and optimize, where possible, the capability of existing renewable generation assets as a preferred supply alternative as compared to new "greenfield" generation. The Mayo Lake Project will provide a long-term enhancement to the energy output of the Mayo plants, and reduce the future consumption of fossil fuel generation, which is costly and has associated environmental effects.

1.4 REQUIRED AUTHORIZATIONS AND REGULATORY APPROVALS

The Project is subject to an evaluation level assessment by the YESAB Designated Office in Mayo. A review of the Project is also anticipated by the Yukon Water Board under Part 3. Table 1-1 lists the regulatory permits and approvals that have been identified as being potentially required for the Project.

Table 1-1: Regulatory Permits and Approvals

Activity	Authorization	Act or Regulation
Water use	Water Use Licence Amendment	Yukon Waters Act, Water Use Regulations
Serious harm to fish that are part of a commercial, recreational or aboriginal fishery. Serious harm to fish is the death of fish or any permanent alteration to, or destruction of, fish habitat.	Fisheries Act Authorization	Fisheries Act (Sections 35 and 36)
Fish research and surveys	Licence to collect fish for Scientific Purposes; Fish Collection Licence	Fisheries Act; Fisheries (General) Regulations (Sec 51 & 52)

1.5 ALTERNATIVES TO THE PROJECT

The main alternative to the Project is continued reliance on existing fossil fuel generation (using natural gas supplied by liquefied natural gas and/or diesel fuel) to supply the energy that the Project would otherwise displace.

The Project is being pursued by Yukon Energy concurrent with all other identified potential enhancements to existing renewable generation, as well as a broad Demand Side Management (DSM) energy conservation and efficiency program. No one renewable energy project currently under study by Yukon

Energy is expected to meet short and medium-term forecasted demand on its own, and the proposed Project will not displace any other renewable energy option or any DSM option under consideration by Yukon Energy.

As Yukon Energy is a regulated utility with an obligation to supply firm power customer loads, the implications of not proceeding with this Project are as follows:

- Yukon Energy would be required to use fossil fuel generation to provide incremental power requirements that cannot be provided through the proposed Project.
- Long-term power costs in Yukon would be higher than with the proposed Project, affecting all Yukon ratepayers.
- Ongoing greenhouse gas emissions (GHG) would be higher than with the Project.
- Economic development benefits arising to the NND from participation in the proposed Project's economic benefits will not be realized.

1.6 SUBMISSION ORGANIZATION & CONTENT

The Project Proposal has been prepared so as to follow the Proponent's Guide to Information Requirements for Designated Office Project Proposal Submissions in structure and content, in all material respects. As the Proponent's Guide describes in general terms, the form of Project Proposal submissions, it has been applied in this document so as to reflect the specific characteristics of the Project.

The following outlines the chapter organization of this Project Proposal:

- Chapter 1: Project Introduction and Overview
- Chapter 2: Project Location
- Chapter 3: Assessment Approach
- Chapter 4: First Nations and Other Public Consultations
- Chapter 5: Environmental and Socio-Economic Scan
- Chapter 6: Project Description
- Chapter 7: Environmental and Socio-Economic Effects Assessment
- Chapter 8: Monitoring and Follow-up Programs
- Chapter 9: List of Acronyms, Glossary, and References
- Chapter 10: Acknowledgement and Certification

2.0 PROJECT LOCATION

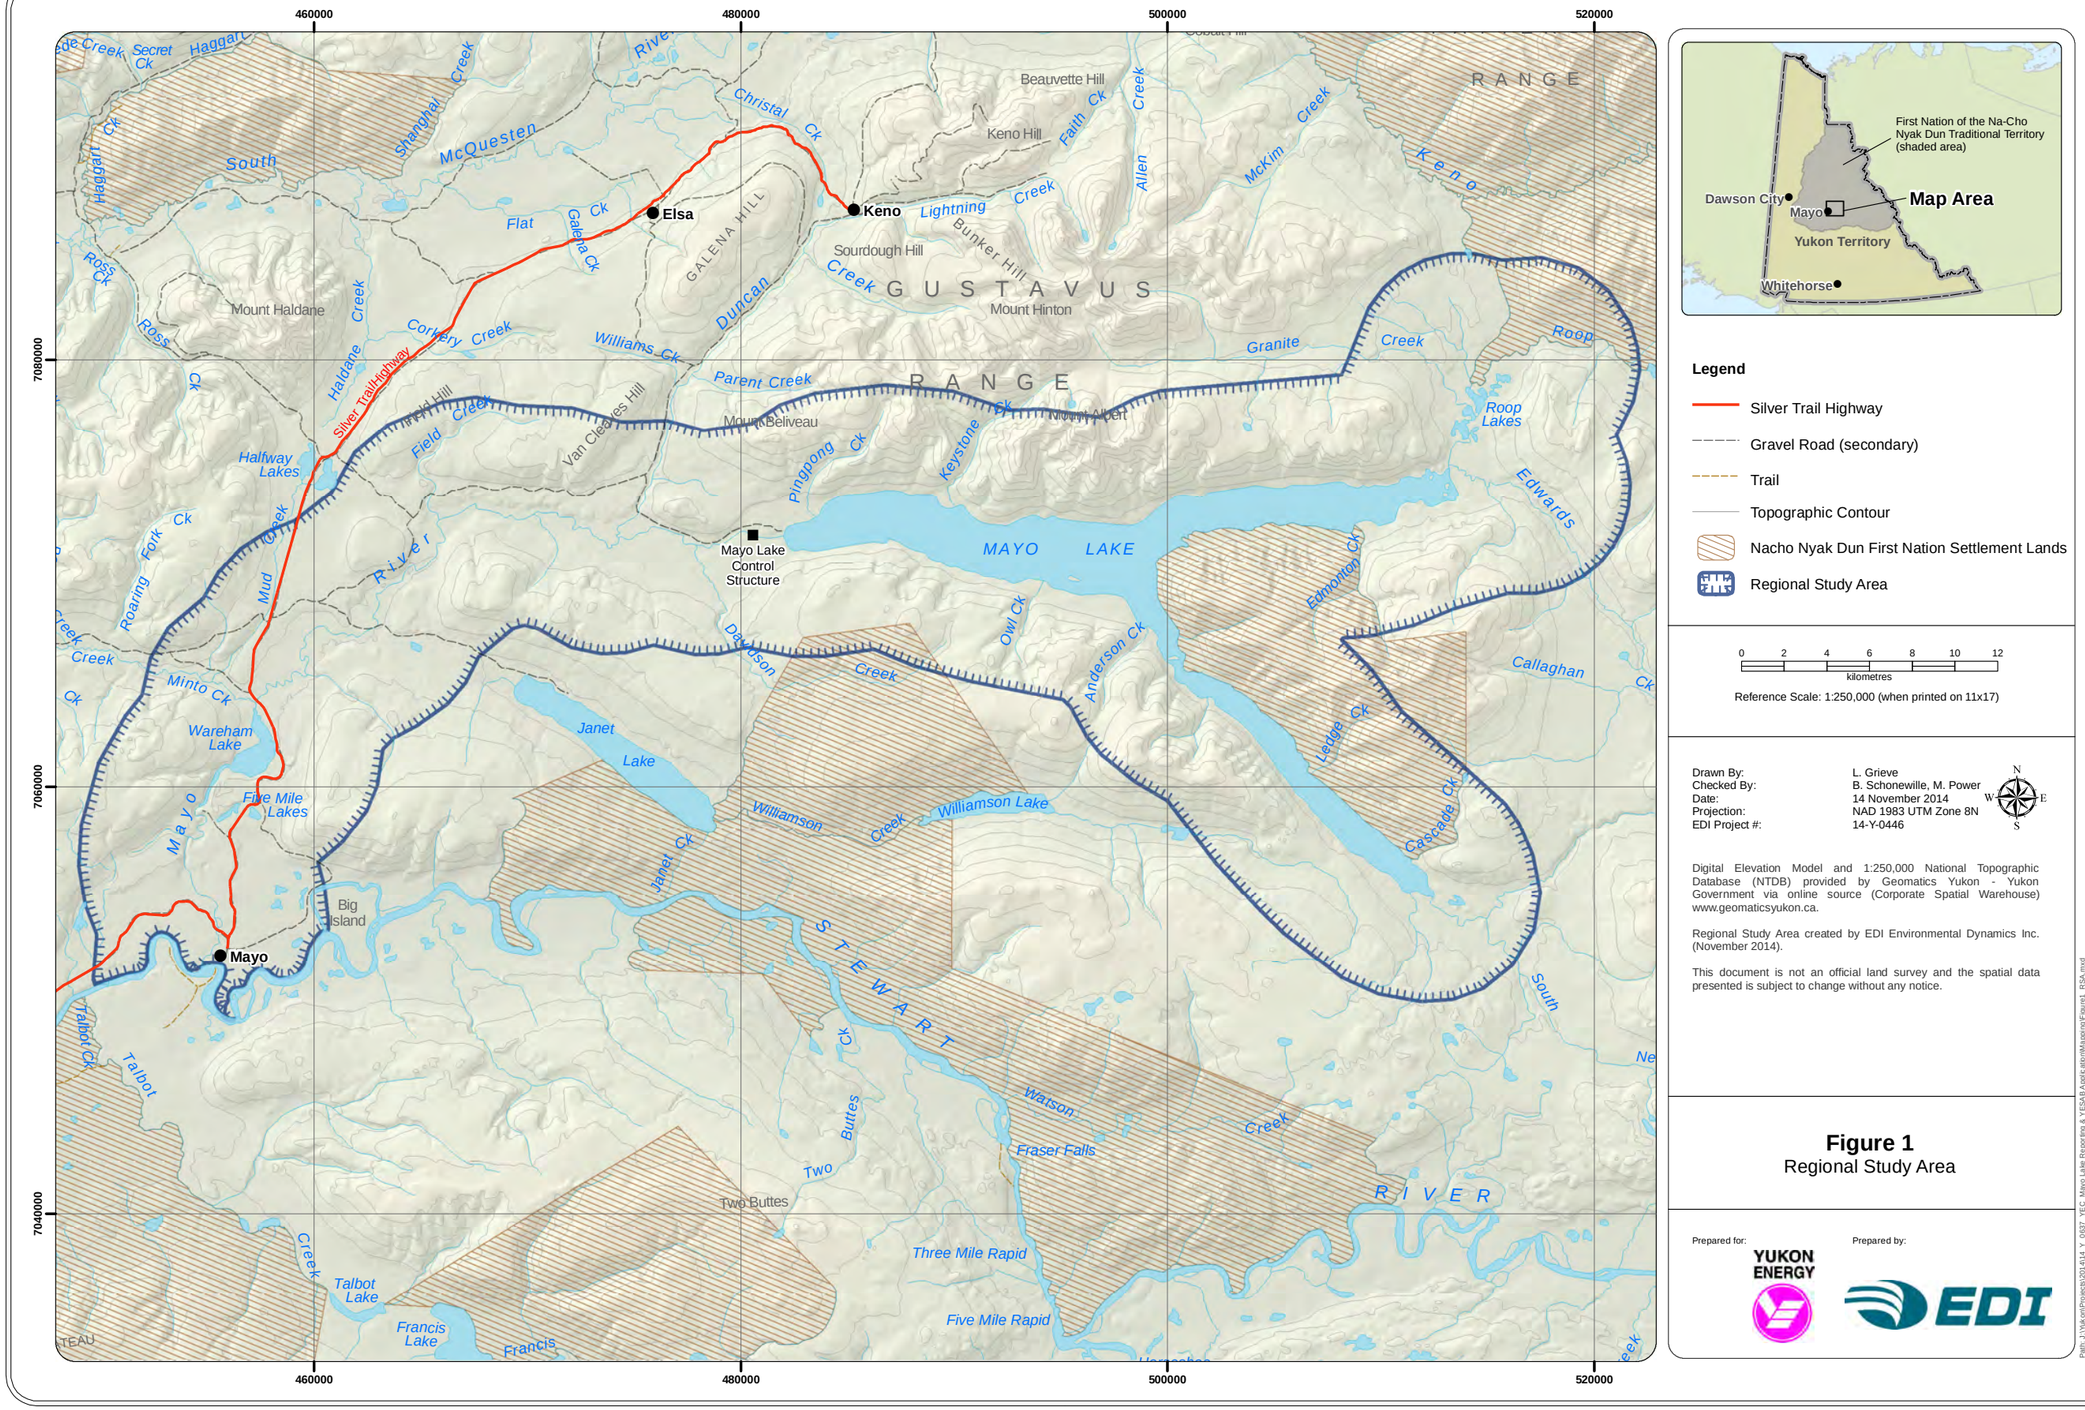
Chapter 2 provides a general geographical setting for the Project Proposal in terms of its location within the Yukon. The chapter sets out information regarding geographic location, land tenure, traditional territory of Yukon First Nations, Yukon Land Use Planning Region and consistency of the proposed Project activities with any existing land and/or resource management plans. It also outlines the Project Regional Study Area for the assessment approach as more fully described in Chapter 3.

2.1 GEOGRAPHIC LOCATION

The proposed Project changes Yukon Energy's licensed operating regime at Mayo Lake in the Yukon interior, northeast of the Village of Mayo. The Project lies within the Traditional Territory of the First Nation of Na-Cho Nyak Dun ("NND") as identified in the NND Final Agreement (NND 1993). The management of First Nation settlement land and resources in the Traditional Territory is guided by the provisions in the NND Final Agreement.

As reviewed in more detail in Chapter 3, the regional study area for the Project Proposal is that portion of the region between the Village of Mayo and Mayo Lake including a 5 km buffer around the lake and upper Mayo River. This Project Regional Study Area also falls within YESAB's Central Yukon Assessment District (Mayo Designated Office). A schematic of the Project Regional Study Area is provided in Figure 2-1.

Figure 2-1: Regional Study Area



The Project is located within the Boreal Cordillera Ecozone and the Yukon Plateau-North ecoregion. This area is generally characterized by tablelands and rolling uplands separated by wide and U-shaped valleys. The Project is also within the Yukon River Major Drainage Area which encompasses approximately 66% of the Yukon Territory and is its largest drainage area. The Mayo River is a tributary of the Stewart River, which in turns flows into the Yukon River.

2.2 LAND TENURE WITHIN THE PROJECT REGIONAL STUDY AREA

A land tenure search within the Project Regional Study Area, focusing on areas in close vicinity (e.g., within 2 km of either shoreline) to Mayo Lake and the Mayo River, is provided in Appendix 2A. Corresponding maps are located in Appendix 2D.

Further information regarding the socio-economic setting as it respects land tenure and associated land use is presented in Appendix 5C. In regard to specific land tenure the following items are noted:

Protected Areas and Parks:

The Project Regional Study Area contains the following protected areas and parks:

- **Five Mile Campground** – Located at 56.8 km of the Silver Trail Highway, the campground is 90 hectares and has 20 campsites. The Project will not interact with use of the campground.
- **Mayo Lake Campground Reserve** – The Project Regional Study Area encompasses the Mayo Lake Campground Reserve.

  Although not a protected area pursuant to legislation or regulation, Yukon Parks holds an 18.2 hectare reserve at the outlet of Mayo Lake, disposition #105M14-003, as well as fee simple lot 1056. The reserve at the lake mouth is not gazetted under the Parks and Land Certainty Act (Yukon Government 2002c). Yukon Parks does not maintain the reserve, or charge fees (A. Jones pers comm. 2008). The public is able to access the water at a boat launch at the reserve.

  The Project is not in the vicinity of any other lands designated under the Parks and Land Certainty Act, National Parks, Special Management Areas, Habitat Protection Areas, Canadian Heritage Rivers, National Wildlife Areas or Wildlife Sanctuaries.
- **Trapping and Outfitting Concession Areas** – There are six trapping concessions within or adjacent to the Project Regional Study Area: those being concessions 74, 84, 85, 86, 89 and 407, the last of which is a community trapping concession. Of the remaining five trapping concessions, three are located along the shoreline of the Mayo Lake, one is on Unnamed Island on Mayo Lake, and another is at the confluence of Davidson Creek and the Mayo River. See Appendix 2A for land tenure tables and Appendix 2D for a map of trapping concessions and owners.

  The Project falls entirely within Yukon Outfitting Concession 7, a 2.2 million hectare area. Concession 7 is held by Rogue River Outfitting, operated by Jim Shockey. A map of the outfitting concession is provided in Appendix 2D.
- **Mineral, Aggregate and Agricultural Claims** – Placer mining is an important economic activity in the Mayo area, to the extent that "[p]lacer mining and mineral exploration provide a non-governmental economic base for the [c]ommunity" (Village of Mayo Integrated Community

Sustainability Plan 2006). Placer and Quartz claims in close vicinity to Mayo Lake and the Mayo River in the Project Regional Study Area are listed in tables and illustrated on maps along with other land dispositions in Appendices 2A and 2D respectively. In addition, Appendix 5C provides details on the water use licenses of projects in close vicinity of Mayo Lake and the Mayo River, including placer mining activities, as supplied by the Yukon Water Board.

There are placer claims on 12 tributaries running into Mayo Lake, and one placer lease on Unnamed Island in the Nelson Arm of Mayo Lake. Duncan Creek and its tributaries Parent Creek, Lightening Creek, and Thunder Gulch descend into the Mayo River from Keno Hill to the north and include heavy placer activity. There are also placer claims on Davidson Creek. As noted in Chapter 5, prior to 2014 there were two or three active placer miners at Mayo Lake (e.g., Owl and Anderson creeks). While placer mining activity around the lake has diminished in recent years, there was at least one active operation in 2014.

In addition to placer mining claims, there are numerous quartz claims surrounding Mayo Lake (see Appendix 2D for maps).

There are no specific agricultural leases, dispositions, or applications within the Project Regional Study Area. Lots 1059 and 1061 near the Wareham bridgehead are fee simple dispositions and are used for agricultural purposes.

- **Water Use Licence Holders** – Numerous Water Licenses exist for activities in close vicinity to Mayo Lake and the Mayo River, primarily related to placer operations (see above). Outside of mining activity, water licenses exist for the Village of Mayo (Type A), Yukon Energy (Type A), Yukon Government (Type B) and for NND (Type B). See Appendix 2C for a list of water licenses within close vicinity of Mayo Lake and the Mayo River.
- **Private Landholdings** – The Project Regional Study Area is dominated by Crown Lands. Private land holdings are shown in the tables in Appendix 2A.

2.3 TRADITIONAL TERRITORY

The proposed Project is located entirely within the traditional territory of the First Nation of Na-Cho Nyak Dun (NND). There are eleven main Settlement Land parcels within the Project Regional Study Area, codified in the 1993 First Nation of Na-Cho Nyak Dun Final Agreement. The largest parcel of Settlement Lands in the area is Lot 1000, NND R-2A lying between the Roop and Nelson Arms of Mayo Lake (see Appendix 2B for a detailed list of NND settlement land parcels; several maps in Appendix 2D include NND Settlement Lands, including the maps detailing Land Tenure of the Mayo Region, Land Tenure for the Village of Mayo, and Quartz Claim Information for Mayo Lake).

2.4 CONSISTENCY WITH OTHER PLANS

The proponent has reviewed publicly available fish and wildlife and community plans in the Project Regional Study Area in order to ensure that the proposed Project is consistent with local plans.

2.4.1 Current Land Use & Management Plans

There is one land use plan currently in place in the Project Regional Study Area – the Village of Mayo Official Community Plan 2005 (Village of Mayo 2005). In addition, there are several management plans that are applicable. These plans include the Village of Mayo Integrated Community Sustainability Plan (Village of Mayo 2006), and the Community Based Fish and Wildlife Management Work Plan for Na-Cho Nyak Dun Traditional Territory 2014-2019 (NND 2014). A summary of the plans considered in relation to the Project is provided in Table 2-1.

Table 2-1: Land Use and Management Plans

Plan	General Description	Objectives Related to Project
Village of Mayo Official Community Plan 2005	Guides aspects of land planning and management, including zoning, development and land use.	Foster local and regional economic diversity, which is environmentally sustainable. Plan collaboratively with NND and other local government.
Village of Mayo Integrated Community Sustainability Plan	Outline the Village of Mayo's vision for an economically and environmentally viable future.	Foresees future resource development in the Mayo area, and seeks to accommodate such development in a sustainable manner.
Community-Based Fish and Wildlife Work Plan for Na-Cho Nyak Dun Traditional Territory 2014-2019	This is the fifth plan, and is based on a collaborative planning exercise between Mayo District Renewable Resources Council, First Nation of Na-Cho Nyak Dun, the Yukon Government - Fish and Wildlife Branch, and citizens of Mayo.	Addresses the following priorities: monitoring and stewardship; habitat; moose; and fisheries in the Mayo area.
Yukon Government Climate Change Plan 2009 and Yukon Government Climate Change Action Plan Progress Report 2012	The plan details actions the Yukon government will undertake to address climate change, within its areas of responsibility-building on the goals set out in the Climate Change Strategy. A progress report on these issues was released in September 2012 to discuss what has taken place, including initiatives that have emerged, during the interim period since the plan was established.	Reduce greenhouse gas emissions and monitor impacts of climate change on water systems in Yukon.

Plan	General Description	Objectives Related to Project
Mayo Watershed Fisheries Act Authorization for Placer Mining	Regulates and establishes sediment discharge standards and conditions for placer mining activities on the Mayo watershed, including Mayo Lake.	Provides for the protection of fish and fish habitat under the Fisheries Act, and establishes habitat suitability classifications for streams and lakes, including Mayo Lake.
Nacho Nyak Dun Tan Sothan – A Good Path Integrated Community Sustainability Plan May 2008	Follow-up to the Integrated Community Sustainability Planning process.	
Yukon Wildland Fire Management	The program aims to protect Yukoners, their communities and resources by enforcing the *Forest Protection Act* and suppressing wildfire from a priority-based approach, which places human life, community value and firefighter safety above all else.	

2.4.2 Project Consistency with Other Plans

The Project planning and assessment took into consideration the objectives of various management plans that are currently in place, and these objectives informed the public involvement and consultations with NND.

Village of Mayo Integrated Community Sustainability Plan and the Village of Mayo Official Community Plan 2005

The Village of Mayo Integrated Community Sustainability Plan (Village of Mayo 2006) and the Village of Mayo Official Community Plan 2005 (Village of Mayo 2005) identify the need to dovetail environmentally and economically sustainable development within Village boundaries, and in the larger Mayo region. Appendix 2E provides a summary of the objectives of the applicable management plans and describes how the Project is consistent with each plan objective. The following provides a summary description showing that the Project is aligned with the objectives and strategies of these management plans.

In Yukon Energy's view, the Project meets the environmental protection and stewardship objectives of the above documents. The Project does not require construction. The Village of Mayo Official Community Plan 2005 states specifically that "[f]uture resource development is anticipated in the Mayo area and the community recognizes the need to prepare in order to maximize and sustain the benefits of resource extraction". The Mayo Lake Enhanced Storage Project is part of ongoing sustainable (renewable) resource use.

Community Based Fish and Wildlife Work Plan for Na-Cho Nyak Dun Traditional Territory 2014-2019

With regard to the Community Based Fish and Wildlife Work Plan for Na-Cho Nyak Dun Traditional Territory 2014-2019 (NND 2014), the plan, in part, identifies the need for local area planning with regard to development in the Mayo area, continued support for the game guardian program (important for monitoring behaviour on the land and encouraging ethical practices), stewardship activities for youth and reporting on animal presence in the Mayo area, such as moose and caribou.

The public involvement process for this Project, which included workshops with local resource users and consultation with NND, contributed to regional dialogue about aquatic and terrestrial fauna and contributed local and traditional knowledge to the assessment. The biophysical studies undertaken as part of preparing this application added to the existing scientific literature on the fauna in the Project Regional Study Area, particularly fish. Lake trout was identified as an environmental component of interest in the Community Based Fish and Wildlife Management Plan. The aquatic field studies addressed lake trout and lake whitefish habitat and populations in Mayo Lake (see Appendix 5A).

Yukon Government Climate Change Plan 2009 and Yukon Government Climate Change Action Plan Progress Report 2012

The Yukon Government's 2009 Climate Change Action Plan (Yukon Government 2009b) seeks to enhance knowledge of climate change, adapt to climate change, reduce greenhouse gas (GHG) emissions, and lead action in response to climate change. The Yukon Government has set a cap on its own GHG emissions by 2010 and a target to reduce its emission by 20 percent by 2015. The Government's goal is to be carbon neutral in 2020 (from YEC's 2012 Strategic Plan). The Mayo Lake Project will reduce greenhouse gas emissions by reducing reliance on thermal generation that will be needed to serve the growing electrical needs of the region and Yukon in general. The Yukon Government's Climate Change Action Plan Progress Report (Yukon Government 2012), published in September 2012, details the progress made on the government's priority climate change actions and on actions that developed during the three years following the Climate Change Action Plan's release.

Mayo Watershed Fisheries Act Authorization for Placer Mining

With regard to the Mayo Watershed Federal Fisheries Act Authorization for placer mining, it sets out the sediment discharge standards and the conditions for related activities such as the construction of access structures, stream diversions, riparian buffers and reclamation requirements within fish habitat and the riparian zones of streams and water bodies.

Yukon Wildland Fire Management

The Yukon Wildland Fire Management aims to protect Yukoners, their communities and resources by enforcing the Forest Protection Act and suppressing wildfire from a priority-based approach which places human life, community value and firefighter safety above all else.

Yukon Energy does not anticipate that the Project will impede the ability of the Protective Services Branch of the Department of Community Services from fulfilling its objectives.

CHAPTER 3
ASSESSMENT APPROACH

TABLE OF CONTENTS

3.0 ASSESSMENT APPROACH 3-1
3.1 OVERVIEW OF APPROACH 3-1
3.2 ASSESSMENT FRAMEWORK 3-2
3.3 DETERMINING SIGNIFICANCE OF RESIDUAL EFFECTS 3-4
3.4 SOURCES OF INFORMATION 3-7

3.0 ASSESSMENT APPROACH

Chapter 3 reviews the assessment approach in the Project Proposal, focusing on the following items:

- Overview of Approach;
- Assessment Framework including Cumulative Effects;
- Determining Significance of Residual Effects;
- Follow Up and Adaptive Management; and
- Sources of Information.

3.1 OVERVIEW OF APPROACH

The Project Proposal has been prepared in accordance with YESAA, the YESAB DO Rules[1] and standard environmental and socio-economic assessment practice. It sets out the information required from Yukon Energy (the Proponent), for an assessment of the Project by the Designated Office. In accordance with the matters to be considered under Section 42(1) of YESAA, likely environmental and socio-economic effects of the Project, as well as likely cumulative adverse environmental and socio-economic effects of the Project and their significance are identified after considering the implementation of proposed mitigation, monitoring and follow-up measures. The submission utilizes and integrates available scientific, traditional knowledge, local knowledge and other information relevant to the assessment of Project effects. The Project will continue to incorporate scientific, local and traditional knowledge as part of the ongoing monitoring and activities under the proposed Adaptive Management Plan.

In accordance with the spirit of YESAA and standard Yukon Energy planning practice, the assessment approach has incorporated an extensive consultation and public involvement process which sought views from the First Nation of Na-Cho Nyak Dun (NND) and residents of Mayo where potential environmental and socio-economic effects of the Project would most likely be experienced (Chapter 4). Early and meaningful ongoing opportunities have been provided to seek views and information about the Project, the environmental and socio-economic planning and the assessment process. Involvement has included NND, Mayo District Renewable Resources Council (MDRCC), other local residents, territorial and federal governments. These consultations have contributed in a material way to the mitigation of adverse environmental and socio-economic effects that could potentially be associated with the Project as well as a consideration of alternatives to the Project or alternative ways of undertaking or operating the Project that would avoid or minimize any significant adverse environmental or socio-economic effects.[2]

The scoping of the Project, as well as a description of Project activities and components, is provided in Chapter 6. The assessment approach addresses the proposed change to the operational licence range and the effects on environmental components applicable to the Project (e.g., land and water environments and associated aquatic and terrestrial life) and socio-economic components (e.g., resource

[1] YESAB Rules refers to the June 2010 Rules for Evaluations Conducted by Designated Offices; and Directive 2: Filing Requirements for Project Proposals Submitted to a Designated Office for Evaluation.
[2] These matters are required to be considered under s. 42(1)(e) and 42(1)(f) of YESAA.

and other land use, economies, and social components including infrastructure and services, cultural/heritage sites and resources, and traditional and other lifestyles).

The Project Proposal ultimately assesses the effects of the proposed change in water management for use of Mayo Lake (see Chapter 7).

As there is no construction phase, the assessment approach focuses on the effects of Project operation. At this time there is no timetable for decommissioning of the existing Mayo facilities, and it is currently not feasible to provide a meaningful assessment of any likely decommissioning plans or the anticipated effects of decommissioning. If at a later date it is determined that the existing Mayo facilities are no longer required, then Yukon Energy would adhere to the legislation and regulations in place at that time and would review decommissioning plans with regulatory authorities, affected First Nations and other local communities.

3.2 ASSESSMENT FRAMEWORK

For the purpose of assessing environmental and socio-economic effects of the Project, current conditions in areas potentially affected by the Project and the projected evolution of these conditions without the Project are considered. As noted in Chapter 6 and 7, the Mayo Lake environment has been previously disturbed when the original Mayo Lake control structure was built and the lake raised by over 5 m. Potential environmental and socio-economic effects of the Project on the existing conditions are predicted separately in the Project Proposal for each environmental and socio-economic component by comparing:

1. **What would be expected without the Project** (i.e., the current and expected future conditions for each environmental and socio-economic component without the Project, including as relevant consideration of other projects or activities that have been or will be carried out without the Project); and
2. **What would be expected with the Project** (i.e., each environmental or socio-economic component as modified or affected by the Project based on direct and indirect effects pathways[3] from the Project to the environmental or socio-economic component, including as relevant consideration of other projects or activities that have been or will be carried out in combination with the Project).

Following from the Project description and determination of the Project scope (Chapter 6), and reflecting standard environmental and socio-economic assessment practice, the assessment framework for the Project Proposal (including cumulative effects assessment) to assess effects of the Project includes the following five basic steps:

1. **Scoping of Assessment:** It is critical at the outset to address assessment scope issues, including selecting valued environmental and socio-economic components (VCs) for the assessment[4].

[3] As reviewed in earlier YESAB Guides, "direct effects" are the initial, immediate effects caused by a specific activity and "indirect effects" are caused by a given action, but occur later in time or further removed in distance.

[4] Valued Environmental and Socio-economic Components (VCs) are elements of the Project Study Region valued for environmental, scientific, social, aesthetic, or cultural reasons. Selecting project-specific VCs (i.e., VCs that could be potentially affected by the Project) is essential for focusing assessments, and for determining the significance of effects.

a) A VC based approach is intended to ensure that potential significant adverse effects to important environmental and social components will be detected and mitigated through the assessment process[5]. This was done initially and in part through the development and implementation of baseline studies and the development of the proposed Monitoring and Adaptive Management Plans in cooperation with NND and in consultation with the MDRRC and the community, regulators and other scientific experts. This selection process of VCs helped to focus the baseline studies and analysis on components deemed to be of particular importance or of special interest to residents or to the ecosystem[6]. Chapter 7 reviews the process used to select VCs; the scoping of baseline and assessment studies for each VC; and the specific methods used to assess potential environmental and socio-economic effects for each VC.

b) The assessment process commenced with the definition of a general geographic location for the Project and a Project Study Region. For assessment purposes the following study areas were defined:

1. **Local Study Area:** represents the much smaller local region examined to assess potential effects of changing water levels and flows on Mayo Lake including the Roop Lakes wetland complex and the upper Mayo River (Wareham Lake to Mayo Lake).

2. **Regional Study Area:** A broader Project Regional Study Area for examining potential environmental and socio-economic effects. The maximum geographic extent of most potential environmental and socio-economic effects is expected to be included in this region. The generic nature of the definition adopted for this regional study area reflects the absence of any specific administrative area available for overall data collection or mapping purposes relevant to this assessment.

   However, it is recognized that the nature of different potential environmental and socio-economic effects requires flexibility in the extent of the study area used for each VC. Specific study areas relevant to each VC, where they are different from the definitions in this chapter, are described in Chapter 7. It should be noted that field studies undertaken early in the Project do not reflect the above definitions; rather they reflect study-specific requirements, and as such definitions such as "study area" used in the field reports in Appendices 5A, 5B and 5D do not in some cases correspond with the Project Proposal definitions indicated above.

[5] It is standard practice to focus an assessment on specific environmental and socio-economic components which are determined to be of particular importance. Measures designed to mitigate adverse effects on major components should serve to also minimize the likelihood of adverse impacts on other environmental and social components.

[6] In this assessment, VCs were determined after consultation with interested parties and experts (particularly NND and government), field studies undertaken on the terrestrial and aquatic environments, socio-economic data collection and consideration of TK and local knowledge as well as any plans and policies applicable to the regional area.

2. **Baseline Conditions:** This is a baseline analysis and includes review of current and evolving future VC conditions without the Project, as affected by past, current and other future projects included in the cumulative effects assessment. Each existing VC is described in the baseline analysis only to the extent needed to predict the effect of the Project on that VC.

3. **Effects and Mitigation:** This describes quantitatively and qualitatively both positive and adverse effects on VCs likely to result from the Project, after consideration of the baseline conditions without the Project as well as proposed mitigation and monitoring measures with the Project beyond those already included in the Project Description. In accordance with YESAA, the scope of this assessment includes an examination of both environmental and socio-economic effects arising from the Project and is described for each VC in Chapter 7.

4. **Cumulative Effects Assessment:** Cumulative Effects Assessment (CEA) is integral to the assessment approach and examines the likely effects of the project in combination with the likely effects of other past, existing and future projects and activities. To be considered a cumulative effect, the other past, existing and future projects being considered in the assessment must affect a VC that is also being affected by the principal project; in this way the projects act cumulatively upon a valued component. The CEA is embedded in the effects assessment in Chapter 7.

5. **Residual Effects and their Significance:** Summarizes the nature and extent of any residual environmental effects of the Project after implementation of proposed mitigation, and includes characterization with rationale as to whether adverse residual environmental and socio-economic effects are significant or not significant. Included as part of mitigation are any plans for responding to any known or predicted residual effects. This assessment is included in Chapter 7.

6. **Adaptive Management and Monitoring:** The proposed Adaptive Management Plan and Monitoring Plan identified in Chapter 6 and detailed in Appendix 8A and 8B are integral to the Project and the assessment of the Project. As stated in Chapter 6, it is the proponent's expectation that these will be included in the amended water use licence for the Project, if the Project were to proceed.

3.3 DETERMINING SIGNIFICANCE OF RESIDUAL EFFECTS

Environmental and socio-economic effects and their significance are identified and determined using standard assessment practice and the requirements of YESAA.

Determining "significance" involves the use of scientific, Traditional and local knowledge, the analysis and interpretation of environmental and socio-economic effects, and consideration of effects of environmental or socio-economic changes caused by the Project on the following (YESAA, s.42):

- The need to protect the rights of Yukon Indian persons under final agreements;
- The special relationship between Indian Yukon persons and the wilderness environment of Yukon; and
- The cultures, traditions, health and lifestyles of Yukon Indian persons and other residents of Yukon.

Mitigation measures and strategies can be important in the assessment of residual effects.

For purposes of effects assessment, the determination of significance of residual effects may involve comparing such effects, including cumulative effects, against thresholds for environmental and socio-economic components such as specified goals or targets, standards or guidelines, carrying capacity, or limits of acceptable change. Land use objectives and trends may also be utilized to determine significance of residual effects. However, it is recognized in standard assessment practice that the assessment of project effects is often hindered by a lack of specific thresholds.

To the greatest degree possible, the significance thresholds identified in this effects assessment are drawn from quantitative data, particularly with regard to the aquatic ecosystem and fish.

The regulatory significance of predicted residual adverse effects on each VC is assessed according to the following criteria (in many cases referencing examples of effect attribute characteristics for aquatic ecosystem components):

- **Direction or Nature of the Effect:** Positive, neutral, or negative/adverse; in the case of socio-economic effects, effects may at times be considered to be both positive/beneficial and negative;

  The assessment of significance for environmental effects typically can determine a clear overall direction of change (positive, neutral or negative/adverse) for a specific VC. In contrast, the assessment of significance for socio-economic effects also considers the following:

  - The relevance of perceptions in affecting how people view changes;
  - Differing perspectives and values among different groups of people about their community and region, as well as their individual and family circumstances (this applies to biophysical affects as well);
  - The problems inherent in assessing separate effects on different aspects or components (i.e., different VCs) of people's lives that each contribute to an overall "effect" on any group of people; and
  - Positive socio-economic effects will not be used to offset any significant negative/adverse environmental effects of a project.

- **Magnitude of the Effect** (the predicted severity or degree of disturbance the residual effect has on a component of the biophysical or socio-economic environment):
  - **Small** (no definable or measurable effect on the VC – the effect is below established thresholds of acceptable change or within the range of natural variability).
  - **Moderate** (the effect on the VC could be detected with a well-designed monitoring program, is outside the normal range of variation (but below established thresholds of acceptable change) and the overall population is still sustainable).
  - **Large** (the effect on the VC would be readily detectable without a monitoring program, is outside the normal range of variation, and exceeds established thresholds of acceptable change and the VC sustainability is threatened).

- **Geographic or Socio-Economic Extent of the Effect:**
    - **Low** (effect is localized within the Local Study Area i.e., effect is limited to localized populations of fish and wildlife or a small portion of the LSA; e.g., beaver populations on Mayo Lake).
    - **Moderate** (effect is within the Local Study Area which includes all of Mayo Lake, Roop wetland complex and the Mayo River).
    - **High** (effect extends beyond Local Study Area to the Regional Study Area; for socio-economic effects, extends to Yukon-wide effects (e.g., effects to ratepayers across the Yukon).
- **Duration of the Effect (how long the effect would last):**
    - **Short-term** (short-term effects lasting less than one generation span or year class of the species affected); e.g., there may be an initial reduction in year class strength at the early fry stage but this is offset by density dependent survival and growth at older life history stages.
    - **Medium-term** (medium-term effects lasting more than one year class, but no more than one-generation span of the species affected); e.g., effect in terms of year class strength is detectible over the longer term in index netting and for the life of the year class.
    - **Long-term** (long-term effect lasting more than one generation of the species affected); e.g., reduction in year class strength and adult spawners effects reproductive capacity of a species.
- **Frequency of the Effect** (how often the effect would occur):
    - **Low** (never, once, seldom);
    - **Moderate** (occasionally e.g., not every year or not in most years); or
    - **High** (continuously - on a regular basis e.g. every year or in most years).
- **Reversibility of the Effect** (is the effect reversible or not reversible):
    - **Reversible:** the effect can be reversed; or,
    - **Irreversible:** the effect cannot be reversed; the effect is permanent or near permanent.
- **Ecological or Socio-Economic Context (sensitivity to environmental or socio-economic disturbance, capacity to adapt to change):**
    - **Low** (VC is resilient to imposed change);
    - **Moderate** (VC has some capacity to adapt to imposed change); or,
    - **High** (VC is fragile and has low resilience to imposed change).

For example, if an environmental VC is known to be highly resilient (i.e., adaptable to changes in environmental conditions and recovers well from such changes or disturbances, e.g., there may be impacts to a year class, but overall the population is healthy and reproductive capacity is not affected),

effects that would otherwise be considered significant may – for the purposes of determination of regulatory significance - be determined as not significant, despite magnitude and/or duration or the extent of the effects. Cumulative effects can be significant in this regard, e.g., if there is a significant increase in harvest of adult spawning fish the missing year classes or reductions in year class strength would be more significant at the population level. Conversely, thresholds or guides may identify highly vulnerable environmental VCs where the loss of even a few individuals may affect the long-term status of the population. Additional factors that may need to be considered for socio-economic VCs include the following:

  - Concurrent effects on other socio-economic VCs affecting the same group of people or others in the same community or region;
  - Effectiveness of mitigation measures and the degree to which the affected people have any control over mitigation (which may affect "vulnerability" in socio-economic terms);
  - The extent to which the socio-economic component is affected by the Project (magnitude, frequency, reversibility of the effects); and
  - Overall confidence in the assessment conclusions after consideration of proposed mitigation measures.

- **Likelihood:** In the event that residual effects on VCs are potentially significant, likelihood is discussed in terms of two criteria: i) the probability of occurrence of the significant adverse effect and ii) the degree of uncertainty. Likelihood differs from frequency in the determination of significance for environmental effects. For example, a building in the 100 year flood zone may only experience flooding during periods of extreme floods (low frequency), but when there are extreme flood events, it is relatively certain the effect will occur (high likelihood).

As addressed in further detail in the Project Description (Chapter 6) and Monitoring and Adaptive Management (Chapter 8), a robust Adaptive Management Plan is integral to the planned operation of the Project and is expected to address issues of uncertainty related to potential project effects and/or mitigation effectiveness, particularly where the effects, if they were to occur, would not result in serious irreversible harm.

Assessment conclusions are supported by technical information, traditional and local knowledge based on experience in Yukon and elsewhere. In this regard, traditional and local knowledge are addressed on an integrated basis throughout the assessment process and on an ongoing basis during operations in the Monitoring and Adaptive Management Process.

3.4 SOURCES OF INFORMATION

The assessment incorporates original studies commissioned by Yukon Energy specific to the Project, including extensive scientific and technical reports and memos on topics relevant to the Project, local knowledge and available experience. Other information sources include meetings with NND resource users, regulatory agencies, the MDRCC, placer miners/land owners on Mayo Lake and existing public and unpublished information.

The assessment process for the Project has included consultation and involvement with potentially affected groups such as NND, local community organizations and individuals, and other interested

groups. This consultation and public involvement has provided the Project Proposal with important information with regard to local knowledge, concerns and interests as well as available experience.

Meetings with territorial and federal government departments were also held to discuss the status of the project and its environmental/socio-economic studies and provide information to assess ongoing changes related to the project.

4.0 FIRST NATION AND OTHER COMMUNITY AND PUBLIC ENGAGEMENT

An overview of the public and community[1] involvement activities is provided in Section 4.1 of this chapter. Section 4.2 describes the principles and approach to consultation, while Section 4.3 describes the methods used. Section 4.4 reviews the activities undertaken with various stakeholders and Section 4.5 describes the key perspectives and issues that were provided. Section 4.6 explains how the key perspectives and issues influenced the Project planning. Section 4.7 describes what will occur in terms of communication about the Project upon the filing of a Project Proposal to the Mayo Designated Office under Yukon Environmental and Socio-Economic Assessment Act (YESAA).

4.1 OVERVIEW

Yukon Energy developed a public involvement approach in order to incorporate community input in the Project design and effects assessment, to meet the regulatory requirements for public consultation in an effective and credible manner, and as a standing corporate principle for good planning. The process was designed to provide on-going opportunities for potentially affected and interested parties to participate in the Project planning by providing information, allowing for sharing of key perspectives and interests regarding the Project and assisting in devising measures to mitigate potential Project-related effects through the environmental and socio-economic assessment process.

The public involvement process for this Project began in 2008 during the Mayo Hydro Enhancement Project (Mayo B), prior to the Mayo Lake component being removed in order to address information requests from the Yukon Environmental and Socio-Economic Assessment Board (YESAB) during Mayo B's adequacy review. Public involvement for the Mayo Lake Enhanced Storage Project resumed in February 2011, when the Project was re-introduced.

Public involvement focused largely on the public and stakeholders residing in closest proximity to the Project, and to which the potential effects would most likely accrue, including Na-Cho Nyak Dun (NND) the Mayo District Renewable Resources Council (MDRCC) and the Village of Mayo, among other organizations and individuals. This included residents of Mayo, private landowners, and resource users (e.g., fishers, trappers, placer miners). In addition, interested non-government organizations, the Mayo Designated Office (YESAA), and federal and territorial government regulators were included in the consultation.

It is important to note that while these community consultation processes included NND and First Nation citizens, representatives from NND also participated formally in all phases of Project development under the Yukon Energy/NND Project Agreement Technical Working Group in a collaborative working arrangement with Yukon Energy.

A list of the potentially affected or interested publics is provided in Appendix 4A.

[1] The term 'community' in this document refers to both place-based communities, which can be defined geographically, and interest-based communities defined by a common interest or activity, also sometimes referred to as 'stakeholder' group.

4.2 PRINCIPLES AND APPROACH TO CONSULTATION

4.2.1 Guiding Principles

Yukon Energy has developed the following principles for public involvement in project planning and implementation:

- **Value of Public Involvement:** Engaging the public in a participatory manner improves the project planning and assessment and will yield better outcomes for the project.
- **Opportunities for Ongoing Involvement:** Provide opportunities for interested or potentially affected parties to learn about the Project and provide inputs with respect to interests, concerns and opportunities. Where possible, work through the consultation process to resolve issues and enable participants to have inputs recorded at each stage.
- **Opportunities at Various Stages:** Before and after filing a Project Proposal for assessment, and during implementation as part of the adaptive management process provide opportunities for public input through such mechanisms as the YESAA review process, community meetings and the Mayo District RRC.
- **Provide Various Communication Mechanisms:** Provide a variety of mechanisms to communicate and interact with the public.
- **Required Consultation with Aboriginal Peoples:** Recognize the unique status of First Nations who may be affected if the Project is developed. In particular, discuss the location and effects of the Mayo Lake Enhanced Storage Project, which is located in the traditional territory of NND, and seek to involve the First Nation as a partner in the development of the Project.
- **Adaptive Approach:** Adjust the public involvement activities, as required and feasible, throughout the environmental review and planning and implementation process, in response to issues, concerns and challenges. Provide ongoing opportunities for input of local and Traditional Knowledge as part of the Adaptive Management implementation process.
- **Full and Fair Consideration:** Provide clarity on how submitted views and information have been considered and how they have informed Yukon Energy's project planning and assessment.

These principles are consistent with the YESAA intentions and guidance, which direct the proponent to provide notice of the proposed project in sufficient form and detail to allow the party (to be consulted) to prepare its views on the matter, a reasonable period of time for people to prepare their views and fair and full consideration of the views presented. It is expected that the public will have further opportunities to participate in the Project review during the Designated Office evaluation process.

Yukon Energy, in its consultation with NND, also took guidance from the First Nation's Guiding Principles Towards Best Practice Codes for Mineral Interests within Na-Cho Nyak Dun First Nation's Traditional

Territory (Appendix 4C). Among the goals and objectives delineated in this document that were particularly captured in the consultation process was[2]:

- **Keeping the Commitment Strong:** The parties are committed to working together to achieve environmentally sound and socially responsible developments.
- **Information Sharing:** The parties will ensure effective decision making though impartial sharing of accessible and accurate information in a timely manner.
- **Open Consultation:** The parties will work together to establish appropriate cooperative agreements that will encourage and provide opportunities for meaningful participation.
- **Protecting Environmental Integrity:** The parties are committed to protect and maintain environmental integrity and minimize the impact on the environment.

Yukon Energy also followed NND's Cooperative Engagement Process for Economic Activities Proposed in the Traditional Territory of the First Nation of Na-Cho Nyak Dun (2008), included in Appendix 4C. Protocol was followed to engage the Chief and Council and particularly the staff of NND and their advisors in the project planning (described in Section 4.4.1).

Yukon Energy's public involvement activities were guided in part by discussions held early in the feasibility stage of the Mayo Hydro Enhancement Project (Mayo B) with key stakeholders in the vicinity of Mayo (NND, Village of Mayo, and the MDRCC). These discussions were considered in the public involvement process. Additional opportunities for public consultation occurred between 2011 and 2014 prior to the filing of this Project Proposal. Further opportunities to communicate with the public after filing with the Mayo Designated Office will also occur. A detailed account of these activities and events are provided in Section 4.4 and referenced appendices.

4.2.1.1 Opportunities before a Filing of the Application

In February 2011, Yukon Energy re-introduced the Mayo Lake Enhanced Storage Project after conducting several additional studies after the Mayo B filing in 2009 to address deficiencies identified by YESAB. Since February 2011, Yukon Energy has provided several opportunities for stakeholders and the public to learn about the Project, as well as time to consider, prepare, and express their views. Where stakeholders expressed particular concerns, efforts were made to address the issues specifically and in as much detail as possible (based on the status of studies). Feedback was welcomed up to the date of filing, and will continue to be accepted and incorporated into the Project planning throughout the review by the Mayo Designated Office and the public. Where written feedback was submitted by an interested party, Yukon Energy acknowledged receipt and responded to the questions and concerns.

4.2.1.2 Public Communication of the Filing of the Application

Yukon Energy will communicate its filing of a Designated Office Project application under YESAA with the stakeholders identified in Appendix 4A. This will continue the open dialogue that has been established

[2] Since the guidelines were developed specifically for mineral development, not all of the goals and objectives are relevant – for example the goal regarding opportunities and capacity building which strives towards things such as "ensuring NND citizens receive the benefits derived from their mineral endowment".

with local stakeholders such as NND, the MDRRC and local residents to ensure that issues they may have identified about Project implementation are addressed.

4.3 METHODS

Several methods to facilitate public involvement were adopted for the Project. These methods were designed to ensure that Yukon Energy was providing information about the Project in a reasonable manner, as well as providing opportunity to receive information and perspectives from potentially affected and interested parties. The audience and methods used for communication varied and included face-to-face interaction, telephone conversations, and electronic and paper communication.

4.3.1 Face-to-Face Interaction

Face-to-face interactions with NND, stakeholders in Mayo, government, and other parties took a variety of forms depending on the desired level of interaction from the consulted party. Section 4.4 describes the various ways different groups were consulted and details of the activities that occurred.

4.3.2 Electronic, Paper & Other Media Communication

Electronic and paper communications were used to inform stakeholders and interested publics about the project. The details and contents of the project newsletter, posters and fact sheets are provided in Appendix 4B.

Mayo Projects Update Newsletter: Newsletters were produced to inform the community about the Project (see Appendix 4B). The June 2011 newsletter provided an update on the Mayo Hydro Enhancement Project (Mayo B) activities, a summary of the proposed Mayo Lake Enhanced Storage Project including the need for and benefits of the Project, regulatory approvals and reviews required, key studies to date, addressing potential effects and public involvement opportunities. Copies were mailed to identify potentially affected or interested stakeholders, as well as used throughout public involvement activities. The newsletter was also inserted into all Village of Mayo post-boxes and posted on the Yukon Energy website (see Section 4.3.2.3). An October 2014 newsletter provided an update on the Mayo Lake Enhanced Storage Project, and was handed out at the community open house October 28, 2014.

Mayo Lake Posters and Fact Sheets: Project-related posters and fact sheets were developed based on results from additional technical studies and environmental field work, and socio-economic and public consultation activities; and were used at the community meal and information sessions held in Mayo during June 2011, October 2011 and October 2014 (see Appendix 4B).

Yukon Energy Website: In June 2011, Yukon Energy created a link on their website posting a brief description of the Project and providing links to the electronic version of the newsletter. The website was subsequently updated in 2014[3].

Event Notification: To inform the community of public involvement activities, flyers were posted in various locations throughout the community. This included postings at the NND offices, MDRRC offices, and the

[3] http://www.yukonenergy.ca/energy-in-yukon/our-projects-facilities/hydroenhancement/mayo-lake-enhanced-storage-concept.

local Yukon Energy office. Local resource users and placer miners received invitations for their respective meetings.

4.4 REVIEW OF PUBLIC INVOLVEMENT ACTIVITIES

The following sections summarize public involvement activities with various groups of stakeholders. Appendices 4C, 4D, and 4E provide meeting notes and supporting materials used during meetings. In many instances, the same materials were used with different stakeholders. As such, some materials are cross-referenced to the first location in which they appear.

4.4.1 Activities Involving NND

Activities involving NND focused on three primary groups: 1) Chief and Council, 2) the Lands and Resources Department, and 4) NND citizens[4]. A summary of these activities, presentation materials used and meeting notes produced are provided in chronological order in Appendix 4C[5]. Methods of interaction are summarized below.

1. **Meetings with Chief and Council:** As per the guidance provided in the Cooperative Engagement Process for Economic Activities Proposed in the Traditional Territory of the First Nation of Na-Cho Nyak Dun (NND, 2008b), protocol was followed to engage the Chief and Council, and subsequently the Lands and Resource Department. This included a written request for a meeting with Chief and Council during the Mayo Hydro Enhancement Project (Mayo B), a subsequent initial meeting between YEC and the Chief and Council in spring 2011 related to the Project, and finally in a formal engagement process related to the Project.

2. **Meetings with NND Lands and Resources Department:** The Land and Resources Department for NND acted and continue to act as a major point of contact for public involvement. Meetings have been held in both Mayo and in Whitehorse in order to discuss the proposed Project, associated field studies, and proposed mitigation measures with NND staff and its consultants. Where appropriate, NND Lands and Resources staff identified other relevant NND departments (e.g., Heritage) and community members to participate in meetings (e.g., resource users). Joint discussions between the Steering Committee and the Technical Working Group (both committees were established under the NND/YEC Project Agreement; the TWG has representatives from NND Lands and Resources Department), as well as meetings of the Technical Working Group itself were held periodically to share and discuss different aspects of the Project. These groups were made up of NND members and technical advisors, as well as Yukon Energy representatives and consultants. A list of these meetings can be found in Appendix 4C.

[4] It should be noted that a Project Agreement Working Team was established during the Mayo B Project. This group was tasked with working towards Project related agreements including the potential business and investment opportunities for NND related to the Project. This Working Team completed their activities during the Mayo B Project with the culmination of a Project Agreement.
[5] Activities in Appendix 4C focus on engagement since February 2011; for information related to public consultation on Mayo Lake associated with the Mayo B Project Proposal, please refer to Chapter 4 and associated appendices in the Mayo Hydro Enhancement Project filing with the YESAB Executive Committee.

3. **Meetings with NND Membership:** Although the majority of contact with NND focused on the Lands and Resources Department through the Technical Working Group, efforts were also made to inform NND membership about the Project. This included invitations to community meal and information/open house sessions, which were targeted not only at NND, but included the entire community of Mayo. The June 2011 newsletter was also provided to local NND Membership through insertion into post boxes in Mayo.

Various other personal communications occurred with NND Government representatives, largely to facilitate public involvement activities; however, some of these interactions also enhanced the level of understanding about the socio-cultural setting and resource use in the region, as well as the key community interests and concerns regarding the Project. These communications were accomplished in person, by telephone and by email.

4.4.2 Activities Involving Local and Municipal Government, Regional and Local Resource Management Organizations, and Other Governments

Activities with local stakeholders were focused on the Village of Mayo Mayor and Council, and the MDRRC. A summary of these activities, presentation materials used and meeting notes produced are provided in chronological order in Appendix 4D (focusing on activities since February 2011).

1. **Village of Mayo:** Meetings were offered to key staff from the Village of Mayo as well as with the Mayor and Council. These meetings were intended to focus on informing the Village of the Project; and to understand the key issues and concerns that arose from a municipal perspective.
2. **Mayo District Renewable Resource Council:** In addition to meetings with the MDRRC associated with the Mayo B proposal, Yukon Energy met with the MDRRC on October 4, 2011. The meeting focused on informing the MDRRC of the Project as well as to understand the Council's key issues and perspectives. Members of the MDRRC also participated in the project workshop on January 24, 2014. This workshop provided participants with a summary of Project activities that had taken place to date. In addition to the January 2014 workshop, in-community meetings with the MDRRC took place in Mayo on November 13, 2013 and October 28, 2014 prior to filing the YESAB submission.
3. **Other Governments:** Yukon Energy met with interested territorial and federal government departments to discuss details, potential effects, and concerns of the Project. During June 2011, representatives from the Department of Fisheries and Oceans (DFO), Yukon Government (Environment and Fisheries) and the Yukon Environmental and Socio-Economic Assessment Board (YESAB) were invited to a one-day Project introduction meeting (Whitehorse) and a two-day workshop that focused on detailed discussions on project description, valued components and fieldwork studies (Mayo).

   Yukon Energy met with Yukon Government (Environment and Fisheries) in January 2012 to discuss concerns raised by Yukon Government representatives. Yukon Energy also met with representatives from the Canadian Wildlife Service in July 2011 to discuss Project details, mainly focusing on aquatic studies and waterfowl.

   On September 7, 2012, a follow-up meeting was held for the same group of regulators that attended the June 2011 sessions. The purpose of this workshop was to provide an update on

developments of the Project. Prior to the workshop, an orientation session was held for YESAB representatives to update new members to the Mayo Designated Office team who were not familiar with this Project.

An additional workshop was held for regulators on December 19, 2013, to update participants on Project activities that had occurred since the group last met in September 2012. A follow-up session was held on January 24, 2014 for those who were unable to attend the December workshop.

Appendix 4D provides a summary of activities, presentation materials used and meeting notes produced.

4.4.3 Activities Involving Local Stakeholders and Other Publics

Consultation efforts also sought feedback from various local stakeholders, non-government organizations, and private citizens. See Appendix 4E for meeting notes and materials.

Local Stakeholders

Various key person conversations occurred during the Mayo Hydro Enhancement Project (Mayo B) consultation process in 2008. Additional follow-up focused on a resource users' workshop held in Mayo in October 2011 to further discuss key issues specific to the Mayo Lake Enhanced Storage Project. In addition, a meeting was held with local placer miners in October 2011 to discuss potential Project-related effects and concerns.

Efforts were taken to notify potentially interested publics about the consultation events associated with the Project. For example, a notification letter and newsletter were sent out to all trappers, placer miners, lease holders, and landowners in the Mayo area to inform them about the Project.

Other Publics

During the Mayo Hydro Enhancement Project (Mayo B), not all of the identified organizations/individuals with potential interest in the Project felt that holding a meeting was necessary as they had no major concerns. For this reason, consultation with other publics was based on interest shown during the 2008 public involvement process.

On July 6, 2011, Yukon Energy met with the Yukon Conservation Society as part of its public involvement process. Yukon Energy agreed to a follow-up meeting and returned to meet with the Yukon Conservation Society on October 7, 2011.

Community Dinner and Information Sessions

On June 22, 2011 Yukon Energy hosted a community meal and information session for local stakeholders in Mayo, including residents of the Village of Mayo and surrounding areas, as well as NND and MDRRC to re-engage the community on discussion focused on the Mayo Lake Project[6].

This event was designed not only to provide the current understanding of the Project and its components, but to describe what was known about potential effects to date. This event was attended by 35 community members, not including Yukon Energy employees and consultants. Attendees included

[6] Community information sessions were also held under the Mayo Hydro Enhancement Project; see previous YESAB filing for details.

representatives from the MDRRC, YESAB, local resource users and placer miners, and the community at large. Yukon Energy gave a PowerPoint presentation on studies undertaken to date. Newsletters, posters and fact sheets providing more detailed information on the Project were available at the event.

During the June community meal and information session, Yukon Energy committed to hosting a follow-up community session focused on questions and concerns identified at the June session.

The second community dinner and information session was held on October 6, 2011, which included a presentation on additional Project study information, specifically on mitigation, monitoring, and adaptive management, as well as to address concerns raised during the first public meeting. The event was attended by 36 participants including community members, representatives from the MDRRC, and town leadership (total does not include Yukon Energy employees and consultants). Materials from these events are provided in Appendix 4E.

In January 2014 at the workshop with Yukon Government and representatives from the MDRRC, a commitment was made to hold another update meeting in Mayo prior to filing the YESAB submission. An open house was held on October 28, 2014 where a series of Project posters were displayed and the Project environmental assessment team was on hand to speak to questions and concerns. The open house was attended by 17 community participants including members of the MDRRC, NND and the community at large. Materials from this event are provided in Appendix 4E.

4.5 INDEPENDENT ADVISOR REVIEW

In November 2012, the Technical Working Group (TWG) hired Dr. Drew Bodaly as an independent advisor to the TWG to provide expert advice on:

- The potential risks of long-term harm to the lake trout and lake whitefish populations and the fish community from the project;
- The suitability of the monitoring and adaptive management (AMP) plans as a means of addressing and managing uncertainties with respect to potential lake trout and lake whitefish responses to the Project; and
- The ability of the monitoring and AMP to detect unacceptable biological impacts within the context of the adaptive management plan of incremental changes over several years (as proposed by NND) in contrast to larger changes over a short period of time as included in the proposed project (as proposed by Yukon Energy).

The TWG held two workshops with Dr. Bodaly to discuss the Project and the process and expectations of him in his review and provision of expert advice (November 2012); and to review and discuss Dr. Bodaly's draft report (February 2013). At the same time, Yukon Energy's team presented a proposal for changes to the monitoring program to address concerns raised by Dr. Bodaly in his draft report which included interim methods (hydroacoustics) in addition to the originally proposed monitoring of young-of-the-year and adults.

Conference calls and email correspondence with Dr. Bodaly also occurred in a transparent manner (i.e., all members of the TWG received information concurrently). Yukon Energy's team as well as NND's team

provided comments on the final draft report prior to Dr. Bodaly's submission of the Final Report to both parties in March 2013.

Conclusions from the independent advisor process are discussed in Chapter 6. A copy of Dr. Bodaly's final report is provided in Appendix 6B.

4.6 KEY ISSUES AND PERSPECTIVES HEARD TO DATE

Participants in the public involvement activities provided a wide range of issues and perspectives over the course of consultation activities. Some concerns were very specific, while others were more general. Some similar perspectives were raised on numerous occasions, while others were only cited by a single individual or organization.

Key interests, concerns, and perspectives raised during the public involvement process to date have been considered by Yukon Energy and incorporated in the Project design and effects assessment process, where applicable and/or feasible.

Table 4-1 provides a summary of specific issues raised during the public consultation process, including issues not directly related to the proposed Project. Stakeholder concerns are documented in the meeting notes presented in Appendices 4C, 4D, and 4E.

In addition, the following list highlights some of the areas where public influence resulted in refinements to the Project.

- Project Description:
    - Yukon Energy originally proposed operating the lake with a full 1 m storage range, with unconstrained use as required on an annual basis at the start of Project approval and licensing. Through discussion at the Technical Working Group, and hearing concerns raised by regulators, MDRCC and the community of Mayo, the Project Description was amended to incorporate a more restrictive operating range at the start and following measures outlined in the Adaptive Management Plan (see Chapter 6 for a full description). This resulted in the Project being proposed with a start at a half meter lowering of the LSL to 3.09 m for the initial years of Project operation, after which the AMP would be used to determine if and how to proceed with the full metre extra storage or if the storage range should be reduced.
    - The definition and details of the Project's Monitoring Plan and the Adaptive Management Plan were iteratively revised based on discussions with the Technical Working Group, regulators and the MDRRC. In addition, due to voiced concerns about different project approaches and whether the monitoring plan and AMP were robust enough to detect change, the Technical Working Group hired an independent expert to provide his opinion on the plans (see Chapter 6 for further details on the independent review).
- Lake Trout and Lake Whitefish Concerns:
    - Yukon Fisheries had specific concerns/questions related to the study design, statistical validity of the results and the ability to detect changes in abundance of juvenile and adult

fish. As a result, Yukon Energy made numerous changes to study design and monitoring methods to address these concerns.

- Various parities indicated concern with the lack of interim monitoring of fish populations between young-of-the-year and adult life stages. As a result, Yukon Energy updated the monitoring plan to include monitoring of sub-adult fish (via hydroacoustics and small-mesh netting).
- Questions were raised regarding how Yukon Energy would react in the event of long term small reductions in fish recruitment and productivity. The Adaptive Management Plan was revised to include an evaluation that will be undertaken after several years of data collection to identify whether incremental changes are occurring.

- Beaver:
  - Concerns were raised by the MDRRC and local community members and trappers over past and future water level effects on the beaver population around Mayo Lake. Additional fieldwork undertaken as part of the 2014 studies confirmed that the current water level management regime provides limited opportunity for beavers to overwinter in the main body of Mayo Lake under the current management regime. However, there is extensive beaver habitat in tributaries to the lake (including Roop Lakes) and these areas will continue to provide suitable habitat despite water level management on Mayo Lake that will likely adversely affect beavers in the lake proper. Therefore from a regional population perspective, there will be no significant adverse effect on the regional population of beavers.

Table 4-1: Interests and Concerns Raised by Stakeholders and Members of the Public and Areas where Feedback from Public Involvement Activities was Considered in the Environmental and Socio-Economic Assessment Process

Issue/Topic	Interest/Concern Raised	Response
Access – placer claims	General concern from local placer miners regarding the difficulties with accessing the land adjacent to their placer claims when water levels are low especially in early spring.	Operation of the lake will, on average, be lower in the late spring prior to the freshet. However, this often coincides with ice still being on the lake, thus preventing access to properties around the lake. In years when the ice has melted early, access may be affected for a short period of time (i.e., two weeks or less).
	Interest in the possibility of compensation for local placer claims.	Means of mitigating access delays to the lake will be mitigated by access improvements if the project creates significant adverse effects. This may include facilitating discussions with DFO around creation of rock groins and/or landings at claim shoreline.
Access – barge landing, boat launch, individual properties	Local resource users of Mayo Lake expressed interest in either relocating (beyond Ping Pong Creek) or replacing (closer to the main channel) the existing barge landing.	Access delays to the lake will be mitigated by access improvements in the channel if the project creates significant adverse effects.
	General concern was expressed regarding the proximity of the existing boat launch to the Mayo Lake Control Structure. The current location poses a potential safety issue for anyone caught in a current and their engine fails.	Dam safety boom was installed upstream of the Control Structure to ensure boating safety in this regard.

Issue/Topic	Interest/Concern Raised	Response
	It was indicated that for two consecutive years (2010, 2011), it was difficult getting barges to the landing due to lower water levels. There is concern that drawing the lake down further will exacerbate these issues and cause them to occur more frequently.	In general, the lake will be operated at a lower elevation (closer to the new Low Supply Level) on an annual basis. In particular, the lake will be drawn down during the winter months, when there is still ice on the lake. The period of time that water levels are expected to be at their lowest is relatively short, often when ice is still on the main lake, and right before lake levels rise with the spring freshet. Access delays to the lake will be mitigated by access improvements in the channel (e.g., improved boat launch, barge landing) if the project created adverse effects.
	It was indicated that at lower water levels, remaining tree stumps are present in the outlet channel causing safety issues (e.g., near the boat launch and barge landing).	If dredging of the outlet channel is undertaken, a deep water channel will be restored. This will facilitate easier access. If other mitigation is required, tree stumps near the boat launch and barge landing could be removed at the time of dredging to ensure easier access within the channel. Yukon Energy will consult with NND, the Village of Mayo Council and MDRRC on whether tree stump removal is required.
Adaptive Management	Defining adaptive management (e.g., what does Yukon Energy mean by adaptive management).	Adaptive Management is a decision process that involves learning by doing where there is minimal risk of serious, irreversible harm from a management action. It is not a 'trial by error' process. In the event that a change occurs in the lake that extends beyond natural variability and results in substantive adverse effects to the valued component, Yukon Energy will respond by implementing the Adaptive Management Plan, which is dependent on annual monitoring results.

Issue/Topic	Interest/Concern Raised	Response
	Several stakeholders expressed concern that Yukon Energy could have the ability to change the Adaptive Management Plan to favour its own interests.	Regulators (YWB and DFO) have the legal mandate for water management and fish habitat management respectively and will make the ultimate decision in approving the overall Project, including whether the Project can be implemented and under what conditions. Yukon Energy expects that the Adaptive Management Plan will be entrenched in their water licence, which will require the corporation to follow the plan. The Mayo Lake Project Management Committee (MLPMC) will be formed as a result of this Project and will include representatives from Yukon Energy and NND with an Advisory Group which may be comprised of the MDRRC and regulators (YG-Fisheries and DFO) (see Appendix 8B).
Adaptive Management Plan – reporting and decision-making	Concern was expressed by the Mayo District RRC over timely access to information and involvement in decisions.	If the Project proceeds, Yukon Energy will work with NND, MDRRC, stakeholders, and regulators during the monitoring and adaptive management processes to review results. This includes an annual meeting with the MDRRC to report on monitoring results and provide opportunity for local and Traditional Knowledge observations and input. The AMP provides for a cooperative oversight committee, independent monitoring and analysis, external reporting to regulators, the MDRRC and the public, and consultative decision-making regarding changes to the project that may be necessary over time. All results will also be available in annual reports that will be publicly available.

Issue/Topic	Interest/Concern Raised	Response
Alternatives to the Project	Has Yukon Energy considered raising the lake instead of lowering it?	Yes, raising water levels at Mayo Lake was considered during the early stages of assessment. However, it was found that raising the lake would impact heritage resources, increase erosion activity at the west end of the lake and encroach on NND settlement lands. For these reasons, this alternative was rejected. The following illustrate the assessment conclusions – for more detail, please see Appendix 5D (heritage) and 5B (erosion). **Heritage** If the lake level was increased, the heritage assessment indicated that all resources with elevations of 2 m (or within active erosion) would likely be impacted by current and increased wave action and soil loss. **Erosion** In general, raising the FSL by 1 m is expected to result in increased bluff recession rates, particularly at locations that are undergoing active bluff recession under existing conditions (bluff recession rates may return to current rates, or even reduced rates due to increased wave energy dissipation caused by a higher water level fluctuation range across a wider near-shore slope).
Climate Change	A general concern regarding the effects climate change is having on Yukon's bodies of water. It was suggested that creeks are already drying up and water levels are lower than in the past, resulting in fish dying.	Drought years are likely to occur but rules will be instituted to regulate the operation of the lake. Management of the lake will be adjusted while adhering to the rules to account for effects related to climate change. As noted in Chapter 7, Effects on the Environment on the Project, climate change models are predicting increased precipitation. Impacts to VC's from climate change will be detected through ongoing monitoring and adjustments made to water management as prescribed in the Adaptive Management Plan.
Confidentiality/Site Sensitivity	Discussions occurred regarding the Project Proposal potentially revealing information on "good fishing" or "great hunting" locations.	Yukon Energy is sensitive about disclosing information on specific sites used for resource activities in order to protect fish/wildlife. The District Office has rules and processes for keeping information confidential. For this reason, and following the rules established, Yukon Energy will discuss with YESAB that any reports containing this sensitive information be kept confidential.

Issue/Topic	Interest/Concern Raised	Response
Costs and Benefits	Concern that benefits from the Project will not be experienced by ratepayers, but instead be absorbed by Yukon Energy.	As discussed in Chapters 6 and 7 of this application, project benefits are expected to be realized by all utility ratepayers when new industrial loads and on-going domestic load growth can be serviced through additional renewable generation capacity on the system. There will be long-term benefits of providing a lower cost (relative to diesel generation) renewable energy and improving grid reliability. Project effects are expected to be positive, long-term, moderate in magnitude, and expected to extend to the whole of Yukon.
	Concern that the Project will only increase costs for ratepayers.	This Project does not involve any capital costs as there is no associated construction activity; the only cost is associated with the assessment and regulatory process. There will be greater cost to ratepayers if this project does not proceed as Yukon Energy will have to use more expensive diesel generation to meet the demand.
Ducks, Geese and Migratory Birds	Concern about effects on nesting and staging areas at the ends of Roop and Nelson arms with the lower water levels. Will the amount of habitat in the early spring at ends of Roop and Nelson arms change at the time when waterfowl require this habitat.	With the Project, water levels will on average, be lower during the spring. In some years, this may result in changes in the availability of staging areas for migratory birds at the ends of Roop and Nelson arms which are open relatively early during the spring. It is expected that suitable staging habitat will remain in these areas; however, there may be shifts in the relative amounts of habitat types (mudflats, shallow water, deep water). It is expected that the end of Nelson Arm will see less shallow water areas (<2 m) and more mudflats and the end of Roop Arm will see a more shallow water habitat (<2 m). Other wetlands in the region (including Roop Lakes) will not be affected by water level management on Mayo Lake and will continue to provide suitable staging area for migratory birds (see Appendix 5A for more detail).
Effects of the Project on Other Yukon Lakes	Questioned if Wareham Lake is expected to be lowered an additional metre with a 1 metre drawdown at Mayo Lake.	The Mayo Lake Enhanced Storage Project will not affect licenced water levels at Wareham Lake. Wareham Lake has its own regulated levels for the purpose of power production at nearby power plants.

Issue/Topic	Interest/Concern Raised	Response
Erosion	Concern related to erosion occurring on the west-end banks of the lake and the potential for the Project to intensify this problem.	Yukon Energy expects average lake levels will be lower by approximately 0.2 to 0.5 metre during the most prominent windy season (October) on average as a result of the Project, which will help reduce the process of erosion (see Appendix 5B – Appendix 6 of the Erosion Summary Report states that lowering the lake by up to 1 m is "expected to result in lower shore erosion rates for the lower license limit simulation as compared to the base case" (which is the existing conditions)). Any potential re-suspension of sediment that may occur (particularly in areas that have not been typically exposed under current conditions) will be monitored post-Project through turbidity loggers (see Appendix 8A – Monitoring Plan).
	It was suggested that Yukon Energy was not doing an adequate job at reacting to existing changes in Mayo Lake, particularly related to erosion issues. The Mayo River is now experiencing erosion issues and no actions have been taken, causing the problem to only get worse.	As stated above, Yukon Energy expects average lake levels will be lower by approximately 0.2 to 0.5 metre (on average) as a result of the Project, which will help slow down the process of erosion on the lake. Any erosion issues related to the Mayo River are not solely attributable to water levels on Mayo Lake. There are considerable uncontrolled inflows between Mayo Lake and Wareham that affect erosion processes along the river. In addition, weather patterns (wind action), amount of precipitation and natural variability in river channels are factors in changing erosion. With the Project late winter flows in the Mayo River would increase relative to historic, but are well below peak spring/summer flows and are not expected to result in any adverse changes to existing erosive forces in the River.

Issue/Topic	Interest/Concern Raised	Response
Existing Water Licence	Several stakeholders questioned Yukon Energy's ability to assess the implications for fish populations given that they have not consistently used the full 2.59 metre range (existing licence) in the past. How can Yukon Energy know what will happen to the fish (and resource use activities) if Mayo Lake is drawn down an additional metre?	The index netting survey conducted in 2010 included the collection of data on older age classes of fish, some of which originated in years with drawdowns greater than 2.0 m. Since baseline studies began during 2008/2009, Yukon Energy has drawn the lake down more than 2.0 m in 2 out of 6 years and the minimum lake elevation during late winter has been below 2.0 m in 5 out of 6 years. Data collected on juvenile fish during these years has not indicated that the current water level management regime is negatively affecting juvenile fish survival and recruitment. For example, the 2012 year class of lake trout and lake whitefish showed the highest abundance since baseline studies began and during this year, the winter drawdown was 2.02 m and the minimum late winter elevation was 2.01 m below FSL.
Fish Passage (at Mayo Lake)	Interest was expressed regarding the potential to introduce a fish ladder, as a form of compensation, to help address connectivity issues between the Mayo River and Mayo Lake. There was also concern that the fish passage may never be built as it has been discussed in the past with no follow-up action.	Yukon Energy commissioned a sub-working group to conduct studies on Chinook salmon enhancement and a Mayo Lake fish passage at the Mayo Lake control structure. The current control structure will require replacement in the future. Over the next few years, Yukon Energy will need to undertake an economic and operational analysis to determine whether proceeding with passage before reconstruction (targeted for 10 yrs. +) would be a wise use of resources and a prudent expense to pass on to rate payers.
Furbearers (beaver, muskrat, otter)	Questions were asked regarding the effects of low water levels on furbearers and if Yukon Energy has conducted any studies to assess these effects.	Furbearers were part of the original Mayo B assessment; in addition, surveys of beaver lodges around Mayo Lake were completed in 2011 and 2014.

Issue/Topic	Interest/Concern Raised	Response
	Question about potential mitigation for beaver near Mayo Lake.	Through surveys of Mayo Lake during 2011 and 2014, a total of 14 beaver lodges were located on the shoreline of Mayo Lake. During the 2011 survey, there were two active lodges in the main body of Mayo Lake and 3 active lodges outside of the influence of the lake (Nelson and Roop watersheds). During the 2014 survey, one lodge was active and although not surveyed during 2014, the lodges in Roop and Nelson creeks are known to be active in the previous 3 years. It is possible that there may be some localized effects to beavers in the main body of Mayo Lake during years with larger drawdowns and/or lower spring water levels. This will likely result in the abandonment of beaver lodges in the main body of the lake in favour of more suitable overwintering habitats in tributaries to the lake. This issue was reviewed in the impact assessment from a regional perspective. Beaver is a regional species with habitat elsewhere within the Mayo Lake tributaries and upper Mayo River areas. Yukon Energy has determined that although the effect on beaver in Mayo Lake may be negative, it is not a significant adverse effect within the regional population.
	Interest in what effect additional drawdown from the Project would have on furbearers in the area.	It was noted that throughout consultation, beavers appeared to be the main furbearer concern in the area, given that other species are generally adaptable and use the Roop wetland system. There is a possibility that effects of the Project could exclude beaver from accessing their lodges/food caches in the main body of Mayo Lake and result in higher mortality rates due to increased predation. It is expected that any potential effects from a regional perspective would be insignificant; however, the effect on the local number of beaver immediately along the shoreline will be affected. The full range of the lake will not be used every year as Yukon Energy is committing to a 1-in-3 rest rule (see Chapter 6 for details), which will help alleviate some of the stress on beavers in Mayo Lake.

Issue/Topic	Interest/Concern Raised	Response
General concerns about the Project and Project Approach	Community consultation events in the summer and fall of 2011 showed an overall negative reaction to the Project, particularly the potential adverse effects on various environmental values.	Yukon Energy spent considerable time and effort on additional aquatic fieldwork and study in 2012, 2013 and 2014 to be able to better understand Project effects. In addition, the Technical Working Group worked through changes to the Monitoring Plan and the Adaptive Management Plan (AMP) to be more responsive to thresholds. Perhaps more importantly, the project design was changed to lowering the Low Supply Level (LSL) by 0.5 m for the initial years of the Project operation – resulting in a storage range of 3.09 m (the original is 2.59 m), after which the AMP would be used to determine if and how to proceed with the full metre extra storage (i.e., lowering the LSL to 3.59 m) or if the storage range should be reduced.
Lake Trout and Lake Whitefish	Most lake trout spawn at depths of more than 2.0 m, how will the Project affect egg survival?	Egg collector data collected from 2009 to 2014 indicates that the highest egg deposition is at depths of 2.0 – 3.5 m based upon the water level at the time of spawning. Four years of egg incubation studies have been conducted to determine how winter drawdown influences over winter egg survival. The results of these studies have indicated that lake trout eggs are resilient and some survival is possible despite being dewatered for a period of time during winter. For survival to occur, the eggs must be rewatered prior to ice off at the spawning area (during early June). Using this information, we have modelled the effect of the increased storage range on egg survival to help understand Project effects (see Appendix 5A for further detail).

Issue/Topic	Interest/Concern Raised	Response
	No matter what mitigation is undertaken by Yukon Energy, there will still be some decrease in (lake trout) egg survival.	It is possible that there will be some decrease in egg survival during some years; however, this does not mean that there will necessarily be corresponding declines in abundance of juvenile and older lake trout during such years due to density dependant factors and influences of other environmental factors. There will be a thorough monitoring and adaptive management plan in place to ensure that the effect of water level management does not reduce the long term sustainability and health of fish populations in the lake. In the case of lake trout, this includes a suite of monitoring methods to track the species at a variety of ages including: egg survival, young-of-the-year, large juveniles and adults. The monitoring and adaptive management plans ensure that effects, positive or negative, will be quickly detected and water level management adjusted as necessary to address unacceptable effects before long term harm could occur.
	Annual monitoring will only pick up catastrophic declines in survival.	Substantial improvements have been made to the monitoring program to ensure that there is an increased ability to monitor smaller changes in fish abundance and year class strength. Refer to a separate document for more detailed information on the power of the monitoring methods to detect change (see Appendix 5A for further detail). The AMP (Appendix 8B) also includes clauses aimed at monitoring long term small reductions to lake trout and lake whitefish recruitment. The proposed monitoring and AMP approach was reviewed by an independent technical expert who confirmed that with the approach proposed there was minimal risk to fish populations.

Issue/Topic	Interest/Concern Raised	Response
	When Yukon Energy does index netting again in 15 years, there is no way it will be sensitive enough to pick up effects of small ongoing declines in reproduction success and juvenile survival. Yukon Energy can set lots of thresholds for monitoring data, but they need to convince us that they can pick up anything other than a catastrophe.	The monitoring program has been updated to include a combination of SPIN and index netting to monitor adult fish populations. SPIN provides a more sensitive and timely method to track smaller changes in long term adult lake trout numbers. The addition of hydroacoustics (sonar) to the monitoring program will provide a more sensitive and timely method of monitoring older juveniles and sub adults (3 to 8 years old) with the ability to detect smaller changes in fish numbers (see Appendix 5A for further detail). Through the analysis of multiple sources of monitoring data, it will be possible to detect and address small ongoing declines of fish stocks in the lake. Very detailed data analysis and statistics have been conducted using the monitoring data to show the smaller changes in fish abundance and year class strength can be detected (see Appendix 5A for further detail). The AMP (Appendix 8B) also includes clauses aimed at monitoring long term small reductions to lake trout and lake whitefish recruitment.
	Will the amount of shallow water habitat in the early spring at ends of Roop and Nelson arms decrease at the time when juvenile whitefish require this habitat?	Using modelled lake elevation data, Yukon Energy has modelled the amount of shallow water habitat available at the ends of the arms during the spring (see Appendix 5A for further detail). During some years, there will be a decrease in this type of habitat at the end of Nelson Arm; however, there will be an increase in the type of habitat at the end of Roop Arm in most years. While the relative importance and productivity of this shallow water habitat in the two arms is not well established, the influence of water levels on lake whitefish rearing will be a key focus of the monitoring program to ensure that both Roop and Nelson arms continue to produce lake whitefish.
Local and Traditional Knowledge	A suggestion was made to include more local and traditional knowledge in the monitoring plan.	Yukon Energy has revised the monitoring plan to include ongoing collection of local observations across many aspects of the plan through regular MDRRC and community meetings. Collaborative review and discussion of the monitoring program results by all parties will bring together scientific, local and Traditional Knowledge to understand/interpret the results.

Issue/Topic	Interest/Concern Raised	Response
Mayo River – lower section	Concerns over existing winter flow issue (i.e., flooding and icing issues) within the Village of Mayo.	Changes to water management respecting winter flows will not proceed until resolution of the lower Mayo River winter flow issue is satisfactorily resolved.
Mayo River – upper section	Concerns over higher flows down the upper Mayo River, resulting in access issues for undertaking traditional and recreational activities.	With the Project in place, water flows in the upper Mayo River will be similar to the current regime during the majority of the year. Flows during the spring and early summer will on average be slightly lower due to the freshet being used to refill Mayo Lake. Summer, fall and winter flows will be very similar to the current regime with the exception of the late winter where the mid-winter flows will persist later into the year as a result of the increased storage range being used on Mayo Lake. Under the current regime, the late winter flows are often relatively low as the storage range is used up on Mayo Lake, and the flows are typically reduced to ensure that Mayo Lake does not go below the low supply level. A large proportion (approximately 40%) of the overall flow in the upper Mayo River originates from uncontrolled inputs from tributary streams including Duncan and Davidson creeks. Given the seasonal timing of these changes and the influence of uncontrolled flows from tributary streams, issues related to access along the river are not expected to occur as a result of the Project.
Moose	Are there anticipated effects to moose as a result of the Project?	Water level management on Mayo Lake may affect shallow water littoral habitat and shoreline vegetation, particularly at the ends of Roop and Nelson arms which are used as summer moose habitat. Effects to habitat are most likely to include a shift away from the moose's preferred aquatic plant forage (tall erect plants) to less desirable short plants. This effect is highly localized to the ends of Roop and Nelson arms and is determined to be not significant due to the large range of moose and the availability of other more productive habitats in the region which are not influenced by water level management on Mayo Lake (i.e., Roop Lakes).

Issue/Topic	Interest/Concern Raised	Response
Overall Health of Mayo Lake	General inquiries on the overall health of Mayo Lake compared to other Yukon Lakes.	The results of baseline studies conducted to date indicate that lake trout and lake whitefish populations are currently healthy (see below) and their abundance is within the range of other similar Yukon lakes. Based on the 2010 index netting data, there is no evidence of recruitment failure for either species and although there is some variability in year class strength and some evidence of cyclic patterns, these patterns are within the range observed in other Yukon Lakes based on similar index netting surveys during the 1990's and not appear to be tied to water level management. Species composition results from the 2010 index netting survey on Mayo Lake indicate that LT represent 40 percent of the total catch by number and 53 percent by weight while the values for LW are 47 percent of the total catch and 30 percent by weight. While highly variable between lakes, these values are within the range of other large Yukon Lakes based on index netting surveys conducted during the 1990's. In other large Yukon lakes, the abundance of these two species typically represents 80-90 percent of the fish community. The SPIN (Summer Profundal Index Netting) survey results from 2013 indicate that the CPUE and density of lake trout in Mayo Lake is relatively low but within the range of other large Yukon lakes with similar fish communities. Note there are few large/deep lakes that have been surveyed to date that are comparable to Mayo Lake. Both LT and LW populations in Mayo Lake are considered healthy based on good abundance of both old and young fish indicating regular and continuing levels of recruitment and survival to the adult stage under the past water management regime, which is indicative of healthy populations.

Issue/Topic	Interest/Concern Raised	Response
Other Fish Species	Interest was expressed in potential effects on other fish in the lake such as lingcod (burbot) and pike. There was concern that all of the attention was being focused on lake trout and lake whitefish.	Lake trout and lake whitefish were chosen as key focal species because they appear to be the most sensitive to water management change; and as the predominant predator and prey species are the main drivers of the fish community and lake productivity and ecology. The monitoring methods being used to monitor lake trout and lake whitefish will also collect incidental information on other fish species which may be used to monitor these populations over the long term.
	Concern that other fish species may not be able to access their spawning habitat in the Roop area under lower water conditions.	During field investigations, EDI has always observed a stream channel that connects the Roop Lakes area to Mayo Lake.
Public Consultation	During the June 2011 public open house, it was suggested that there was a need for better advertising of public events and that key methods of contact were not effective.	Yukon Energy has tried to address this concern for its open house held in the fall of 2011 and the fall of 2014 by working more closely with the MDRRC.
Recreational Activities (hunting, fishing)	Several local resources noted that Mayo Lake was experiencing an increase in harvesting activities. Ethel Lake has suffered from the effects of over-harvesting and resources users would not like to see the same happen to Mayo Lake. All lakes in the area are currently being over hunted. In the past, MDRRC have put restrictions on particular lakes to reduce hunting activity.	Yukon Energy is not responsible for managing harvesting activities. However, the assessment acknowledges the importance of understanding and monitoring fishing pressure and harvest and YEC is proposing to work with the MDRRC and the community of Mayo in this regard. The Project's monitoring plan includes a fish harvest study one year Pre-Project and then every 5 years post-Project. This harvest study will provide a measure of fishing pressure and harvest which will be used as supplementary data when analyzing changes in adult lake trout abundance over time.
Regional Economy	If Yukon Energy wants to lower water levels then power rates should be lowered as well for residents of Mayo.	Yukon Energy does not set rates based on increasing or decreasing water levels; rather on loads on the overall system. All rates are regulated by the Yukon Utilities Board.

Issue/Topic	Interest/Concern Raised	Response
Roop Lakes	Interest in KGS study on backwater effects.	KGS prepared a study on backwater effects in the Roop wetlands. A one-dimensional backwater model was developed along the reach of Roop Creek from Mayo Lake to approximately 7 km upstream to understand the backwater effects caused by Mayo Lake levels on the Roop lakes and creek in the wetlands area. A sonar survey, along with cross-sections of Roop and Edwards creeks and a water profile of Roop Creek were undertaken. Also, a variety of Mayo Lake water levels and Roop Creek flows were analyzed. It was determined that when water levels in Mayo Lake are high, there is a backwater effect on Roop Lakes which is more pronounced closer to Mayo Lake. When water levels in Mayo Lake are lower, there is no backwater effect and water levels in Roop Lakes act independently from Mayo Lake. With lower water levels anticipated as a result of the Project, Roop Lakes will be backwatered less frequently which will be more similar to pre-impoundment conditions. A copy of this study can be found in Appendix 5A.
Sharing of Information/ Project Communication		To address community concerns identified by NND and the MDRRC, Yukon Energy will designate a Project Liaison Contact person if this Project proceeds.
Trapping	Is Yukon Energy considering compensation for trappers?	Access to trapping activities at Mayo Lake will not materially change with the Project.

4.7 FUTURE STEPS IN PUBLIC CONSULTATION

Yukon Energy will make efforts to continue communication with stakeholders about the filing of its submission to YESAB through the Mayo Lake Enhanced Storage Project tab on its website. Opportunities for public engagement are also provided for during YESAB's review of the Project proposal.

5.0 ENVIRONMENTAL AND SOCIO-ECONOMIC SCAN

This chapter provides a high-level environmental and socio-economic scan of relevant conditions in the vicinity of the Project, as required to address items set out in the Proponent's Guide Section 6.0, Description of the Existing Environment and Socio-economic Conditions. It is comprised of a summary of existing and known evolving conditions in respect of the following:

- Overview;
- Environmental Conditions;
- Socio-Economic Conditions; and
- Existing and Planned Developments.

5.1 OVERVIEW

The Mayo Lake Enhanced Storage Project is proposed to occur within an existing environmental and socio-economic setting that has seen considerable development and activity over a sustained period of time. Of particular note, a dominant feature of the existing conditions arises from the presence and operation of the existing Mayo Lake control structure. This facility was constructed in the early 1950s, retrofitted in 1988/89 and is currently owned and operated by Yukon Energy. It has been in operation for over 60 years (see Figure 5-1).

Figure 5-1: Mayo Lake Control Structure

The existing conditions provide key inputs for the selection of valued components, for the baseline analysis of each valued component (VC), for determining relevant projects to be considered in the cumulative effects assessment, and for the assessment of Project effects, cumulative effects and mitigation, which are detailed in Chapter 7.

Chapter 3 of this Project Proposal sets out the key geographic areas of focus for the assessment work.

Further detail in respect to the existing conditions is provided in the reports contained in appendices associated with Chapter 5 as follows:

- Aquatic Existing Conditions – Appendix 5A;
- Terrestrial Existing Conditions – Appendix 5B;
- Socio-Economic – Appendix 5C; and
- Heritage Resources – Appendix 5D.

5.2 EXISTING ENVIRONMENTAL SETTING

The Mayo region is situated within the Boreal Cordillera ecozone and is bordered to the north by the Wernecke Mountains and by the Stewart Plateau to the south. To the west of the Stewart Plateau is the Tintina Trench, a linear, geological fault and large valley. The topography around Mayo is characterized by tablelands and rolling uplands with wide u-shaped valleys (Smith et al 2004).

Vegetation and wildlife habitat around Mayo are influenced by elevation, slope, aspect, precipitation, fire cycles and permafrost. The following sections describe the general physiography, surficial geology, soil conditions, and climate of the Mayo region, as well as vegetation, fish and wildlife, and water resources in the area.

5.2.1 General Physiography, Surficial Geology/Soil Conditions and Climate

Mayo sits in the Selwyn Basin, a geological region characterized by chert, shale, and schist, which transects the Yukon, parallel to the Tintina Trench (Roots 2006). The Selwyn Basin has several granite masses with nearby gold-tipped veins rich in silver, lead, zinc and quartz. The mountains in the area are sedimentary and metamorphic rock, underlain and case-hardened by granite (Roots 2006).

In the Quaternary ice age, parts of central and western Yukon were uncovered by ice, and formed a cold, dry habitat corridor known as Beringia. Fossil evidence from Beringian flora and fauna are found around Mayo and present-day descendants of plants and animals from Beringia exist in the region (Burn 2006a). More recent glaciations which left deposits of sediment and moraine in the Mayo area were the McConnell glaciation and the Reid glaciation (Burn 2006b).

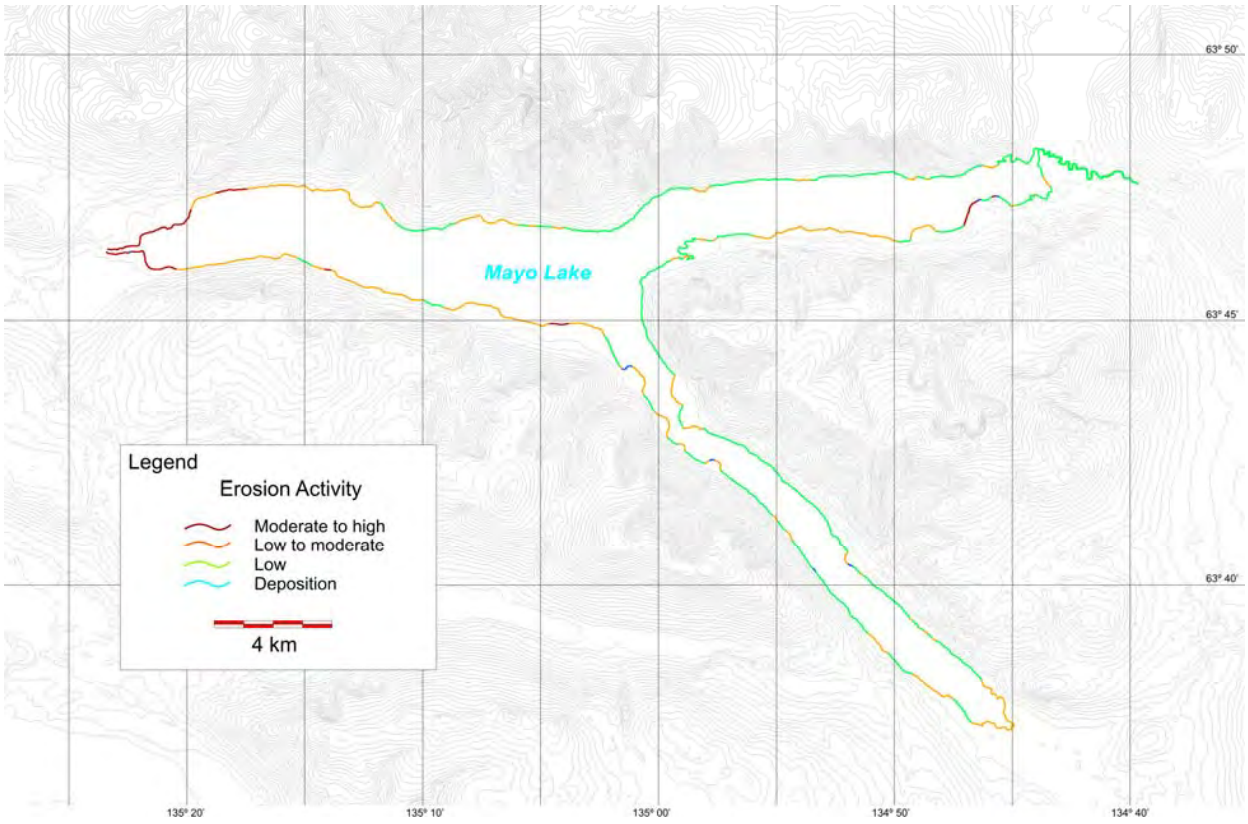
The Mayo region is underlain by discontinuous permafrost, which covers 50% to 90% of the ground below the active layer. The permafrost layer can thaw and cause sinking or slumping of the active layer (Burn 2006c).

The Mayo area is relatively dry and experiences extreme temperature variations and temperature inversions, where the higher elevations can be warmer than low lying valleys. There is relatively little

wind, save at higher altitudes. Average monthly temperatures measured in Mayo between 1904 and 2001 are -25.8°C for January and 15.4°C for July. About 42% of the precipitation in Mayo is snowfall, which begins sporadically in the late fall and leaves about 40cm on the ground by March. The melt period occurs primarily in May, and lakes and rivers in the valley bottoms flood in May and June. The summer is generally a season of higher precipitation than the spring, due to evaporation from lakes and transpiration from vegetation. April has an average monthly precipitation of 11.0mm, while the average for August is 47.1mm (Burn 2006d).

Mayo Lake was raised approximately 5 m (or 16.5 feet) when the original Mayo Lake control structure was built and began operation in 1952, flooding the adjacent shoreline and the lower portion of the Roop Lakes wetland complex. The flooding changed the habitat in areas flooded as well as the shallow littoral habitat within the lake (i.e., fish spawning and shallow rearing areas). Trees were not removed prior to inundation and standing dead trees remain in some sheltered areas of the lake. Flooding of the lake likely increased shoreline erosion and destabilization for a period of time. New shorelines that were more stable would have developed over much of the lake as a result of these erosion processes. Preliminary analysis of existing erosion conditions on Mayo Lake using topographic maps, photos and video evidence of the lake's shoreline areas indicates that the majority of the shoreline is characterized by relatively low bluffs that experience relatively low rates of erosion. About 26% of the shoreline has hard surfaces such as bedrock, which experience very slow rates of erosion (Refer to Appendix 5B). The remainder of the shoreline consists of varying types of sediment materials that are more susceptible to erosion, depending on water level and wave conditions. There is a wide range of materials in this remaining shoreline, including coarser sediments that are less susceptible to erosion, and fine-grained materials that are highly susceptible to erosion. The shoreline areas most susceptible to erosion on Mayo Lake are the bluffs at the west end of Mayo Lake. See Figure 5-2 for locations of shoreline areas most susceptible to erosion. Appendix 5B provides a more detailed analysis of existing shoreline conditions.

Figure 5-2: Erosion Conditions along the Mayo Lake Shoreline



Produced by J.D. Mollard and Associates Limited, 2008.

5.2.2 Water Resources and Aquatic Species in the Region

5.2.2.1 Water Resources

Hydrology

The Mayo River is located in the Stewart River basin that drains into the upper Yukon River. The headwaters of the Stewart River originate in the Wernecke and Hess Mountains. In the Project Regional Study Area, the Mayo River drains Mayo Lake, before flowing into the Stewart River just southwest of the Village of Mayo. Mayo Lake itself is fed by numerous creeks and tributaries, the largest of which are Roop and Nelson creeks, which flow into each respective arm (i.e., Roop and Nelson arms). Roop Creek has a large wetland area (Roop Lakes Wetland) just to the north of Roop Arm. Edwards Creek, another major tributary, flows into Roop Creek immediately upstream of Mayo Lake. Other smaller tributaries include Anderson, Granite (tributary to Roop Creek), Ledge, Cascade, Ping Pong, Steep and Owl creeks.

The peak discharge of water into the Stewart River drainage system occurs in May and June from snowmelt. Inflows slow considerably in July and August (depending on the year). There is relatively little natural lake storage in this region during the peak discharge. After the ground freezes in late fall and the surface is covered with snow, deep groundwater is the only ongoing source of water. Mayo Lake is typically ice covered by late November or early December and the lake is not completely ice free until

early or mid-June. The areas near the ends of Roop and Nelson arms, the narrows on Nelson Arm and the lake outlet begin opening up in early to mid-May.

Water levels on the Stewart River tend to peak between May 17th and June 25th, at times resulting in floods of low lying areas in the river's floodplain. Sediment loads in rivers are lowest in winter and highest during the spring runoff season. Freeze-up begins in October and is usually complete in December (Burn 2006e).

Flows in the Mayo River downstream of Mayo Lake are partially regulated by Yukon Energy for the purposes of power generation. Water levels on Mayo Lake are modified by the permitted operation of Mayo Lake as a storage reservoir, and releases are regulated by Yukon Energy except when the lake is at or above the licenced Controlled Maximum Level. Up to one-third of the Mayo River inflows to Wareham Lake come from uncontrolled local inflows downstream of Mayo Lake with natural unmodified seasonal flows. As a result, the lower Mayo River is still influenced by a notable spring freshet particularly due to inflows from two larger tributary streams (Duncan and Davidson creeks) located between Mayo and Wareham lakes.

Groundwater

The Project Regional Study Area currently experiences an active water table that results in groundwater exchange with surface water sources such as the Mayo River and Mayo Lake, and causes groundwater upwelling into back channels in many areas surrounding the Mayo River. During spring, summer and fall, groundwater can provide a cooling influence on surface water sources. In the winter, groundwater provides a warming influence that can keep areas of river environment from freezing. As a result, winter open water occurs in places on the local rivers, including the Mayo River. This groundwater effect can be seen by winter open water occurring in areas where the current is not otherwise fast enough to prevent ice from forming.

The lower portion of Edwards Creek, which empties into Roop Creek near Mayo Lake, does not freeze completely and as such, the stream can be difficult to cross during the winter months. The rest of the Roop Lakes area experiences extensive ice coverage, although small areas of groundwater discharge have been observed throughout the wetland complex. Open water was also noted in Granite Creek near its outlet to Roop Lakes, which may be an indication of groundwater inputs (EDI 2009).

Aerial monitoring of winter snow cover across the Project Regional Study Area during 2008 showed many areas in the main river channel and in back and side channels where groundwater had melted surface snow and ice, indicating the possible presence of groundwater influences in the specific location. Other areas with indications of groundwater influence are seen in the lower Mayo River (downstream of the Wareham Dam), as well as a high level of open water occurring near the outlet of Edwards Creek and a few small areas at Roop Lakes (EDI 2009).

See Appendix 5A for a more detailed discussion of groundwater in the Project Region.

Water Chemistry

Lakes in the Mayo region tend to have a neutral pH, buffered by calcium carbonate, which originates from local bedrock. Mayo Lake pH and nutrient levels in lakes in the region are generally low and overall

productivity is limited by lake size and depth (i.e., the amount of wetlands and shallow littoral area). Nitrogen levels are low and phosphorous levels are low to moderate in Mayo Lake making it less productive thus less capable of supporting zooplankton and phytoplankton (oligotrophic). These measures are within the range of other Yukon lakes in terms of productivity (Shortbreed and Stocker 1983).

5.2.2.2 Aquatic Species

The water bodies around Mayo are habitat for Chinook salmon, which are anadromous (i.e., they spawn and spend the first year of their lifecycle in freshwater before migrating to the ocean) as well as resident fish species, which complete their entire lifecycle in freshwater. Chinook salmon migrate up the Yukon River from the ocean and reach the Stewart and Mayo Rivers by mid-July/August. They spawn in tributary clear streams to the Stewart on gravelly river bottoms. The alevins hatch in the late winter/early spring and survive on their nutrient-rich yolk sacks for weeks until spring breakup and warming streams become more productive. Fry (yolk sack used up) can move into tributaries and smaller creeks and clearer larger streams to feed in the spring and summer. They rear in freshwater for a year before migrating down the Yukon River to the ocean. In four to seven years, Chinook salmon return as adults to the same rivers and creeks to spawn, and die shortly afterwards. The McQuesten River and the lower Mayo River (below Wareham Dam) are prominent spawning locations in the Stewart River Watershed. Historically, Chinook utilized all of the Mayo River (not just the lower portion). Access to the Upper Mayo River and Mayo Lake has been blocked by the Wareham Dam. Some Chinook reach the headwaters of the Stewart River upstream of Mayo, however, many do not get farther than Fraser Falls, about 60 km upstream of the village (O'Donoghue 2006a).

Lake trout, a non-anadromous char, live in the deepest, coolest lakes of the Mayo Region, including Mayo Lake, Janet Lake, Williamson, Minto, Ethel, Big Kalzas and Little Kalzas. They generally spawn in September on steep, wind exposed rocky shoal lake bottoms and hatch in the spring. Juveniles grow slowly and do not reach sexual maturity until they are between 10 and 12 years old. They can weigh over 25 kg, and are piscivorous, in that they mainly feed on fish including whitefish. Lake trout do not die after spawning and have a long lifespan of 30 – 40 years of age and may spawn 10 to 20 times or more in their life. Because Lake trout have high longevity and survival rates they often do not spawn every year, which allows them to divert energy resources into growth. In some lakes, the adults feed on aquatic invertebrates and remain smaller in size, and develop a reddish flesh (O'Donoghue 2006a). Lake trout are considered a sport fish and are often the primary target by anglers in Yukon.

There are six species of non-anadromous fish in the whitefish family around Mayo, including lake whitefish and round whitefish, which live in most lakes, larger rivers and creeks in the region. Least cisco are a smaller whitefish species that is found in some lakes and rivers. The inconnu is the largest whitefish in the region, and tends to live in rivers and is found in the Stewart and Pelly rivers, but is not very abundant anywhere. Broad whitefish are widely distributed in the Yukon River watershed including the Stewart and Pelly Rivers, but are not abundant anywhere. They are known to migrate relatively far to spawn, and to over-winter in larger water bodies (O'Donoghue 2006a). Pygmy whitefish are a small species of whitefish typically found in deep-water habitats of large lakes. Lake, round and pygmy whitefish are the only whitefish species currently present in Mayo Lake. Historic reports of 'lake herring' in Mayo Lake have lead to speculation of a historic occurrence of cisco in Mayo Lake (de Graff pers comm 2011).

Arctic grayling are also common in the watercourses around Mayo, especially in clear water streams. They spawn shortly after ice out during the spring in areas of moderate current and gravel/cobble substrates (McPhail 2007). While they are found in lakes (including Mayo), they are most prominent in clear water streams including tributary streams to Mayo Lake such as Roop, Edwards and Nelson creeks.

Northern pike are common in the Mayo area, especially in lakes and slower moving streams. They prefer shallow, warm weedy bays and areas, and lake shoals. They are mainly piscivorous, but can eat small mammals and waterfowl, and even other pike. Longnose sucker and burbot are also widely distributed in the area and in the Yukon, as is slimy sculpin, which is the fish with one of the most extensive geographical distributions in the Yukon and in the Mayo area, as they are found in virtually all creeks, rivers and lakes (O'Donoghue 2006a). Along with whitefish, slimy sculpin are also a common dietary item for lake trout in Mayo Lake (EDI 2011).

The construction of the Wareham Dam and the Mayo Lake control structure in the 1950s resulted in habitat fragmentation, impeding upstream movements of fish into the middle portion of the Mayo River and Mayo Lake. These dams blocked upstream fish migrations on the Mayo River including a known Chinook salmon spawning area near the outlet of Mayo Lake (Buchan 1993). There are some accounts of salmon being observed as far upstream as Roop Lakes prior to the construction of these dams (Buchan 1993).

Recent lake trout and whitefish spawning studies have indicated that adaptations have occurred in the years following the installation of the Mayo Lake Control Structure which raised water levels in the lake by about 5m. For example, lake trout are now primarily spawning in areas with clean rock and cobble substrates that would have been above the pre-impoundment lake level. Lake whitefish spawning have been documented in several areas including in tributary streams to Mayo Lake. Significant spawning outside of the lake may have been a response to the changes that have occurred to the lake in the past. Lake whitefish spawning has been documented elsewhere in Yukon lakes near river outlets, as well as in rivers and creeks (Bryan and Kato 1975).

5.2.3 Vegetation and Wildlife Common to the Region

5.2.3.1 Vegetation

Typical northern boreal forest within the Yukon Plateau-North ecoregion is present at elevations up to approximately 1,500 m with shrubs and lichen dominating in alpine areas (Smith et al. 2004). Extensive shrub lands are present at mid elevations and in valley bottoms due to cold air drainage. The most common forest type is comprised of open black spruce with a moist feathermoss understory or a drier understory comprised of lichens. On warmer and better drained sites, white spruce and occasionally aspen or lodgepole pine are present. Throughout the region, paper birch is found scattered throughout and is usually found in cooler locations. Due in part to the high frequency of thunderstorms within the region, forest fires are frequent and result in mixed canopy forests. The high incidence of fires often results in extensive stands of lodgepole pine and occasionally aspen. Steep, south facing slopes along the large rivers (including the Stewart River) within the ecoregion are inhabited by grassland communities which are remnants of the last glacial period.

The forests at lower elevations tend to include stands of balsam popular growing among white spruce, with an understory of willow, rose, Labrador tea, northern comandra, bluebells, and lowbush cranberry.

At mid-elevations, white and black spruce are populous, with the typical understory being willow, Labrador-tea and rose. Lodgepole pine grows in recently burned areas and in drier, sandier soils. Sub-alpine fir and black spruce are found in the lower reaches of north-facing slopes and paper birch also prefers ridges where the temperature is lower. Aspen can be found on warmer, south-facing slopes. Crowberry, blueberry and bearberry are also common boreal plants found in the area (O'Donoghue 2006b).

In the area along the Mayo River within the Project Regional Study Area, there are two wetland complexes north of Wareham Lake. The extensive Roop Lakes wetland complex on the north eastern Roop Arm of Mayo Lake, fed by the Roop and Granite creeks and the wetland at the south end of the Nelson Arm of Mayo Lake. While neither the Roop Lakes wetland nor the wetland at the southern end of Nelson Arm has a specific designation by Yukon Environment, wetlands are recognized as very important components in both aquatic and terrestrial ecosystems in the Yukon.

Larger wetland complexes in the Mayo area outside of the Mayo Lake and Mayo River areas are located along the Stewart River at Horseshoe Slough and at U-Slough. McQuesten Lake is also the site of a large wetland complex. Larger wetland complexes in the region tend to be a mixture of different wetland types. Horseshoe Slough has been designated a Habitat Protection Area under the Yukon Wildlife Act and is described in the Na-Cho Nyak Dun Final Agreement. The *Community Based Fish and Wildlife Management Plan*, *Na-Cho Nyak Dun Traditional Territory* (NND and Wildlife Planning Team 2008) identifies Devil's Elbow along the Stewart River as an important moose calving and waterfowl nesting site.

5.2.3.2 Birds

The Tintina Trench, west of the Mayo region, is an important migratory flyway for many bird species. Many migratory birds also nest in the area including numerous species of waterfowl, waterbirds, raptors, shorebirds and passerines. The assemblage of breeding birds in the Mayo area is typical of the Boreal Cordillera ecozone with a moderate level of diversity as compared to other areas of the Yukon. The majority of species in the area are migratory. Spring migration occurs from mid-April to early June and fall migration from late July until early October. Areas free of ice early in the season (such as the inlets and outlet of Mayo Lake) are important areas for staging waterfowl, waterbirds and shorebirds. Year round resident birds in the area are limited and include, grouse, owls, woodpeckers and some species of passerines.

Bird species of conservation concern (Committee on the Status of Endangered Wildlife in Canada) known or likely to occur within the Mayo region include the following: Horned Grebe (special concern), Peregrine Falcon (special concern), Short-eared Owl (special concern), Common Nighthawk (threatened), Olive-sided Flycatcher (threatened), Barn Swallow (threatened) and Rusty Blackbird (special concern).

The Yukon Government's Wildlife Key Areas (WKA) Database identifies only two key wildlife areas within the Project Regional Study Area:

- WKA ID 2726 for "unspecified raptors" – along the Mayo River from the Stewart River to 6km upstream of Wareham Lake;
- WKA ID 2734 for Bald Eagle – summer nesting at Roop Lakes, lower Edwards Creek and the eastern end of Roop Arm in Mayo Lake; and

- WKA ID 2727 for Golden Eagle along the Stewart River upstream of Mayo.

Bald Eagle, Golden Eagle, Northern Goshawk and Gyrfalcon are raptors living year round in the area, while Osprey, Red-tailed Hawk, Northern Harrier, Sharp-shinned Hawk, American Kestrel, Merlin and Peregrine Falcon are all summer residents (O'Donoghue 2006c). Peregrine falcon nest on cliffs, usually near water and may be expected to be found within the Project Regional Study Area along the lower Mayo River. A cliff nesting raptor survey completed within the Project Regional Study Area during July 2008 did not locate any cliff nests or evidence of nesting activity.

5.2.3.3 Mammals

Nineteen rodent species are resident in the Mayo region. Red squirrels are found in spruce or pine stands, and northern flying squirrels are found in dense, low elevation forests. Least chipmunks tend to live near waterbodies. Arctic ground squirrels and hoary marmots are often in the alpine tundra. Beavers are found in watercourses throughout most of the area, from lowland marshes to subalpine creeks. Muskrats are also found in creeks, rivers, streams and particular at wetlands. A number of smaller rodents, voles and shrews are also present (O'Donoghue 2006d).

Snowshoe hares tend to be found in dense shrub thickets near wetlands and shorelines, and in areas with regenerating vegetation in burns less than 30 years old. Porcupines are also found in the area. Red fox, wolf and coyote are abundant in the area. Coyotes moved into the area from the south around the turn of the twentieth century (O'Donoghue 2006d).

Least weasels and ermine live in the Mayo region, hunt small rodents, and tend to fluctuate in population. Marten are larger and live in old forests; while mink live near watercourses and wetlands. River otters are an aquatic member of the weasel family, common to the large creeks and rivers in the Mayo area. Wolverines are rarely seen residents. Lynx, another seldom-seen, local animal, stalk snowshoe hares in wet places where willows grow and in burned out forests. Lynx populations follow the snowshoe hare cycle (O'Donoghue 2006d).

Black bears and grizzly bears are resident, and are often sighted at the junction of the Mayo and Stewart Rivers. Black bears hibernate in forested areas, where they stay most of the year. Grizzlies hibernate on south-facing slopes at higher elevations, and tend to spend the summer and fall in the subalpine. The bears feed primarily on berries, plant shoots and roots, turning to fish and other animals, particularly when berries are scarce (O'Donoghue 2006d). Black bear scat and tracks were observed in the northern and western portions of the Project Regional Study Area.

Moose are widely dispersed in the Mayo area, with an estimated 200 animals per 1000km2. Calving occurs in late May in densely forested shoreline habitat, and the summer is spent feeding on plants and shoots in wetlands and along streams and creeks, or in recently burned patches. They mate in mid-September and then move to higher altitude willow thickets, where they form feeding groups, descending back into dense spruce forests along the larger rivers by mid-winter (O'Donoghue 2006d).

Caribou used to be more abundant within the broader Mayo region. The Ethel Lake and Clear Creek woodland caribou herds are the closest herds; however, neither frequent the Project Regional Study Area. Mule deer are often sighted along the Silver Trail highway between Wareham Lake and Stewart Crossing (O'Donoghue 2006d).

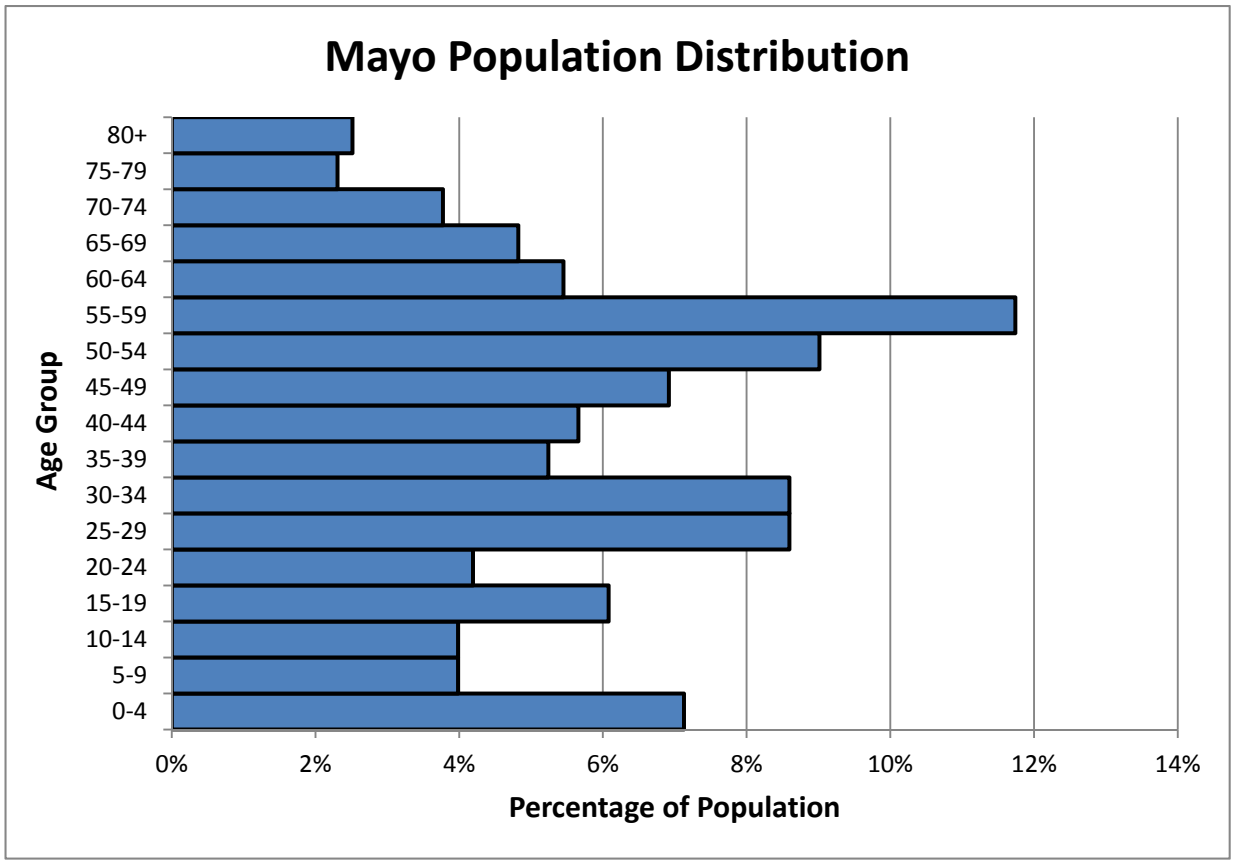
5.3 EXISTING SOCIO-ECONOMIC CONDITIONS

The dominant socio-economic conditions in the Project Regional Study Area relate to the Village of Mayo and the First Nation of Na-Cho Nyak Dun, as well as various resource-related developments. The following provides a high-level scan.

5.3.1 Population

As of December 2014, the population of Mayo was estimated at 477 residents (Yukon Bureau of Statistics 2014). Figure 5-3 provides a population breakdown by age group for the Village of Mayo.

Figure 5-3: December 2014 Mayo Population Distribution



Source: Yukon Bureau of Statistics, Population Report December 2014

The First Nation of Na-Cho Nyak Dun (NND) has a registered population of 547 members as of April 2015 (AANDC 2015), although many of the community members live outside of Mayo, including communities such as Stewart Crossing and Whitehorse. NND is governed by an elected Chief and Council who work under the First Nation Assembly of Na-Cho Nyak Dun, the body which has overall responsibility for First Nation government powers and responsibilities. The Assembly and the Chief and Council govern primarily by consensus. The Council is elected to a three-year term by a majority vote of NND citizens. The current Chief and Council are shown in Table 5-1.

Table 5-1: First Nation of Na-Cho Nyak Dun Chief and Council

Title	Surname	Given Name	Appointment Date	Expiry Date
Chief	Mervyn Sr.	Simon	03/19/2015	03/20/2018
Councillor	Hummel	Kalie-Ann	03/19/2015	03/20/2018

5.3.2 Local and Regional Economy

Although NND have lived throughout the Mayo area for generations, the community of Mayo began to establish itself with the arrival of gold seekers in the late 1800s. The Village of Mayo was officially established in 1903 as a river settlement and port that served the transportation requirements of the mining industry in the Keno mining district. The 1950s marked one of the most active periods of silver mining in the region (Mayo Historical Society 1990) "Year round employment opportunities created by the expansion of the silver mines and the supporting businesses and government offices that sprang into service the mines, as well as jobs with highways and public works, road maintenance camps, and employment with the Northern Canada Power Commission all resulted in Mayo's steady growth as a community" (Bleiler 2006).

Though an important component, today Mayo is no longer a primarily mineral-based economy. The community has recognized that diversification is necessary, and is promoting options such as tourism to strengthen local activity. Accommodation, food services, guiding and outfitting, and retail services provide work for local residents. Government services, including First Nation, territorial, and municipal administration provide over a third of jobs in the community. Placer mining and mineral exploration continue to be part of the local economy.

5.3.3 Resource Use

The Project Regional Study Area is characterized by relatively moderate use of the local natural resources for domestic, traditional and commercial purposes.

5.3.3.1 Traditional and Domestic Resource Use

Hunting, trapping and fishing remain important to the community of Mayo and to NND for both traditional (socio-cultural) and domestic/subsistence purposes. The Mayo River and Mayo Lake are used both directly in terms of resource use, as well as indirectly by providing access to resource use areas.

Hunting and/or trapping for species such as moose, beaver and muskrat is common in the Project Regional Study Area; the Mayo River, Mayo Lake and Roop Lakes Wetlands offer varying degrees of access to hunting areas. Moose are a species of particular importance to the community and the 2008-2013 Community-Based Fish and Wildlife Work Plan (NND and Wildlife Planning Team 2008) indicated

that the 2006 moose survey "showed that the proportion of bulls is low (about 42 bulls/100 cows), reflecting the relatively high harvest (known harvest 3-4%) in the area" (NND and Wildlife Planning Team 2008).

Concern voiced through the public consultation program for the 2008-2013 Community-Based Fish and Wildlife Work Plan identified increased pressure on moose hunting within the broad Mayo region, including the Project Regional Study Area, primarily due to the voluntary closure of McQuesten Lake to moose hunting. While this closure is not being respected by everyone, it is forcing others to relocate and harvest at other sites (creating harvest issues at other lakes); as well as hunters not following "traditional laws" by harvesting more than what was needed (NND and Wildlife Planning Team 2008).

Fishing occurs at various locations along the Mayo River, as well as on Mayo Lake. Common species in the Study Region (particularly Mayo Lake) include lake trout, lake whitefish, northern pike, Arctic grayling, round whitefish and burbot (EDI 2011). Mayo Lake previously had commercial fishing, but this was closed prior to the 1990s. Prior to the closure, the annual commercial quota for Mayo Lake was 3,600 kg for all species combined and 1,800 kg species quota for lake trout. Prior to the 1990s, harvest records from 1974 to 1984 suggest two commercial licenses and up to 11 domestic licenses were issued annually. Lake trout were the primary target species with the maximum recorded yearly harvest of 160 kg in 1979-80. A more intensive fishery may have existed coincident with the mining activity at Elsa and Keno during the 1950s and 1960s. There is little recorded information with respect to harvests of freshwater fish from Mayo Lake by the First Nation subsistence or domestic fisheries. There is however, anecdotal information that suggests harvests were substantial (de Graff 2011). In addition, the outlet of Mayo Lake was the site of an important First Nation subsistence fishery for Chinook salmon prior to the construction of the Wareham Dam and Mayo Lake control structure (in the 1950s). Today, Mayo Lake remains an important fishing location for some members of NND and the community of Mayo. However, some officials with the NND government believe that fish populations in Mayo Lake are less robust and the outlet area can no longer support the former traditional uses (de Graff 2011).

Trapping within the area provides economic and sustenance benefits for trappers. The Project Regional Study Area in the vicinity of Mayo Lake and the Mayo River includes portions of registered trapping concessions ("RTC"s) #74, #84, # 85, #86, #89, and #407; the latter being a community trapping concession. Local stakeholders identified marten, lynx, mink, beaver and muskrat as species of importance for trapping. However, according to the 2008-2013 Community-based Fish and Wildlife Work Plan, there is a concern with trapping sustainability as fewer people are trapping (NND and Wildlife Planning Team 2008). Collection of berries along with other medicinal plants occurs throughout the Project Regional Study Area, including along the Mayo Lake access road and inland from the shores of Mayo Lake.

5.3.3.2 Other Resource Use

Although Mayo Lake is not heavily used by local residents (i.e., compared to other locations such as Ethel Lake), outfitting and outdoor recreation activities such as camping occur in Mayo Lake and in downstream Mayo River areas. The Project is located in Rogue River Outfitters' hunting concession.

5.3.3.3 Mining and other Private/Commercial Land Use

Historically, mining has played a major role in the Mayo area and continues to be active on numerous tributaries of Mayo Lake and Mayo River.

Placer mining typically begins with the spring thaw, and continues over the summer until the freeze-up in fall (approximately 120 days).The mouth of Mayo Lake is the site of leased properties where miners with claims along Mayo Lake launch their barges and boats. For a complete table of mining activity within the Mayo Lake and relevant Mayo River areas and for maps showing placer claims see Appendix 2 (2A, 2C and 2D).

Prior to 2014, there were two to three fairly active placer miners at Mayo Lake who accessed their claims during the summer by boat and barge; and if necessary, by snowmobile or truck in the winter (generally considered more expensive than using a barge). More recently, placer mining activity around the lake has diminished but there is at least one who continues to be active. The main season for placer mining activity is late May/early June up until late October – depending on ice and water levels. The water needs to have risen with the spring freshet to a point where the barges can float, and access at their placer claims is close enough to enable off-loading of equipment.

Special measures and restrictions for placer mining on Mayo Lake were developed in 2009 for the protection of fish stocks and fish habitat on the lake. These measures and standards are part of the placer management system and are implemented through fish habitat authorization under the Fisheries Act (Canada).

5.3.4 The Social and Cultural Context

Traditionally, NND "are known to have used many traditional camps, lookout sites, hunting areas, berry patches and trails in the larger project area with extensive use of rivers" (Ecofor 2010).

In 2008, a shoreline inspection of Mayo Lake revealed several prehistoric artifacts including items largely associated with traditional camps. First Nations people adapted to the dramatic changes that followed the early arrival of early explorers, traders, and later prospectors. Today, NND have taken elements of both First Nation and non-First Nation culture. While people are more often educated and employed in the mainstream system, they continue to practice their culture and traditional pursuits through the traditional teachings of their "families, Elders and the community" (Peter and Hogan 2006).

Today, the Chief and Council of NND often work in close cooperation with the Village of Mayo Mayor and Council. The two governments hold joint council meetings on a regular basis to "discuss issues of mutual importance" (Cooper and Lecki 2006). The two councils collaborated to establish a local youth centre, which is among the many services that the two communities share. In addition, provisions under the NND Umbrella Final Agreement have resulted in the establishment of the Mayo District Renewable Resources Council whereby members of NND and the Mayo community make recommendations on fish and wildlife management within the Mayo District.

5.4 EXISTING AND PLANNED DEVELOPMENTS

The Project Regional Study Area in the vicinity of Mayo Lake and the Mayo River contains a relatively extensive list of developments, including the existing Mayo Hydro Generation Facilities – Mayo A (including the control structure at Mayo Lake) and Mayo B ("Existing Facilities"). In addition, there are many small developments and projects that are either licenced to occur, or are in the process of being reviewed for licencing. As noted in Section 3.2 of Chapter 3, the assessment approach considers other projects and activities which may potentially act cumulatively with effects of the Project and affect selected Valued Components (VCs). The cumulative effects assessment, inherent in the effects assessment in Chapter 7, identified all inputs from other projects that could act in concert with effects of the principal Project and influence the VCs identified, including:

- Past, present and likely future projects and activities in the area that may affect identified VCs; and
- Other existing or anticipated pressures (direct or indirect) on identified VCs.

The Mayo Lake Enhanced Storage Project is proposed to occur within this context of existing and planned developments, and as such their presence is relevant to the assessment of effects from the Proposed Project. Section 5.4.1 below describes the existing Mayo facility and Section 5.4.2 reviews other existing and planned developments.

5.4.1 The Existing Mayo Hydro Generation and Mayo Hydro Enhancement Facilities and Loads

The Existing Facilities consists of the Mayo Hydro Generation Facility ("Mayo A"), Mayo Hydro Enhancement Facility ("Mayo B") and the existing Mayo Lake Control structure. It has a combined installed capacity of approximately 15.4 megawatts and consists of several different structures. A copy of amended water licence HY10-056 is provided in Appendix 2F. The Existing Facilities consist of the following components (see Appendix 6A for further details):

- Mayo Lake Control Structure: The Mayo Lake control structure is a six meter high rock-filled wooden structure complete with a control valve building that allows Yukon Energy to control the level of Mayo Lake within a licensed operating range of 2.59 metres.
- Mayo B: A new 10 MW powerhouse downstream from the existing Mayo A plant. Water is transported from Wareham Lake to the new powerhouse by way of a new tunnel and underground pipe (penstock) system. The Mayo A and B facilities are licenced under Water Licence HY10-056, a Type A Class 3 licence that expires December 31, 2025.
- Mayo A: Consists of two 2.7 megawatt turbines and the Wareham spillway, which is a 32 metre-high earthen dam that controls Wareham Lake levels.

Further information on existing facilities can be found in the 2009 Mayo Hydro Enhanced Project (Mayo B) YESAB submission.

5.4.1.1 Existing Facility Water Levels and Flows

Details on existing facility water levels and flows are described in Chapter 6 – Appendix 6A and 6B.

5.4.2 Other Existing and Planned Development

Outside of Yukon Energy's Existing Facilities, a variety of past and current projects and activities comprise the existing and evolving built environment. A list of past and current projects and activities can be found in Appendix 5C.

6.0 PROJECT DESCRIPTION

6.1 PROJECT IDENTIFICATION/SCOPE OF PROJECT

6.1.1 Overview and Background

The proposed Project revises the existing licensed range within which Yukon Energy is permitted to operate Mayo Lake as a storage reservoir for the Mayo hydro system to store spring and summer flows to support generation of power during the fall and winter. The proposed Project provides increased bottom storage in the lake by lowering the allowed Low Supply Level by up to 1 m, thereby enabling increased water capture and storage in years when extra water is available.

Water management in terms of altering water levels at Mayo Lake as a result of the proposed Project will be subject to the Adaptive Management Plan (AMP) and the Monitoring Plan that provides the supporting data inputs for the AMP, each of which will be part of the proposed licence and not discretionary. The overall purpose of the AMP is to ensure a fully functioning, healthy and sustainable aquatic ecosystem at Mayo Lake based primarily on healthy and sustainable lake trout and lake whitefish populations. The AMP is intended as a primary instrument for managing water levels and water use for hydroelectric generation at Mayo Lake and establishing ecologically relevant water management constraints within the overall operating range. The AMP is a tool for implementing timely changes in water management to address ecological conditions, while providing the flexibility to obtain the most benefit of water storage for power generation. Under the AMP, water management for the Project responds to ongoing monitoring and can be readily adjusted as required or completely reversed if necessary.

For the first three years of the Project operation, the lake will be operated with an additional 0.5 m storage range (i.e., between the existing Full Supply Level of 665.84 m to a revised Low Supply Level of 662.75 m which is 0.5 m below the current Low Supply Level of 663.25 m)[1]. After the first three years, the results of monitoring and the AMP will be used to determine if and how to proceed with up to a full metre extra storage (lowering the Low Supply Level to 3.59 m below the Full Supply Level [LSL] of 665.84 metres) or if the storage range should be reduced to less than 3.09 m.

The Mayo Lake Enhanced Storage Project is proposed to enhance the renewable power generation capability of the existing hydro generating units installed on the Mayo River (see Appendix 6A for a description of existing facilities and modeled water management levels) to displace thermal generation that would otherwise be required during winter/spring to meet the overall power loads throughout the Integrated Yukon grid.

Prior to 1980, winter water levels at Mayo Lake frequently approached the current maximum licensed lower limit of 2.59 m below Full Supply Level because of the energy needs associated with the communities of Elsa, Keno and Mayo (including the mine load requirements at Elsa); however, from 1980

[1] The current controlled range reflects that under certain water conditions, it is possible for the water level of Mayo Lake to be outside of the stated range due to drought or flood conditions. Under those circumstances, Yukon Energy would be required to operate its facilities at the lake so as to not further exacerbate the elevation conditions. In particular, clause 25 of the Mayo Water Licence requires that when the lake elevation exceeds the licensed maximum range, Yukon Energy is required to have all of the gates open; a similar practice would be exercised in the event the licensed minimum range was exceeded, consistent with minimum downstream flow requirements.

to 2010, winter drawdown in Mayo Lake averaged only approximately 1.3 m, in part because the hydro generation plant was not run at full capacity in most years and more so after the 1988/89 closure of the United Keno Hill Mines operation. With interconnection of the Mayo/Dawson and Whitehorse-Aishihik-Faro grids during the spring of 2011 and the added hydropower generation capacity on the Mayo River through construction of the Mayo B project in 2010/11, additional water storage options in Mayo Lake are currently being sought.

The increased storage provided by the Project will enhance the ability to sustain water flows downstream to the Mayo hydro generating units during the winter/spring pre-freshet period, thereby enhancing thermal generation displacement on the Integrated Yukon grid. The Project maintains the existing maximum controlled elevation for Mayo Lake (the Full Supply Level) and requires no physical works for water storage beyond the Mayo Lake Control Dam facilities already in-service for the existing Mayo generation. The existing Water Board licence that governs water management is currently in effect and will be subject to review/renewal in 2025.

Implementation of the proposed Mayo Lake Project will not proceed until resolution of the lower Mayo River winter flow issue is satisfactorily resolved. Yukon Energy continues to work with Yukon Government and the Village of Mayo to address this issue.

Yukon Energy is also involved in a separate process related to dredging of the Mayo Lake outlet channel due to the build-up of sediment deposits. Recent investigation has confirmed that, over the 60 years of operation to date, sediment deposits have aggregated in the outlet channel to a level that is currently reducing long-term average hydro generation capability at Mayo A and B. A separate process to develop a project description and environmental and socio-economic assessment for regulatory review to remove these sediment deposits is now required (with or without the Mayo Lake Project), and is within Yukon Energy's planning process to restore full hydro generation capability under the existing licence. Removal of these sediment deposits will be required in order to utilize additional storage at Mayo Lake as provided for in the proposed Project.

The proposed Project is consistent with Yukon Government policy, as set out in the *Energy Strategy for Yukon* (2009), which includes the goal of increasing renewable energy supply by 20% by 2020. It also is in alignment with Yukon Government's *2009 Climate Change Action Plan*, which includes the reduction of carbon emissions.

6.1.2 Identification of Key Project Aspects

The proposed Project involves increasing the water level operating range on Mayo Lake by lowering the Low Supply Level (LSL) up to 1 m, increasing the current controlled operating range from 2.59 m (from 663.25 to 665.84 metres[2]) to 3.59 m (i.e., adding bottom storage). For the first three years of the Project operation, the storage range would be 3.09 m (lowering the LSL by 0.5 m) after which the results of monitoring and the AMP would be used to determine if and how to proceed with up to a full metre extra storage (lowering the LSL to 3.59 m below the Full Supply Level of 665.84 metres) or if the storage range should be reduced to less than 3.09 m.

[2] The licence is stated in imperial units, using an older datum, as 2,203.0 feet to 2,211.5 feet.

The proposed change to regulation of Mayo Lake is to the bottom part of the operating range and does not constitute any raising of maximum lake levels (i.e., 665.84 metres would remain the regulated Full Supply Level of Mayo Lake).

The available inflows to Mayo Lake do not allow for the full 3.09 metre or 3.59 metre range to be used every year. However, the increased storage range will result in lower average water levels at Mayo Lake.

Yukon Energy's general operational approach for Mayo Lake will be to store late spring and summer flows to support generation requirements between fall and early spring. Lake levels will usually peak in the fall, and slowly decrease until they reach a minimum just before freshet in the spring. The lake will be operated in conformance with the following water management principles and requirements:

1. The overall water management concept and objectives for the Mayo system will not change: Yukon Energy's use of water storage will remain focused on ensuring that peak spring/summer flows are used to fill Mayo Lake within the bounds of the licence and other operational constraints, and that water stored at Mayo Lake is generally released during winter/spring periods (pre-freshet) to provide for required downstream flows and the maximum generation that can be used to serve firm power loads and, where possible, secondary power loads. This general concept for future operation with the Project is the same as the situation today or in the future with or without the Mayo Lake Project[3].
2. Implementation of an environmental protection reservoir management rule to ensure that winter drawdowns (September 15th elevation to the minimum elevation the following spring) are not more than 2.59 metres more than 2 years in a row (the one-in-three "rest rule"). The effect of this rule is that for at least one year in every three, the winter drawdown shall not exceed 2.59 metres.
3. Adoption of the Adaptive Management Plan (AMP) with specific ecological thresholds, as overviewed below and as set out in detail in Appendix 8B, provides for specific mitigation management responses (including limitations on the operating range in certain circumstances) as appropriate when specific environmental conditions are observed through the comprehensive ecological monitoring program proposed as part of the Project.

Both the proposed operational regime changes and the AMP consider the Precautionary Principle and the elements of risk for serious and irreversible harm.

The proposed Project begins with a cautionary approach, utilizing half of the proposed additional 1 m water level range, and relying on the AMP to guide decisions about future increases or decreases from the starting point. Throughout the operation of the proposed Project, the AMP will continue to apply, leading to implementation of appropriate responses if ecological conditions reach action thresholds.

The AMP provides technically and economically feasible approaches for dealing with predicted and any observed impacts. Specifically, the AMP addresses both short term annual monitoring of reproductive success/recruitment (in terms of an early warning/indication of adverse impacts) and long term

[3] The Mayo hydropower facilities (including the Project) will operate in future to help reduce fossil fuel generation otherwise required to supply energy on the Integrated Yukon Grid, i.e., the Project will not change or impact the load requirements on the Yukon grid.

monitoring of adult abundance. Where thresholds for adverse effects are identified either in the short and long term monitoring programs, mitigation measures and changes to water management identified in the plan will be implemented as part of the AMP. It is expected that these programs and operational requirements will be entrenched in the Project authorizations (e.g., water use licence amendment).

As outlined in Appendix 8B, the objectives of the AMP are intended:

- To identify how the proposed Mayo Lake Project may affect the aquatic ecosystem focusing on the effects on lake trout and lake whitefish.
- To establish appropriate indicators of a fully functioning, healthy and sustainable aquatic ecosystem.
- To define a monitoring program that is appropriately sensitive and can measure and report, in a timely way, changes in identified indicators.
- To establish thresholds that define acceptable and unacceptable conditions or changes in identified indicators.
- To describe responses that will be undertaken if indicators and thresholds identify unacceptable conditions or trends.
- To establish a framework for interpretation of monitoring results, and decision-making about adaptive management responses.

The specific Project proposed serves to increase the long-term average hydro generation potential to displace fossil fuel generation on the Yukon system by approximately 2 to 4 GW.h/year[4] (the specific yearly benefit will depend on the overall load level on the Yukon grid, flow conditions throughout Yukon, the Mayo Lake LSL then allowed under the AMP, and the extent of future new renewable generation on the grid).

The proposed Project requires no new physical works. It will utilize the Mayo Lake Control Structure facilities already in-service for the existing Mayo hydro generation, and ongoing maintenance activities of the structure and associated infrastructure from Mayo Lake to the Mayo Lake Control Dam[5]. Hydro power generation will occur at the existing Yukon Energy facilities at Mayo A and B.

Most Yukon Energy operations at Mayo Lake or on the Mayo River are related to and required by the existing projects, and are not expected to be significantly affected by the Mayo Lake Project. There are no "accessory activities".

[4] By way of example, at loads ranging from of 437 to 454 GW.h/year, additional long-term average fossil fuel displacement due to the Project's enhancement of long-term average hydro generation ranges from 1.9 to 2.8 GW.h/year with 0.5 m enhanced Mayo Lake storage and from 3.4 to 4.2 GW.h/year with 1.0 m enhanced Mayo Lake storage. Within the load range of about 460 to 480 GW.h/year, fossil fuel generation displacement benefits with 0.5 m enhanced Mayo Lake storage range between 2.9 and 3.2 GW.h/year.

[5] Maintenance activities noted here refer to any ongoing works required to keep the control structure operational. As reviewed in Section 6.1.1, a separate process to develop a project description and environmental and socio-economic assessment for regulatory review to remove sediment deposits within the outlet channel is now required (with or without the Mayo Lake Project), and is within Yukon Energy's planning process to restore full hydro generation capability under the existing licence.

6.2 PROJECT TIMELINE AND LIFESPAN

Yukon Energy is working to secure fossil fuel displacement benefits from the Project by 2017. To achieve this target and be able to reduce Mayo Lake below its current LSL in spring 2017, the Project approval and licensing process (including the YESAB and Yukon Water Board processes) needs to be concluded no later than during 2016.

As stated above, in order to sustain generation benefits under the current licence regime and gain the estimated benefits of the Project, resolution of the lower Mayo River winter flow issue and outlet channel dredging will also require resolution. These activities are being addressed under separate processes by Yukon Energy. Implementation of the Mayo Project (i.e., changing the water management regime of Mayo Lake) will not occur until these issues are resolved.

Subject to resolution of the lower Mayo River winter flow issues and outlet channel dredging that (as reviewed above) are being addressed under separate processes by Yukon Energy, operation of the Project will begin with the receipt of all final approvals from the required regulatory agencies. The actual use of the additional storage range will primarily occur in late winter/spring although in some years, the lower portion of the proposed storage range will be used over a greater portion of the year. Actual use will be affected by required loads on the Yukon grid, natural inflows, licence conditions including minimum downstream flows and by the ongoing AMP requirements.

There are no added maintenance works required by the Project as compared to maintenance required of the existing works (e.g., travel to the lake to make flow modifications as required, occasional maintenance of the dam structure, and periodic removal of woody debris). The only additional ongoing activity anticipated as a result of the Project is enhanced monitoring of the environmental conditions of the lake, as compared to the status quo operation over the last 50 years, and the related AMP activities.

The Project's proposed amendment to Yukon Energy's existing Class A Water Use Licence HY99-012 for the Mayo hydroelectric facility will be subject to further regulatory review when this licence is renewed. Yukon Energy's current licence expires on December 21, 2025. It is anticipated that any renewed licence would be subject to further review at least once every 25 years.

The extensive fisheries and aquatic monitoring that has been done since 2009 and that will continue to be carried out through to relicensing under the Adaptive Management Plan focused on operational issues will provide a very significant long term data base that will greatly benefit assessment and relicensing in 2025.

There is currently no timetable or plan for final disposition or decommissioning of the main Mayo generating facilities, or of the requirement for water storage to service these facilities. As reviewed in the recent Mayo B licensing, it will be 50 to 100 years before the main generating facilities will require substantial refurbishment. This is far into the future such that it is not feasible today, based on the available information and agreements, to provide meaningful assessment of likely plans or their effects for reclaiming the components of the Mayo generating facilities or the water storage at Mayo Lake. When such plans need to be developed, Yukon Energy will submit these plans as then required for assessment and regulatory review and approval prior to implementation. Accordingly, as was done for the Mayo B application, this Project proposal does not provide any further assessment of final disposition.

6.3 ALTERNATIVES

6.3.1 Alternatives to the Project

The main alternative to the Project is continued reliance on existing fossil fuel generation (using natural gas supplied by LNG and/or diesel fuel) to supply the energy that the Project would otherwise enable.

As noted in Section 6.1, the prime purpose of the Project is to enhance the renewable power generation capability of the existing hydro generating units installed on the Mayo River to displace fossil fuel generation that would otherwise be required during winter/spring (pre-freshet) to meet the overall power loads throughout the Integrated Yukon grid under long-term average hydro generation conditions.[6]

The Project is being pursued by Yukon Energy concurrent with all other identified potential enhancements to existing renewable generation (ongoing feasibility studies related to Whitehorse and Aishihik), as well as a broad Demand Side Management (DSM) energy conservation and efficiency program. Based on Yukon Energy's recent review of near-term resource supply options[7] and updated grid load forecast scenarios[8], there is no alternative near-term renewable energy project or any DSM option currently under study by Yukon Energy that is expected to displace the short and medium-term forecasted default fossil fuel energy generation on the Yukon grid that the Project would displace. This reflects the fact that the Project's annual fossil fuel displacement impact is relatively small (i.e., it tends to offset only one to two year growth on the grid in new default fossil fuel generation requirements absent new renewable generation), and the fact that new greenfield renewable generation typically requires material additional sustained long term loads to justify the required capital costs.

In summary, as Yukon Energy is a regulated utility with an obligation to supply firm power customer loads, the implications of not proceeding with this Project are as follows:

- As an alternative, Yukon Energy would be required to use fossil fuel generation to provide incremental power requirements that cannot be provided through the proposed Project.
- Long-term power costs in Yukon would be higher under an alternative of fossil fuel generation than with the proposed Project, affecting all Yukon ratepayers.
- Ongoing greenhouse gas emissions (GHG) would be higher under an alternative of fossil fuel generation than with the Project.
- Economic development benefits arising to the NNDFN from participation in the proposed Project's economic benefits will not be realized under the alternative of fossil fuel generation.

[6] In the recent Board Order 2013-01, the Yukon Utilities Board approved the amortization of permitting and licencing costs then forecast for the Project over the term of the Mayo generation facility water use licence, and supported the Project as a renewable project.

[7] See Chapters 6 and 8, Yukon Energy Corporation, *Overview of 20-Year Resource Plan: 2011-2030*, July 2012.

[8] See Appendix C: Updated Near-Term Grid Load Scenarios, in Yukon Energy Application for an Energy Project Certificate and an Energy Operation Certificate for the Proposed Whitehorse Diesel-Natural Gas Conversion Project, December 9, 2013 [this project was designated by OIC 2013/200 as a "regulated project" under Part 3 of the *Public Utilities Act*.]

6.3.2 Alternative Ways of Undertaking the Project

Yukon Energy's concept studies for Mayo B[9] reviewed the potential benefits from enhancements to the operating range of Mayo Lake from a "no change" scenario, up to a scenario with 2 metres of additional water level fluctuation.

The 2 metre scenario incorporated up to 1 metre of added top storage (i.e., raising the controlled maximum licensed lake elevation, or FSL) combined with up to 1 metre of added bottom storage (i.e., lowering the minimum licensed lake elevation, of LSL). The 2 metre increase to the storage range (i.e., 1 metre increase and 1 metre decrease) was excluded from further consideration because there was rarely enough inflow to permit this full range at Mayo Lake to be used (i.e., modeling indicated that there was little power generation advantage to increasing the current storage range at Mayo Lake by the full 2 metres as compared to 1 metre); and initial investigations indicated potential concerns with a new higher controlled elevation, including material changes needed to the control structure and potential adverse effects (flooding) on land rights, heritage resources, and erosion of lands adjacent to the lake.

Within the remaining range of up to 1 metre of additional bottom storage, Yukon Energy worked with NNDFN to examine the potential impacts of alternative LSL changes and reservoir management options. As Figure 6-1 and Figure 6-2 illustrate, there is material value or benefit to increased generating potential between the existing licence storage and 0.5m of increased storage; however, between 0.5 m and the full 1 m additional storage, the generating potential improves, but not as much as for the initial half meter of storage.

[9] Concept studies that explored alternatives to the proposed 1 metre drawdown of the Mayo Lake Project were done as a part of the Mayo B Project concept studies. For an in-depth discussion, refer to Yukon Energy's Mayo B YESAB Project Proposal, February 27, 2009.

Figure 6-1: Mayo Lake Benefits at 442 GW.h/year Load

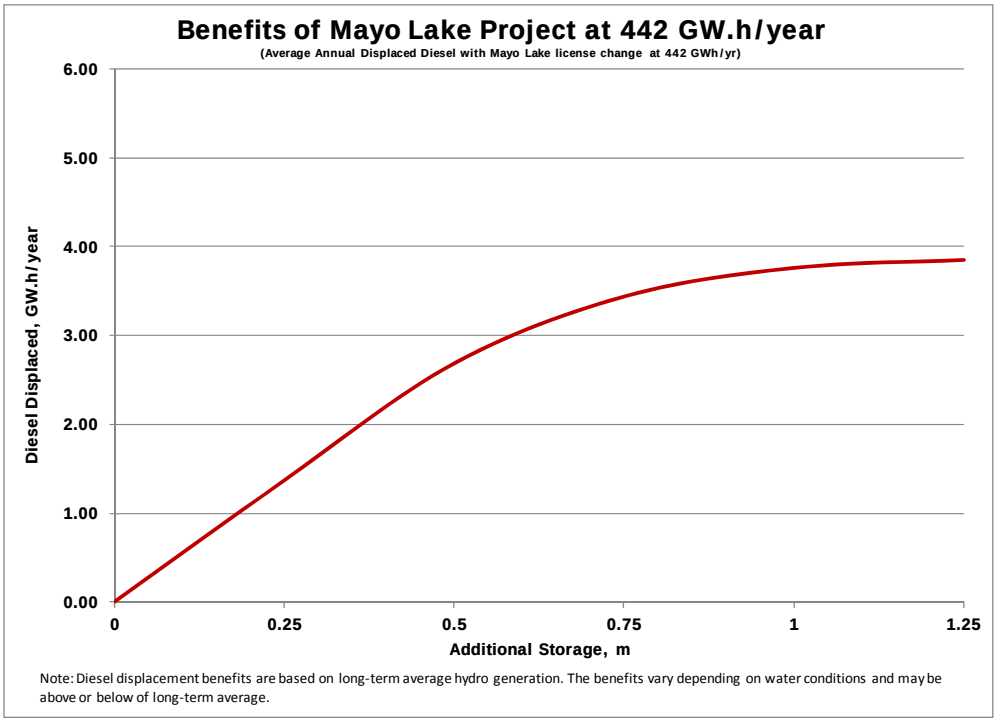

Figure 6-2: Mayo Lake Benefits at 545 GW.h/year Load

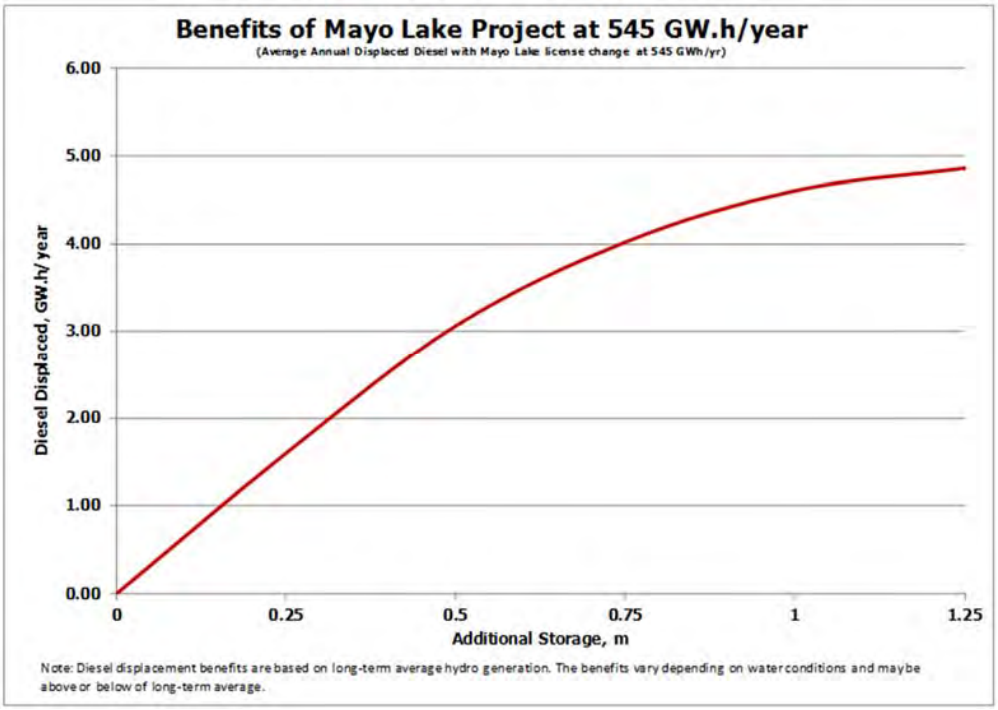

As part of this work, the NND/YEC Technical Working Group (TWG) hired an independent fisheries expert to assist the TWG in understanding the options; and to seek the expert's advice on the suitability of the monitoring plan and AMP as a means of addressing and managing uncertainties with respect to potential lake trout and lake whitefish responses to the Project (see Appendix 8C for a copy of the independent expert's final report).

Based on the work of the TWG, Yukon Energy has adopted the approach set out in this Project Proposal, including the proposal during the first three years of the Project operation for the storage range to be 3.09 m (lowering the LSL by 0.5 m) after which the results of monitoring and the AMP would be used to determine if and how to proceed with up to a metre of extra storage (lowering the LSL to 3.59 m below the Full Supply Level of 665.84 metres) or if the storage range should be reduced to less than 3.09 m.

As stated earlier, there is sufficient benefit from this renewable resource Project over the initial 0.5 m storage range to justify the costs of implementing the Project (i.e., regulatory review and on-going monitoring costs). This approach reflects the following considerations as regards environmental impact management:

1. **Monitoring Plan and AMP are integral to the proposal**: Both plans provide for a continual and robust complement of observations, with specific ecologically-based thresholds and prescribed response mechanisms and ongoing assessment by all interests including the proponent, NNDFN, Mayo RRC, regulators and stakeholders that are expected to be effective in early detection of, and response to, any unanticipated and potentially important adverse effects.
2. **The proposed approach is low risk**: The species of interest on the lake are presently in a self-sustaining condition comparable to other similar natural Yukon Lakes, and there is a high degree of resilience to a possible perturbation. Moreover, the predominant mechanisms for potential adverse effects to occur on the lake would require multiple years of repeated occurrence to be considered to have caused significant harm as both lake trout and lake whitefish are long-lived species. Implementing the proposed Project at the initial 0.5 metre level, combined with the sensitive Monitoring and AMP Programs, will consequently not cause serious irreversible harm and thus is considered reasonably precautionary in nature (as discussed in Chapter 7).
3. **The proposed approach provides better opportunity for cause – effect observation than a more gradual incremental phase-in approach (e.g., 0.25 m phase-in stages):** The species of interest on the lake are subject to a high degree of natural variability in such factors as their population levels, spawning success, and growth rates. It was determined that discerning any effects of the proposed Project as compared to natural variability would be extremely difficult if not impossible in the event a smaller perturbation (via a 0.25 m or other smaller incremental phase-in approach) were adopted.

6.4 OPERATION PHASE – WATER MANAGEMENT

The proposed Project will result in a different water regime on Mayo Lake than the situation in future without the Project[10]. In general, the lake will operate on average at a lower elevation with the proposed

[10] Lake elevations have been modeled for the future scenarios both with and without the proposed Project, using Yukon Energy's integrated grid supply (power benefits) model. This model considers the overall operation of the system (all hydro plants, plus

Project than without the proposed Project, with the size of this change varying somewhat by season and by year, as well in response to the overall load on the integrated grid and the LSL allowed at any time under the conditions of the AMP.

The proposed initial 0.5 m extra bottom storage in Mayo Lake, with the ability to increase that to 1 m in the future subject to the conditions of the AMP, retains characteristics of an annual storage system (where the inflows are stored for release the following winter), rather than a multi-year system (where a large range is provided that may take many years to oscillate between the lower reaches and upper reaches of the range). As a largely annual storage system, the proposed Project can be conceptually understood as providing something akin to a new "flood reserve" rather than a "drought reserve", such that the bulk of summer inflows will be released the following winter of each year, to permit storage room to capture the subsequent year's freshet and summer flows. The larger storage range allowed by the Project increases the amount of summer flows that can be stored, and this increased storage will be maximized during very wet years. During average and dry years, the inflows would be insufficient to fill the lake to the current FSL.

Given that inflows to Mayo Lake vary each year, lake storage utilization (i.e., the range and rate of drawdown each winter, and the scheduled releases) depends on the quantity of inflows during each year as well as power system loads. Consistent with existing practice on each reservoir, Yukon Energy will determine the optimum range of Mayo Lake drawdown possible for each week of each year by using a "rule curve," which enables water stored within the licensed range to carry the system from winter until the following spring freshet without violating lake water level and river minimum flow requirements set out in Yukon Energy's water use licence.

Modeling of this water regime is important to understanding both the feasibility of the Project (as it relates to power production) and the environmental and socio-economic implications.

Yukon Energy has completed modeling of the above water management parameters on the basis of a detailed integrated power/water flow model operating on a weekly time step, using a period of historic inflows (1981-2008) and consolidated power system loads of 442 GW.h/year and 545 GW.h/year as a representative range of flow and load conditions that could potentially occur during the first 10 years of the operation phase of the Project[11]. During the operation phase of the Project, with the adoption of the above water management parameters, the water levels and flows on the system from time to time are forecast to assess how these are likely to vary from what would have been the case had the storage

thermal generating units) to meet all required loads, including operation of each of the hydro reservoirs including Mayo Lake. The model operates on a weekly time step over a multi-year horizon. The model incorporates actual hydrological data from 1981 through 2008 inclusive and represents "what would have happened" had a given load level and a given complement of generation been present on the system in the hydrological year in question. This modeling approach reflects the industry standard for multi plant hydro based systems.

[11] These grid loads reflect a range of potential conditions as indicated in Yukon Energy's December 2013 Application for an Energy Project Certificate and an Energy Operation Certificate for the Whitehorse Diesel-Natural Gas Conversion Project (Appendix C: Updated Near Term Grid Load Scenarios): 442 GW.h/yr. reflects the 2015 forecast load for the Base Case with Alexco's Bellekeno mine and the 2017 forecast load for the Base Case with no Alexco (Base Case includes Capstone's Minto mine as well as wholesale and retail Yukon grid loads as then forecast); 545 GW.h/year reflects peak loads forecast (in 2021) under Scenario A2 (Base Case with Alexco and Carmacks Copper mine). The model includes all assumed loads and load profiles, operating characteristics of each system power facility (e.g., unit efficiencies), and licensed parameters for each plant as approved or proposed.

range remained unchanged from the current licence (for detailed information on modeled Mayo Lake levels and outflows please see Appendix 6B).

The following subsection includes the results of the representative modeled water levels and flows, under the two assumed grid loads (442 and 545 GW.h/year) comparing the conditions without the Project (i.e., the "baseline", or Mayo A and Mayo B operating parameters without the proposed Mayo Lake additional drawdown), and the expected operational conditions under the proposed Project (i.e., the baseline conditions with the proposed Mayo Lake initial half metre drawdown and the full 1 metre drawdown that may ultimately occur under the proposed licence amendments).

6.4.1 Mayo Lake Water Levels

Figure 6-3 and Figure 6-4 below show the average baseline, and proposed Mayo Lake water levels with and without the Project over the course of a single calendar year at the representative grid loads of 442 GW.h/year and 545 GW.h/year, respectively. The diagrams show that under both load scenarios, winter drawdown of Mayo Lake typically begins in mid-September/early October and continues to approach the LSL until mid-April/early May when the spring freshet begins. At that point, Mayo Lake refills based on natural inflow, and the lake level will be raised toward the licensed FSL.

The diagrams demonstrate that the general water management strategy and operation of Mayo Lake under the baseline and proposed conditions remain the same. The key difference is that, under the proposed conditions of the Mayo Lake Project, the range in drawdown will be increased to provide Yukon Energy with increased storage capacity each spring – i.e., to allow for additional space in the lake to store larger inflows if the spring and summer runoff are bountiful and to otherwise avoid this extra water from having to be spilled at the Mayo Lake Control Structure over the course of the summer and early fall due to constraints imposed by the FSL.

Table 6-1 below shows weekly average water levels with and without the Project (both 0.5 m and 1 m additional storage options) for the relevant weeks[12]. Averages are calculated from the outputs of a 28-year model assuming inflows are the same as the period from 1981 to 2008.

Table 6-1:
Simulated Weekly Average Water Levels and use of Additional Storage (metre)

		Mid-May		Mid-June		Mid-September		Mid-November		Annual
At 442 GW.h		Week 19	Week 20	Week 24	Week 25	Week 37	Week 38	Week 45	Week 46	Average
No Additional Storage	A	663.64	663.90	665.18	665.33	665.70	665.72	665.45	665.36	664.79
With 1 m Additional Storage	B	663.14	663.40	664.70	664.86	665.47	665.51	665.28	665.19	664.50
With 0.5 m Additional Storage	C	663.29	663.55	664.85	665.01	665.55	665.59	665.34	665.25	664.60
Difference between no Additional Storage and 1 m Additional Storage	D=A-B	0.50	0.50	0.48	0.46	0.23	0.22	0.17	0.17	0.29
Difference between no Additional Storage and 0.5 m Additional Storage	E=A-C	0.35	0.35	0.33	0.32	0.15	0.14	0.11	0.11	0.19

[12] Relevant weeks from a biological perspective are in mid-May (Lake Whitefish habitat availability), mid-June (ice-off) and mid-September (Lake Trout spawning). Mid-November has been added to show the minimum range between water levels. The highest difference in weekly average water levels occurs in weeks 18-19.

At 545 GW.h		Mid-May		Mid-June		Mid-September		Mid-November		Annual Average
		Week 19	Week 20	Week 24	Week 25	Week 37	Week 38	Week 45	Week 46	
No Additional Storage	A	663.63	663.89	665.13	665.23	665.17	665.17	664.79	664.71	664.48
With 1 m Additional Storage	B	662.82	663.08	664.34	664.47	664.67	664.67	664.31	664.23	663.87
With 0.5 m Additional Storage	C	663.16	663.42	664.68	664.80	664.91	664.91	664.53	664.46	664.14
Difference between no Additional Storage and 1 m Additional Storage	D=A-B	0.81	0.80	0.79	0.76	0.50	0.50	0.47	0.48	0.61
Difference between no Additional Storage and 0.5 m Additional Storage	E=A-C	0.47	0.47	0.45	0.43	0.26	0.26	0.25	0.25	0.33

On average, the Project will result in the following lower operating levels of lake operation based on the modeling assessments shown in Figure 6-3 and Figure 6-4, as well as Table 6-1 (the ranges shown are for 0.5 m and 1.0 m LSL):

- At 442 GW.h/year grid load level, the average Mayo Lake operation with additional 0.5 m storage for the year compared to the existing licence conditions will be 0.19 metres lower, and 0.29 metres lower under 1 m storage. At the higher load of 545 GW.h/year these values would be 0.33 metres and 0.61 metres respectively.

- At the 442 GW.h/yr. load level, the modeling results show that depending on water conditions, the difference in lake elevation as compared to the baseline (no additional storage) will vary over the year ranging from 0.11 m to 0.35 m under the 0.5 m additional storage range; and ranging from 0.17 to 0.50 m under the 1 m additional storage range.

- At the 545 GW.h/yr. load level, the modeling results show that depending on water conditions, the difference in lake elevation as compared to the baseline (no additional storage) will vary over the year ranging from 0.25 m to 0.47 m under the 0.5 m additional storage option; and between 0.47 m and 0.81 m for the 1 m additional storage option.

Figure 6-3:
Average Water Levels by Month Derived from Water Modeling (1981-2008)
(assuming grid load of 442 GW.h/year)

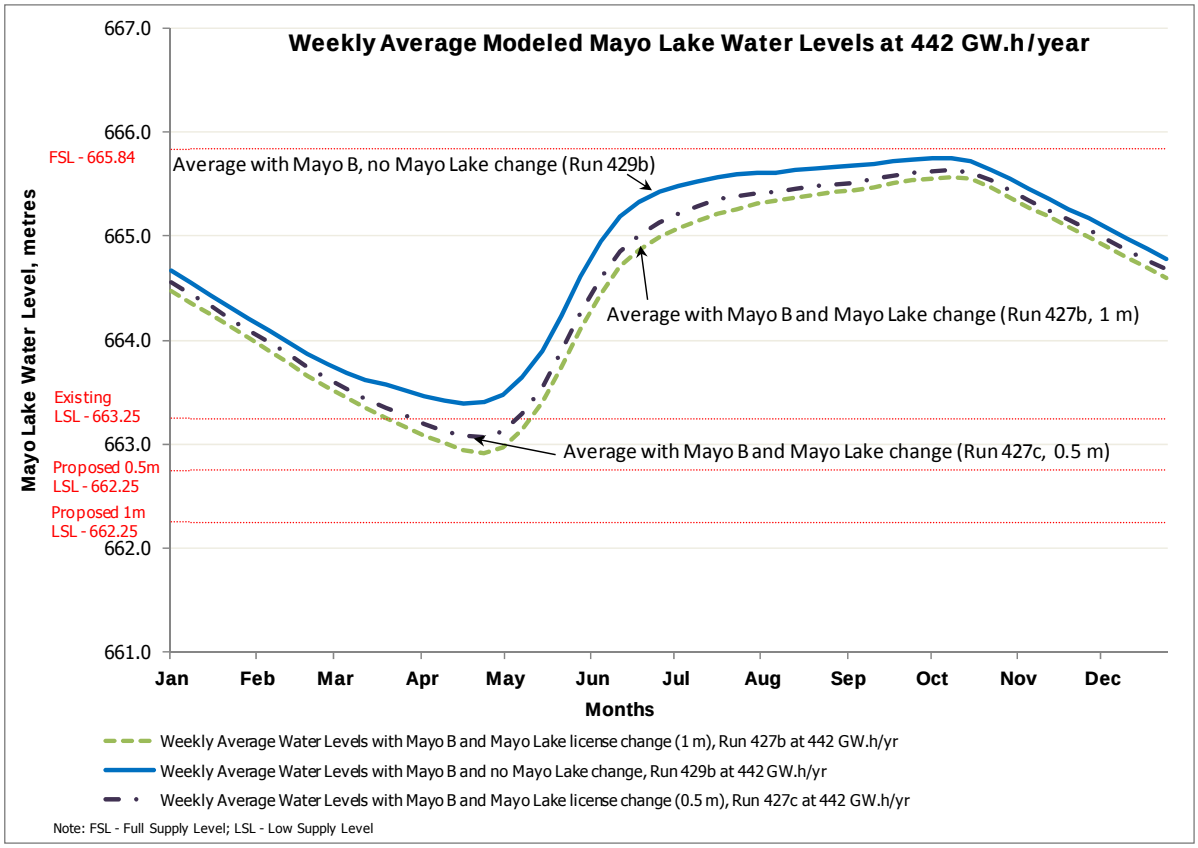

Figure 6-4:
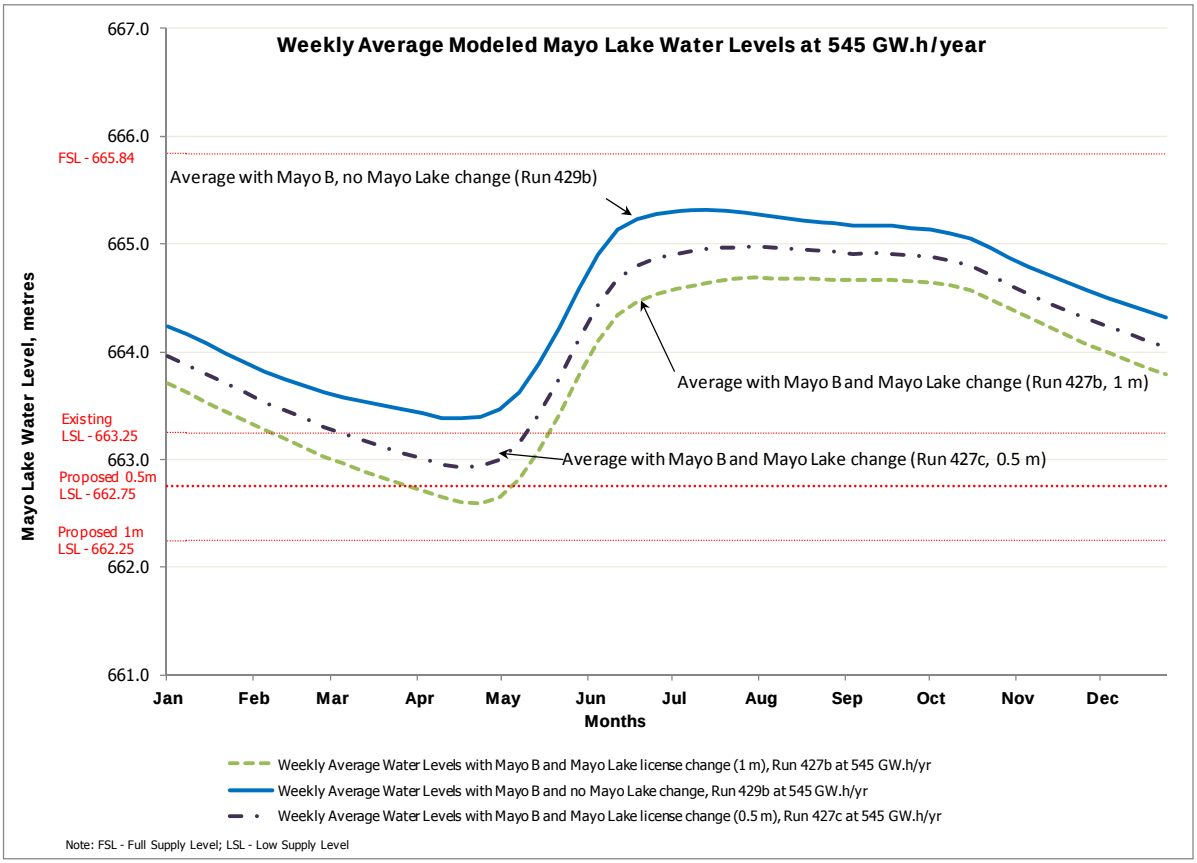
Average Water Levels by Month Derived from Water Modeling (1981-2008)
(assuming grid load of 545 GW.h/year)



Additional power generation benefits will not be realized every year. In low inflow years, there could be little to no incremental benefits; however, in high inflow years (i.e., flood years), benefits of having a larger storage reservoir could be substantial. In that regard, the average changes to lake levels throughout the year do not fully demonstrate the economic value of the Project, as it arises in the different water conditions that can be experienced over several years. On an annual basis, the variations in water levels are shown in Figure 6-5 and Figure 6-6 for the range of representative grid loads. The water elevations shown in these figures are derived from the outputs of modeling the respective water inflows from each year shown on the horizontal axis – from 1981 to 2008. These figures demonstrate the flood reserve nature of the Project, particularly in years with large refills, such as 1988; in that year the lower elevation permitted with the proposed Project allows a large spring freshet to be stored, as the lake is raised back up to the full supply level by summer. Absent the proposed Project, this water condition would lead to major spillage starting in early summer.

Figure 6-5:
Modeled Mayo Lake Water Levels at 442 GW.h/Year, by Water Year 1981 to 2008

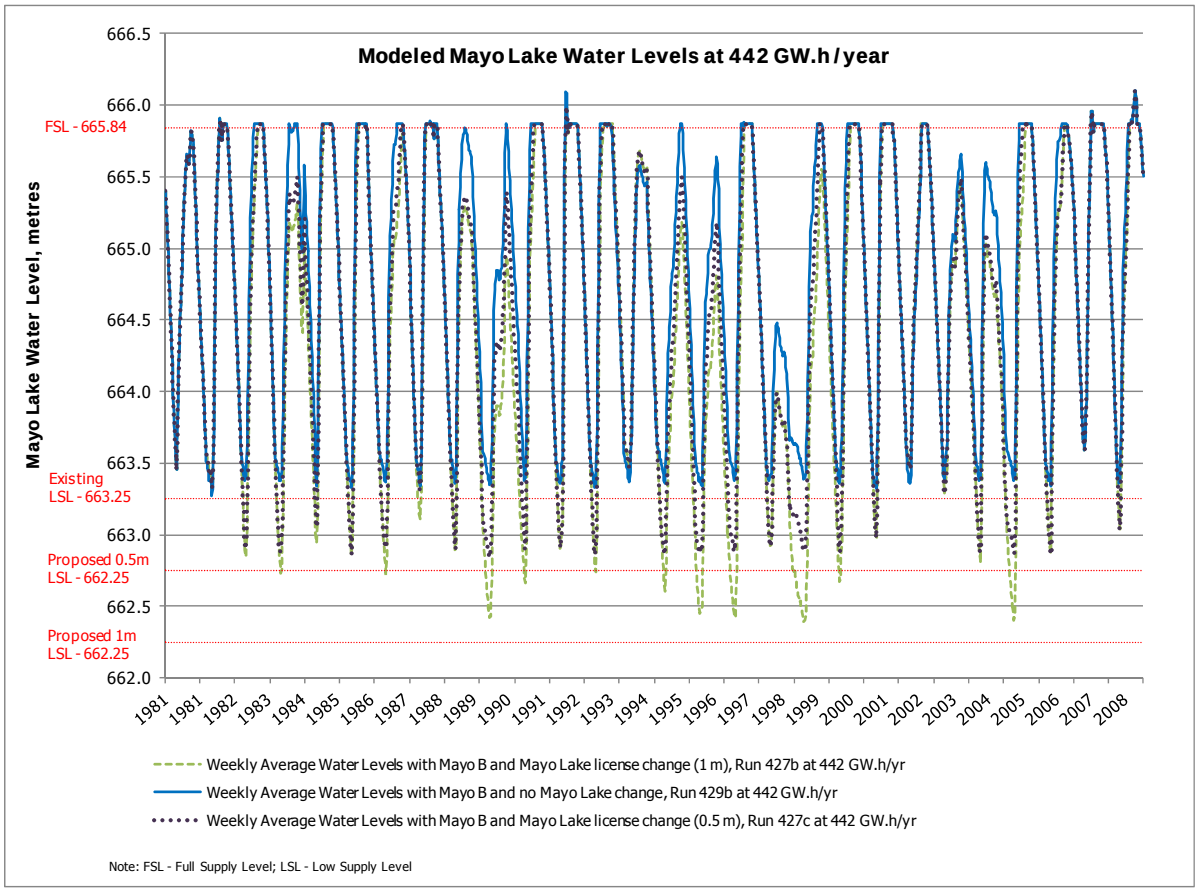


Figure 6-6:
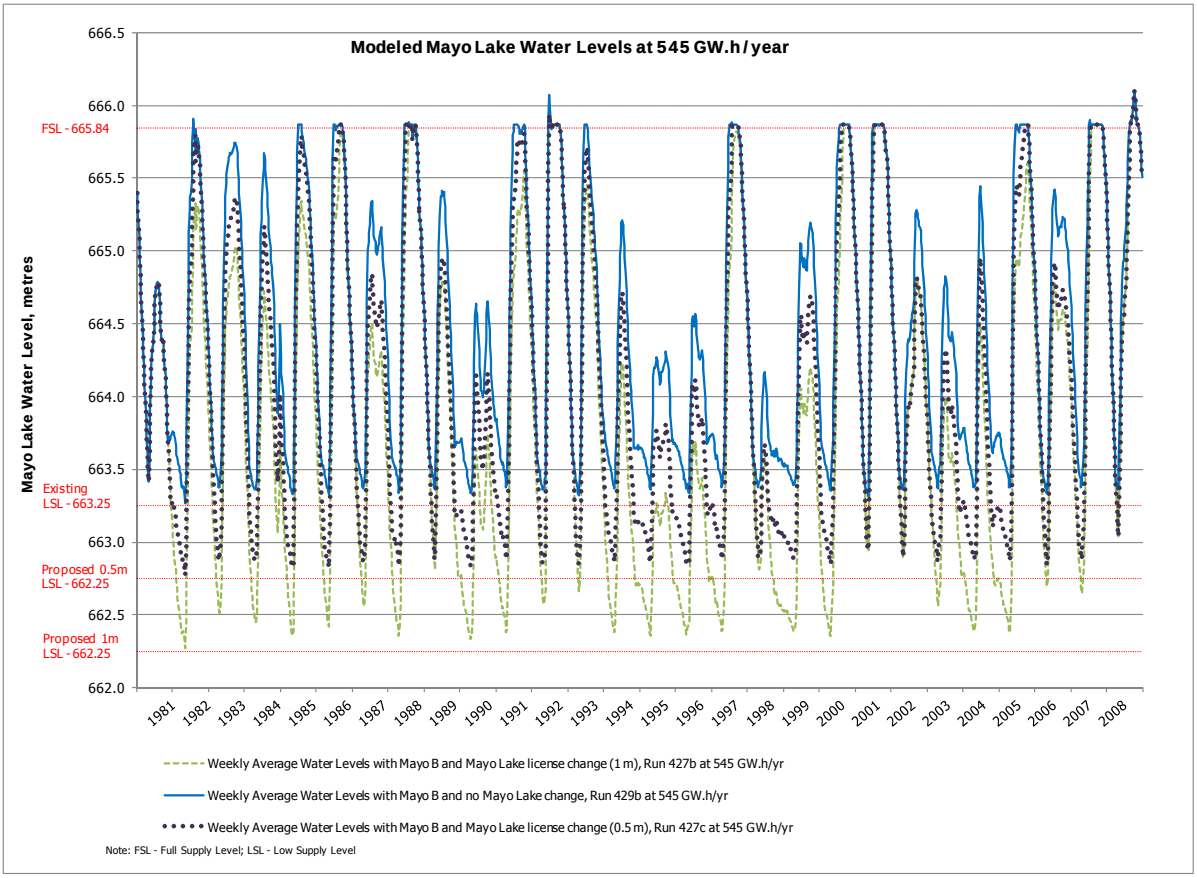
Modeled Mayo Lake Water Levels at 545 GW.h/Year, by Water Year 1981 to 2008



In summary, the following conclusions are provided based on the above figures the range of expected grid load conditions:

- With the proposed Project, the new lower range will be expected to be used to some degree in each year to ensure the ability to capture the extra water when it may come. The degree of use will be reduced for lower grid loads versus higher grid loads within the range examined in the above figures.
- The typical maximum water elevation (summer peak level) will be lower than with the baseline conditions.
- As provided in Figure 6-3 and Figure 6-4 above, based on long-term average hydro generation with the Mayo Lake Project, cycling within a year would be similar to the baseline conditions but at a lower average elevation.

The Project includes a comprehensive Monitoring and Adaptive Management program (Appendix 8A and B), which in some instances can lead to progressive revisions to the water management parameters, most notably the lower supply level. In the event these provisions are triggered, the water management objectives for Mayo Lake would remain the same. Specifically, with a slightly increased LSL, Yukon Energy would continue to attempt to maximize the potential provided by the enhanced range as flood

reserve by making maximum use of the water storage resource through the winter season, and permitting spring freshet refill to be stored to the extent permitted by the then-governing range.

7.0 ENVIRONMENTAL AND SOCIO-ECONOMIC EFFECTS ASSESSMENT

Chapter 7 provides an assessment of the effect of the Project, focusing on the following:

- Overview of Approach;
- Identification of Valued components (VCs);
- Assessment of Environmental and Socio-Economic Effects; and
- Other Potential Effects.

7.1 OVERVIEW OF APPROACH

This chapter provides an assessment of the environmental and socio-economic effects of the Project to determine whether, after the implementation of mitigation measures, the Project is likely to result in significant adverse residual effects (including significant adverse cumulative effects) on identified VCs. The effects assessment builds on the framework established in earlier chapters, including:

- The assessment approach as reviewed in Chapter 3;
- The public consultation as described in Chapter 4;
- The results of an environmental and socio-economic scan provided in Chapter 5;
- The Project Description as discussed in Chapter 6; and
- The proposed monitoring and adaptive management plans in Chapter 8.

There are two main pathways for effects from the Project on VCs:

- **Project-related direct and indirect changes to the aquatic and terrestrial environment:** Changes to the aquatic and terrestrial VCs (including associated wildlife and aquatic life) as a result of a change in the water management regime. Environmental changes can also be linked indirectly to subsequent socio-economic effects such as resource use (as noted under next bullet).
- **Project-related direct and indirect socio-economic effects:** Supply of lower cost grid electricity to displace thermal generation during Project operation resulting in saving benefits to ratepayers, benefits flowing to NND and a decrease in greenhouse gas emissions. Changes to access for users and resource harvesters on Mayo Lake as a result of a change in the water management regime. As noted above, environmental changes to the biophysical environment can be linked indirectly to socio-economic effects.

Both beneficial and adverse environmental and socio-economic effects are explored, where appropriate, along with the potential effects of the environment on the Project (i.e., climate change).

The assessment focuses on effects of the Project that are considered "likely" to occur. Based on the approach set out in Chapter 3, the expected effects of Project activities are assessed for each

environmental and socio-economic VC, focusing on the effect attributes, or criteria, described in Chapter 3 (See Chapter 3 for details on each):

- Direction or nature of the effect;
- Magnitude of the effect;
- Geographic or socio-economic extent of the effect;
- Duration of the effect;
- Frequency of the effect;
- Reversibility of the effect;
- Ecological or socio-economic context; and
- Likelihood of effect being significant.

Significance for the Project's effects on any VC is determined using the approach and criteria set out in Chapter 3 based on scientific analysis of ecosystem effects including Traditional Knowledge and local knowledge, socio-economic research and professional judgment. Noted uncertainties in the information base about potential effects on VCs, but where the risk of serious irreversible effects is negligible, are addressed further in Chapter 8 Monitoring and Adaptive Management Plans.

7.2 IDENTIFICATION OF VALUED COMPONENTS

As discussed in Chapter 3, a VC based approach is intended to ensure that potential significant adverse effects to important environmental and social components will be detected and mitigated through the assessment process. Consistent with environmental assessment best practice, VCs for this assessment were identified based on the following considerations:

- Focal species and habitat (i.e., defining landscape attributes required to meet the needs of biota, and also the management regimes that should be applied to them);
- Representation (i.e., seeking to maintain an appropriate representation of ecosystem networks and populations on the landscape over time, while recognizing and managing for natural temporal fluctuations in composition that occur);
- Special elements (for example rare or under-represented ecosystems, rare and/or threatened flora or fauna species, important harvested species, and unique landforms);
- Socio-economic context (i.e., a socio-economic component recognized as being important because of its integral connection to, or reflection of, the socio-economic system; its commercial or economic value; and/or its role in maintaining quality of life in a community);
- Ecological processes (processes of social or environmental importance); and
- First Nation/Resident/Community values or concerns.

The selection of VCs helped to focus the assessment on components deemed to be of particular importance or of special interest to residents/users or to the ecosystem. The VC selection process also helped to define and describe effects pathways, and to identify temporal and spatial boundaries for the assessment of Project effects.

In this assessment, the analysis focuses on those environmental and socio-economic components that may potentially be affected by the Project. As such, the VCs selected for this assessment must be valued in environmental or socio-economic terms, and have some connection to or overlap with the Project that could create a pathway for effects to occur. VCs were identified through:

- Consultation with interested parties (as described in Chapter 4);
- Consideration of the environmental and socio-economic setting (as discussed in Chapter 5 and appendices). This includes field studies undertaken within the aquatic and terrestrial environments; heritage resources field studies; socio-economic data collection; a consideration of Traditional Knowledge and local knowledge and plans and policies applicable to the Project; and
- Consideration of the Project Description (as described in Chapter 6) and likely pathways of effect on the environmental and socio-economic setting.

During the consultation process, certain issues were identified that are of social or environmental importance related to the existing environment, but that do not have pathways of effect flowing from the Project (e.g., raptors, caribou, climate change, changes to existing fish passage); these topics are discussed in Chapter 4. The proposed Project is not anticipated to have effects related to these existing environmental concerns and as such no VCs have been defined related to these concerns for the current assessment.

Consistent with Environment Canada's *Environmental Assessment Best Practice Guide for Wildlife at Risk in Canada* (Lynch Stewart, 2004), all species at risk (that are either listed federally under the Species at Risk Act, or by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC)) that may be present in the proposed Project Regional Study Area were initially considered in the environmental VC scoping. As described in Chapter 5, bird species of conservation concern (Committee on the Status of Endangered Wildlife in Canada) known or likely to occur within the Mayo region include the following: Horned Grebe (special concern), Peregrine Falcon (special concern), Short-eared Owl (special concern), Common Nighthawk (threatened), Olive-sided Flycatcher (threatened), Barn Swallow (threatened) and Rusty Blackbird (special concern).

Nesting of Peregrine Falcons in the regional study area is unlikely and even if nesting did occur, effects of the Project on Peregrine Falcons or their habitat are extremely unlikely. As such Peregrine Falcon, which is a species at risk, is not considered as a VC for the purposes of this assessment. Similarly, although the environmental surveys included a survey of raptor nests to determine their relative abundance and distribution in the Project Regional Study Area, nest trees were located above the waterline in taller trees that are not expected to be affected by the Project. Therefore raptors are not considered a VC for this assessment.

Finally, well-chosen VCs can provide a representative measure of the Project's effects on the non-selected environmental and socio-economic components. Further, measures designed to mitigate adverse effects

on VCs also serve to minimize the likelihood of adverse impacts on other environmental and social components. For example, in this assessment two key aquatic environmental VCs were identified: lake trout and lake whitefish. While there are other aquatic fish species that may potentially be affected by the Project, the assessment related to these two VCs substantially addresses potential pathways of effect of the Project on other fish species. The Mayo Lake population of lake trout and lake whitefish were selected as VCs as they represent the dominant predator and prey species in Mayo Lake and are thus major components of the aquatic ecosystem and they appear to be more sensitive to water level changes due to general life history and spawning/rearing habitat requirements. Measures to protect or evaluate impacts for these species would also likely cover other shallow lake spawning and rearing by other fish species. It is anticipated that mitigation measures adopted relative to potential effects on these VCs will also be effective for other aquatic species.

The following sections summarize and characterize the VCs considered in this assessment.

7.2.1 Environmental Valued Components

This section provides a description of the environmental VCs considered in the effects assessment. Environmental VCs include both aquatic environment VCs and terrestrial environment VCs that are of particular concern in the Local Study Area and that may potentially be affected by the Project. Table 7-1 summarizes the Environmental VCs, the characterization of potential effects on the VC and the parties who identified the VC as a potential concern.

Table 7-1: Environment Valued Components Considered for the Assessment of the Mayo Lake Enhanced Storage Project

Key Interests	Valued Component	Identified by[1]:	Pathway of Potential Effect
Freshwater Fish and Habitat	Lake Trout Population	NND, OP, OG	Increase in winter drawdown range of Mayo Lake may result in potential increased dewatering and duration of dewatering of lake trout spawning areas, resulting in decreased egg survival during incubation.
	Lake Whitefish Population	NND, OG, OP	Increased operating range and reduction of the LSL of Mayo Lake may result in a change of the amount of shallow littoral rearing habitat quantity and fry growth and survival in early spring; and potential effects on spawning success for fish that may spawn in the lake not influenced by streamflow.

[1] NND = Government and Citizens of the First Nation of Nacho Nyak Dun; OP = Other Interested Persons; and OG = Federal, Territorial, or Municipal, Government.

Key Interests	Valued Component	Identified by[1]:	Pathway of Potential Effect
	Fish community productivity	OG	Increase in winter drawdown and reduced LSL of Mayo Lake water levels may affect the fish community productivity and species composition, Such changes may arise due to reduction in juvenile lake trout/lake whitefish abundance and/or changes in invertebrate/aquatic macrophyte communities. Over the longer term, ongoing small effects in terms of reduced growth and survival of sub adult and adult year classes of lake trout and lake whitefish could result in lower productivity and sustainable harvest potential and result in increased vulnerability to overharvest.
Wetland Type Habitat	Roop Lakes	NND, OP	Increase in winter drawdown range of Mayo Lake may alter wetland habitat quality in the Roop Lakes area.
	Shallow Water Littoral Areas at the ends of Roop and Nelson Arms	NND, OP, OG	Increased use of lowered LSL storage may potentially affect quality and quantity of shallow water littoral area in Roop Arm and Nelson Arm. This includes potential changes in aquatic macrophyte and in vertebrate communities and productivity.
	Ducks, Geese and Migratory Birds	NND, OP, OG	Increased winter drawdown and water level management range with reduced LSL may potentially affect waterfowl breeding and staging areas in the wetland areas at the end of Roop Arm and Nelson Arm.
Aquatic Mammals	Aquatic Furbearers – Beaver/Muskrat	NND, OG	Increased winter drawdown and water management range and reduced LSL of Mayo Lake may directly affect lake shoreline habitat resulting in challenges exiting and entering lodges; likely will lead to effects on beaver & muskrat (access to food caches; increased predation) in the lake proper only during the winter months. Adjacent systems such as the Roop Lakes area will not be affected.
Mammals	Moose	NND, OG	Mayo Lake water level fluctuations may affect littoral and wetland moose habitat. Potential changes to forage distribution, quality and/or quantity.

7.2.2 Socio-Economic Valued Components

This section provides a description of the Socio-economic VCs considered in the effects assessment. Socio-economic VCs include components related to traditional and domestic resource use (including commercial trapping); other resource use (including placer mining, tourism, outfitting, outdoor recreation, and private & commercial land use); and regional economy. Table 7-2 summarizes the socio-economic VCs, the characterization of potential effects on the VC and the parties who identified the VC as a potential concern.

Table 7-2: Socio-Economic Valued Components Considered for the Assessment of the Mayo Lake Enhanced Storage Project

Key Interests	Valued Component	Identified by[2]:	Pathway of Potential Effect
Traditional and Domestic Resource Use	Hunting - Access	NND, OP	Mayo Lake water level fluctuations may potentially affect access for hunting in some years in the spring (i.e., boat access to Roop Lakes Complex).
	Fishing - Access	NND, OP	Lower water levels in spring may affect access for a short time period in late May/early June.
	Fishing – Harvest Success	NND	Mayo Lake water level fluctuations may indirectly affect fish harvest success.
	Trapping - Access	NND, OP	Access to trapping activities at Mayo Lake will not be adversely affected.
	Trapping - Success	NND, OP	Trapping success for beaver may be affected due to less beaver along the Mayo Lake shoreline (including the ends of Roop and Nelson arms).
Other Resource Use	Placer Mining - Access	OP	Short-term effects in late May/early June (after ice-off) may affect placer miners using the barge access in the outlet channel and shoreline access to claims.
	Tourism, Outfitting and Outdoor Recreation	NND, OP	Increased winter flows may affect snowmobiling and access to trails along the Mayo River Zone 4 if suspended ice occurs in late winter/early spring. Lower early spring water levels on Mayo Lake may affect timing and ability to use beach and boat launch at west end of Mayo Lake.

[2] NND = Government and Citizens of the First Nation of Nacho Nyak Dun; OP = Other Interested Persons; and OG = Federal, Territorial, or Municipal, Government.

Key Interests	Valued Component	Identified by[2]:	Pathway of Potential Effect
	Private & Commercial Land Use	OP, OG	Lower early spring water levels on Mayo Lake may affect water access to commercial and private lease-holders (including placer miners) and property owners at Mayo Lake. Increased winter flows from Mayo Lake to Wareham Lake – there is no expectation of an adverse effect on private lease-holders and property holders between Mayo Lake and Wareham Lake.
Regional Economy	Government Fiscal Flows	NND	Yukon Energy and NND have reached an investment agreement; NND has the opportunity to accrue benefits in the form of financial returns commensurate with their investment.
	Utility Ratepayers	NND, OP, OG	Improved system capability and reliability through new renewable power generation at stable costs, and reduced fossil fuel generation costs to service future load growth. Reduced reliance on fossil fuel generation to meet the growing demand will reduce greenhouse gas emissions as per Yukon Government policy.

7.3 ASSESSMENT OF EFFECTS

As reviewed in Chapter 3 (Section 3.2), for the purpose of assessing environmental and socio-economic effects of the Project, current conditions in areas potentially affected by the Project and the projected evolution of these conditions without the Project are considered. Project effects on existing conditions are predicted for each environmental and socio-economic VC by comparing (a) "what would be expected in the future without the Project" and (b) "what would be expected in the future with the Project".

7.3.1 Assessment of Effects on Environmental Valued Components

Section 7.3.1 provides assessment of Project effects and mitigation measures with regard to the following environmental VCs:

- Lake trout population;
- Lake whitefish population;
- Fish community productivity;
- Roop Lakes;
- Shallow water littoral habitat at the ends of Roop and Nelson arms;
- Ducks, geese and migratory birds;
- Aquatic furbearing mammals – Beaver; and
- Moose.

With respect to cumulative effects, the effects assessment considers several existing environment activities, including fishing and recreation, and sediment releases and transport related to various existing activities in the Project Regional Study Area. No specific future changes to these existing conditions are identified based on other projects known to be occurring in the future; therefore, current conditions are expected to continue.

Table 7-3 summarizes the effects assessment for each of the environmental VCs. More detail on certain specific effects on environmental VCs is provided below.

Table 7-3: Environmental Effects Assessment

ID #	Description/Nature of Potential Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring/Follow-up
Lake Trout Population						
1	Increase in winter drawdown range of Mayo Lake may result in potential increased dewatering of lake trout spawning areas, resulting in decreased egg survival during incubation.	• 1 in 3 year rest rule. • Experimental deepwater spawning habitat enhancement and/or use of temporary covers to direct choice of spawning habitat. • Progressive water management responses as specified in the AMP. • Reduce dewatering period by delaying the timing of drawdown if necessary and/or faster early spring refilling by reducing outflows (within operational and licensing constraints).	• Potential increased harvest pressure especially by anglers who select for large spawning size fish; this would reduce resilience of the population.	• Potential short-term adverse effects on lake trout spawning and incubation success. • No long-term adverse effects on lake trout at the population level.	• Direction: Adverse • Magnitude: Moderate • Geog. Extent: Low • Duration: Short-term • Frequency: Moderate • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	• Comprehensive field monitoring program with annual reporting and review of results. • Adaptive management with defined thresholds and rules. • Annual meeting with Mayo RRC and local residents to review field monitoring results and collect local and TK observations (see details in Monitoring and AMP).
Lake Whitefish Population						
2	Increased operating range and reduction of LSL of Mayo Lake may result in some potential short-term decrease in shallow littoral rearing habitat quantity and fry growth and survival in early spring, especially in the end of Nelson Arm; and potential effects on lake spawning success.	• 1 in 3 year rest rule. • Progressive water management responses as specified in the AMP. • Faster early spring refilling by reduction of outflows if necessary (within operational and licencing constraints).	• Potential increased harvest pressures by subsistence gillnet fishers in the future.	• Potential short term adverse effects on lake whitefish rearing, growth and survival of fry. • No long-term adverse effects on Lake whitefish populations.	• Direction: Adverse • Magnitude: Small to Moderate • Geog. Extent: Low to Moderate • Duration: Short-term • Frequency: High • Reversibility: Reversible • Ecological/SE Context: Moderate No significant adverse effect.	• Comprehensive field monitoring program with annual reporting and review of results. • Adaptive management with defined thresholds and rules. • Annual meeting with Mayo RRC and local residents to review field monitoring results and collect local and TK observations.

ID #	Description/Nature of Potential Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring/Follow-up
Fish Community Productivity						
3	Increase in winter drawdown and reduced LSL of Mayo Lake water levels may affect the fish community productivity in terms of reduced survival and growth, especially in terms of Lake trout incubation success and juvenile lake whitefish rearing in shallow littoral habitat, at the ends of Roop and Nelson arms. Over the longer term, ongoing small effects in terms of reduced growth and survival of sub adult and adult year classes could result in lower productivity and sustainable harvest potential and result in increased vulnerability to overharvest.	• 1 in 3 rest rule. • Progressive water management responses as specified in the AMP. • Ongoing evaluation of monitoring data to determine if long term small changes (i.e., chronic effects) are occurring. • Periodic harvest monitoring to allow for timely changes to harvest management if necessary.	Increased harvest pressure by anglers on adult lake trout spawners could result in fish community changes including an increase in abundance of other prey fish species.	• No likely short to medium effects but over long term fish community could change in terms of reduction in lake trout and lake whitefish populations and increased abundance of other species especially with increased harvest pressure.	• Direction: Adverse • Magnitude: Moderate • Geog. Extent: Moderate • Duration: Medium Term • Frequency: Moderate • Reversibility: Reversible • Ecological/SE Context: Moderate No significant adverse effect.	• Comprehensive long term monitoring program involving hydro acoustic surveys and SPIN netting and other interim sub-adult and adult monitoring. • Adaptive management with defined thresholds and rules including changes in year class strength of Lake trout and Whitefish; long term overall combined abundance as the major predator/prey species that remains within the range of natural variability for healthy Yukon populations. • Annual meeting with Mayo RRC and local residents to review field monitoring results and collect local and TK observations.
Roop Lakes						
4	Increase in winter drawdown range of Mayo Lake may alter wetland habitat quality in the Roop Lakes area.	None required (see Monitoring and Follow-up).	None identified.	• None.	• Direction: Positive • Magnitude: Moderate • Geog. Extent: Moderate • Duration: Long-term • Frequency: Moderate • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	• A follow-up wetland health assessment in 5-10 years post Project to compare the Pre-Project assessment of 2010. • Monitoring of water elevations in Roop Lakes to confirm independency from Mayo Lake at lower water levels. • Monitoring of water levels in Roop Lakes in response to changes in water level management of Mayo Lake.

ID #	Description/Nature of Potential Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring/Follow-up
Shallow Water Littoral Areas at the ends of Roop and Nelson arms						
5	Increased use of lowered LSL storage may potentially affect quality and quantity of shallow water littoral area in Roop Arm and Nelson Arm. This includes potential changes in aquatic macrophyte communities and invertebrate productivity.	• Progressive water management responses as specified in the AMP.	None identified.	• Potential shifts in aquatic macrophyte community and invertebrates.	• Direction: Positive and/or Adverse • Magnitude: Moderate • Geog. Extent: Low • Duration: Medium to Long-term • Frequency: High • Reversibility: Reversible • Ecological/SE Context: Moderate No significant adverse effect.	• Comprehensive field monitoring program (focus on fish use of these habitats) with annual reporting and review of results. • Periodic sampling of aquatic macrophytes. • Annual meeting with Mayo RRC and local residents to review field monitoring results and collect local and TK observations.
Ducks, Geese and Migratory Birds						
6	Increased winter drawdown and water level management range with reduced LSL may potentially affect waterfowl breeding and staging areas in the wetland areas at the end of Roop Arm and Nelson Arm.	None required.	None identified.	• Potential shifts in locations for waterfowl breeding and staging areas within the Mayo Lake watershed.	• Direction: Neutral No significant adverse effect.	• Incidental collection of Post Project bird observations. • Annual meeting with Mayo RRC and local residents to collect local and TK observations.
Aquatic Furbearing Mammals						
7	Increased winter drawdown and water management range and reduced LSL of Mayo Lake may directly affect lake shoreline habitat, resulting in challenges exiting and entering lodges; likely will lead to effects on beaver & muskrat (access to food caches; increased predation) in the lake proper only. Adjacent systems such as the Roop Lakes area will not be affected.	None required.	None identified.	• Potential for adverse effects on aquatic furbearers due to reduced water levels in winter and reduced overwintering habitat.	• Direction: Adverse • Magnitude: Low • Geog. Extent: Low • Duration: Long term • Frequency: High • Reversibility: Reversible (at project decommissioning or if storage range reduced) • Ecological/SE Context: Low No significant adverse effect.	• Post Project observation of use of lake lodges through technical, local and traditional knowledge.

7.3.1.1 Lake Trout Population

Lake trout are the most abundant and dominant predatory fish in Mayo Lake and therefore perform important ecological functions in terms of fish community stability and balance. Lake trout are also most sought after for recreational and subsistence fisheries. Lake trout are a cold water fish species well adapted to large lakes and are found in numerous lakes throughout much of the Yukon.

As determined by 6 years of baseline data collection, the peak spawning activity for lake trout occurs during the last week of September. Lake trout are broadcast spawners and eggs are deposited over loosely sorted cobble/boulder areas in a number of areas of Mayo Lake; Gull Island is the primary spawning site with secondary spawning sites in the Main Arm and western portion of Roop Arm. Eggs incubate within the substrate over the winter months, hatch during the spring and emerge as a fry when the lake becomes free of ice in early June.

Determining the water depth of egg deposition was a key component of aquatic baseline studies conducted from 2009 to 2014. This was accomplished through the use of egg collector bins which allow for a density of eggs to be measured across a range of depths (Figure 7-1). When data from all years are combined, eggs have been captured at full supply depths of 1.4 to 4.2 m with peak deposition in the 2.5 to 3.5 m range. As the lake is not always at the full supply level during spawning, it is also possible to view the egg collector data in terms of spawning water depths[3] where eggs were captured at depths ranging from 1.0 to 3.9 m with the peak deposition in the 2.0 to 3.0 m range. Refer to aquatic baseline reports 2009 - 2014 in Appendix 5A for additional information on egg collector results.

Figure 7-1: Lake Trout Egg Collector

Lake trout egg incubation studies were done in combination with the egg collector studies to determine how lake trout egg survival is influenced by water level management during the incubation period (Figure 7-2; Figure 7-3; Figure 7-4). Conducted for 4 years, these studies involved the collection of a small number of spawning adults, the onsite fertilization of eggs, placement of eggs into incubators and deployment into the lake across a range of depths. When retrieved the following spring, it is possible to determine how winter drawdown influenced survival of eggs exposed to differing amounts and duration of dewatering. The results of these studies indicate that lake trout eggs are resilient and are able to

[3] Spawning water depths refer to the depth of water at the time of spawning (last week of September) whereas full supply depths refer to the depth of water when the lake is at the full supply level.

survive despite being dewatered during the winter months provided that they are rewatering prior to ice off (emergence period) of the lake and ice cover/snow is maintained through the dewatering and rewatering period. The level of survival of dewatered eggs is dependent on dewatering duration. For example, egg survival for incubators dewatered up to 8 weeks was within the range of variation of non-dewatered incubators. When dewatering increased to 9 weeks or greater, there was a notable trend of decreased survival with an increased duration of dewatering. The ability for salmonid eggs to survive in dewatered conditions has been documented in published literature on the subject. Refer to aquatic baseline reports 2009-2014 and Attachment 5A-7 in Appendix 5A for additional information on egg incubation studies and the ability for eggs to survive dewatered conditions.

Figure 7-2: Collecting Lake Trout Eggs

Figure 7-3: Lake Trout Egg Incubators Deployed in the Lake Bed

The proposed reduction in LSL and increased overwinter drawdown may result in potential increased dewatering of lake trout spawning areas and increased duration of dewatering, resulting in decreased egg survival during incubation. In order to predict how the change in water management may influence lake trout egg survival, egg collector and egg incubation data was used to develop a model which combined modelled lake elevation data with existing egg deposition and survival data. The results of this

model (Appendix 5A, Attachment 5A-7 – Lake Trout Egg Survival technical memo) indicate that there may be a decrease in egg survival during some years; however, there are also a number of years where egg survival is very high and similar to Pre-Project levels. The modelling exercise also indicated the importance of spring water levels on egg survival, in particular the magnitude of spring water level increases prior to complete ice off on the lake during early June. A rapid increase in water levels during the month of May provides the potential to rewater eggs that were dewatered during the winter months and thus allow for increased survival of these eggs. Reducing the duration of dewatering and/or modifying the timing of water level fluctuations has the potential to result in higher egg survival.

Since baseline data collection activities specific to Mayo Lake began in 2009, lake trout eggs have been captured at full supply depths[4] of 1.4 to 4.2 metres at the main Gull Island spawning area, the primary spawning site in the lake. Despite predicted reductions in egg survival during some years, lake trout are long-lived species, which may spawn for 10-20 years and as such are somewhat resilient to variable year-to-year spawning success. They are also known for their adaptability to changing conditions[5]. Existing sources of data (historic and baseline) for Mayo Lake indicate that there are normal distributions of age and size ranges of lake trout despite the lake being used as a reservoir since the 1950s. For example, 2010 index netting data for the period of time when more of the existing storage range was used (1980s) indicate that successful lake trout recruitment was occurring every year, and there do not appear to be relationships between age class strength and magnitude of winter drawdown/minimum winter elevation.

Potential increased harvest pressure, especially from anglers who select for large spawning size fish, could act cumulatively in the future, thus reducing the resilience of the population to the effects of water level management.

Figure 7-4: Lake Trout

Mitigation and Monitoring

The primary mitigation for the Project includes the application of monitoring results to a well-designed Adaptive Management Plan (AMP; Appendix 8A) with well-defined thresholds and responses. An adaptive

[4] Full supply depths refers to the water depths measurements based on the water level being at the full supply level (665.87 m); Spawning water depths are depths based at the peak time of lake trout spawning for a particular year (last two weeks of September).

[5] Refer to Aquatic Baseline reports in Appendix 5A.

management approach is acceptable given the Project and project effects are reversible and lake trout are a long lived species that may spawn multiple (10-20) times during their lifespan. The extensive baseline studies and lake trout egg survival modelling help to predict Project effects on lake trout. The AMP will ensure that effects are detected and addressed in a timely fashion to ensure that long term effects to lake trout do not occur.

The AMP is driven by an extensive monitoring plan for the Project. The monitoring plan includes a number of components which focus on lake trout and will include the following (see Chapter 8 and Appendix 8A Monitoring Plan for details). The collection of monitoring data for several life stages from egg to juvenile and adult is intended to ensure that any potential effects of the Project are detected and addressed in a timely fashion without causing long term harm to the lake trout population.

- Lake trout spawning and incubation through egg collectors and incubators to monitor changes in spawning and incubation success at the primary spawning site;
- Beach seining of juvenile lake trout to provide an index of young-of-the-year (YOY) abundance and monitor spawning, incubation and rearing success;
- Hydroacoustic surveys to provide an index of sub-adult lake trout to monitor overall recruitment of a number of year classes and support the results of the YOY monitoring (i.e., beach seining); and
- Summer Profundal Index Netting (SPIN) of large sub-adult and adult lake trout is proposed to monitor long-term change to large juvenile and adult Lake trout populations and year class abundance and variability.

As originally proposed in the Mayo B YESAA Proposal, Yukon Energy will implement a one year-in-three rest rule, which states that in the event that winter drawdown exceeds 2.59 metres for two years in a row, the third year's drawdown will be equal to or less than 2.59 metres. Maintaining the existing maximum water level drawdown of 2.59m (as described in Chapter 6) in at least one out of any three year period, at a minimum, should provide a safeguard to allow successful spawning and incubation in these years.

Experimental lake trout spawning habitat rehabilitation of potential deepwater spawning areas at key spawning locations (i.e., Gull Island) has been initiated and will be continued and expanded in accordance with the AMP (see the Monitoring Plan in Appendix 8A) (Figure 7-5; Figure 7-6). The frequency of additional cleaning will depend on the rate of sedimentation as observed during the monitoring, as well as overall level of usage by spawning lake trout. A description of the deep substrate cleaning trials and results are provided in Appendix 5A – 2013 and 2014 Baseline Studies Report. Additionally or alternatively, the use of temporary covers to direct choice of spawning habitat may also be employed as an experimental mitigation measure (it has been done successfully in other southern lakes) to potentially increase lake trout egg survival by limiting access to shallow water areas subjected to longer periods of winter dewatering and thus decreased egg survival.

Figure 7-5: Deepwater Lake Trout Spawning Habitat Before Rehabilitation

Figure 7-6: Deepwater Lake Trout Spawning After Rehabilitation

An alternative method of increasing lake trout egg survival may be to reduce the duration of dewatering of eggs by delaying the timing of drawdown if necessary, and/or faster early spring refilling by reducing outflows during the month of May (if feasible and within operational and licensing constraints for the upper and lower Mayo River).

Monitoring data will be reviewed on an annual basis by the Mayo Lake Project Management Committee (MLPMC), a joint committee comprised of YEC and NND representatives and an advisory group comprised of members from the Mayo District RRC and regulators (Yukon Environment). The data will be reviewed in a timely manner each year to allow for AMP responses and/or mitigation measures to be applied during the following year. This will ensure that in the event that the identified thresholds are breached, the appropriate AMP response is made in a timely fashion.

To summarize, lake trout monitoring will include the following (see Chapter 8 and Appendix 8A Monitoring Plan for details):

- Immediate Indicator: Lake trout spawning and incubation through egg collectors and incubators to monitor changes in spawning and incubation success;
- Immediate Indicator: Beach seining of juvenile Lake trout to monitor spawning, incubation and rearing success;
- Near to Medium Term Indicator: Hydroacoustic surveys of sub-adult Lake trout to monitor sub-adult recruitment to support the results of the early year class monitoring (i.e., beach seining); and
- Long-Term Indicator: Summer Profundal Index Netting of adult Lake trout to monitor long-term change to large juvenile and adult Lake trout populations.

The independent expert hired by the Technical Working Group, Dr. Drew Bodaly, reviewed the monitoring plan and the AMP and concluded that risk of irreversible, long-term harm to lake trout populations was low given the implementation of these plans (see Appendix 8C for further details on Dr. Bodaly's report).

Determination of Significance

In summary, residual adverse effects on lake trout are expected to be moderate in magnitude (may be small if in the range of natural variability and harvest pressures remain low), short-term in duration, low in geographic extent, of moderate frequency, reversible, and ranks low in ecological context. Overall, Project effects are deemed **not significant**.

7.3.1.2 Lake Whitefish Population

Lake whitefish are the dominant and most abundant prey fish species found in Mayo Lake and are the primary food source for predatory fish in the lake including lake trout, northern pike and burbot. Lake whitefish are found throughout a wide range of habitats in the Yukon including large deep lakes and shallower more productive waterbodies. Tagging studies and juvenile fish sampling conducted during the baseline studies have indicated that the majority of lake whitefish spawning in the Mayo Lake system occurs in large tributary streams to the lake and in areas where these streams flow into the lake; spawning was confirmed in Edwards, Roop, Granite and Nelson creeks (Figure 7-7). It is possible that lake whitefish have adapted to spawn in or adjacent to tributary streams since the impoundment of the lake in the 1950s although stream spawning has been documented in other areas of the Yukon for this species. The timing of spawning is somewhat variable and is determined by water temperatures with stream spawning occurring earliest (late September), followed by stream mouth areas in mid-October and lake spawning after mid-November.

Figure 7-7: Lake Whitefish Spawning Area in a Tributary to Mayo Lake (Upper Roop Creek)

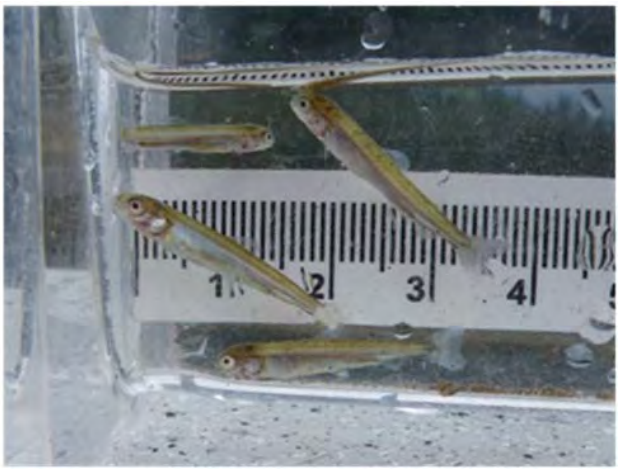
Lake whitefish have a reproductive strategy that involves large numbers of small eggs and fry with minimal yolk sacs and less swimming ability compared to other salmonids such as lake trout. They spawn in areas where early spring river and wind lake currents will deposit the fry in warm shallow waters that are productive in terms of planktonic food when the main part of the lake is still frozen. Thus shallow littoral and wetland areas such as the ends of Roop and Nelson arms that become ice free and warm up weeks before ice off are critical to survival of lake whitefish fry (Figure 7-8; Figure 7-9) (see Appendix 5A – Mayo Lake Aquatic Baseline Studies 2010 for additional information on ice off conditions). It is important to note that Roop Lakes constitute an important early rearing habitat for lake whitefish and a number of tagged lake whitefish from Mayo Lake were found to migrate to Roop Creek upstream of the lakes for spawning.

The proposed reduction in LSL and lower spring water levels may result in changes to the amount of shallow water littoral habitat in Mayo Lake for lake whitefish fry during the spring (mid-May). A reduction is predicted (see Appendix 5A, Attachment 5A-8 Lake Whitefish Early Spring Rearing Habitat technical memo) at the end of Nelson Arm where lower water levels result in less shallow water habitat due to the bathymetry of the lake bed in this area. The bathymetry at the end of Roop Arms differs from Nelson Arm in that lower water levels will result in an increased amount of shallow water habitat available in this area.

It is possible that a reduction in shallow water habitat quantity during the important spring rearing period may have a potential effect on fry growth and survival in Nelson Arm. There is also potential for water level changes to have minor effects on egg survival in lake spawning areas; however, these are not expected to be considerable due to the presence of flowing water in the vicinity of these areas.

Figure 7-8: Early Spring Lake Whitefish Rearing Habitat in Nelson Arm

Figure 7-9: Lake Whitefish Fry



Despite predicted reductions in spring rearing habitat during some years, lake whitefish are long-lived species that may spawn for 10 years or more and as such are somewhat resilient to variable year-to-year spawning success. In populations not affected by water management, periodic reductions in juvenile recruitment have not resulted in long term reductions in adult abundance. This is supported by population status data from other large Yukon lakes that show considerable variation in age class strength (see Appendix 5A – Mayo Lake Aquatic Baseline Studies 2010). Existing sources of data (historic and baseline) for Mayo Lake indicate that there are normal distributions of age and size ranges of lake whitefish despite the lake being used as a reservoir since the 1950s.

Potential increased harvest pressures by subsistence gillnet fishers in the future could act cumulatively, reducing overall numbers of lake whitefish in Mayo Lake and thus reducing the resiliency of the population to respond to changes in water management.

Mitigation and Monitoring

The primary mitigation for the Project includes the application of monitoring results to a well-designed Adaptive Management Plan (AMP; Appendix 8B) with well-defined thresholds and responses. An adaptive management approach is acceptable given the Project and its potential effects do not pose the risk of

serious irreversible harm and also that lake whitefish are a long lived species that spawn multiple times during their lifespan. The extensive baseline studies and lake whitefish rearing habitat area analysis help to predict Project effects on lake whitefish. The AMP will ensure that effects are detected and addressed in a timely fashion to ensure that long term effects to lake whitefish do not occur.

The AMP is driven by an extensive monitoring plan for the Project. The collection of monitoring data for numerous life stages is intended to ensure that any potential effects of the Project are detected early and are addressed without any long term harm accruing to the lake whitefish population. The monitoring plan includes a number of components which focus on lake whitefish and will include the following (see Chapter 8 and Appendix 8A Monitoring Plan for details):

- Immediate Indicator: Beach seining of juvenile lake whitefish to provide an index of young-of-the-year (YOY) abundance and monitor early changes (i.e., in the year they occur) due to spawning, incubation and rearing success (Figure 7-10);
- Near to Medium Term Indicator: Hydroacoustic surveys to provide an index of sub-adult lake whitefish (along with lake trout) to monitor overall recruitment of a number of year classes and support the results of the YOY monitoring (i.e., beach seining); Shallow water small mesh netting to monitor changes in relative age class strength of sub-adult lake whitefish; and
- Long-Term Indicator: Index netting and/or SPIN surveys to monitor long-term changes in age class strength of adult lake whitefish and overall species composition in the lake.

Figure 7-10: Beach Seining for Juvenile Lake Whitefish

As described above, the one in three rest rule will maintain the existing maximum water level drawdown of 2.59 m in at least one out of a three year period (at a minimum), which may reduce effects on lake spawning in these years and result in an increased amount of spring rearing habitat availability in shallow water littoral areas at the ends of Roop and Nelson arms due to higher spring water levels with the reduced overwinter drawdown.

An alternative method of increasing early season juvenile lake whitefish survival may be to allow for faster early spring refilling by reducing outflows during the month of May (if feasible and within operational and licensing constraints for the upper and lower Mayo River). This would result in increased shallow water littoral habitat availability at the ends of Roop and Nelson arms.

The independent expert hired by the Technical Working Group, Dr. Drew Bodaly, reviewed the monitoring plan and the AMP and concluded that risk of irreversible, long-term harm to lake whitefish populations was low given the implementation of these plans (see Appendix 8C for details on Dr. Bodaly's report).

Determination of Significance

In summary, residual adverse effects on the lake whitefish population are expected to be small to moderate in magnitude, short-term in duration, low to moderate geographic extent, high frequency, reversible, and ranks moderate in ecological context. Overall, Project effects are deemed **not significant**.

7.3.1.3 Fish Community Productivity

The proposed increased storage range of Mayo Lake may potentially affect fish community productivity as a result of many factors that may include a reduction in juvenile lake trout and lake whitefish abundance, changes in plant or invertebrate communities and productivity and/or increase in harvest pressure. A reduction in the proportion of lake trout and lake whitefish in the lake may lead to shifts in overall species composition within the lake. For example, some Yukon lakes that have historically had high lake trout harvest pressure have experienced a shift in species composition with more adaptable and prey species such as burbot, longnose sucker and round whitefish becoming more common than lake trout and lake whitefish (inferred from index netting results – Mayo Lake Aquatic Baseline Studies 2010).

Mitigation and Monitoring

Mitigation measures include the one in three rest rule described above, progressive water management responses specified in the AMP, and periodic harvest monitoring to allow for timely changes to harvest management if necessary.

Monitoring related to fish community productivity includes the following (see Chapter 8 and Appendix 8A Monitoring Plan for further details):

- Hydroacoustic surveys to provide an index of lake whitefish to monitor overall recruitment of a number of year classes and support the results of the YOY monitoring (i.e., beach seining);
- SPIN surveys to monitor long-term changes in lake trout abundance with incidental information on age class strength;
- Index netting and small mesh netting surveys to monitor long-term changes in age class strength of lake whitefish and determine overall species composition in the lake; and
- Harvest monitoring every five years Post-Project to provide a measure of fishing pressure and harvest.

Determination of Significance

In summary, residual adverse effects on the lake whitefish population are expected to be moderate in magnitude, medium-term in duration, moderate geographic extent, moderate frequency, reversible, and rank moderate in ecological context. Overall, Project effects are deemed **not significant**.

7.3.1.4 Roop Lakes

The Roop Lakes wetland is a wetland complex located to the northeast of Mayo Lake (Figure 7-11). The wetland covers an area of approximately 12 km^2 (de Graff 2010) and is a complex network of lakes, ponds and interconnected channels. The wetland is drained by Roop Creek, which includes one major tributary (Granite Creek), and flows into Mayo Lake at the eastern end of Roop Arm. Edwards Creek, an important spawning area for lake whitefish enters Roop Creek immediately upstream of Mayo Lake.

An increase in storage range of Mayo Lake, which will involve somewhat lower average summer water levels, increased winter drawdown and lower spring water levels on Mayo Lake may alter wetland habitat quality in the Roop Lakes area. NND and Can-nic-a-nick Environmental Sciences undertook a Roop Lakes Wetland Health Assessment in 2009/10 (see Appendix 5A, Attachment 5A-14 for details) and concluded the following:

- The pond closest to Mayo Lake (Pond 1) had diminished biological diversity and richness, increased presence of decaying organic matter, low abundance of sensitive species and high abundance of a single invertebrate group compared to Ponds 2 and 3, which are further upstream from Mayo Lake;
- There was diminished evidence of impact as one moved upstream into the Roop Lakes system (towards Ponds 2 and 3);
- There was no evidence of impact from water management of Mayo Lake on upper most water body sampled (Pond 3); and
- The Roop Lakes wetland is important habitat for flora, fauna and rearing and spawning habitat for some species of fish.

Figure 7-11: Roop Lakes Wetland Complex

In addition to the Roop Lakes Wetland Health Assessment, KGS Group undertook a backwater study in 2008 to understand the effects of Mayo Lake water levels on the hydraulic conditions of Roop Creek and Roop Lakes (see Appendix 5, Attachments 5A-16 and 17).

In general, the extent of backwater effects and the threshold water levels at which these occur vary with higher or lower flow levels coming out of Roop Creek. When flows in Roop Creek are low, the Roop Lakes

complex is more susceptible to backwater effects from Mayo Lake. The Mayo Lake elevations that result in backwater effects on Roop Lake include the following:

- In the lowermost portion of the wetland (closest to Mayo Lake), the minimum Mayo Lake water elevation (El.) that causes backwater effects ranges from El. 664.0 m at low Roop Creek flows (1 m^3/s or less) to El. 664.8 m at high Roop Creek flows (25 m^3/s or more).
- In the uppermost portion of the wetland (furthest from Mayo Lake), the minimum Mayo Lake elevation that causes backwater effects ranges from El. 664.3 m at low Roop Creek flows (1 m^3/s or less) to El. 665.0 m at high Roop Creek flows(25 m^3/s or more).

The results of the wetland health assessment and the backwater effects study are consistent and indicate that the portion of Roop Lakes immediately upstream of Mayo Lake is frequently watered and rewatered as a result of backwater effects from the lake and this is reflected by more lake like characteristics rather than wetland characteristics conditions in this area. With the proposed changes in water management on Mayo Lake, water levels will be lower on average and Roop Lakes will be backwatered less frequently as a result. This should be considered a positive or neutral effect. Less frequent backwatering of the wetlands closer to Mayo Lake will be more similar to the pre-impoundment condition of this area and may allow for the area to stabilize.

Mitigation and Monitoring

Based on the results of the studies described above and in Appendix 5A, it is not anticipated that mitigation will be required.

It is expected that the Project will have a positive or neutral effect on lower pond inundation with shallow water levels and more exposed shoreline that may result in stabilization of this wetland. There are no anticipated effects on the upper Roop wetlands. The Monitoring Plan includes a follow-up wetland health assessment in 5-10 years and 3 years of Post-Project water level monitoring in Roop Lakes at varying distances from Mayo Lake. The results of this monitoring will be compared to Pre-Project data to determine if there are any discernible effects due to the Project.

Determination of Significance

In summary, Project effects on wetlands are expected to be positive and long-term in duration. No further assessment is presented.

7.3.1.5 Shallow Water Littoral Areas at the ends of Roop and Nelson Arms

Baseline studies conducted from 2008 to 2010 identified that the primary lake whitefish spawning areas were located in tributaries to the lake (i.e., Roop, Granite, Edwards and Nelson creeks) and near the outlet of Nelson Creek. In early spring, larval lake whitefish originating in the spawning tributaries emerge and are transported downstream into the shallow water areas within the Roop Lakes wetlands and at the ends of Roop and Nelson arms in Mayo Lake (Figure 7-12). The Roop Lakes wetlands provide a relatively large area of productive shallow water habitat that is not subjected to water level management conditions on Mayo Lake. A larval whitefish drift sampling program conducted during the spring of 2010 documented the downstream movement of larval lake whitefish in the spawning streams from late April until early June, with the highest numbers captured in mid-May. Beach seining conducted

in June and July throughout the lake from 2009 to 2014 has identified the shallow water areas at the ends of the arms as the most important lake whitefish rearing areas in the lake.

Figure 7-12: Shallow Water Littoral Area of Mayo Lake (Roop Arm)

Wetland and shallow littoral areas at the ends of the lake arms become ice free up to a month prior to other areas of the lake due to the inflow of warmer water from tributaries and the presence of shallow water that warms quickly during the spring. These rapidly warming waters provide productive early spring rearing habitat and feeding areas for newly hatched lake whitefish fry.

As noted in Chapter 6, Project Description, the Project will result in increased use of the lower portion of the storage range and lower spring water levels, which may potentially affect the quality and quantity of shallow water littoral area in Roop and Nelson arms. This includes potential changes in aquatic macrophyte and invertebrate communities and productivity.

The presence of aquatic macrophytes in shallow water littoral areas at the ends of Roop and Nelson arms are a distinguishing characteristic of these areas. Aquatic macrophyte surveys conducted during 2010 and 2013 (see Appendix 5A – Mayo Lake Aquatic Baseline Studies) indicate that a variety of aquatic macrophyte species can be found in this area including tall erect plants (ex - *Potamogeton richardsonii*), short plants (*ex - Callitriche hermaphroditica)* and mat forming species (charaphytes). Aquatic macrophytes provide a variety of important ecological processes in shallow water littoral areas of Mayo Lake including water oxygenation, nutrient cycling, provision of shelter for fish and habitat for plankton and invertebrates that are eaten by fish.

With the proposed changes in water management on Mayo Lake, changes in the distribution and relative abundance of the three different plant types are likely to occur. Increasing the magnitude of water level fluctuations may result in a shift towards a higher relative abundance of short and mat forming species such as *Chara* sp., *Callitriche* sp. and *Eloecharis* sp. at the expense of tall, erect species such as *Potamogeton* sp. (Wilcox and Meeker 1990; Hellsten 2002).

In addition to aquatic plants, it is possible that larger water fluctuations may result in changes to the invertebrate communities in these areas, which are the primary food source of lake whitefish in Mayo Lake. With larger water level fluctuations, adaptable invertebrates such as the chironimids are likely to increase (Hunt and Jones 1972) due to a rapid life cycle and strong dispersal abilities. Other invertebrates that have been found to increase with larger fluctuations include amphipods, copepods and oligocheates (McEwen and Butler 2010, Furey et al. 2006, Hunt and Jones 1972). Overall diversity typically decreases in reservoirs with greater diversity often found directly below the maximum extent of drawdown (Fillion 1967). However, the presence of cover features (woody debris) were found to shelter dewatered macro invertebrates (Fillion 1967). Mayo Lake has extensive amounts of woody debris within the current and proposed drawdown zone due to impoundment of the lake and this material may help to offset the effects of winter drawdown on macro invertebrate abundance.

Groups of invertebrates known to decrease in abundance as a result of drawdown conditions include megoptera, plecoptera (Fillion 1967), coleoptera, odonata, ephemeroptera (Hunt and Jones 1972) and mollusca (Fillion 1967, Hunt and Jones 1972). The decline in abundance of these species has been attributed to association between these taxa and aquatic macrophytes, which are sometimes less abundant with larger drawdowns. The ability for some macro invertebrates such molluscs (and presumably gastropods) to survive periods of dewatering has been suggested to be linked to the presence of unfrozen lake bed substrates during drawdown. Late winter investigations in the shallow littoral areas of Mayo Lake have documented the presence of unfrozen substrates despite being dewatered and contacted by ice (Appendix 5A, Mayo Lake Aquatic Baseline Studies 2013). Some researchers have also proposed that increased winter drawdown can result in a larger zone of photosynthetic activity due to greater light penetration as a result of lower water levels (Palomaki 1994). If this were to occur in Mayo Lake, it is likely that the littoral area at the end of Roop Arm would benefit as average spring depths post project are predicted to decrease (see Appendix 5A, Attachment 5A-8 Lake Whitefish Early Spring Rearing Habitat technical memo).

Despite the potential for shifts in aquatic macrophyte and invertebrate communities, the effects on overall fish productivity are expected to be balanced by the positive and negative effects. For example, average lower lake levels may influence the plants and invertebrates in shallow areas, increased light penetration and photosynthesis will increase plants and invertebrate diversity in slightly deeper areas. The effects of the proposed changes in water management on the productivity of these areas will be monitored through an intensive monitoring program aimed at various life stages of fish[6]. In particular, it is anticipated that a decrease in the productivity of these habitats will be detected as changes in the abundance of juvenile/sub-adult lake whitefish, which will be monitored through a variety of methods including beach seining, small mesh netting and hydroacoustic surveys.

[6] Fish have been chosen to be the main method to monitor aquatic productivity as they are an important VC and productively effects will be reflected in the fish data. While aquatic macrophytes will be monitored Post Project, it is considered supplemental information that can be used to explain trends in fish data. Information on changes to plants or invertebrates does not provide clear answers on the overall productivity of a system. Changes to plant and invertebrate communities could be a positive or negative influence the important fish species identified as VCs and as such by focusing the monitoring on the fish, changes in productivity can be put in the context of impacts to VC's that are most important from an ecological and socio-economic perspective.

Mitigation and Monitoring

Mitigation focuses on progressive water management responses as specified in the AMP. The Monitoring Plan contains a comprehensive field monitoring program including Post Project monitoring of aquatic macrophytes and various sampling methods (beach seining, small mesh netting) for fish which use the shallow water littoral areas of Mayo Lake These methods are intended to provide an indirect but important index measure of habitat productivity of shallow littoral areas of the lake including aquatic macrophytes and invertebrates. An annual meeting with the Mayo RRC and local residents to review the field monitoring results and to collect local and Traditional Knowledge observations will also occur.

Determination of Significance

It is uncertain whether the potential project effects will be positive or negative. In the circumstance where the effects are considered adverse, the effects on shallow water littoral areas at the ends of Roop and Nelson arms would be moderate in magnitude, low in geographic extent (i.e., localized to the ends of the arms), medium to long-term in duration, high in frequency, reversible, and rank moderate in ecological context. Overall, Project effects are deemed **not significant**.

7.3.1.6 Ducks, Geese and Migratory Birds

No potential Project effects on nesting songbirds, including species at risk such as the Rusty Blackbird have been identified.

Various species of migratory birds commonly use the Roop Lakes wetland area as well as the shallow water littoral areas at the ends of Roop and Nelson arms (Figure 7-13) (see the Terrestrial Studies Report filed in Appendix 7 of the Mayo B Hydro Enhancement Project). These areas are used for both summer nesting and as stopover habitat during spring and fall migration. Mossop and Sinott (1998a) rated the Roop Lakes wetlands of high importance to waterbirds and other wetland species based on results of an air reconnaissance survey of several wetlands in the central Yukon. NND and Can-nic-a-nick's Wetland Health Assessment report of 2009-2010 identifies a list of species observed during their survey (see Appendix 5A, Attachment 5A-14; Table 11). This report also noted the ends of the Roop Arm and the Roop Lakes areas as important habitat for ducks, geese and waterfowl.

Figure 7-13: Bird Species Frequently Observed at Mayo Lake / Roop Lakes during Migration. From Left to Right: Bald Eagle, Trumpeter Swan, Northern Pintail and Pectoral Sandpiper

Yukon Government's Wildlife Key Areas Database identifies one key wildlife area in the vicinity of Mayo Lake:

- WKA ID 2734 (Figure 7-14) is a summer nesting area for the Bald Eagle and is located at the eastern end of Roop Arm of Mayo Lake and extending into the Roop Lakes system. Note that there is an active Bald Eagle nest where Roop Creek flows in Mayo Lake.

Figure 7-14: Aerial View of WKA 2734 at the East End of Roop Arm

Increasing the storage range of Mayo Lake by reducing the LSL may potentially affect waterfowl breeding and staging areas in the shallow water areas at the ends of Roop Arm and Nelson Arm. The most likely effect on migratory birds is anticipated during the spring migration period when open water areas provide key stopover habitats for these species. During this time of year (late April through late May), much of the landscape remains snow covered and most waterbodies in the region remain frozen until late in May or early June. For this reason, areas that become free of ice early in the year provide important stopover habitat for many bird species. This is the case for the shallow water areas at the ends of Roop Arm and Nelson Arm.

Effects during the summer breeding season and fall staging are not anticipated as water levels during these times of year will on average be lower but more comparable to the baseline. During the summer and fall, birds within the region are much more spread across the landscape due to the considerable increase in available habitat and it is for this reason that the spring migration period, when stopover habitats are limited, is the focus of this effects assessment.

With the increased storage range on Mayo Lake, water levels during May will on average, be lower than the current water level regime by 0.3 m (0.5 m additional storage) to 0.8 m (1.0 m additional storage). This may result in changes in the quantity of different habitat types used as spring stopover habitat. Stopover habitat can be separated into four general types, described below.

- Type I - Shrubs and other terrestrial vegetation - used as spring stopover habitat by numerous species of passerines. Examples of species expected include ruby-crowned kinglet, yellow warbler, yellow-rumped warbler, Wilson's warbler, white-crowned sparrow, dark-eyed junco and rusty blackbird.

- Type II - Mudflats (exposed bare ground and mud) - used as spring stopover habitat by shorebirds and some species of passerines. Examples of species expected include semi-palmated plover, lesser yellowlegs, pectoral sandpiper, American robin, American pipit and Lapland longspur.
- Type III - Shallow water (less than 2.0 m) - used as spring stopover habitat by swans, geese and dabbling ducks. Examples of species expected include Canada goose, trumpeter swan, American wigeon, mallard and northern pintail.
- Type IV - Deep water (greater than 2.0 m) – used as spring stopover habitat by loons, grebes and diving ducks. Examples of species expected include common loon, red-necked grebe, ring-necked duck, lesser scaup and goldeneye.

Based upon existing bathymetric data (see Appendix 5A, Mayo Lake Aquatic Baseline Studies 2009), it is possible to make predictions about how lower spring water levels will influence the availability of each broad habitat type in the shallow littoral areas at the ends of Roop and Nelson arms. In both Roop Arm and Nelson Arm, changes in the availability of Type I Habitat as stopover habitat are not anticipated. Under the current regime and proposed regime, these areas are above the influence of water levels during the spring and will continue to be in the future despite the reduced LSL.

In the Nelson Arm littoral area, lower water levels during May would result in a reduced amount of Type III habitat, which will result in more area of Type II habitat (Table 7-4). In the Roop Arm littoral area, the amount of Type II and III habitat increases Post-Project due to lower water levels (Table 7-4).

The reduction of Type III habitat in Nelson Arm is offset by a larger increase of this habitat in Roop Arm and birds are capable of moving between the two areas. Type II habitat will increase in both arms due to lower water levels. The extent of Type IV habitat cannot be modelled; however, it is not expected to change. Deeper areas become ice free shortly after shallow water areas at the ends of the arms. Notable amounts of this type of habitat typically become available as Nelson and Roop arms become ice free beginning in early May (see Appendix 5A, Mayo Lake Aquatic Baseline Studies 2010 for information on relative time of ice melt).

Table 7-4: Comparison of Spring Stopover Habitat Availability for Migratory Birds During Weeks 18 – 22 (average); 442 GWh Load Scenario

Habitat Type	Storage Range	Habitat Area (ha)[1]		
		Nelson Arm	Roop Arm	Total
Type II - Mudflats (exposed ground[2])	3.59 m	77.46	51.93	129.39
	3.09 m	72.75	44.68	117.44
	2.59 m	58.02	31.50	89.52
	Historical	44.76	19.04	63.80
Type III - Shallow Water (less than 2 m)	3.59 m	28.47	132.48	160.95
	3.09 m	32.07	133.39	165.47
	2.59 m	41.46	125.27	166.73
	Historical	52.84	101.5	154.34

1. The same calculations were done for the 545 GWh scenario which showed a similar pattern to the data shown here.
2. The area between the Full-supply level and the water level.

Despite changes in the relative amount of habitat types available in the two areas during spring migration, it is anticipated that there will be sufficient stopover habitat for all bird species, despite the lower water levels. Given that birds are highly mobile, they are also able to use other wetlands in the region, such as Roop Lakes, a regionally important wetland, which would be relatively unaffected by lower spring water levels in Mayo Lake and would continue to provide a diversity of spring stopover habitat for migratory birds. Incidental observations of Roop Lakes and the ends of Roop and Nelson arms during May of 2010 indicate that Roop Lakes is currently used more extensively by migratory birds than Mayo Lake during spring migration.

Mitigation and Monitoring

No mitigation is required as effects are considered neutral. There is sufficient habitat within the overall Mayo Lake area for shifts in locations of waterfowl breeding and staging areas to occur and not affect the species' populations. As part of the Project's Monitoring Plan, incidental collection of Post-Project observations of migratory birds will occur; as well as annual review with the Mayo District RRC and local residents to collect local and Traditional Knowledge observations.

Determination of Significance

Project effects from a species or regional perspective are expected to be positive and medium term in duration. No further assessment is presented.

7.3.1.7 Aquatic Furbearing Mammals

Aquatic mammals, in particular beaver, activity was observed throughout the aquatic portions of the Project Regional Study Area. Beaver food caches were observed on Mayo Lake, and beaver activity was visible along most of the Mayo River between Mayo Lake and Wareham Lake, including dams on several tributary streams and back channels flowing into that portion of the river.

NND and Can-nic-a-nick's Wetland Health Assessment Report also noted beaver lodges along the Mayo Lake shoreline and in the Roop Lakes wetland area. In addition to beaver, the Report also noted mink and river otters as using the Roop Lakes area.

Beaver lodge occupation surveys during the fall of 2011 and 2014 indicated a low number of active lodges in the main body of Mayo Lake (2 in 2011, 1 in 2014) and 12 inactive lodges (Figure 7-15) (see Appendix 5A, Attachment 5A-12 Current Status of Beaver and Potential Project Effects). Incidental observations from 2008 to 2010 indicated that there may have been up to 4 active lodges in Mayo Lake at this time. Annually since 2009, a combination of incidental observations and survey data indicate that active beaver lodges are located throughout Roop Lakes and also in Nelson Creek immediately upstream of Mayo Lake. A local trapper at Mayo Lake also indicates that beaver appear to be colonizing new habitats in tributaries to Mayo Lake, including Ping Pong Creek (see Appendix 5A, Attachment 5A-12 Current Status of Beaver and Potential Project Effects).

Figure 7-15: Active Beaver Lodge and Food Cache in Mayo Lake (Nelson Arm) During 2014

Increasing the storage range on Mayo Lake by reducing the LSL, and the increased winter drawdown may directly affect beaver overwintering habitat, resulting in challenges exiting and entering lodges, interfering with access to food caches and resulting in an increased risk of predation to beavers exiting their lodges in search of food during the late winter. This effect is limited to the shoreline of Mayo Lake where beavers are currently uncommon. Beavers in the nearby Roop Lakes area and other tributaries to Mayo Lake will not be affected by the increased storage range on Mayo Lake. Effects to beavers in the upper Mayo River are not anticipated as flows in the Mayo River will only change slightly in magnitude and duration with the project.

Observations of other aquatic furbearers such as muskrats, otters and mink have been very infrequent in the main body of Mayo Lake. Incidental observations of these species are primarily limited to the Roop Lakes area and other tributary streams to Mayo Lake, such as Edwards Creek. This is expected as these areas provide more suitable habitat for these species. Seeing as these habitats are not affected by the current water fluctuations or proposed Project, effects to aquatic furbearers other than beaver are not anticipated in the Project area.

It is important to note that tributary streams as well as the Roop Lakes wetland area and the Nelson Creek area will continue to provide suitable overwintering habitat for beavers and other aquatic mammals, thereby providing a source of furbearers for harvest by local trappers and subsistence hunters. Beavers are not likely to re-colonize Mayo Lake under the current or proposed management regime; however, the effect is highly reversible since beaver populations will continue to thrive in Roop Lakes and adjacent tributary systems and they may be able to recolonize the lake in the future if there are changes to the water level management regime that are more conducive to their preferred ecological needs.

Mitigation and Monitoring

Although no mitigation is required, Post-Project monitoring through observation of lake lodges will occur through technical and local knowledge observations. An annual meeting with the Mayo District RRC and local residents to review the field monitoring results and to collect local and Traditional Knowledge observations will also occur.

Determination of Significance

It is expected that adverse effects on aquatic furbearing mammals will be low in magnitude and geographic extent, long-term in duration, high frequency, reversible, and low in ecological context. Although effects on local aquatic furbearers in the Project Local Study Area may remain, there are substantial populations and habitat for aquatic furbearers throughout the Mayo River/Lake and Stewart River watersheds such that the effects from a species or regional perspective will **not be significant**.

7.3.1.8 Moose

Within the Project Regional Study Area, most observations of moose and quality moose habitat occurred within the upper Mayo River, between Wareham Lake and Mayo Lake and in the Roop Lakes wetland area[7] (Figure 7-16). The Terrestrial Studies Report noted frequent observation of bulls and cows with calves along the Mayo River, particularly in the upper Mayo River. Moose trails were also observed during winter overflights, travelling in all directions on the upper Mayo River, with habitat use in high elevation habitats east of the upper Mayo River.

Figure 7-16: Cow Moose at Roop Lakes

According to the NND and Can-nic-a-nick Wetland Health Assessment report, the Roop Lakes area is a popular moose hunting area. The Wetland Health Assessment report indicated sightings of cows and calves in the wetland area during their September 2009 survey. Moose have been observed incidentally on numerous occasions at all times of the year in the Roop Lakes area. Observations from other areas of Mayo Lake have been infrequent.

The above information related to moose is consistent with resource use data collected both during the Mayo B Hydro Enhancement Project and this (Mayo Lake) Project.

Mayo Lake water level fluctuations may potentially affect littoral and wetland moose habitat at the end of Roop Arm and Nelson Arm, with potential changes to forage distribution, quality and/or quantity particularly during late winter/early spring. In particular, the lower average summer water levels and

[7] Refer to Terrestrial Studies Report filed in Appendix 7 with the 2009 Mayo B Hydro Enhancement Project.

reduced LSL and lower spring water levels may result in a shift in aquatic plants that are a major portion of the summer diet of moose, to more shorter 'mat-forming' species of plants that are less desirable forage for moose. These effects are expected to be localized (to Mayo Lake proper) and will not have any predictable effect on the use of the area by moose. Given the large home range of moose, the extensive amount of moose habitat for all life cycles through the Project Regional Study Area, as well as the Local Study Area, effects on moose are not expected to be significant.

Mitigation and Monitoring

Although no mitigation is required, Post-Project monitoring through observation will occur through technical, local and Traditional Knowledge observations. An annual meeting with the Mayo District RRC and local residents to review the field monitoring results and to collect local and traditional knowledge observations will also occur.

Determination of Significance

The likelihood of adverse effects on Moose is uncertain, but in the circumstance where the effects were considered to be adverse they would be low in magnitude and geographic extent, long-term in duration, high in frequency, reversible, and low in ecological context. Overall, potential Project effects are deemed **not significant**.

7.3.2 Assessment of Effects on Socio-Economic Valued Components

This section generally focuses on those VCs of the socio-economic environment that are of particular concern in the Project Regional Study Area and that may be potentially affected by the Project based on the above noted pathways. For the majority of socio-economic components, potential Project effects of operation remain relatively close to the Project Regional Study Area. However, there are some effects of the Project that can extend beyond the Project Regional Study Area (e.g., utility ratepayer effects) to affect the overall Yukon economy in particular.

Section 7.3.2 provides an assessment of Project effects and mitigation measures with regard to the following socio-economic VCs:

- Hunting - Access;
- Fishing - Access;
- Fishing – Harvest Success;
- Trapping - Access;
- Trapping – Success;
- Placer mining - Access;
- Tourism, Outfitting and Outdoor Recreation;
- Private & Commercial Land Use;
- Government Fiscal Flows; and
- Utility Ratepayers.

Table 7-5 summarizes the effects assessment for each of the socio-economic VCs. More detail on certain specific effects on socio-economic VCs is provided below.

Table 7-5: Socio-Economic Effects Assessment

ID #	Description/Nature of Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring/Follow-up
Traditional and Domestic Resource Use						
Hunting - Access						
9	Mayo Lake water level fluctuations may potentially affect access for hunting in some years (i.e., boat access to Roop Lakes Complex).	• Water management to optimize rapid spring refill when feasible.	None identified.	• None; access in fall/winter is when water levels are higher.	• Direction: Adverse • Magnitude: Moderate • Geog. Extent: Low • Duration: Short term • Frequency: Low to Moderate • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	• Annual meeting with Mayo RRC and local residents to collect local and TK observations.
Fishing - Access						
10	Lower water levels in spring may affect access for short time period in late May/early June.	• Improvement of boat ramp/access [also applies to hunting].	None identified.	• Access in early June may be affected in some years.	• Direction: Positive No significant adverse effect.	• Annual meeting with Mayo RRC and local residents to collect local and TK observations.
Fishing - Harvest Success						
11	Mayo Lake water level fluctuations may indirectly affect fish harvest success.	• 1 in 3 year rest rule. • Experimental deepwater spawning habitat enhancement and/or use of temporary covers to direct choice of spawning habitat. • Progressive water management responses as specified in the AMP. • Reduce dewatering period by delaying the timing of drawdown if necessary and/or faster early spring refilling by reducing outflows (within operational and licensing constraints).	None identified.	• None.	• Direction: Neutral to Adverse • Magnitude: Low • Geog. Extent: Low • Duration: Short term • Frequency: Moderate • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	Angler Harvest survey as specified in Monitoring Plan. • Annual meeting with Mayo RRC and local residents to collect local and TK observations.
Trapping - Access						
12	Access to trapping activities at Mayo Lake will not be adversely affected.	• None required.	None identified.	• None.	No affect – determination of significance is not required.	• Annual meeting with Mayo RRC and local residents to collect local and TK observations.

ID #	Description/Nature of Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring/Follow-up
Trapping - Success						
13	Habitat changes along the lake shoreline will result in fewer beaver along the lake proper. No expected effects on trapper success along the tributaries and creeks that feed into the lake, as well as the Roop Lakes system.	• None required.	None identified.	• None.	• Direction: Adverse • Magnitude: Low • Geog. Extent: Low • Duration: Short term • Frequency: Moderate • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	• Annual meeting with Mayo RRC and local residents to collect local and TK observations.
Other Resource Use						
Placer Mining						
14	Short-term effects in late May/early June (after ice-off) will affect placer miners using the barge access in the outlet channel – delayed by approximately 2 weeks.	• The separate project of dredging noted in Chapter 6 will assist with access in the outlet channel.	None identified.	• None.	• Direction: Positive • Magnitude: Moderate • Geog. Extent: Low • Duration: Long term • Frequency: High • Reversibility: N/A • Ecological/SE Context: Low No significant adverse effect.	Occasional follow-up with barge landing users to ascertain effectiveness of access improvement.
Tourism, Outfitting and Outdoor Recreation						
15	Increased winter flows may affect snowmobiling and access to trails along the Mayo River Zone 4 (between Mayo Lake and Wareham Lake) if suspended ice occurs in late winter/early spring. Increased drawdown of Mayo Lake may affect timing and ability to use beach and boat launch at west end of Mayo Lake.	• Improvement of boat ramp/access.	None identified.	• Changes in winter flows may affect snowmobiling and access to trails along Zone 4.	• Direction: Adverse • Magnitude: Low • Geog. Extent: Low • Duration: Short term • Frequency: High • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	Post-license observation through local and traditional knowledge.
Private & Commercial Land Use						
16	Increasing the bottom storage range of Mayo Lake may affect water access to commercial and private lease-holders (including placer miners) and property owners along Mayo Lake (effects likely to occur prior to freshet and will be short-lived).	• Improvement of boat ramp/access.	None identified.	• None.	• Direction: Adverse • Magnitude: Low • Geog. Extent: Low • Duration: Short term • Frequency: High • Reversibility: Reversible • Ecological/SE Context: Low No significant adverse effect.	Yukon Energy to facilitate discussions with regulators to enable land owners access if issues emerge post-project.

ID #	Description / Nature of Project Effect	Mitigation	Cumulative Effects Assessment	Residual Effects after Mitigation	Effect Attribute Ratings & Determination of Significance	Monitoring / Follow-up
17	Increased winter flows from Mayo Lake to Wareham Lake – there is no expectation of an adverse effect on the property owners between Mayo and Wareham lakes.	• None required.	None identified.	• None.	No effect – determination of significance is not required.	Monitoring of water levels at Wareham Lake and Minto Bridge as part of normal operations.
Regional Economy						
Government Fiscal Flows						
18	YEC and NND have reached an investment agreement; NND has the opportunity to accrue benefits in the form of financial returns commensurate with their investment.	None required.	None identified.	• Potential participation in the Project by NND including financial returns commensurate with their investment.	• Direction: Positive • Duration: Long term • Frequency: High No significant adverse effect.	N/A.
Utility Ratepayers						
19	Improved system capability and reliability through new renewable power generation at stable costs and reduced diesel fuel generation costs to service future load growth. Reduced reliance on diesel generation to meet the growing demand will reduce greenhouse gas emissions as per YG policy.	None required.	None identified.	• Lower cost (relative to alternative sources of supply), renewable energy and enhanced system reliability. • Displaced diesel generation resulting in reduced GHG emissions.	• Direction: Positive • Duration: Long term No significant adverse effect.	N/A.

7.3.2.1 Traditional and Domestic Resource Use

Hunting – Access

Hunting is an important activity within the Project Regional Study Area. The majority of moose hunting occurs along the Mayo River between Mayo Lake and Wareham Lake, as well as the area around Mayo Lake, including the Roop Lakes system (Figure 7-17). The Mayo Lake access road is a key area for hunting and access to Mayo Lake and the upper Mayo River areas. Some community members generally launch their boats downstream of the Mayo Lake control structure and float downstream to the Minto Bridge area. The Roop Lakes area is accessible by traversing the length of Mayo Lake by boat and following Roop Creek upstream into the wetland complex.

Figure 7-17: Lower Roop Creek

Mayo Lake water level fluctuations may potentially affect access for hunting in some years. However, most moose hunting occurs in the fall when water levels are at the highest levels. As the LSL will result in the lake being operated at overall lower water levels than in the past, access within the lowest reach of Roop Creek (immediately upstream of Mayo Lake) will experience the most effect.

Flows in the upper Mayo River during hunting season (September) are expected to be similar to the baseline scenario. For example, historical flows (1981-2008) during weeks 37 through 39 (September 10 – 30) have averaged 15.7 cms. Depending on the load scenario and amount of additional Mayo Lake drawdown, modelled outflows from Mayo Lake range from 12.8 to 18.7 cms during this time period (Table 7-6). It is important to note that these flows only represent reaches 11 and 12 (upstream of the Davidson Creek Bridge) as uncontrolled inputs from Davidson and Duncan creeks are not included in this analysis. Flows from these tributaries would be expected to buffer the minor effects to flows on the upper Mayo River during weeks 37 through 39.

Table 7-6: Modelled Mayo Lake Outflows

Load Scenario	Storage Range	Week 37-39 Average Mayo Lake Outflow
442	2.59	18.7 cms
	3.09	18.4 cms
	3.59	17.8 cms
545	2.59	14.6 cms
	3.09	12.8 cms
	3.59	12.8 cms
Historical	2.59	15.7 cms

Boat access to Roop Lakes can be more challenging when water levels in Mayo Lake are low. The very lower portion of Roop Creek does include a deepwater channel that allows for boat access across a wide range of Mayo Lake levels. However, the lower portion of the Roop Lakes wetland complex contains a number of shallow water areas that may become challenging to pass with larger boats when water levels in Mayo Lake are greater than 1.7 m below FSL. This value is based upon field experience by EDI field crews who have accessed the upper portion of the wetland complex when water levels were 1.65 m below FSL. Also of note are the Mayo Lake elevations described by the KGS backwater effect model. This model predicts that the lower portion of Roop Lakes is backwatered when Mayo Lake elevations are between 664.0 and 664.8 m (1.87 and 1.07 m below FSL, respectively. Collectively, this information indicates that a lack of backwater effect on lower Roop Lakes may make boat access to this area more challenging, especially for larger boats (propeller driven boats that have a notable draft). In some years more effort may be required to navigate past shallow areas in the lower portion of the channel nearest Mayo Lake (e.g., lining the boat may be required for short sections).

A comparison of historical and modelled future mid-September water levels (at the 442 GWh load) indicates that with the Project, there may be an increased frequency of years where boat access to Roop Lake may be more challenging (Table 7-7). Lower water levels associated with the 545 GWh load scenario indicate a higher number of years where Roop Lakes access may be more challenging (ex – 8 out of 28 years with 0.5 m of additional storage).

Table 7-7: Mid-September Water Levels at 442 GW.h/yr. Load Scenario

Load Scenario	Storage Range	# of Years with mid-September Water Levels		Average Elevation below FSL
		< 1.7 m below FSL	> 1.7 m below FSL	
442	2.59	28	0	0.17
	3.09	27	1	0.32
	3.59	27	1	0.40
Historical	2.59	28	0	0.53

Mitigation and Monitoring

Operating within technical and licence constraints, Yukon Energy will aim to optimize rapid spring refill when feasible. The one in three rest rule will ensure that in one out of three years, the lake will be

operated with a drawdown of 2.59 m which would allow for greater refilling and subsequently higher mid-September water levels in the following year. Yukon Energy will also be improving the boat launch ramp/access at the west end of Mayo Lake during future outlet channel maintenance activities. Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect local knowledge observations related to a variety of topics including hunting access and can work to resolve issues associated with access, where practical.

Determination of Significance

Project effects on hunting access will be adverse, of moderate magnitude, low geographic extent, short-term in duration, of low to moderate frequency, reversible and low in socio-economic context;. Overall, Project effects are deemed **not significant**.

Fishing – Access

There is a moderate level of fishing activity within the Project Regional Study Area, with lake trout being the primary species of interest. Fishing effort is not as high as compared to other lakes in the Project Regional Study Area due to a number of factors. These factors include the distance from major centers (i.e., Whitehorse) and the unpredictable weather conditions on the large body of Mayo Lake. Ethel Lake is also used more extensively by residents of the Village of Mayo for fishing.

Subsistence fishing occurs on Mayo Lake; specifically local First Nation members have set nets to capture whitefish and this may increase in the future due to harvest restrictions on other important food fisheries (Chinook salmon).

Lower water levels in the spring, especially immediately after ice-off, may potentially affect boat access for a short time period in early June (Figure 7-18).

Figure 7-18: Mayo Lake Boat Launch

Mitigation and Monitoring

Future maintenance to the lake outlet channel will provide the opportunity to improve access to the lake over the current condition. Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect observations and information related to a variety of topics, including fishing access.

Determination of Significance

With mitigation the effects of the Project are considered positive. No further assessment is presented.

Fishing – Harvest Success

Fishing success is mainly dependant on the number of target fish species in the lake. Most fishers target lake trout and the monitoring and adaptive management plans ensure that key thresholds for lake trout at various life stages are maintained (Figure 7-19). There are also key thresholds and adaptive management for the lake trout's primary food source, lake whitefish. Over the short term, there may be some effects to year classes of lake trout and/or lake whitefish; however, the AMP will outline corrective actions if thresholds are reached. Occasional poor age classes are not thought to represent a major effect on the adult population (i.e., the catchable fish). Recruitment into the adult population is typically density dependant, as such the age classes before and after poor years are likely to have higher survival rates (i.e., from less intra-specific competition; North South Consultants 2008).

Figure 7-19: Lake Trout

Mitigation and Monitoring

Mitigation is addressed indirectly by the AMP components that focus on fish; as such, no specific mitigation is required. The Project's Monitoring Plan includes a fish harvest study to be undertaken every five years Post-Project to provide a measure of fishing pressure and harvest success levels. In addition,

Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect local and Traditional Knowledge observations related to a variety of topics, including fishing success.

Determination of Significance

Project effects on fishing success are predicted to be neutral to adverse. In the case of the latter outcome, the effects would be small in magnitude and low geographic extent, short-term in duration, of moderate frequency, reversible and low in socio-economic context. Overall, Project effects are deemed **not significant**.

Trapping – Access

There is limited trapping activity within the Project Local and Regional Study areas although some domestic trapping does continue in the vicinity of Mayo Lake and the upper Mayo River. Due to economic factors (lower prices for pelts and increased cost of being on the land), trapping is not as prevalent in the Local and Regional Study areas as it likely once was.

Access to the land and water for trapping activities will not be adversely affected by the Project. Snowmobile trails on land and across the frozen lake will be comparable to existing conditions.

Mitigation and Monitoring

No mitigation is required as there is no adverse effect. Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect observations and other information related to a variety of topics including trapping access to address any concerns.

Determination of Significance

No significant effects are predicted.

Trapping – Success

As stated above, trapping activity within the Local and Regional Study areas is relatively low. However, as noted in the aquatic furbearing section, Project effects on beaver and muskrat include habitat changes along the lake shoreline (due to increased winter drawdowns and a lower overall LSL) that will result in fewer beaver along the lake proper. There are not expected to be any effects to beaver habitat along tributaries and creeks that feed into the lake, as well as the Roop Lakes system. Taking this into consideration, there is considerable habitat available for the beaver within the Regional Study Area, thus enabling long-term trapping availability for local resource users.

Mitigation and Monitoring

No mitigation is proposed.

Determination of Significance

Project effects on trapping success will be adverse, of small magnitude and low geographic extent, short-term in duration, of moderate frequency, reversible and low in socio-economic context;. Overall, Project effects are deemed **not significant**.

7.3.2.2 Other Resource Use

Placer Mining - Access

As described in Chapters 2 and 5, placer mining activity occurs at Mayo Lake and in the upper-most reaches of the Upper Mayo River (Duncan and Davidson Creeks) within the Local Study Area. Over recent years (i.e., since the Mayo B YESAB submission), the number of active operators around Mayo Lake have declined; however, claim staking in the surrounding land around Mayo Lake has increased.

Operation and management of Mayo Lake water levels pursuant to the revised water management regime will result in a short-term effect in late May/early June (after ice-off) on those placer miners along the lake that require access by barge (Figure 7-20). There will be no effect on placer mining access downstream of the control structure (i.e., Duncan and Davidson creeks).

Figure 7-20: Barge Transporting Heavy Equipment on Mayo Lake

The barges are used to haul heavy equipment, fuel drums and supplies out to placer claims, leaving from the west end of the lake. Mayo Lake must refill sufficiently to enable the barges to float off the mud-flats and subsequently get close enough to the placer claim property to off-load the equipment and supplies on site. Under the proposed management regime, the lowest lake levels will occur at the end of winter/early spring, after the lake has been drawn down to meet winter energy demands. This will

typically occur in late April/early May, just prior to spring freshet in May/June, and prior to the normal ice free season on the lake.

Operating the lake at a lower LSL may potentially result in access issues for some placer claims at the site of operation (each site is unique and does not experience the same access issues). Dredging of the outlet channel is a required activity for the operation of the Mayo Lake Control Structure and will also assist the existing active placer mining operator travel through the channel. Currently, there are few other placer miners operating on the lake; those that remain are aware that the lake is very active, with shifting shoreline conditions due to high wind and wave action.

Mitigation and Monitoring

As noted in Chapter 6, Yukon Energy needs to undertake outlet channel maintenance dredging to remove a build-up of sediment and a cofferdam remnant that is currently affecting their ability to take full advantage of the existing Mayo Lake storage capability. The dredging will assist in removing sediment build-up in the area of the channel next to the barge landing and will ultimately assist placer miners' access to their claims. If issues emerge post-Project, Yukon Energy will facilitate discussion with regulators to address the issue of access to the barge landing and/or placer claims on Mayo Lake.

Yukon Energy will post water levels on their website for easy access by lake users prior to accessing the lake. Occasional follow-up with placer miners and users of the barge landing to ascertain effectiveness of access improvement will be undertaken.

Determination of Significance

Project effects on placer mining are expected to be positive and long-term in duration. No further assessment is presented.

Tourism, Outfitting and Outdoor Recreation

Tourism activities are focused on the vicinity of the Village of Mayo and will not be affected by the Project. Outfitting activities occur beyond the Project Regional Study Area and will not be affected by the Project. Mayo Lake is used for a variety of outdoor recreation purposes (e.g., boating, fishing, camping); and the Upper and Lower Mayo River has some boating/canoeing use although it is not considered "high Use" as other areas in the vicinity of the Village are used more frequently (e.g., Ethel Lake, Five Mile Lake). The Upper and Lower Mayo River will remain available for recreational canoeing and boating for community residents, if so desired.

In years where a part or all of the licenced additional storage is used, there may be some increased winter flows that may affect crossings of the Upper Mayo River if suspended ice occurs in late winter/early spring when flows have to be reduced to meet licence requirements for minimum lake levels. This is expected to be an uncommon occurrence. The area adjacent to and surrounding the Upper Mayo River and Mayo Lake access road provide abundant and suitable areas for snowmobiling, without concerns for late winter/early spring ice conditions.

As noted above, an increased draw-down of Mayo Lake and operation of the lake at a lower supply level may affect timing and ability to use the beach and boat launch at the west end of Mayo Lake. The lowest

lake levels are anticipated to occur in April or early May, just prior to spring freshet in May/June, which generally results in an increase in the lake elevation over a short time period. The potential effect on timing and ability to use the beach and the boat launch is expected to be short in duration.

Mitigation and Monitoring

Yukon Energy will improve the boat launch ramp/access upstream of the Mayo Lake control structure during outlet channel maintenance activities in advance of utilizing the increased storage range. Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect observations and other information related to a variety of topics, including outdoor recreation and access.

Determination of Significance

The residual Project effects on outdoor recreational activities are expected to be adverse, low in magnitude and geographic extent, short-term in duration, of high frequency, reversible and low socio-economic context. Overall, Project effects are deemed **not significant**.

Private and Commercial Land Use

It is unlikely that there will be any discernible Project effects on private or commercial land use within the Project Regional Study Area. There is no expectation of an adverse effect on the property owner near the Minto Bridge from the slight increase in winter flow magnitude and/or duration between Mayo and Wareham lakes.

An increase in the bottom storage range of Mayo Lake may potentially affect water access to commercial and private leaseholders (including placer miners), as well as property owners along the shoreline. However, the timing of affected access will at most be a short window in early June. The majority of property owners and leaseholders are at the west end near the mouth of Mayo Lake, and have existing road access. The Project will potentially provide a positive effect on the issue of erosion, as lower average lake levels will slow down the erosion process.

Mitigation and Monitoring

Yukon Energy is committed to improving the boat launch ramp/access upstream of the Mayo Lake control structure and is currently planning maintenance to the outlet channel that will improve access to the lake over the current condition. Yukon Energy will meet on an annual basis with the Mayo District RRC and local residents to collect observations and information related to a variety of topics, including potential effects on private and commercial land use. If issues emerge post-Project, Yukon Energy will facilitate discussion with regulators to address the issue. Monitoring of water levels and flows downstream of Mayo Lake will continue post-Project.

Determination of Significance

The residual Project effects on private and commercial land use are expected to be adverse, low in magnitude, low in geographic extent, short-term in duration, of high frequency, reversible and low socio-economic context. Overall, Project effects are deemed **not significant**.

7.3.2.3 Regional Economy

The Project is expected to provide regional economic benefits within the Project Regional Study Area and the broader Yukon region.

Government Fiscal Flows

Yukon Energy and the First Nation of Na-Cho Nyak Dun reached a Project agreement in 2010 and an Investment Agreement in 2013 whereby NND has the opportunity to accrue benefits in the form of financial returns commensurate with their investment in the Project. The two Agreements cover both the Mayo B Hydro Enhancement Project and the Mayo Lake Enhanced Storage Project. No mitigation or monitoring is required.

Determination of Significance

Project effects on government fiscal flows are expected to be positive and long-term; no further assessment is presented.

Utility Ratepayers

As discussed in Chapter 6, benefits are expected to be realized by all Yukon utility ratepayers when new industrial loads and on-going domestic load growth can be serviced through additional renewable generation capacity on the system. The Project will result in long-term benefits of providing lower cost (relative to fossil fuel generation) renewable energy and improved system capability and reliability. The Project will also result in reduced reliance on diesel generation, which will reduce greenhouse gas emissions[8].

The Project is consistent with Yukon Government policy, as set out in the *Energy Strategy for Yukon* (2009), which includes the goal of increasing renewable energy supply by 20% by 2020. It also is in alignment with Yukon Government's *2009 Climate Change Action Plan*, which includes the reduction of carbon emissions.

No mitigation or monitoring is required.

Determination of Significance

Project effects on utility ratepayers are expected to be positive and long-term; no further assessment is presented.

7.3.3 OTHER POTENTIAL EFFECTS

In environmental assessment practice, the effects that the environment can have on the project is considered as part of the environmental assessment and appropriate measures are applied to ensure that

[8] By way of example, at the representative range of grid loads (442 GW.h/year to 545 GW.h/year) that potentially could occur during the first 10 years of Project operation, the Project would reduce thermal generation at long-term average hydro generation water conditions by 2.4 to 3.1 GW.h/year with 0.5m reduced LSL and by 3.3 to 4.5 GW.h/year with 1.0 m reduced LSL.

there will be no significant adverse effects in this regard. During the operational phase of the Project, for example, potential effects of the environment could occur as a result of climate change.

Climate Change

The Yukon Government *Climate Change Action Plan*, released in February, 2009 and the Energy Strategy for Yukon, released in January, 2009 both note that increases in renewable generation support government objectives. The plan and strategy, which were developed to complement one another, set reduction of greenhouse gas emissions as a priority. The Yukon Government Climate Change Action Plan identifies renewable resource development, including hydro, as a mitigation strategy that will help reduce or delay global warming (Yukon Government 2009b). The *Energy Strategy for Yukon* sets out the goal of increasing renewable energy supply, including hydro, in the Yukon by 20% by the year 2020. Furthermore, the Energy Strategy seeks to "…optimize the efficiency and reliability of electricity generation and distribution" (Yukon Government 2009a) and recognizes the importance of investing in electricity infrastructure to meet future needs and leverage economic development in the Territory. "Investments in additional renewable energy infrastructure will be required in order to enhance the kinds of long term legacy benefits that are currently enjoyed with the existing hydro system. These investments will also buffer Yukon's energy sector from volatile fossil fuel prices and help to minimize greenhouse gas emissions from diesel generated electricity" (Yukon Government 2009a).

As stated in Yukon Government's *Climate Change Action Plan – 2012 Progress Report*, "Yukon's temperature, wind and precipitation patterns have experienced significant changes. Since 1948, Yukon's annual average temperature has increased by 2.2°C and the average winter temperature by 5.5°C (Environment Canada, Trends and Variations, 2011)" (Yukon Government 2012). The 2012 Progress Report reported on Goal # 2: Adapting to Climate Change, with a specific initiative focused on preparing community adaptation plans. Mayo was part of this initiative with the Yukon Government and the Northern Climate Exchange to complete the Mayo community adaptation plan – these plans are to evaluate vulnerabilities and identify plans to adapt to climate change challenges or opportunities (Yukon Government 2012).

The Mayo Region Climate Change Adaptation Plan indicates that temperature and precipitation trends since 1947 have experienced change, particularly in the years since the 1960s where temperatures warmed in both summer and winter; and precipitation increased in summer and decreased slightly in winter (with high variability).

The Mayo Region Climate Change Adaptation Plan (Hennessey, Stuart, Duerden, 2012) indicates that projections for temperature and precipitation in the region (including the Project Regional Study Area) show an increase between now and 2050 as follows:

- An annual temperature increase of 2.5°C by 2050 under a modest climate change scenario and a 3.6°C increase under a medium-high scenario (with the greatest temperature increase occurring in the winter or spring months); and
- An annual precipitation increase of 10% by 2050 under a modest climate change scenario and a 14% increase under a medium-high scenario (with the greatest precipitation occurring in spring – typically the driest time of year).

Yukon Energy monitors changes in the regional climate in the Project Regional Study Area as necessary using climate information including measurements of temperature, precipitation, and wind speed provided by the Meteorological Service of Canada.

Using climate change predictions for the Mayo region, it is possible to make general predictions in terms of how water levels and the flow regime in Mayo Lake may change. Specifically the following scenarios could occur:

- The predicted increase in air temperature could potentially reduce the period of ice coverage on Mayo Lake and could increase water temperatures in the lake.
- An increase in precipitation within the watershed could translate to overall higher average water levels in the lake.
- In the event of increased snowpack accumulation, this could result in a more rapid increase in water levels during freshet (May). Freshet may also occur earlier in the spring.

On average, the climate change predictions appear to result in a positive effect to fish within Mayo Lake. Increased air temperatures would translate into a slight increase in surface water temperatures in the lake which could increase the overall productivity of the lake. In terms of lake trout, this increase in water temperature could result in a longer growing season which in turn may result in an increased growth rate of juveniles and adults. Lake trout is a cold water species and an increase in water temperatures can be detrimental to populations in small and/or shallow lakes; however, Mayo Lake is a relatively cold and deep lake and even a considerable increase in water temperature would not be expected to negatively affect the species. A reduced period of ice coverage combined with a more rapid increase in water levels during the spring (May), could reduce the potential for egg loss due to dewatering. This may result in increased egg to fry survival which may increase the recruitment success of lake trout over the future water level management scenarios modelled (REF egg survival memo here).

Lake whitefish could also benefit from the climate change predictions due to a potential overall increase in juvenile and adult productivity due to a longer growing season. An increase in air temperatures and precipitation could result in increased winter flows which could in turn positively affect lake whitefish egg survival in the primary spawning areas (tributaries and tributary inlets). An earlier timing of ice off on the lake could also increase early survival of lake whitefish fry by providing warmer water temperatures during the critical spring rearing period. A more rapid freshet would result in an increase in water levels during the month of May and an increased availability of shallow water habitat in the ends of the arms. If this occurred the water levels may be on average higher than the modelled water level management scenarios (REF LW habitat area memo here).

Yukon Energy expects to continue to monitor the capability of major Global Climate models and Regional Climate models to accurately represent climate change variables. As these models are calibrated to predict climate regimes with confidence they potentially may be able to predict the frequency and magnitude of extreme events in the Project Regional Study Area (e.g., severe storms, wind events, flooding). In the event such technological developments are successful, it is anticipated that the results of such models would form a component of Yukon Energy's future planning.

CHAPTER 8
ADAPTIVE MANAGEMENT AND MONITORING

8.0 ADAPTIVE MANAGEMENT AND MONITORING

8.1 INTRODUCTION

Environmental and socio-economic monitoring and adaptive management can be undertaken for the following reasons:

- To ensure the implementation and success of any mitigation measures identified as required or preferred during the assessment process.
- To confirm the accuracy of baseline information or any assumptions made with regard to the Project during the assessment process.
- To test the accuracy of predictions made during the assessment process and ensure that effects are consistent with conclusions in the assessment and any conditions of the approvals provided by the regulator. Adaptive management practices will be applied to ensure effects are consistent with the findings of the assessment and/or to provide adjustments to project operation under the guidance of regulators, the NND First Nation, the Mayo RRC, and technical and traditional knowledge experts to ensure protection of identified valued components.
- To detect any unanticipated project effects and implement mitigative or corrective measures as necessary to ensure that no significant adverse effects result from long term operation of the project under licence conditions and criteria.

This chapter outlines the monitoring and adaptive management plans for the Mayo Lake Project. As stated in Chapter 6, water management in terms of altering water levels at Mayo Lake as a result of the proposed Project will be subject to the Adaptive Management Plan (AMP) and the Monitoring Plan that provides the supporting data inputs to the AMP, each of which will be part of the proposed licence and are non-discretionary.

8.2 MONITORING PLAN

The Monitoring Plan (see Appendix 8A) provides added detail to the methods, types, location and timing of programs identified for Project monitoring. The monitoring components outlined in Section 1.1 of the Monitoring Plan are meant to collect additional baseline data and provide supporting data to be used when interpreting other components of the monitoring plan (e.g., fish sampling). These components do not feed directly into the AMP. These programs include (see Appendix 8A for details):

- Review of lake elevation and climate data;
- Water temperature and turbidity monitoring;
- Late winter ice thickness and water quality monitoring;
- Aquatic macrophyte surveys; and
- Fish harvest (creel) surveys.

The components outlined in Section 1.2 of the Monitoring Plan provide the data to feed into the AMP and depending on the outcome of the monitoring, may require adaptive management responses. These programs include:

- Fisheries studies in Mayo Lake:
    - Annual Lake trout spawning and incubation monitoring using egg collectors and incubators;
    - Annual Juvenile lake trout and lake whitefish monitoring by beach seining in known important index rearing and spawning areas and in new spawning areas ;
    - Periodic medium term Sub-adult lake whitefish/lake trout and monitoring using hydroacoustic surveys and shallow water small mesh gillnetting; and,
    - Periodic medium to long term Adult lake trout and lake whitefish monitoring using SPIN surveys and potentially, lethal index netting.
- Roop Lakes water level and wetland health monitoring; and
- Upper Mayo River geomorphology monitoring.

8.3 ADAPTIVE MANAGEMENT PLAN

The overall purpose of the AMP is to ensure a fully functioning, healthy and sustainable aquatic ecosystem at Mayo Lake based primarily on healthy and sustainable lake trout and lake whitefish populations. Lake trout and lake whitefish are highly sensitive to water management and are the dominant predator and prey species in the lake and thus critical indicator species for the ecosystem. The AMP is intended as a primary instrument for managing water levels and water use for hydroelectric generation at Mayo Lake and establishing ecologically relevant water management criteria and constraints within the overall operating range.

The following objectives for the plan are intended to achieve the overall purpose stated above:

- To identify how the proposed Mayo Lake Project may affect the aquatic ecosystem focusing on the effects on lake trout and lake whitefish as key indicator species;
- To establish appropriate key indicators of a fully functioning, healthy and sustainable aquatic ecosystem;
- To define a monitoring program that is appropriately sensitive and can measure and report, in a timely way, changes in identified key indicators;
- To establish thresholds that defines acceptable and unacceptable conditions or changes in identified key indicators;
- To describe responses that will be undertaken if indicators and thresholds identify unacceptable conditions or trends; and

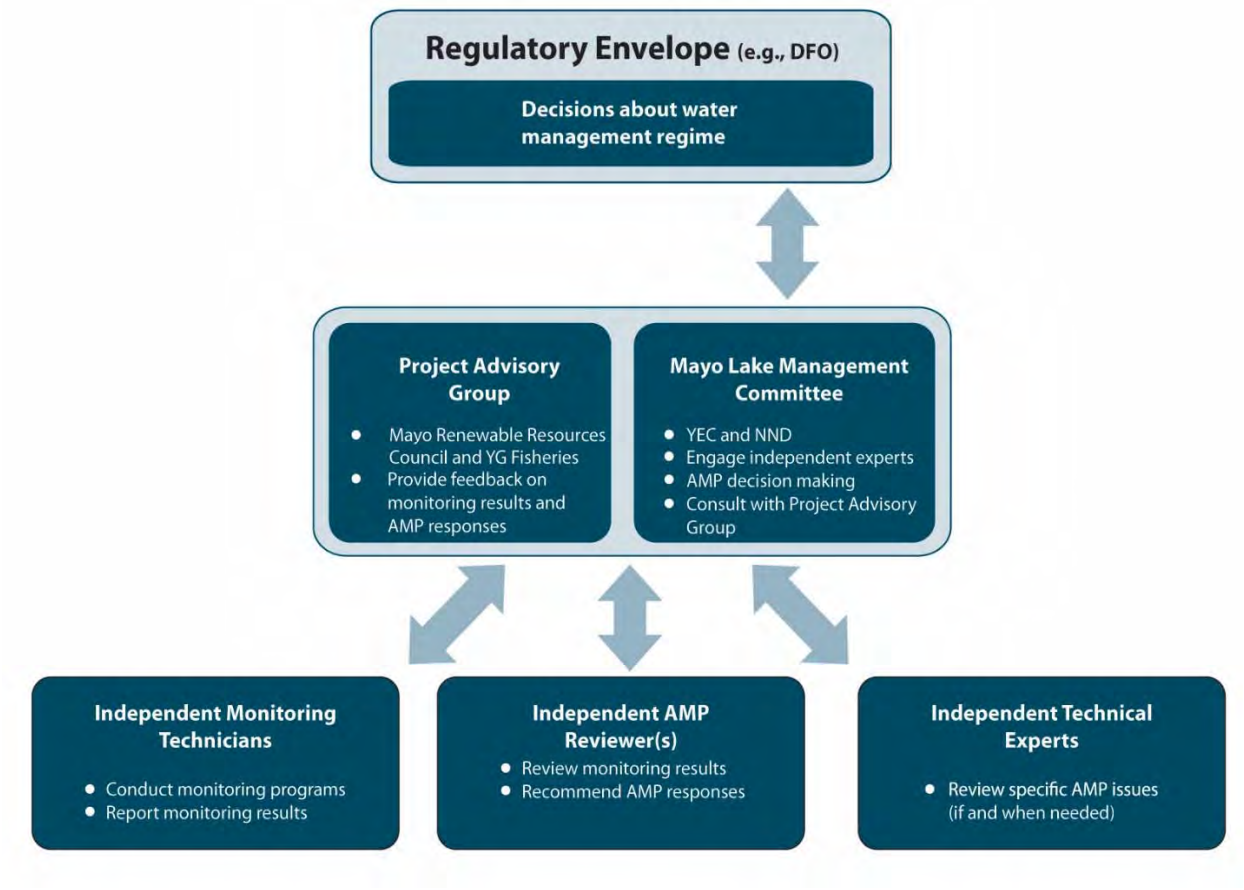
- To establish an inclusive framework involving regulators, NNDFN, Mayo RRC, technical and traditional knowledge experts as well as local users for interpretation of monitoring results, and decision-making about adaptive management responses.

The AMP provides technically and logistically feasible approaches for modifying water level management parameters based on observed impacts and prescribed thresholds and water management responses. Specifically, the AMP addresses both short term annual monitoring of reproductive success/recruitment (in terms of an early warning/indication of adverse impacts) and long term monitoring of sub-adult and adult abundance. Where thresholds for adverse effects are identified either in the short and long term monitoring programs, mitigation measures and changes to water management identified in the AMP will be implemented. It is expected that these programs and operational requirements will be entrenched in the Project authorizations (e.g., water use licence amendment).

The project begins with a cautionary approach, utilizing half of the proposed additional water level range of 1.0 m as a starting point, and relying on the AMP to guide decisions about future increases or decreases from the original storage range increase of 0.5 m. Throughout the operation of the project, the AMP will continue to apply, leading to implementation of appropriate responses if ecological conditions reach action thresholds. Please see Appendix 8B for details on the AMP.

It should be noted that the AMP outlines a framework for evaluation of monitoring results and AMP decision-making – this is described in Section 2 of the AMP. The framework is illustrated in Figure 1 below. Details on each component (e.g., Project Advisory Group, Mayo Lake Management Committee etc.) are described in Appendix 8B.

Figure 1: AMP Evaluation Framework



8.4 EXTERNAL TECHNICAL EXPERT REVIEW PROCESS

Working together as a Technical Working Group, Yukon Energy and NND hired an external independent advisor and technical expert and in 2012 to provide expert and scientific advice on the following:

- The potential risks of long-term harm to the lake trout and lake whitefish populations in Mayo Lake of an increased drawdown range;
- The suitability of the Monitoring and Adaptive Management plans as a means of addressing and managing uncertainties with respect to potential lake trout and lake whitefish responses to the Project; and
- The ability of the Monitoring and Adaptive Management plans to detect unacceptable biological impacts within the context of the AMP of incremental changes over several years in contrast to larger changes over a short period of time.

Process

A scope of work and specific questions were developed by the TWG and provided to the independent advisor Dr. Bodaly who is a highly qualified scientist with significant working experience and expertise on Yukon fish populations. The TWG held two workshops with Dr. Bodaly:

- November 2012: to discuss the Project and the process and expectations of him in his review and provision of expert advice; and
- February 2013: a discussion and review of this draft report. At the same time, YEC's team presented a proposal for changes to the monitoring program to address concerns raised by Dr. Bodaly in his draft report. These changes included proposals for interim monitoring of sub-adult and adult fish in addition to the young-of-the-year and long term adult monitoring included in the original monitoring plan.

Conference calls and email correspondence with Dr. Bodaly also occurred in a transparent manner (i.e., all members of the TWG received information concurrently).Yukon Energy's team as well as NND's team provided comments on the final draft report prior to Dr. Bodaly's submission of the Final Report in mid-March 2013.

Results

The results of the independent review process (see Appendix 8C for the final report) indicated that:

- Risk of irreversible, long-term harm to lake trout and lake whitefish populations is low under either drawdown scenario (i.e., 0.5 m vs 1.0 m additional storage), with the implementation of the comprehensive monitoring and adaptive management plans as proposed; and
- The revised monitoring plan (including hydroacoustic monitoring) and adaptive management plan are deemed "effective at detecting, addressing, and managing any impacts that might result from increased drawdown".
    - The ability to detect adverse impacts through monitoring and adaptive management is acceptable regardless of which drawdown scenario is implemented.

The independent reviewer did note that from purely a scientific biological perspective (and not including economic and social factors), his preference was incremental changes over several years as this would have less uncertainty and risk. However, Yukon Energy must consider and balance a variety of factors when putting forward a Project proposal, including the views and inputs of the project partner NNDFN and costs and benefits of a Project and impacts to ratepayers. When all factors are considered, Yukon Energy has chosen to propose the initial 0.5 m of additional storage, with the ability to increase this storage range up to 1.0 m subject to the conditions in the AMP. This approach maintains a low environmental risk while potentially gaining the largest renewable power and economic benefits over time.

9.0 GLOSSARY AND REFERENCES

9.1 GLOSSARY OF ACRONYMS AND TERMS

9.1.1 List of Acronyms

AMP	Adaptive Management Plan
C	Celcius
CEA	Cumulative Effects Assessment
COSEWIC	Committee on the Status of Endangered Wildlife in Canada
CPUE	Catch per Unit Effort
DFO	Department of Fisheries and Oceans
DO	Designated Office
DSM	Demand Side Management
FSL	Full Supply Level
GHG	Greenhouse gas
GW.h	Gigawatt Hours
ID	Identification
LNG	Liquefied Natural Gas
LSA	Local Study Area
LSL	Low Supply Level
LT	Lake Trout
LW	Lake Whitefish
m	Metre
MDRRC	Mayo District Renewable Resources Council (also RRC)
NND	Na-cho Nyak Dun First Nation (also NNDFN)
OG	Other Government (Federal, territorial or municipal)
OP	Other Public
RRC	Renewable Resource Council (also MDRRC)
RSA	Regional Study Area
SPIN	Summer Profundal Index Netting
TK	Traditional Knowledge
TWG	Technical Working Group
VC	Valued Component
WKA	Wildlife Key Area
YECL	Yukon Electrical Company Limited
YESAA	Yukon Environmental and Socio-Economic Assessment Act
YESAB	Yukon Environmental and Socio-Economic Assessment Board

9.1.2 List of Terms

Aboriginal community: A community where most of the residents are Aboriginal (i.e., Indian, Métis, Inuit or other Aboriginal Peoples) and that has a separate form of government; provides some level of service to its residents; and has clear community boundaries.

Adaptive management: Involves the implementation of new or modified mitigation measures over the life of a project to address unanticipated environmental effects. The need for the implementation of adaptive management measures may be determined through and effective follow-up program.

Adverse effects: Negative effects on the environment and people that may result from a proposed project.

Alevin: A young fish; a newly hatched salmon when still attached to the yolk sac.

Anadromous: Fish that migrate from the sea into fresh water to spawn; or one which stay entirely in fresh water and migrate upstream to spawn.

Assessment: An evaluation by a designated office, a screening by the executive committee or a review by a panel of the Yukon Environmental and Socio-Economic Assessment Board established by Section 8 of YESAA.

Authorization: A licence, permit or other form of approval that is issued or given by: (a) the Governor in Council, a government agency, an independent regulatory agency or a municipal government, or (b) a First Nation under its final agreement or a First Nation law, but does not include an access order issued under the Yukon Surface Rights Board Act or a consent given by a First Nation for access to settlement land in circumstances where an access order could be issued under that Act.

Baseline: Past and current conditions in which a Valued Component is or has existed.

Bathymetry: The study or underwater depth and the mapping of underwater environments using contour lines.

Berm: Structures, generally made of earth, used to control erosion and sedimentation by reducing the rate of surface runoff. The berms either reduce the velocity of the water or direct water to areas that are not susceptible to erosion, thereby reducing the adverse effects of running water on exposed top soil.

Biodiversity: The existence of a wide range of different species in a given area or during a specific period of time.

Board: The Yukon Environmental and Socio-economic Board established by Section 8 of the Yukon Environmental and Socio-Economic Assessment Act.

Compliance monitoring: A broad term for a type of monitoring conducted to verify whether a practice of procedure meets the applicable requirements prescribed by legislation, internal policies, accepted industry standards or specified terms and conditions (e.g., in an agreement, lease, permit, licence or authorization). Mitigation monitoring is one type of compliance monitoring.

Conservation: Any various efforts to preserve the earth's natural resources, including such measures as: the protection of wildlife; the maintenance of natural prairie grasses, wetlands of wilderness areas; the control of air and water pollution; and the prudent use of farmland, mineral deposits and energy supplies.

Cumulative effects: The likely effects of the project in combination with the likely effects of other past, existing and future projects and activities. To be considered a cumulative effect, the other past, existing and future projects being considered in the assessment must affect a VC that is also being affected by the principal project; in this way the projects act cumulatively upon a valued component.

Decision document: A decision document issued by a decision body under section 75, 76 or 77 of YESAA.

Demographic: Information pertaining to human population dynamics, including the size, structure and distribution of populations and how populations change over time due to births, deaths, migration and ageing. Demographic analysis can relate to whole societies or to groups defined by criteria such as education, nationality, religion and ethnicity.

Designated Office: An office maintained under subsection 22(1) of YESAA.

Determination of significance: Taking into account the implementation of appropriate mitigation measures, a conclusion about whether adverse environmental effects are likely to be significant The significance of adverse environmental effects is determined by a combination of scientific data, regulated thresholds, standards, social values and professional judgment. For example, the ecological context of a project may be a determinant of whether likely adverse effects are significant.

Drawdown: The difference between the highest level a lake reaches in one summer and the lowest level a lake reaches during the following winter. For hydro reservoirs, drawdown indicates the amount of water required to satisfy the electrical loads placed in it and its water use licence commitments.

Duration of the effect: How long the effect would last. Effects may be considered low, moderate or high. Low effects are short term, lasting less than one year or not materially beyond the duration of the construction phase or the decommissioning phase of the Project. Moderate effects are medium term, lasting from 1 to 10 years or no more than one-generation span of the species affected. High effects are long term, lasting more than 10 years or more than one generation of the species affected or lasting throughout a major portion of the operations phase of the Project.

Ecological or socio-economic context: The sensitivity to environmental or socio-economic disturbance, capacity to adapt to change. This may be ranked as low, moderation or high; where ranked low, the VC is resilient to imposed change, where ranked moderate the VC has some capacity to adapt to imposed change and where ranked high the VC is fragile and has low resilience to imposed change.

Effects monitoring: The monitoring of environmental and socio-economic effects, or of the effectiveness of mitigative measures.

Environmental component: Fundamental element of the physical, biological or socio-economic environment, including the air, water, soil, terrain, vegetation, wildlife, fish, birds and land use that may be affected by a proposed project, and may be individually assessed in the environmental assessment.

Environmental monitoring: Periodic or continuous surveillance or testing, according to a predetermined schedule, of one or more environmental components. Monitoring is usually conducted to determine the level of compliance with stated requirements, or to observe the status and trends of a particular environmental component over time.

Erosion: Physical and chemical breaking down and transportation of geologic material.

Fee simple settlement land: Land that is, or is to be treated as, fee simple settlement land, as referred to in the definition "settlement land". Settlement Land owned under the same form of fee simple title as is commonly held by individuals who own land. For example, buying an individual lot in a subdivision will normally be held in fee simple title.

First Nation: A Yukon First Nation, within the meaning of the Umbrella Final Agreement.

Fish habitat: Spawning, nursery, rearing, food supply and migration areas upon which fish depend.

Fish ladder: A structure on or around artificial barriers to facilitate fishes' natural migration.

Flow: Motion characteristic of fluids (liquids or gases); any uninterrupted stream or discharge.

Frequency of the effect: Refers to how often an impact would occur, and may be ranked as low, moderate or high. Low frequency means the effects would never occur, occur once or seldom occur. Moderate frequency means the effect would occur occasionally. High frequency means the effect would occur continuously, on a regular basis or at regular intervals.

Fry: the young of fish.

Furbearer/ furbearing mammals: Referring to those mammal species that are trapped for the useful or economic value of their fur.

Gigawatt: A Gigawatt is the unit of electrical power equivalent to one billion watts or one million kilowatts.

Government agency: A federal agency or a territorial agency.

Greenhouse gas (GHG): Gaseous components of the atmosphere that contribute to the "greenhouse effect". Some greenhouse gases occur naturally in the atmosphere, while others result from human activities. Naturally occurring greenhouse gases include water vapor, carbon dioxide, methane, nitrous oxide, and ozone. Certain human activities, however, add to the levels of most of these naturally occurring gases.

Groundwater: The portion of sub-surface water that is below the water table, in the zone of saturation.

Habitat: The area or environment where an organism or ecological community normally lives or occurs. It is the space uniquely suited to required functions (e.g., breeding) through the arrangement of food, water, shelter, and cover.

Hectare (ha): A metric unit of square measure equal to 10,000 square metres or 2.471 acres.

Heritage resource: (a) a moveable work or assembly of works of people or of nature, other than a record only, that is of scientific or cultural value for its archaeological, palaeontological, ethnological, prehistoric, historic or aesthetic features; (b) a record, regardless of its physical form or characteristics, that is of scientific or cultural value for its archaeological, palaeontological, ethnological, prehistoric, historic or aesthetic features; or (c) an area of land that contains a work or assembly of works referred to in paragraph (a) or an area that is of aesthetic or cultural value, including a human burial site outside a recognized cemetery.

Heritage site: A heritage site is a location where a landmark of natural or cultural importance is legally protected. Heritage resources in the Yukon are protected under the Historic Resources Act and are defined as (i) historic sites, (ii) historic objects, and (iii) any work or assembly of works of nature or human endeavour that is of value for it archaeological, palaeontological, pre-historic, historic, scientific, or aesthetic features.

Hydroelectric power: Hydroelectric power is electricity harnessed from the energy of moving or falling water. Most hydroelectric power comes from the potential energy of dammed water driving a water turbine and generator.

Hydrology: The science dealing with the properties, distribution and circulation of water.

Hydrograph: Hydro (meaning water) and graph (meaning chart) refers to a record of discharge (flow) in a stream or river through time.

Impact: A positive or negative effect of a disturbance on the environment or a component of the environment.

Interested publics/ other publics: Any person or body having an interest in the outcome of an assessment, for a purpose that is not frivolous or vexatious, and includes: (a) the Fish and Wildlife Management Board established under the Umbrella Final Agreement, in relation to a project that is likely to affect the management and conservation of fish or wildlife or their habitat; (b) the salmon subcommittee of the Fish and Wildlife Management Board, in relation to a project that is likely to affect the management and conservation of salmon or their habitat; and (c) a renewable resource council established under a first nation's final agreement, in relation to a project that is likely to affect the management and conservation of fish or wildlife or their habitat within the traditional territory of that first nation.

Kilowatt (kW): The unit of power equivalent to 1,000 watts.

Kilowatt Hour (kWh): The unit measure of electrical power equivalent to use of 1,000 watts for a period of one hour (e.g., ten 100-watt light bulbs switched on for one hour would use one kWh [or 1,000 watts for one hour]).

Land Use Permit: A Land Use Permit allows a specific activity over a specified period of time. It does not give any exclusive rights or tenure to the land.

Littoral area: On or near a shore or the shallow area of a lake. This is an area where there is vegetation growth, providing primary habitat and eco-system food sources.

Local knowledge: Information held by community members, such as farmers, hunters, fishers and naturalists, who are familiar with the environment in a specific geographic area. Community knowledge may be used in the environmental assessment of a proposed project. For example, fish harvesters in a specific area may know where the best "fishing spots" are, and therefore may contribute to identifying potential fish habitat.

Megawatt (MW): A watt is the unit used to measure electric power. A megawatt (MW) is 1,000,000 watts.

Mitigation (mitigative measures): measures for the elimination, reduction, or control of adverse environmental or socio-economic effects, which include: (a) Avoiding effects altogether by not taking a certain action or parts of an action. (b) Minimizing effects by limiting the degree of magnitude of the action and its implementation. (c) Rectifying the effects by repairing, rehabilitating, or restoring the affected environment. (d) Reducing or eliminating the effects over time by preservation and maintenance operations during the life of the action. (e) Compensating for effects by replacing or providing substitute resources or environments.

Monitoring: Any ongoing process or program for measuring the actual effects of constructing or operating a development.

Northern Tutchone Land Use Planning Region: One of eight planning regions in the Yukon.

Operating regime: The pattern of use applied to the operations of a hydro facility, including any constraints placed on it by its water use license or other legislation and the strategy developed to maximize the electricity that can be produced within those constraints.

Physiography: A description of the natural features of the surface of the earth.

Phytoplankton: Microscopic organisms that live in watery environments, both salty and fresh.

Piscivorous: Habitually feeding on fish; fish-feeding.

Placer: Deposit of river sand or gravel containing particles of gold or another valuable mineral.

Probability: The chance or possibility that a specific event will occur.

Project: An activity that is subject to assessment under section 47 or 48 and is not exempt from assessment under section 49 of YESAA. For the purposes of this submission document it is the Mayo Lake Enhanced Storage Project.

Project Study Region: An area extending beyond the Construction Footprint Area identified to examine potential environmental and socio-economic effects of a project. For the Mayo Lake Enhanced Storage Project, this includes adjacent aquatic and terrestrial regions within a 5km buffer along the Mayo River, from the Village of Mayo to and around Mayo Lake.

Proponent: Proponent, in relation to a project or other activity, means a person or body that proposes to undertake it, or a government agency, independent regulatory agency, municipal government or first

nation that proposes to require — under a federal or territorial law, a municipal by-law or a First Nation law — that it be undertaken.

Ratepayer: A person who pays a regular charge for the use of a public utility, as gas or electricity, usually based on the quantity consumed.

Registered Trapping Concession (RTC): A parcel of land on which the holder is given exclusive rights to harvest furbearing animals.

Regulatory: Relating to a regulation or pertaining to legal requirements.

Renewable Resources Council (RRC): The Yukon First Nation Final Agreement provided for the establishment of Renewable Resources Councils (RRC's) in each of First Nation's Traditional territories. Acting as independent public interest advisory bodies, the RRC's may make recommendations on any matter related to fish and wildlife conservation, the establishment of Special Management Areas and to forest resources management.

Reservoir: A large natural or artificial lake used for collecting and storing water for human use.

Residual effects: Effects of a project that are expected to remain after mitigation measures have been implemented.

Scoping: The iterative process of identifying issues of concern related to the project, including the selection of Valued Components (VCs), identification potential pathways of effects along with the spatial and temporal boundaries for assessing effects of the project.

Settlement land: Land that is category A settlement land, category B settlement land or fee simple settlement land under a final agreement or under section 63 of the Yukon Surface Rights Board Act, or land that is to be treated as such by virtue of a self-government agreement, and includes Tetlit Gwich'in Yukon land, but does not include water or mines and minerals defined to be non-settlement land.

Shoreline: The narrow strip of land in immediate contact with the sea, lake or river.

Significance: A measure of the residual effects after the application of mitigation measures. Effects may be considered significant (high residual effect), potentially significant (moderate residual effect), not significant/ insignificant (low residual effect) or not significant/ negligible (no definable effects).

Socio-economic effects: Includes effects on economies, health, culture, traditions, lifestyles and heritage resources.

Species: A group of inter-breeding organisms that can produce fertile offspring.

Staging: Resting and gathering of waterfowl such as geese and ducks on a water body prior to, or during fall migration.

Subsistence economy: An economy in which a group obtains the necessities of life through self-provisioning. In such a system wealth is not measured in any form of currency, but rather exists in the form of natural resources.

Terrestrial: Living on or in the ground, or related to the ground.

Territory: (a) in relation to a first nation for which a final agreement is in effect, that first nation's traditional territory and any of its settlement lands within Yukon that are not part of that traditional territory; (b) in relation to the first nation known as the Tetlit Gwich'in, the areas described in Annex A of Appendix C to the Gwich'in Agreement; and (c) in relation to any other first nation, the geographic area within Yukon identified on the map provided by that first nation under the Umbrella Final Agreement for the purpose of delineating the first nation's traditional territory.

Threshold: A limit of acceptable change. Threshold measurements enable both project proponents and regulators to evaluate the acceptability of a project-related effects on a specific component of the environment by comparing the effects of the project against a pre-determine limit of acceptable change. Thresholds may be refined over time, as understandings of populations and ecological interactions evolve.

Traditional economy: A traditional economy is an economic system in which decisions such as the who, how, what, and for whom questions are all made on the basis of customs, beliefs, religion, habit, etc.

Traditional knowledge: The accumulated body of knowledge, observations and understandings about the environment, and about the relationship of living beings with one another and the environment, that is rooted in the traditional way of life of first nations. Note: Often referred to as Aboriginal Traditional Knowledge (ATK), which is knowledge held by, and unique to Aboriginal peoples. It is a living body of knowledge that is cumulative and dynamic and adapted over time to reflect changes in the social, economic, environmental, spiritual and political spheres of the Aboriginal knowledge holders. Sometimes used interchangeably with Traditional Ecological Knowledge (TEK), however TEK is generally considered to be a subset of ATK and is primarily concerned about knowledge about the environment.

Traditional lifestyle: Activities which have been followed by communities and people for long periods, often for generations.

Traditional resource use: Hunting, trapping, fishing and food gathering by Aboriginal peoples whether for subsistence purposes or otherwise.

Traditional territory: Lands designated under the Umbrella Final Agreement that provide rights for subsistence hunting and fishing activities; allocation of 70 percent of traplines; representation on land use planning bodies; membership on the Yukon Water Board, Development Assessment Board, Surface Rights Board, Fish and Wildlife Management Board and the Renewable Resources Councils.

Tributary: A stream or river that flows into another river or other body of water.

Uncertainty: The possible error or range of error which may exist within assumptions.

Valued Component (VC): Described in YESAB guides as an element of a project area that is valued for environmental, scientific, social, aesthetic, or cultural reasons. For the Project, VCs were identified in the process of scoping the Project and through the Public Involvement Program (PIP).

Waterfowl: Ducks, geese and swans (game birds that frequent water).

Water regime: A description of water body (i.e., lake or river) with respect to elevation, flow rate, velocity, daily fluctuations, seasonal variations, etc.

Watershed: The area within which all water drains to collect in common channel or lake.

Wetlands: Those lands where the water table is at, near or above surface or where land has been saturated for a long enough period to produce such features as wet-altered soils and water-tolerant vegetation.

Wildlife habitat: Any area providing food, shelter, cover, air and space, or any one of the aforementioned, to wildlife such as mammals, birds, reptiles, amphibians and/or invertebrates.

Wildlife Key Areas (WKA): Any area that is critical to wildlife during at least a portion of the year. This importance may be due to vegetative characteristics such as residual nesting cover, or behavioral aspects of the animals such as lambing areas. Key areas include: winter ranges, lambing/fawning/calving areas, dancing/strutting grounds, nesting areas, breeding grounds, riparian and woody drainages, and roosting areas.

Yukon Environmental and Socio-Economic Assessment Act (YESAA): An Act to establish a process for assessing the environmental and socio-economic effects of certain activities in Yukon.

Zooplankton: A freshwater community of floating or weakly swimming non-photosynthetic, mostly microscopic organisms such as rotifers and copepods.

RE: Aishihik Turbines Uprate Study RFP #2014-053 – Final Report, Rev 1

Dear Mr. Gee:

KGS Group is pleased to submit two hard copies and a digital copy of this revised report for the Aishihik Turbines Upgrade Study. Table 1 of the report was revised to clarify the information.

Please contact the undersigned if you have any questions on the report.

We thank you for the opportunity to providing Yukon Energy Corporation with engineering services for this project.

Yours truly,

J. Lambert, P.Eng.
Senior Mechanical Engineer

EXECUTIVE SUMMARY

The Aishihik Generating Station ("AGS") was built in the mid-1970's. It originally consisted of two vertical Francis turbines, AH1 and AH2, manufactured by Dominion Engineering Works and coupled to General Electric generators. A third horizontal Francis unit, AH3, manufactured by Kossler/Voith was added in 2011. Both the AH1 and AH2 stators were eventually re-wound with varying amounts of additional generator capacity in 2003 and 2006 respectively; AH2 generator has more capacity than AH1 generator.

Due to their vintage, AH1 and AH2 are not as efficient as modern turbines. Combined with the fact that their associated generators having additional capacity, this provides an opportunity to increase energy production by uprating and refurbishing them with modern runners. The study examines two options: firstly, uprating only AH2 and secondly, uprating both AH1 and AH2.

The Aishihik Generating Station unit AH2 could be uprated at a cost of $3.0M with a discounted payback of 6 years. The major components to be uprated include the runner, the generator air coolers, the excitation system, and the cables from the generator to the circuit breaker and from the outdoor switchgear to the transformers. YEC could, at its discretion, add opportunity work on the balance of turbine/generator components and on the AGS balance of plant.

Alternatively, AH1 and AH2 can both be uprated with new runners for a cost of $4.7 M and a discounted payback of 8 years. The incremental amount of work to add the uprate AH1 to the scope of work is limited to the new runner and optional opportunity work since it will not require new cabling or a new excitation system.

The uprated units would provide an increase in plant capacity, which would displace diesel generation, and would increase Yukon Energy Corporation's annual energy generation.

1.0 BACKGROUND

The two original vertical Francis turbine generating units (AH1 & AH2) at the Aishihik Hydro facility were manufactured by Dominion Engineering Works Limited in 1974 and placed into service in 1975. They are 15 blade runners rated at 20,500 HP (15.3MW) at 592 feet of head. These turbines were coupled to Canadian General Electric generators rated at 15.6MVA / 14.0MW.

In 2003, the AH1 generator was rewound by General Electric, increasing its stator capacity to 17MVA / 15.3MW. The generator's capacity now matches the turbine's output of 15.3MW.

In 2006, the AH2 generator was rewound by Voith, increasing its stator capacity to 19.2MVA / 17.2MW. The generator's capacity now exceeds the turbine's output of 15.3MW.

The newer horizontal Francis turbine generating unit AH3, manufactured by Kossler/Voith, was placed into service in 2011. It produces 9,625 HP (7.180 MW) turbine at 592 feet of head and it is connected to an 8.25MVA TDPS-India generator. This unit is not considered for uprating.

Although uprating AH2 offers the greater opportunity for a single unit uprate, the benefits of fitting AH1 with a higher efficiency runner were also reviewed.

Only the components related to turbine, generator and power train capacity and efficiency uprate are examined in this report. These uprate elements are justified and costed out. A project payback is then calculated using a calculation spreadsheet provided by YEC. Opportunity work normally performed during runner and generator uprates are identified, but are not costed out, since they do not have capacity or energy benefits and payback. Similarly, project indirect costs such as camp facilities and internal YEC engineering costs are not considered.

KGS Group used an integrated multi-disciplinary team of experienced engineers to carry out the Aishihik Turbine Uprate Study. They conducted engineering reviews, sent vendors requests for information (RFI's) and compiled capital cost estimates for two options for YEC's consideration. KGS Group also performed computations of payback based on KGS calculations of energy benefits.

2.0 PRESSURE SHAFT AND TAILRACE TUNNEL HYDRAULIC STUDY

The initial task in the turbine uprate study was to conduct a high level hydraulic review of the conveyance system in order to determine the maximum flow that can be conveyed before affecting functionality and safety of the system.

2.1 HYDRAULIC REVIEW

KGS Group reviewed the existing documentation and developed a one dimensional computer model to confirm the conveyance system hydraulics. It was determined that the limiting factors for increasing plant flow capacity are the requirements to maintain the emergency evacuation path in the tailrace tunnel and to maintain the tunnel operating at less than full flow.

The current plant capacity provides 1.06 m of emergency freeboard throughout the tunnel during normal downstream river conditions. During flood conditions, no data is available about water levels in the West Aishihik River. These river water levels have the potential to limit the available emergency freeboard at the downstream end of the tailrace tunnel. Until further information about flood stages in the West Aishihik River is obtained and analyzed, no increase in plant flow is recommended.

Should the tunnel transition from partially full to full flow, there is a possibility of backwater effects such as a significant rise in tailwater level at the plant and possibly pressure transient issues. The magnitudes of these effects have not been determined. KGS Group recommends that the Turbine Rerate Specification includes a section on limiting water flow through the new runner, or runners, such that the total plant flow limit is respected under all operating conditions.

KGS Group's hydraulic review is provided in Appendix A.

2.2 TRANSIENT PRESSURE FLUCTUATIONS

A high level assessment of transient pressure fluctuations in the pressure tunnel during unit start-ups and shut-downs was not required since the maximum plant flow conditions will not change as a result of runner uprates.

3.0 TURBINE UPRATE REVIEW

KGS Group issued a Request for Information (RFI) for budget pricing, as well as technical information on a new runner for Unit 2, and other required turbine modifications or new components that may be beneficial to the efficiency or power output of the turbine. Two proposals were received, one from Alstom Power and one from Norcan Hydraulic Turbine Inc., hereafter called Alstom and Norcan. The vendor responses are presented in Appendix B.

3.1 TYPICAL OPERATION AND OPTIMIZATION OF NEW RUNNERS

The Vendors were informed that in order to provide a “spinning reserve” to accept sudden load increases on Yukon Energy Corporation’s electrical grid, the AH1 and AH2 units are typically operated at approximately 80% of their maximum power output. They may, however, be operated at relatively low power levels during periods of low demand and at maximum output during periods of high demand.

Because of the above-mentioned operation strategy, the proposed new runners should be optimized to provide, in order of importance:

1. The highest efficiency at approximately 80% gate opening.
2. The highest maximum output at full gate opening.
3. The highest efficiency at gate openings lower than 80%.

3.2 ANALYSIS OF RUNNER UPRATE OPTIONS

Based on the above criteria, Alstom and Norcan focused on obtaining higher efficiencies by taking advantage of modern design and manufacturing techniques. Both vendors offered runners that would fit within the existing runner chamber. The principal elements of the turbine that were targeted were the runner blade shapes and labyrinth seal design. Alstom also foresees potential extra improvements by changing wicket gate profiles. The future RFP to vendors should prompt them to explore these and other areas of potential efficiency gains.

Alstom and Norcan picked runners from their stock of prior designs as reference runners for Aishihik. They provided expected curves of turbine power and efficiency for a net head of 180.4 m. A summary of the budgetary proposals follow in Table 1.

TABLE 1
AISHIHIK TURBINE BUDGETARY PROPOSALS

ITEM	NORCAN	ALSTOM
Budgetary cost (not adjusted)	$497,273	$743,000
Description of new runner	40” Francis Cast CA6NM or Forged A182F6NM	40” Francis Forged martensitic steel
Fabrication method	Runner will be forged and machined.	Runner will be fabricated. Crown and band will be cast or forged and pre machined.
Proposed scope of the upgrades, beyond the provision of new runners	none	Refurbish Wicket Gates. Different runner bolting pattern. Redesign labyrinth.
Number of runner blades proposed	15	15
Performance at 180.4 m net head: • Max Power at rated flow 9.72 cms • Best efficiency • Flow at best efficiency point	 16.1 MW 93.83% 9.32 cms	 16.1 MW 93.5% 8.4 cms
Maximum runaway speed	Not given	185%
Delivery time for major equipment after placement of order	11-12 months	9-10 months
Time required for installation in the field	6-8 weeks	Not given

4.0 ENERGY AND CAPACITY BENEFITS ANALYSIS

4.1 ENERGY

The energy benefit analysis for the potential upgrades of Aishihik Generating Station (AGS) were conducted using the long term energy model YECSIM developed by KGS Group for Yukon Energy Corporation (YEC). The options for potential upgrades of AGS could include the upgrades of either AH1 or AH2 or both.

The software YECSIM is a detailed integrated power / water flow model operating on a weekly time step. It can be used for analysis of the operation and future expansion of the YEC electrical generating capacity. This model includes all assumed loads and load profiles, operating characteristics of each system power facility (e.g. unit efficiencies), licensed parameters for each plant as approved or proposed, and desired operating parameters for the system (such as reducing line losses or voltage stability), as well as the hydrological conditions. More information about the model can be found in the YECSIM User's Manual.

As required by the YECSIM model, the 3-tier systems for specification of efficiency were developed for the the existing conditions based on the original turbine and generator efficiency curve and the potential upgrade options based on the turbine and generator efficiency curves provided by vendors. The plant maximum flow was limited at the 23.7 m^3/s. The two energy demand levels for the WAF/MD integrated system, including the low energy demand level (468.1 GWh/year) and the high energy demand level (575.1 GWh/year), were used in the YECSIM model simulations.Those two energy loads could reasonably be expected to occur or be surpassed within the future 20 to 30 years starting from 2009, as described in the report for the proposed Mayo Hydro Enhancement Project prepared by YEC (Ref. 2). More information related to the YECSIM model setup is provided in Appendix C.

The hydro energy generation from the WAF/MD system for the existing conditions and the potential upgrade options were forecasted using the YECSIM model. The detailed description of the energy benefit analysis is provided in Appendix C. Table 2 below shows the modeled net hydro energy contributions to the WAF/MD integrated system for the potential upgrade options.

The model results show:

- For the upgrades of AH1 only, using Alstom turbine would generate energy benefit from 2.19 GWh/year to 2.26 GWh/year to the system, while using Norcan turbine would generate energy benefit from 0.96 GWh/year to 1.27 GWh/year to the system.
- For the upgrades of AH2 only, using Alstom turbine would generate energy benefit from 2.25 GWh/year to 2.35 GWh/year to the system, while using Norcan turbine would generate energy benefit from 1.14 GWh/year to 1.40 GWh/year to the system. The energy benefit for the upgrades of AH2 only is slightly higher than the one for the upgrade of AH1 only.
- For the upgrades of both AH1 and AH2, using Alstom turbines would generate energy benefit from 2.74 GWh/year to 3.04 GWh/year to the system, while using Norcan turbine would generate energy benefit from 1.81 GWh/year to 2.37 GWh/year to the system. The energy benefit for the upgrades of both AH1 and AH2 are higher than the one for the upgrades of either AH1 or AH2.

TABLE 2
ENERGY BENEFITS

Unit Upgrade Option	Net Energy Contribution due to the Upgrades using Alstom Turbine (GWh/year)		Net Energy Contribution due to the Upgrades using Norcan Turbine (GWh/year)	
	Low Energy* Demand	High Energy** Demand	Low Energy* Demand	High Energy** Demand
Upgrade of AH1 Only	2.26	2.19	0.96	1.27
Upgrade of AH2 Only	2.35	2.25	1.14	1.40
Upgrade of AH1 and AH2	2.74	3.04	1.81	2.37

*: Low energy demand (468.1 GWh/year)

**: High energy demand (575.1 GWh/year)

Going forward in this report, only the Alstom proposal will be analyzed for economic benefits. This proposal has the higher initial cost and the higher net energy contribution to the WAF/MD System.

4.2 CAPACITY

Incremental capacity represents an important benefit to the proposed turbine upgrade project. Although the proposed turbine capacity may exceed the existing turbine capacity, hydraulic conditions limit the effectiveness of this additional capacity. According to YEC, Aishihik GS is typically run at around 80% plant flow, so any excess turbine capacity requiring additional plant flow may not be realized. Therefore, the evaluation was based on plant capacity at 80% plant flow instead of the individual turbine capacity.

Plant capacity was estimated for each configuration based on the typical plant flow of 19 m^3/s. The estimated plant capacities for each proposed plant configuration are shown in Table 3.

TABLE 3
PLANT CAPACITY

SIMULATION SCENARIO	PLANT EFFICIENCY (%)	PLANT CAPACITY (MW)	INCREMENTAL PLANT CAPACITY (MW)
Existing Condition	87.8	29.8	-
New AH1 - Alstom	89.9	30.5	0.7
New AH1- Norcan	89.7	30.5	0.6
New AH2 - Alstom	89.9	30.5	0.7
New AH2 - Norcan	89.7	30.5	0.6
New AH1 and AH2 - Alstom	91.6	31.1	1.3
New AH1 and AH2 - Norcan	91.3	31.0	1.2

Incremental plant capacity varies depending on how many units are upgraded. Alstom units provide a marginal capacity benefit relative to Norcan units. Upgrading both AH1 and AH2 provides close to double the incremental capacity of upgrading only one unit.

For the purpose of designing electrical components, the plant capacity was evaluated at maximum flow and maximum expected net head using an optimistic estimate of conveyance

system losses. For a plant flow of 23.7 m^3/s and net head of 182.2 m, the existing plant capacity is 37.2 MW. Proposed configurations range in capacity from 37.9 MW for the Norcan AH1 replacement to 38.6 MW for the Alstom 2 unit replacement.

4.3 VALUE OF CAPACITY AND ENERGY

YEC provided the following values for capacity and energy increase:

- Capacity: $2,500,000 per MW based on avoided capital cost of new natural gas generation.
- Energy: $200,000 per GWh per year based on avoided operating (i.e. variable cost) cost of natural gas.

5.0 ELECTRICAL EQUIPMENT ASSESSMENT

5.1 INTRODUCTION

This section summarizes the results of the electrical assessment carried out on the major electrical components associated to AH2 unit, with the purpose of determining if these components are able to support an uprated capacity of 19.2 MVA.

The scope of the assessment includes the generator, excitation system, medium voltage power cables, switchgear and generator step up transformers. This report assumes that as a result of a runner replacement, AH1 unit will not increase its rating beyond 17 MVA. Furthermore, it is assumed that all generators could be expected to operate at 95% of nominal voltage (13.1 kV) while operating at nominal rating.

This study was solely based on equipment ratings as provided by datasheets and nameplates. Results presented on this report have not factored equipment age, condition, or maintenance.

5.2 EXISTING ELECTRICAL ARRANGEMENT

With reference to single line diagrams P130 and S137, the Aishihik Generating Station is composed of three hydro generating units, with the following ratings:

- AH1: 17 MVA, 13.8 kV
- AH2: 19.2 MVA, 13.8 kV
- AH3: 8.25 MVA, 13.8 kV

The combined plant nominal output is 44.45 MVA.

These generators are connected to a common 13.8 kV switchgear with medium voltage (MV) power cables. This switchgear, which is located at the generator level, includes dedicated generator circuit breakers (one for each unit). This switchgear is connected to a second 13.8 kV switchgear, which is part of the substation S167, using two sets of MV power cables (feeders F1

and F2), and run vertically in cable trays. These two cable systems are normally operated in parallel.

The 13.8 kV switchgear part of substation S167 is then connected with medium voltage power cables to two generator step up transformers.

5.3 ELECTRICAL EQUIPMENT UNDER STUDY

Since the scope of the electrical review is to assess the limits of electrical components associated to AH2 unit, the following components have been analyzed:

- AH2 stator winding
- AH2 excitation system
- MV power cables interconnecting AH2 to the generator breaker switchgear
- AH2 generator circuit breaker and associated switchgear
- MV power cables interconnecting the generator breaker switchgear to the S137 switchgear
- S137 switchgear and associated circuit breakers
- MV power cables interconnecting the S137 switchgear to the generator step up transformers
- Generator step up transformers

5.4 GENERATING STATION POWER OUTPUT

In order to assess the capability of the electrical equipment associated to AH2 unit, the expected station output needs to be defined. Based on an uprate of 19.2MVA for unit AH2, the following system ampacity would be required:

5.4.1 Electrical Components Associated to AH2 Only

The electrical components associated only to AH2 need to be able to continuously carry the nominal output of AH2 unit:

- 803 A at nominal (13.8 kV) voltage
- 846 A at 13.1 kV (95% of nominal voltage)

5.4.2 Electrical Components Common to All Units

The electrical components that are associated to all units (i.e. switchgears) need to be able to continuously carry the nominal output of the three units operating in parallel and at nominal capacity:

- 1860 A at 13.8 kV (nominal voltage)
- 1959 A at 13.1 kV (95% of nominal voltage)

5.5 ELECTRICAL EQUIPMENT RATING

5.5.1 AH2 Generator Stator Winding

According to Voith's drawing 4671A49 (AH2 unit nameplate after stator rewind), AH2 stator winding is rated for 19,200 kVA at nominal 13,800 V. Since this information was provided by Voith Siemens, the Company retained by YEC to rewind the unit, KGS Group assumes this information to be accurate, and therefore, no further studies or investigations were undertaken.

5.5.2 AH2 Excitation System

The AH2 generator is equipped with a DC exciter, controlled by SR125E Basler automatic voltage regulator (AVR). As a part of the generator rewind, project the generator rotor field poles were reinsulated, however, the DC exciter was not upgraded.

Based on the documentation provided by YEC and discussions with Voith Siemens, the following conclusions can be made:

- According to the machine data provided by Voith-Siemens, to produce the rated power of 19.2 MVA, the generator rotor field voltage and field current requirement is 75 V and 720A respectively, while the DC exciter is rated at 670 A.

- The DC exciter will operate beyond its design limit to produce the rated voltage at 19.2 MVA, 0.9 power factor.

To operate AH2 unit at the uprate power of 19.2 MVA, the following two alternatives should be investigated:

- The existing exciter could be replaced with a static exciter to match the generator field requirements. The generator field leads and associated slip rings should be checked so that these are properly rated for operation at 19.2 MVA.
- The rotating DC exciter could be upgraded to meet the rewound generator field requirements. The associated AVR would need to be replaced to meet the requirement of the upgraded exciter. The generator field leads and associated slip rings should be checked so that these are properly rated for operation at 19.2 MVA.

5.5.3 AH2 MV Power Cables to Generator Breaker Switchgear

According to the information provided by YEC's drawing O111D4956 "AH2 Cable Tray and Termination Diagram, AH2 unit is connected to its generator circuit breaker with 3 x 1C 750MCM, 15 kV, copper MV power cable. Based on this drawing, these cables run in a steel ladder tray. Assuming these cables are provided with one diameter spacing, the ampacity of this feeder can be obtained from the 2015 edition of the Canadian Electrical Code, Table D17M. Based on this table, and assuming an ambient temperature of 40°C, this feeder is expected to have an ampacity of 706 A.

Since AH2 unit will have an output of 803 A at nominal voltage, the existing feeder will be overloaded. Based on the configuration provided in drawing O111D4956, this feeder will operate at its limit when AH2 operates at the following ratings:

- 16,875 kVA at nominal (13.8 kV) voltage
- 16,019 kVA at 13.1 kV (95% of nominal voltage)

To reach a nominal output of 19.2 MVA, a second, parallel run of similar cables should be installed to ensure equal load distribution. AH2 feeder cables could also be replaced for 6 X 1C 350MCM 15kV copper power cables, installed in cable tray, providing one diameter spacing, assuming an ambient tempearure of 40°C.

5.5.4 AH2 Generator Breaker

Based on the single line diagrams provided by YEC, the AH2 generator circuit breaker (equipment tag P130-52-AH2) has a rating of 1200 A. When the generator supplies its uprate nominal power rating of 19.2 MVA, this generator circuit breaker will be loaded at the following ratings:

- 67% of 1200 A at nominal (13.8 kV) voltage
- 71% of 1200 A at 13.1 kV (95% of nominal voltage)

According to these results, AH2 generator circuit breaker has sufficient rating to support an uprate capacity of 19.2 MVA.

5.5.5 Generator Breaker Switchgear

According to single line diagrams, the generator breaker switchgear, which is installed at the generator level and is common to all units, has a rating of 2000 A. When all generators supply their nominal power rating of 44.45 MVA, the generator breaker switchgear will be loaded at the following ratings:

- 93% of 2000 A at nominal (13.8 kV) voltage
- 98% of 2000 A at 13.1 kV (95% of nominal voltage)

Based on these results, the generator breaker switchgear has marginally sufficient rating to support an uprate capacity of 19.2 MVA.

5.5.6 F1 and F2 MV Power Cables

The MV power cable system that connects the generator breaker switchgear to the S167 switchgear is composed of two sets of 15 kV cables run in vertical cable trays, inside the vertical shaft leading to the surface. These cable systems, which normally operate in parallel, have the following characteristics:

- Feeder F1: 9 x 1C 750MCM Okonite Okoguard 15 kV 133%
- Feeder F2: 9 x 1C 750MCM Okonite Okoguard 15 kV 133%

When these cable systems operate in parallel, it is expected that they will equally share the load, as both systems use the same cable type and quantity. When a single cable system is in service, it will be required to carry the entire plant output. This study has assessed both operating conditions.

According to the CEC Rule 28.108 (a) conductors supplying a group of two or more motors (generators) shall have an ampacity not less than 125% of the full load current rating of the motor (generator) having the largest full load current rating, plus the full load current ratings of all the other motors (generators) in the group. For this assessment, it has been assumed that since generator outputs are limited by the water conveyance system and turbines, generators are not able to produce more than their nominal outputs (i.e. 44.45 MVA combined).

The ampacity of each feeder system was calculated based on the following assumptions:

- Cables are run in ventilated cable trays, with approximately 25% diameter spacing between each cable
- Elevator shaft temperature was assumed to be 40°C

The 2015 edition of the CEC, Table D17N, provides cable ampacities for single conductor cables in cable trays, installed in contact or spaced less than one diameter apart. Based on this table, F1 and F2 feeders are expected to have the following ampacity:

- F1 and F2 Feeders: 678 A per 750 MCM conductor (2034 A)

When all generators supply their nominal power rating of 44.45 MVA, and both cable systems are operating in parallel, and assuming equal load sharing, each cable system is expected to be loaded at the following ratings:

- F1 Feeder: 46% of 2034 A at nominal (13.8 kV) voltage

- F2 Feeder: 46% of 2034 A at nominal (13.8 kV) voltage
- F1 Feeder: 48% of 2034 A at 13.1 kV (95% of nominal voltage)
- F2 Feeder: 48% of 2034 A at 13.1 kV (95% of nominal voltage)

Based on these results, F1 and F2 feeders have sufficient excess capacity to support an uprate capacity of 19.2 MVA.

When all generators supply their nominal power rating of 44.45 MVA, and only one feeder is in service, the cable is expected to be loaded at the following rating:

- F1 or F2 Feeder: 91% of 2034 A at nominal (13.8 kV) voltage
- F1 or F2 Feeder: 96% of 2034 A at 13.1 kV (95% of nominal voltage)

According to these results, F1 or F2 feeder would be operating close to their limit when AH2 operates at uprate capacity of 19.2 MVA.

5.5.7 S167 Switchgear

According to single line diagrams, the S167 switchgear is rated 2000 A and is equipped with 2000 A circuit breakers. When all generators supply their nominal power rating of 44.45 MVA, the S167 switchgear will be loaded at the following ratings:

- 93% of 2000 A at nominal (13.8 kV) voltage
- 98% of 2000 A at 13.1 kV (95% of nominal voltage)

Based to these results, the S167 switchgear has marginally sufficient rating to support an uprate capacity of 19.2 MVA.

5.5.8 MV Power Cables to T1 and T3 Transformers

According to drawings provided by YEC and site photos, the MV power cable systems that connect the S167 switchgears to T1 annd T3 generator step up transformers have the following characteristics:

- Feeder to T1 Transformer: 9 x 1C 750 MCM 15 kV cable in cable tray
- Feeder to T3 Transformer: 9 x 1C 750 MCM 15 kV buried cables transition to overhead line and to 6 x 1C 750 MCM 15 kV cable in buried conduit.

The 2015 edition of the CEC, Table D17N for outdoor installations, provides cable ampacities for single conductor cables in cable trays, installed in contact or spaced less than one diameter apart. Based on this table, the feeder connected to T1 transformer is expected to have the following ampacity:

- Feeder to T1 Transformer 545 A per 750 MCM conductor (1635 A)

Based on this analysis, the feeder to T1 Transformer could carry the following load:

- 39.1 MVA, equivalent to 88% of the uprate plant capacity (44.45 MVA) at 13.8 kV
- 37.1 MVA, equivalent to 83% of the uprate plant capacity (44.45 MVA) at 13.1 kV

Since the feeder to T3 transformer is composed of three distinctive arrangement (underground duct, overhead line and cable in buried conduit), each arrangement is analyzed individually.

The cable run connecting the S167 switchgear to the overhead line is assumed to be an underground duct bank. For this arrangement, the feeder ampacity was estimated from IEEE Standard 835-1994, Table 342, for 25°C earth temperature, 100 load factor and average ground resitivity. Table 342 provides the following ampacity:

- Feeder to T3 Transformer (underground duct): 444 A per 750 MCM conductor (1332 A)

Based on this analysis, the feeder to T3 Transformer (underground duct) could carry the following load:

- 30.2 MVA, equivalent to 68% of the uprate plant capacity (44.45 MVA) at 13.1 kV
- 31.8 MVA, equivalent to 72% of the uprate plant capacity (44.45 MVA) at 13.8 kV

The overhead line connecting to disconnect switch S167-89-LT3 is assumed to be two parallel runs of 266 MCM ACSR (Partridge). The line ampacity was estimated from ACSR cable catalogues for 25°C ambient temperature and wind velocity of 2 ft/sec. ACSR cable catalogues provide the following ampacity:

- Feeder to T3 Transformer (overhead line): 455 A per 266 MCM conductor (910 A)

Based on this analysis, the feeder to T3 Transformer (overhead line) could carry the following load:

- 20.6 MVA, equivalent to 46% of the uprate plant capacity (44.45 MVA) at 13.1 kV
- 21.8 MVA, equivalent to 49% of the uprate plant capacity (44.45 MVA) at 13.8 kV

According to site photos, the feeder connecting the disconnect switch S167-89-LT3 to the T3 transformer runs in buried conduit. For this arrangement, the feeder ampacity was estimated from IEEE Standard 835-1994, Table 488, for 25°C earth temperature, 100 load factor and average ground resitivity. Table 488 provides the following ampacity:

- Feeder to T3 Transformer (buried conduit): 521 A per 750 MCM conductor (1042 A)

Based on this analysis, the feeder to T3 Transformer (buried conduit) could carry the following load:

- 23.6 MVA, equivalent to 53% of the uprate plant capacity (44.45 MVA) at 13.1 kV
- 24.9 MVA, equivalent to 56% of the uprate plant capacity (44.45 MVA) at 13.8 kV

Since the feeder to T3 Transformer has three different ampacities, the rating of this feeder should be assumed as the lowest of the three ampacities. Therefore, the overall ampacity of the feeder to T3 Transformer would be limited by the overhead line:

- 20.6 MVA, equivalent to 46% of the uprate plant capacity (44.45 MVA) at 13.1 kV
- 21.8 MVA, equivalent to 49% of the uprate plant capacity (44.45 MVA) at 13.8 kV

5.5.9 T1 and T3 Transformers

YEC's single line diagrams show that T1 and T3 generator step up transformers (GSU) are oil filled 30/40 MVA (ONAN/ONAF). When both transformers are operating in parallel, and assuming these transformers have similar reactances (equal load sharing), it is expected that each transformer would be loaded to 22.2 MVA or 56% of their ONAF rating.

If a single GSU is assumed in to be in service, that transformer will be loaded to 111% of its ONAF rating. If YEC expects a single GSU to be in service while the three units operate at their nominal rating, KGS Group recommends transformer temperatures be properly monitored. Transformer operation beyond its nameplate rating is normally associated with accelerated loss of service life.

5.6 ELECTRICAL CONCLUSION

From the above information and assumptions, the following conclusions can be made:

- AH2 excitation system: The DC exciter will operate beyond its design limit to produce the rated voltage at 19.2 MVA, 0.9 power factor.
- MV Power cable from AH2 to generator breaker switchgear: This feeder does not have enough ampacity to operate at 19.2 MVA. To reach a nominal output of 19.2 MVA a second, parallel run of similar cables should be installed to ensure equal load distribution. AH2 feeder cables could also be replaced for 6 X 1C 250MCM 15kV copper power cables, installed in cable tray, providing one diameter spacing, assuming an ambient temperature of 40°C.
- Generator breaker: AH2 generator circuit breaker has sufficient rating to support an uprate capacity of 19.2 MVA
- Generator Breaker Switchgear: The generator breaker switchgear has marginally sufficient rating to support an uprate capacity of 19.2 MVA.

- F1 and F2 MV power cables: F1 and F2 feeders have sufficient excess capacity to support an uprate capacity of 19.2 MVA when these feeders operate in parallel. However, F1 or F2 feeder would be operating close to their limit when a single feeder system is in service.

- S167 Switchgear: The S167 switchgear has marginally sufficient rating to support an uprate capacity of 19.2 MVA.

- MV power cables to T1 Transformer: The feeder can carry up to 37.1 MVA, equivalent to 83% of the uprate plant capacity at 13.1 kV and 39.1 MVA, equivalent to 88% of the uprate plant capacity at 13.8 kV

- MV power cables to T3 Transformer: The feeder is limited by the ampacity of the overhead line to 20.6 MVA, equivalent to 45% of the uprate plant capacity at 13.1 kV or to 21.8 MVA, equivalent to 49% of the uprate plant capacity at 13.8 kV

- T1 and T3 transformers: T1 and T3 transformers have sufficient excess capacity to support an uprate capacity of 19.2 MVA when these transformers operate in parallel. However, if a single transformer is assumed to be in service, that transformer will be loaded to 111% of its ONAF rating.

6.0 MECHANICAL EQUIPMENT ASSESSMENT

The main mechanical system that is affected by the additional power output of an upgraded runner is the generator surface air cooling system.

6.1 SURFACE AIR COOLING SYSTEM

The generator surface air coolers (SACs) are assumed to be the original ones provided by Canadian General Electric in the early circa 1973. There are four SACs per unit. They are fed with river water through a common header and 2" branch lines and they discharge to the tailrace.

Through first principle calculations, we estimate that the heat exchange rate across the SACs could increase by a maximum of 25% if the stator temperature rise increases to 80°C above ambient from its present 60°C. Given the age of the SAC piping and cooling coils, the heat exchangers could possibly be fouled and/or internally corroded. This would reduce their effectiveness in transmitting the heat from the air into the cooling water. As such, the heat exchangers should be considered near the end of their life cycle, making them unsuitable for higher duty usage. The entire SAC piping system and heat exchangers should be changed out with the unit rerate project. The T/G contractor could be asked to provide this service.

6.2 OPPORTUNITY WORK

The rerunnering project offers an opportunity to address work items identified in the 2014 Aishihik Hydro Asset Assessment Report. Table 4 contains data from Table 1: Summary of Assessment Results, in the assessment report. It identifies work items that could be performed, at YEC's discretion, during the unit rerate outage. Although the assessment report focused on AH2, the results can be applied to AH1 in this study. A more detailed assessment of AH1 would have to be conducted if YEC decides to uprate its runner as well.

Opportunity work has no payback. The cost of performing the opportunity work is outside the scope of this report as it is not directly related to unit uprates. A discussion on the opportunity work items is provided in the section below Table 4.

TABLE 4
SUMMARY OF ASSESSMENT RESULTS

PRIORITY #	ENGINEERING DISCIPLINE	COMPONENT	ASSESSMENT RESULTS
26	Mechanical	Turbines	Study and potential replacement of turbine air, oil and water piping.
27	Mechanical	Generator	Study and potential replacement of generator air, oil and water piping.
37	Mechanical	Turbines	Study and potential replacement of addition of greasing points to reduce binding of wicket gate links and levers.
40	Mechanical	Fire Protection	Provide deluge fire suppression systems.
43	Mechanical	Turbines	Provide wicket gate shear pin detection and annunciation.
44	Mechanical	Turbine Inlet Valve (TIV)	Automation of TIVs to allow remote closure. Clean and Paint TIV
47	Electrical	P&C	Vibration Monitoring Review.
76	Civil	TIV	Monitor and potential repairs of TIV and distribution pipe leakage.

ITEM 26, TURBINE PIPING

The air, oil and water pipes and related valves and instrumentation servicing the turbines and generators are almost 40 years old. Their condition should be assessed and the remaining life estimated utilizing NDT (Ultrasonic) inspection techniques. In the event that the above program

cannot be executed in its entirety, focus should be placed on the Piezometer piping and the turbine air admission piping which have visible signs of distress.

ITEM 27, GENERATOR PIPING

The air, oil and water pipes and related valves and instrumentation servicing the turbines and generators are almost 40 years old. Their condition should be assessed and the remaining life estimated utilizing NDT (Ultrasonic) inspection techniques. The generator surface air cooling pipes and heat exchangers are addressed in Subsection 6.1.

ITEM 37, GREASING POINTS

Some areas of the turbine may benefit from adding greasing points or self-lubricated materials to wicket gate levers and arms. We understand that levers and arms have bonded to each other in the past.

ITEM 40, FIRE PROTECTION

There is no fire suppression on the generators in the powerhouse. The former Halon suppression systems have been removed. We recommend providing water deluge fire suppression systems on units AH1 and AH2.

ITEM 43, WICKET GATE SHEAR PIN DETECTION

The units are currently not equipped with wicket gate shear pin breakage sensors. A broken shear pin detection and annunciation system would alert station operators or SCC of the fact that a unit may not stop turning after being shut down. Consideration should be given to adding shear pin breakage monitoring capabilities, complete with annunciation to SCC.

ITEM 44, TIV CLOSURE AUTOMATION

The AH1 and AH2 TIVs can now only be operated locally. Due to the limited access to the powerhouse and the lack of emergency closure capability at the intake, the TIVs should be remotely operable. A loss of unit control (wicket gate operation failure), or a breach in the water passage could not be stopped without sending staff into the powerhouse. This situation would more than likely be unsafe. With no way to stop the water, the plant would be flooded for some

time. As such, remote operation capability should be implemented for the AH1 and AH2 TIVs. At this time, the addition of a counterweight could also be investigated to improve reliability.

ITEM 44 B, RE-PAINT TIV

The Turbine Inlet Valve for Unit AH-2 is showing signs of external surface corrosion. As such, the TIV should be tool cleaned (wire brushed) or sandblasted and re-painted.

ITEM 47, VIBRATION MONITERING REVIEW

Review minor discrepencies on the vibration monitering equipment.

ITEM 76, LEAKAGE IN TIV SUPPORTS

YEC staff have indicated that there is a water leak on unit AH2. Water reportedly leaks from between the spiral case and the concrete. During the AH2 rerunnering outage, further investigations should be carried out to determine the source of the leak. It should be noted that the leak may be from embedded sections of piezometer piping. Selectively pressurizing these tubes, or possibly the use of dyes may assist in finding the source of this leak.

7.0 ECONOMIC ANALYSIS

The economic analysis performed in the following sections utilizes the scope of work and costs described in Sections 3.0, 5.0 and 6.0 above and the capacity and energy values provided by YEC in Section 4.3. The details of the analysis, including runner costs, energy and capacity benefits, related uprate costs and payback, are given in Appendix C.

7.1 COSTS ASSOCIATED WITH RERUNNERING

KGS Group has prepared a Class 4 capital cost estimate and payback calculation for the turbine uprate project based on the value of energy provided by YEC. A Class 4 (-30%/+50%) cost estimate, as defined by AACE International, is used for project screening, determination of feasibility, concept evaluation, and preliminary budget approval.

The Turbine Upgrade pricing in Table 5 below is the one associated with the Alstom budget proposal, since it is the most costly of the two budget prices, and it also offers the most capacity and energy benefits.

Other costs associated with the uprate project were estimated by KGS Group.

No estimates are provided for opportunity work since they do not provide a definable payback. KGS Group could provide a proposal to estimate the opportunity costs if requested to do so.

TABLE 5
BUDGET ESTIMATE TO UPRATE UNITS

ITEM	DESCRIPTION / ASSUMPTIONS	ONE UNIT	TWO UNITS
Turbine Uprate - Alstom			
Turbine field work		$250,000	$500,000
Turbine runner engineering		$106,000	$137,800
Runner and coupling bolts, supply		$343,000	$686,000

Generator Breaker			
Unit step-up transformer			
Controls and Protection			

* Notes:
Contingency No. 1 accounts for unforeseen items that may need to be repaired when unit is dismantled.
Contingency No. 2: T/G vendors identified scaffolding, if required, as Owner's responsibility
Contingency No. 3 accounts for unforeseen scope of work and changing market conditions.

7.2 CAPACITY AND ENERGY BENEFITS

The following economic parameters were provided by YEC for use in the payback calculations.

- One-time benefit of an increase in capacity - $2,500,000 per MW based on avoided capital cost of new natural gas generation.
- Annual benefit of an increase in annual energy - $200,000 per GWh based on avoided operating (i.e. variable cost) cost of natural gas.
- Discount rate of 7.2%.
- For paybacks less than 5 years a simple payback should be used.
- For paybacks exceeding 5 years the discounted payback should be used as the time value of money becomes more significant.

KGS Group determined capacity and energy financial benefits from the above economic parameters and the capacity and energy values determined in Section 4.0.

The time schedule of the project is assumed to be as follows:

- Year 1, engineering
- Year 2, fabrication
- Year 3, installation of first unit
- Year 4, installation of second unit.

The benefits summarized in Table 6 incorporate the following simplified cash flow assumptions:

For rerunnering a single unit:

- 10% of project costs are spent in Year 1
- 45% of project costs are spent in Year 2
- 45% of the project costs are spent in Year 3
- 100% of Capacity Benefits are credited in Year 3
- Energy Benefits are credited annually from Year 4 onwards

For rerunnering two units:

- 10% of project costs are spent in Year 1
- 30% of project costs are spent in Year 2
- 30% of the project costs are spent in Year 3
- 30% of the project costs are spent in Year 4
- 50% of Capacity Benefits are credited in Year 3
- 50% of Capacity Benefits are credited in Year 4
- 50% of Energy Benefits are credited in Year 4
- 100% of Energy Benefits are credited annually from Year 5 onwards

TABLE 6
FINANCIAL BENEFITS

BENEFIT OF INCREASED CAPACITY at 80% PLANT FLOW	Increase in Capacity MW	Value of Increase in Capacity $ per MW	One Time Benefit
Upgrade AH2	0.7	$2,500,000	$1,750,000
Upgrade AH1 and AH2	1.3	$2,500,000	$3,250,000

BENEFIT OF INCREASED ENERGY FOR LOW ENERGY DEMAND SCENARIO	Energy Benefits to the WAF+MD System (GWh/Year)	Value of Increase in Energy $ per GWh/year	Annual Benefit
Upgrade AH2	2.26	$200,000	$452,000
Upgrade AH1 and AH2	2.74	$200,000	$548,000

BENEFIT OF INCREASED ENERGY FOR HIGH ENERGY DEMAND SCENARIO	Energy Benefits to the WAF+MD System (GWh/Year)	Value of Increase in Energy $ per GWh/year	Annual Benefit
Upgrade AH2	2.15	$200,000	$430,000
Upgrade AH1 and AH2	3.04	$200,000	$608,000

7.3 PAYBACK PERIOD

Payback periods for the following options were calculated using a spreadsheet provided by Yukon Energy Corporation. The spreadsheet is presented in Appendix C.

TABLE 7
PAYBACK PERIODS

PROJECT OPTIONS	ENERGY DEMAND SCENARIO	DISCOUNTED PAYBACK PERIOD (see note)
AH2 uprate	low energy demand	6 years
AH2 uprate	high energy demand	6 years
AH1 and AH2 uprate	low energy demand	7 years
AH1 and AH2 uprate	high energy demand	6 years

Note: Payback period is measured from the start of the uprate project, not from the time the uprated unit(s) is put back into service.

A single unit uprate has a discounted payback of 6 years in both the low energy years and the high energy years. A two unit uprate project also has a discounted payback of 6 or 7 years depending on energy demands.

7.3.1 Sensitivity Analysis

KGS Group conducted a sensitivity analysis on the following:

- Capacity benefits of between $1M (high speed diesel gensets) and $10M (wind or higher cost new hydro).
- Energy benefits going from $100,000 (best possible natural gas operating cost) to $300,000 (diesel operating cost).

The analysis was conducted on the AH2 Uprate – Low Energy Demand scenario only.

TABLE 8
SENSITIVITY ANALYSIS

Base Information

Nominal Capital Cost	$2,978,976
Discount Rate	7.2%
Capacity Increase	0.7 MW
Energy Increase	2.26 GWh/year

Sensitivity to CAPACITY Value (holding energy value constant at $200,000/GWh/yr)					
	TRIAL 1	TRIAL 2	TRIAL 3	TRIAL 4	TRIAL 5
Variable Benefit, $ per MW	$1M	$2.5M	$5M	$7.5M	$10M
Payback Period, years	11	6	2	2	2
Sensitivity to ENERGY value (holding capacity value constant at $2,500,000/MW)					
	TRIAL 6	TRIAL 7	TRIAL 8	TRIAL 9	TRIAL 10
Varialbe Benefit, $/GWh/yr	$100,000	150,000	$200,000	$250,000	$300,000
Payback Period, years	11	7	6	5	5
Worst Case: Capacity Value at $1,000,000/MW and Energy value at $100,000/GWh/yr					
	TRIAL 11				
Payback Period, years	>21				

Notes and Observations on Sensitivity Analysis:

- A 2 year payback means that the project is paid back in the year that the unit is returned to service.
- The lowest Capacity Benefit of $1M per MW has a payback of 11 years.
- Once the Capacity Benefit reaches $5M per MW, the project has a payback on the first year that the unit is returned to service since this benefit exceeds the cost of the project.
- The lowest Energy Benefit of $100,000 per GWh per year has a payback of 11 years.
- The highest Energy Benefit of $300,000 per GWh per year has a payback of 5 years.
- The worst case scenario of lowest capacity and energy benefits has a payback of 24 years. This value is beyond the 21 year limit of YEC spreadsheet.

8.0 CONCLUSION

Aishihik GS Generating Unit AH2 can be uprated by installing a new Francis runner at a cost of $3.0 M resulting in a discounted payback of 6 years (3 years after uprated unit is returned to service), using current capacity and energy benefit values. This cost includes a new excitation system, generator coolers, new cables from the unit to its generator circuit breaker and possibly new cables from the outdoor switchgear to the T1 and T2 transformers.

Alternatively, both AH1 and AH2 units could be uprated with new Francis runners at a cost of $4.7 M. This option would have a discounted payback of 8 years.

The two uprate options would keep plant water discharge within existging maximum flows. Hydraulic stability during unit start-ups and shut-downs would not be affected and the height of water in the discharge tunnel would not change.

The uprate project budgetary costs in the above sections do not include expenses associated with opportunity maintenance work, or other work on the units not directly related to unit uprate objectives. They also do not cover indirect costs, such as camp facilities, and YEC engineering and project management costs.

Given the strong influence of the capacity and energy benefits on the project payback time, we recommend that YEC revisit the payback projection using updated benefit values at project evaluation time.

The payback was calculated with unit capacities at 80% in keeping with, what we undestand to be, current operating practice. The payback periods would be shorter if the calculations were done at 100% of rated output.

9.0 STATEMENT OF LIMITATIONS AND CONDITIONS

9.1 THIRD PARTY USE OF REPORT

This report has been prepared for YEC to whom this report has been addressed and any use a third party makes of this report, or any reliance on or decisions made based on it, are the responsibility of such third parties. KGS Group accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions undertaken based on this report.

9.2 CAPITAL COST ESTIMATE STATEMENT OF LIMITATIONS

The cost estimates included with this report have been prepared by KGS Group using its professional judgment and exercising due care consistent with the level of detail required for the stage of the project for which the estimate has been developed. These estimates represent KGS Group's opinion of the probable costs and are based on factors over which KGS has no control. These factors include, without limitation, site conditions, availability of qualified labor and materials, present workload of the bidders at the time of tendering and overall market conditions. KGS Group does not assume any responsibility to the Client, in contract, tort or otherwise in connection with such estimates and shall not be liable to the Client if such estimates prove to be inaccurate or incorrect.

PROJECT NO: **14-1404-004**

RE: **Aishihik Turbine Uprate Study**
Hydraulic Capacity Review

1.0 INTRODUCTION

As part of the Aishihik Generating Station (GS) uprate study, KGS Group performed a high level hydraulic review of the conveyance system for Yukon Energy Corporation (YEC) in order to determine the maximum flow that can be conveyed before affecting functionality and safety of the system. This memorandum describes KGS Group's hydraulic review of the conveyance system, including a review of existing documentation and a confirmation of conveyance system hydraulics.

2.0 EXISTING CONDITIONS

The Aishihik GS was commissioned in 1975 as a two-unit hydroelectric facility located northwest of Whitehorse, Yukon. In 2011, a horizontal Francis turbine (Unit #3) was added to the GS. KGS Group has been tasked with undertaking a feasibility study to upgrade Unit #2, including how much additional flow could safely be carried by the conveyance system.

Figure 1 shows the Aishihik GS general arrangement. Flow enters the underground powerhouse through a 5.6 km long power canal, a 175 m deep intake, and a 915 m long pressure tunnel. A wye diverts water towards Unit #3, followed by two 35 m long penstocks that bifurcate to the original units. The water exits the powerhouse first through a surge chamber, then a 1,460 m long tailrace tunnel and a 900 m long tailrace channel before discharging into the West Aishihik

River. The tailrace tunnel is intended to be operated under open-channel flow conditions and doubles as an emergency exit for plant staff that, in case of an emergency can use a raft to make their way out of the powerhouse through the tunnel. The original plant had a rated flow of 19.4 m^3/s, while the current plant has a rated total flow of 23.7 m^3/s [Ref 1].

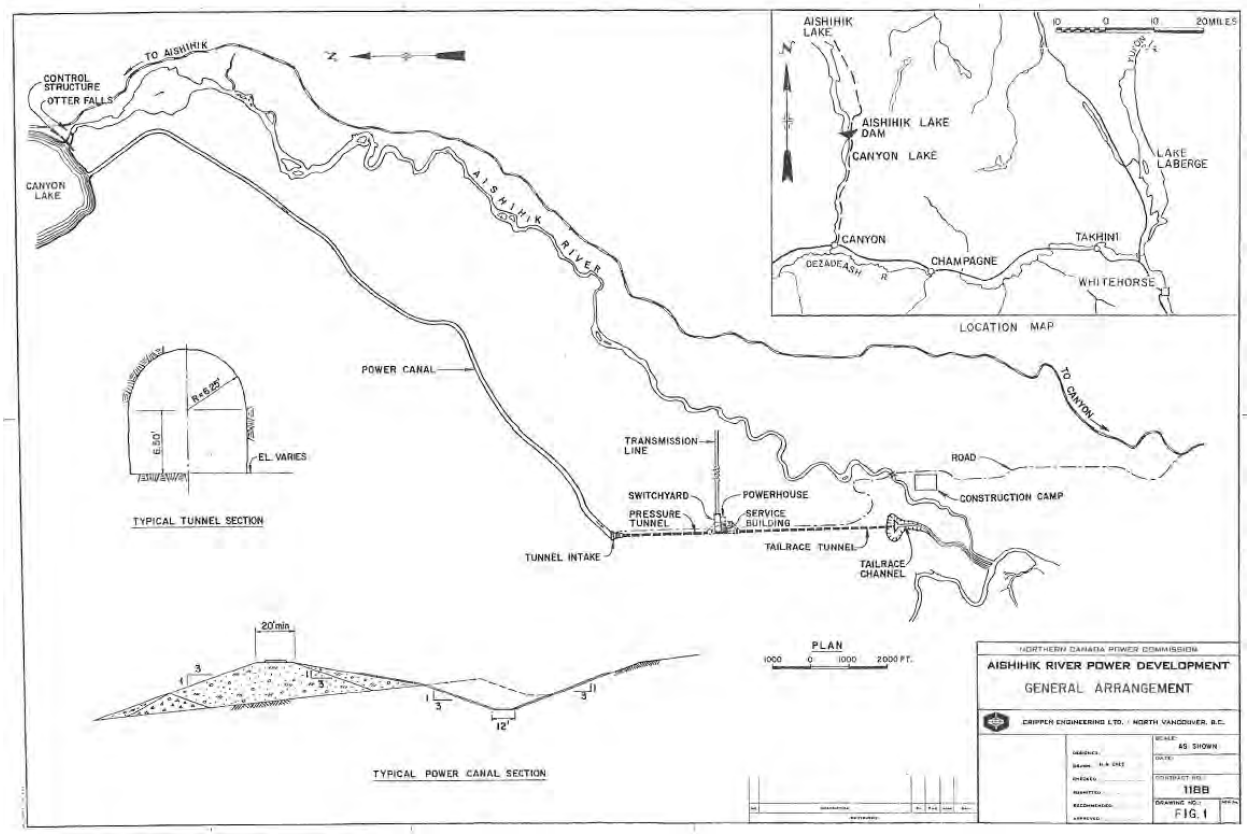

Figure 1: Aishihik GS General Arrangement

Hydraulic concerns raised by YEC of increased plant flow include:

- Reliability of tailrace tunnel as an emergency exit
- Transition of tailrace tunnel from open-channel to full flow
- Back-up of water into the powerhouse from the tailrace tunnel
- Transient pressures in the power and tailrace tunnels

The operational concerns of tailrace tunnel flow will likely limit the safe flow capacity of Aishihik

GS. As such, the tailrace tunnel and channel were the focus of this review.

The tailrace tunnel was constructed by the drill and blast method with approximately 50% of the length lined with shotcrete and 50% left exposed. The shotcrete and exposed rock sections were generally in excellent condition during an August 2008 inspection by Klohn Crippen Berger [Ref 2], however construction rails and ties were left in place, which may have a minor effect on actual tunnel dimensions. As-built tunnel dimensions are unknown, and could have a significant effect on hydraulic conveyance of the tunnel. A survey of the tailrace tunnel dimensions and invert elevations could be performed to confirm the actual tunnel area and confirm hydraulic capacity.

3.0 DEVELOPMENT OF HYDRAULIC MODEL

KGS Group developed a one-dimensional computer model of the downstream conveyance system from the powerhouse to the West Aishihik River using the XP-SWMM Software package. This software allows for accurate modelling of both closed conduit and open channel flows, and solves dynamic wave routing using the St. Venant equations. The model was developed using information obtained from the design drawings as well as the 2008 hydraulics report [Ref 2].

The Manning's n value for surface roughness of the tailrace tunnel and channel were estimated based on results from the 2008 inspection and accompanying photographs such as Photo 1 which shows the tailrace channel material. Tailrace tunnel roughness was estimated as 50% well-trimmed, normal blasted and 50% well-trimmed and shotcreted for a composite Manning's roughness of n = 0.026. Tailrace channel roughness was estimated as a Manning's roughness of n = 0.033, corresponding to a gravel bottom with dry rubble sides. Minor losses were included for the surge tank exit, and the tailrace tunnel junction and exit.

Photo 1: Tailrace Tunnel Outlet and Tailrace Channel

The hydraulic model was verified using two powerhouse tailwater levels measured by YEC and two powerhouse tailwater levels included in the design drawings at specific plant flows. West Aishihik River downstream boundary condition water levels were not measured with the powerhouse tailwater levels, so a sensitivity of river water levels was completed instead.

4.0 ANALYSIS OF RESULTS

The model was simulated for a range of West Aishihik River water levels to determine the relationship between river level and safe plant flow.

Figure 2 shows a water surface profile of the Aishihik GS downstream conveyance system flowing at full plant capacity with normal depth downstream boundary condition. Higher West Aishihik River stages could cause a backwater effect on the downstream end of the tailrace tunnel, reducing the capacity of the tunnel. No data was available for expected water levels in the West Aishihik River so the frequency of such backwater effects is unknown. Further refinement of results would require a rating curve or measured water levels at specific flows in the West Aishihik River.

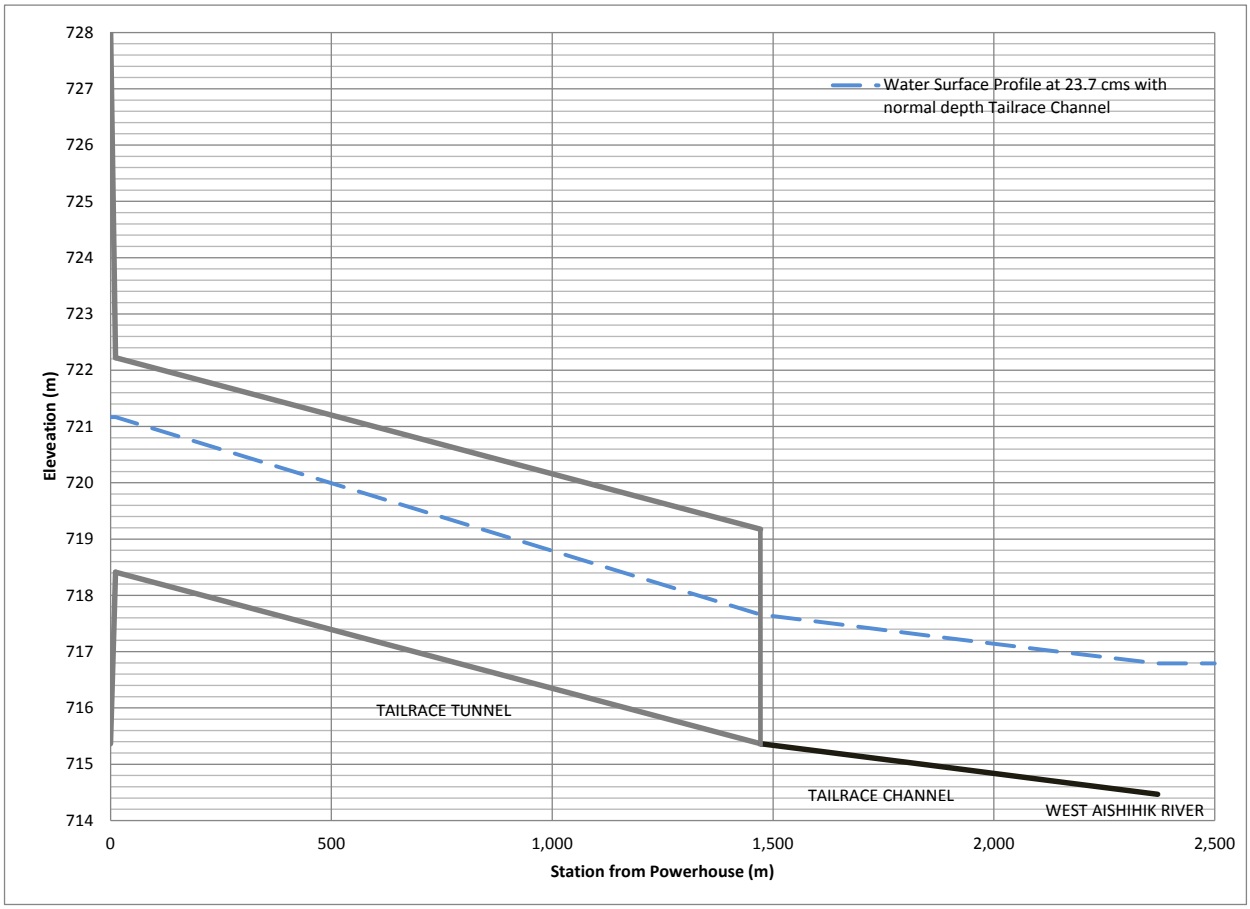

Figure 2: Aishihik GS Downstream Conveyance System Water Surface Profile

Figure 3 shows the maximum flow that can be passed through the tailrace tunnel without pressurized flow for various water levels in the West Aishihik River. Unit #3 is assumed to flow at its full capacity of 4.26 m^3/s for all the scenarios. Figure 3 indicates that as the West Aishihik River stage increases, less flow can be passed through the tailrace tunnel due to backwater effects along the tailrace channel. Depending on the river water level, the tailrace tunnel could pass more flow than the existing 19.43 m^3/s (Unit #1 and #2) with open-channel flow. As long as the tunnel maintains open-channel flow, transient pressures and backup of water into the powerhouse are not expected.

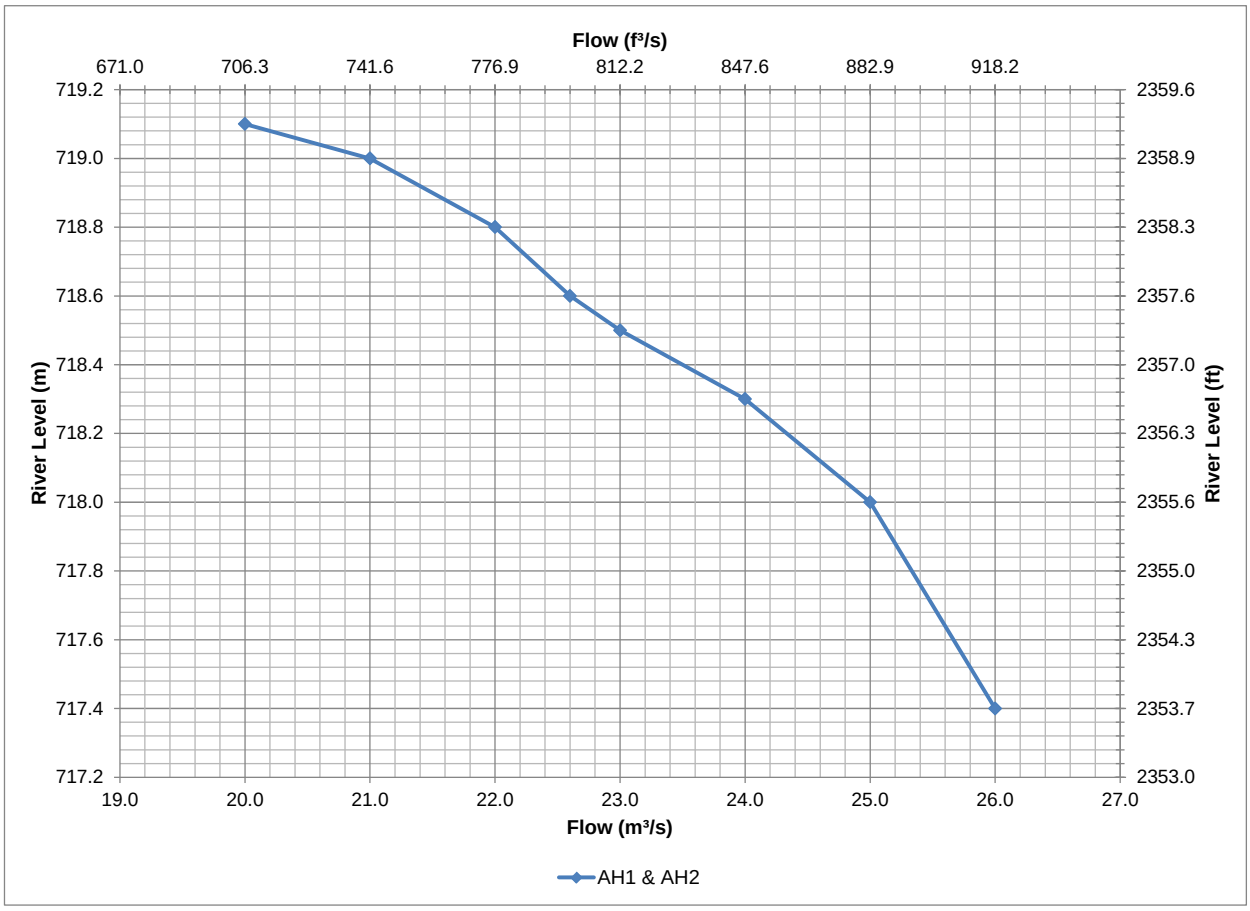

Figure 3: Maximum Flow Through Units 1 and 2 Without Pressurized Tunnel Flow

The other hydraulic concern is ensuring the tailrace tunnel remains open as a safe emergency exit at all times. This is the limiting factor for increasing flow through Unit 2. A reasonable estimate for safe tailrace tunnel flow using the powerhouse tailwater elevation-discharge equation has been compiled by Acres and is described in their February 1999 memo [Ref 3]. This relationship indicates expected powerhouse water levels under normal circumstances and is shown in Figure 4. According to this relationship, water level at the upstream end of the tailrace tunnel (ie. at the powerhouse) would be 721.17 m with current plant flow capacity. This would leave at least 1.06 m of freeboard available for emergency evacuation during normal conditions throughout the tunnel. Using the same equation, a total plant flow of 24.4 m^3/s may be possible while maintaining a 1.00 m freeboard. However, the 1.00 m freeboard may not still be available during extreme conditions if the elevated river levels drown out the tunnel outlet, so increasing plant flow would not be recommended at this point.

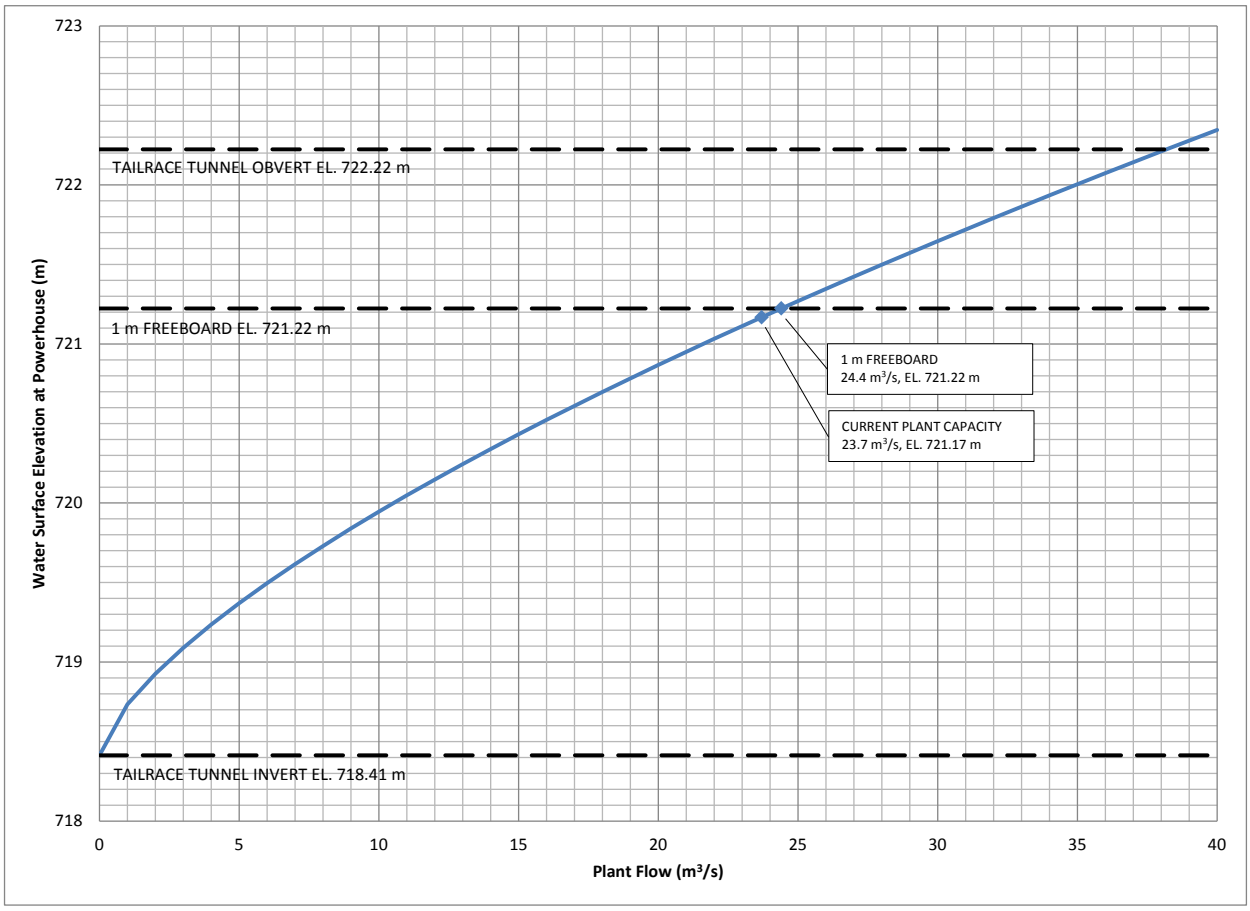

Figure 4: Powerhouse Tailwater Stage-Discharge Relationship

Without further West Aishihik River water level information, it would be impossible to confirm that the tailrace tunnel would be a safe emergency exit at all times. Although there is currently adequate freeboard during normal conditions, the extreme flood conditions of the river are unknown. It is recommended to gather additional information about flood levels in the West Aishihik River to confirm the safety of emergency evacuation under a wider range of conditions. Without further study regarding the West Aishihik River, the discharge through the Aishihik GS should not be increased beyond its current capacity.

5.0 CONCLUSIONS

KGS Group performed a high level hydraulic review of the Aishihik GS conveyance system, including a review of previous documentation and the development of a one-dimensional XP-

SWMM hydraulic model of the tailrace. From this analysis, the following conclusions about the maximum safe plant flow were drawn:

1. The limiting factor for increasing plant flow capacity is the requirement to maintain emergency evacuation access in the tailrace tunnel; however a survey of actual tailrace tunnel dimensions could be conducted to confirm the assumptions adopted in the hydraulic analysis described in this memorandum.
2. The current plant capacity of 23.7 m^3/s provides 1.06 m of emergency freeboard throughout the tailrace tunnel during normal conditions.
3. Flows as high as 24.4 m^3/s could be passed through the tunnel while still maintaining 1.00 m of emergency freeboard throughout the tunnel during normal downstream river levels.
4. During flood conditions, no data is available about expected water levels in the West Aishihik River. The river water levels have the potential to limit the available emergency freeboard at the downstream end of the tailrace tunnel.
5. Further information about flood stages in the West Aishihik River should be gathered. Until such information is obtained and analysed, no increase in plant flow is recommended.

DRAFT

1.0 BACKGROUND

The Aishihik Generating Station (AGS) is located northwest of Whitehorse, Yukon. The site is accessible by an all-weather road. From the Whitehorse airport, it is approximately 122 km West on the Alaska Highway and approximately 20 km North on an un-nammed road. The closest community with services is Haines Junction, approximately 60 km away.

The AGS was constructed in 1972 and originally consisted of two 15 MW vertical Francis turbines (AH1 and AH2) with a net head of 180 metres. In 2011, a third 7 MW horizontal Francis turbine (AH3) was added.

The AGS units are located in an underground powerhouse approximately 110 metres below the surface. Water is drawn from Canyon Lake using a 5.6 km long power canal, through a concrete intake structure and a 1.1 km long tunnel. AH1 and AH2 are equipped with spherical valves that allow for isolation of the units for maintenance. Water discharges from the draft tubes, into a 1.4 km long tailrace tunnel and a 900 m tailrace channel before discharging into the West Aishihik River.

In 2003, the AH1 generator was rewound that increased the electrical capacity to 17,000 kVA. In 2006, the AH2 generator was rewound that increased the electrical capacity to 19,200 kVA. AH1 underwent a ten year overhaul in 2012 and the AH2 ten year overhaul was done in 2013.

While the project is not exclusive to the upgrade of the AH2 unit, it is perceived that it offers the greater opportunity for upgrade/uprate. It is the intent to also review the merits of upgrading both the AH1 and AH2 units.

DRAFT

2.0 REQUESTED INFORMATION

KGS Group has been retained by Yukon Energy Corporation to conduct a study into the potential upgrade of the turbine on Unit #2 at the Aishihik Generating Station. To this end, we are requesting budget pricing, as well as technical information on the runners you may have that are suitable, and other required turbine modifications or new components that may be beneficial to the efficiency or power output of the turbine.

Although currently at the concept study stage, the project, should it proceed, would eventually include the design, supply, manufacture, quality assurance, delivery, installation, testing, commissioning, and warranty for one or two new turbine runner(s) and any other modifications required to achieve the proposed improved performance.

To determine the feasibility of upgrades, the following preliminary information is requested:

- Budgetary cost. Please be sure to include for new coupling bolts
- Description of the proposed new runner, including number of blades, materials, and method of fabrication (single piece casting, welded etc.)
- A description of the proposed scope of the upgrades, beyond the provision of new runners
- Number of runner blades proposed
- Efficiency curves (Hill Chart) for the proposed turbines
- Sigma critical value
- Expected cavitation characteristics based on setting, referenced to limits in Figures A.1 and A.2 in IEC 60609-1-2004
- Any operational constraints, such as maximum number of hours above and below the recommended operation envelope
- Maximum runaway speed
- Expected hydraulic thrust load
- Indicate delivery time for major equipment after placement of order
- Indicate anticipated time required for installation in the field

DRAFT

Clearly indicate in your budgetary proposal where requested items are excluded or are not in compliance with this document.

DRAFT

3.0 TYPICAL OPERATION AND OPTIMIZATION OF NEW RUNNERS

In order to provide a “spinning reserve” to accept sudden load increases on Yukon Energy Corporation’s electrical grid, the AH1 and AH2 units are typically operated at approximately 80% of their maximum power output. They may, however, be operated at relatively low power levels during periods of low demand and at maximum output during periods of high demand.

Because of the above-mentioned operation strategy, the proposed new runners should be optimized to provide (in order of importance):

1. The highest efficiency at approximately 80% gate opening
2. The highest maximum output at full gate opening
3. The highest efficiency at gate openings lower than 80%

A preference will be shown for fabricated (welded) runners over one-piece cast runners. Cast runners may be accepted, depending on efficiency, cavitation and equipment guarantees.

DRAFT

4.0 REFERENCE FIGURES

DRAFT

5.0 EXISTING EQUIPMENT DETAILS

In this section, elevations are reference to mean sea level.

5.1 TURBINES

Make:	Dominion Engineering Works
Rated net head:	180.4 m
Rated discharge (per unit):	9.72 m^3/s
Power at rated net head and discharge (per unit):	15 MW
Speed:	720 RPM
Number of runner blades:	15
Number of wicket gates:	20
Throat diameter:	1016 mm
Setting elevation (centreline of distributor):	715.52 m

5.2 GENERATORS

Make:	Canadian General Electric
Synchronous Speed:	720 RPM
Maximum runaway speed rating of generators:	1330 RPM
AH1 capacity:	17,000 kVA
AH2 capacity:	19,200 kVA
Power factor:	0.9

Refer to Appendix B and C for pictures of the generator nameplates.

5.3 TAILWATER RATING INFORMATION:

TWL elevation at 8.5 m^3/s:	719.9 m
TWL elevation at 21.25 m^3/s:	721.4 m
TWL elevation at 25 m^3/s:	722.0 m

DRAFT

6.0 CONSTRAINTS

6.1 HYDRAULIC

The rated flow of the proposed new turbine runners cannot exceed the rating of the existing runners. This is due to a limitation in the tailrace tunnel. The tailrace tunnel is designed to operate at partially filled (i.e. the tunnel has a free water surface for its entire length). Increasing the flow beyond the existing maximum values may cause the tunnel to switch to full flow, resulting in backwater effects and potential dynamic issues that would result if the flow alternated between flowing filled and partially filled.

The tailrace tunnel is also used as an emergency egress route from the underground powerhouse. For this reason, a minimum freeboard is required between the roof of the tunnel and the maximum water level.

DRAFT

6.2 MECHANICAL

Other than the maximum runaway speed rating of the existing generators, no mechanical limitations that would limit a runner upgrade have been identified.

If any changes to the distributor or wicket gates are recommended by the Supplier, the capacity of the servo and governor oil system would need to be confirmed.

6.3 ELECTRICAL

The switchgear, power conductors and generator step-up transformers have the sufficient capacity to accommodate the increased power generated by the upgraded units.

The excitation system is currently under review, but for the purposes of this RFI, please assume that there is no constraint on the maximum power output based on the excitation system.

7.0 OTHER RELEVANT DATA

7.1 SEISMIC INFORMATION

The design seismic coefficient (PGA) shall be 0.17g.

DRAFT

8.0 BASIS OF BUDGETARY COST ESTIMATE

For the purposes of the budgetary cost estimate requested, please assume the following.

8.1 SCOPE OF SUPPLY

Allow for:

- Provision of a one new runner
- Provision of new coupling bolts
- Provision of new runner blade templates in accordance with IEC 60193-1999 to measure both blade profile and angle
- Provision of all stationary parts required for the installation of the new runner and of any new turbine components to be replaced to enhance turbine performance
- The submission and review of drawings, design documentation and quality assurance documentation by Owner's Engineer.
- The provision of 3 paper copies and one electronic copy of Operating and Maintenance (O&M) manuals for all equipment supplied.

DRAFT

8.2 WARRANTY

Warranty work for a period of two years from substantial performance.

8.3 PERFORMANCE GUARANTEES

If the turbine re-runnering project proceeds, it is likely that the Owner will seek performance guarantees for efficiency and power output, supported by liquidated damages. The level of liquidated damages has not been determined at this point.

8.4 SITE INSTALLATION

Please include a cost estimate for complete site installation of the new runner (assuming only one runner is replaced) and any other required modifications.

Provide:

- Duration and person-days of work
- Cost for person-day of work

Indicate whether or not values include living out allowances and accommodation costs.

Project description: Potential Runner Upgrade Request For Information 14-1404-004

Our reference: OB-Yukon Energy Aishihik Generating Station

We are pleased to submit our budgetary proposal for the supplies and works for Aishihik Generating Station runner upgrade.

At this stage, this budgetary proposal gives a preliminary indication of the conditions under which we could perform the works and DOES NOT CONSTITUTE A BINDING OFFER. Alstom reserves the right to alter any aspect of this budgetary proposal, including the pricing information.

Nevertheless we trust the information provided is sufficiently detailed to enable you to assess the benefits which you can obtain from Alstom and we confirm our keen interest in working with you.

We remain at your disposal to further discuss the contents of our budgetary proposal and to offer you a firm proposal with definitive prices, price escalation details, as well as full terms and conditions in the event that this project goes forward.

Best regards

Alex Viens 450-372-0755 ext 289

Alstom is please to respond to "*Aishihik Generating Station Potential Runner Upgrade, Request for Information, Draft revA*" 14-1404-004 to estimate the turbine performances with a new runner.

Based on the information provided by KGS for Yukon Energy, Alstom understand that the power plant has currently 3 units having the following characteristics:

Unit 1	15 MW vertical Francis runner (1972), net head= 180 m, generator rewound in 2003 to 17 000 kVA
Unit 2	15 MW vertical Francis runner (1972), net head= 180 m, generator rewound in 2006 to 19200 kVA
Unit 3	7 MW horizontal Francis runner (2011)

KGS is asked in the RFI to investigate the refurbishment of unit 2. The hydraulic characteristics of unit 2 are the following:

Original Equipment Manufacturer	Dominion Engineering Works
Rated net head:	180.4 m
Rated discharge (per unit):	9.72 m3/s *
Synchronous Speed	720 RPM
Runaway speed	1330 RPM
Nb of stay vanes	10
Nb of wicket gates	20
Nb of runner blades	15
Runner exit diameter	1016 mm
Distributor height (estimated)	218 mm
Distributor centerline elevation	715.52 m
Tailwater level (normal)	721.4 m

*The new runner cannot use more flow than 9.72 m^3/s as there is an evacuation tunnel in which the water is flowing and this tunnel cannot be more filled than now.

Alstom has studied the replacement of the runner of unit 2 and provides in this document expected performances for the rated net head of 180.4 m. Alstom has more than 100 years in hydroelectric runner design with a huge selection of projects realized worldwide. Francis, Kaplan, Pelton and Bulbs hydroelectric turbines are designed and manufactured every day 24h/day by Alstom employees all around the Globe. Vertical Francis runners represent an important part of Alstom Hydro.

Alstom takes advantage of its past experiences for the design of new runners. Indeed, the design process is based on the selection of an existing reference from which adaptations/changes are applied to reflect the situation of the turbine to refurbish. All parts of the turbines are studied, from the spiral case inlet up to the draft tube outlet. Calculations of the fluid flow with the use of computers (CFD) are part of the normal design process. For the present budgetary proposal, the expected performances were estimated using the reference Alstom runner shown on the image in Figure 1. Adaptations and changes to the chosen Alstom reference to fit Aishihik's configuration were done relying on analytic relations and experience.

Alstom has selected a reference which has a very good cavitation behavior, a high efficiency, a runaway speed close to 1330 RPM and acceptable mechanical static stresses at synchronous speed. As seen in the figure, the distributor height of the reference (in blue) is higher than Aishihik's distributor height. Alstom proposes for Aishihik a runner with the same distributor height as the current distributor height and the shift in performance induced by this change of height is already taken into account. The main characteristics of the proposed runner are given in Table 1 below.

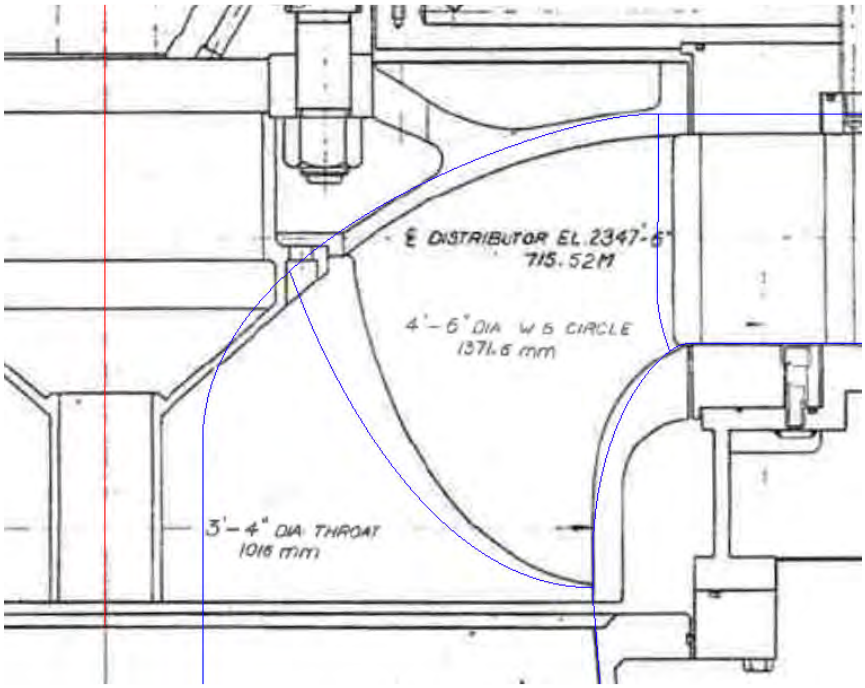

Figure 1 : Alstom reference (in blue), Aishihik in black

Table 1: Main characteristics of the proposed runner

Nb of blades	15
Distributor height	218 mm
Exit diameter	1016 mm

The proposed runner would be made from a forged martensitic stainless steel ingot. After removal of steel by machining, the final shape would be obtained. As the runner is not obtained from a casting, the numerous metal defects generally obtained from cast parts would not be found. Moreover, the mechanical solidity of the runner would be further enhanced as no welds would be done, resulting a high quality runner. Runners could be delivered within 9-10 months with this industrial scheme.

Alstom is currently manufacturing runners for Soo River G.S, a project similar to Aishihik . Dimensions of both runners are very close to each other, Figure 2 allows a better comparison of both runners. On this figure, the Soo River runner is pictured at the outlet diameter of the Aishihik runner. The outlet diameter of Soo River is 1100 mm, which is very close to the outlet diameter of the Aishihik runner. As it is seen, dimensions and overall shape are quite close to each other.

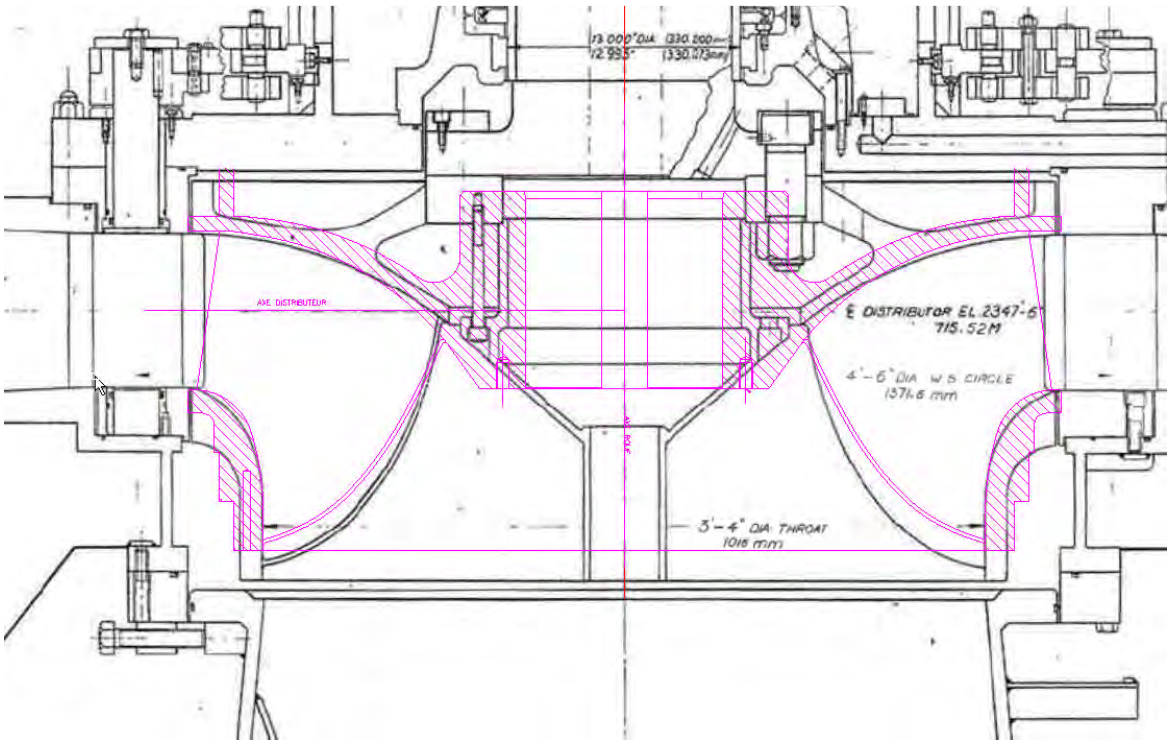

Figure 2: Comparison of Aishihik runner with Soo River runner (Soo river in purple, Aishihik in black)

Estimation of the expected performances at Hnet=180.4 m is presented below in Figure 3. The green curve is the expected efficiency whereas the blue curve is the expected turbine power. A tailwater level of 721.4 m is assumed at this point. As mentioned earlier, the discharge cannot exceed 9.72 m^3/s. This is represented by the vertical red line. At this maximum discharge, the expected power is 16.1 MW and the efficiency is 93.5%. The peak efficiency at this head is expected to be obtained at roughly 85% of the maximum discharge, i.e. at 8.4 m^3/s.

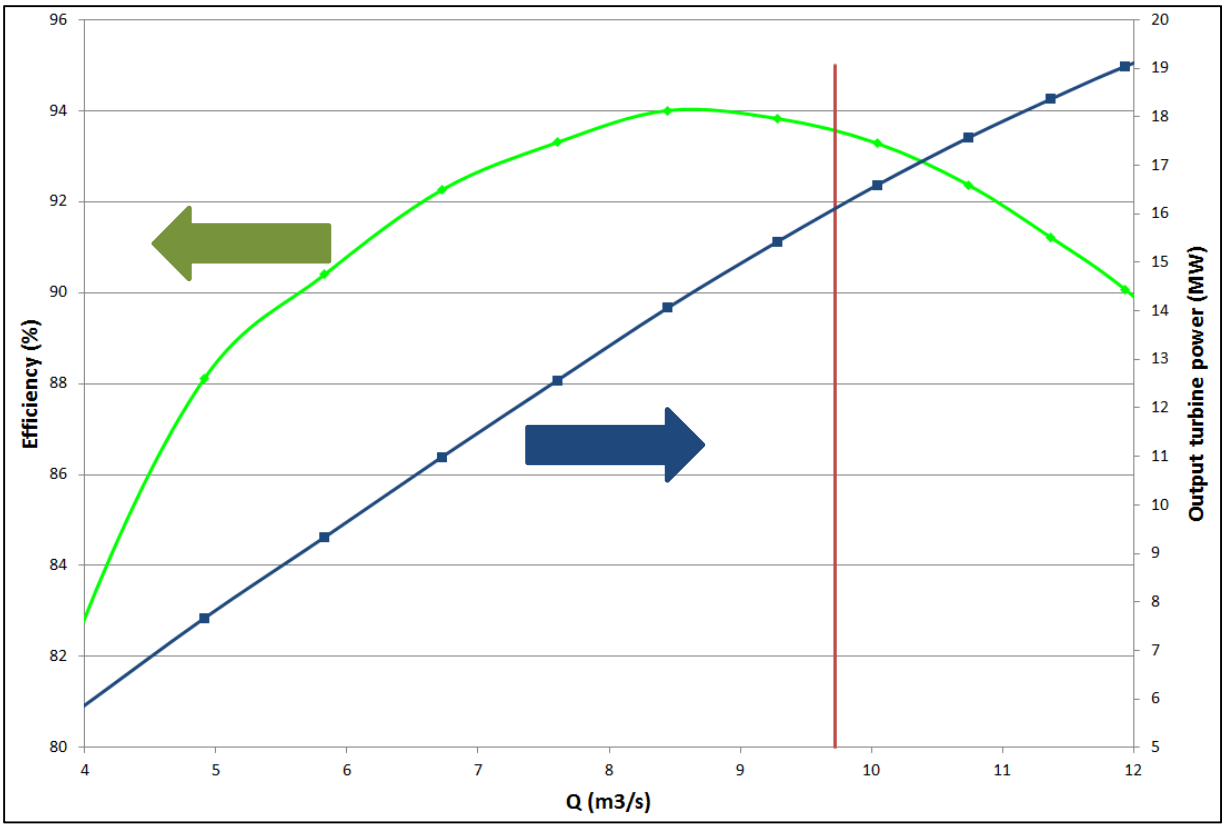

Figure 3: Expected performance for Hnet = 180.4 m and at tailwater level = 721.4 m.

The Figure 3 shows expected efficiency and power as single lines. However, at this stage of the process, a non-negligible uncertainty exists and as a consequence the efficiency line should be viewed rather as band with +0.5/-1% limits. The uncertainty comes from, on one part, the incomplete information received by Alstom.

Alstom will require some more information atop of the information already given to reduce the uncertainty. Amongst the additional required information, there are:

- The maximum and minimum net head. This information is necessary to ascertain that there is no cavitation induced at leading edge due to a net head not taken into account;

- The position of the pressure taps in the draft tube and spiral casing to measure the net head. In the drawings supplied, the draft tube appears to be much longer than Alstom's existing draft tube. This might just be wrongly assumed as the position of the end of the draft tube is not indicated;

- The installation/dismounting of the runner. Alstom has already made in the recent past another Francis runner whose shape in the meridian plane is even closer to Aishihik's shape than the shape of the first reference indicated above. The efficiency, cavitation, stability, mechanical and runaway behaviour of this runner is also very good. Its stability behavior for instance, is better than the stability behavior of the reference chosen to construct the expected performances. For this reason it seems that this second reference is also a very good starting point for Aishihik. One drawback however is the lower exit altitude of the blade near the crown. It is understood that the current runner may be dismantled from the shaft from underneath by first removing the runner cone and then removing the coupling nuts connecting the runner to the shaft. If dismantling from below is not required or unfrequently expected, we recommend indicating it in the RFQ. We will have to choose between keeping this second reference and modifying the shaft (for instance in order to have a sole central bolt to couple the runner to the shaft) and keeping the first reference identified whose trailing edge is at a higher altitude (closer to Aishihik current runner). The final choice will be a tradeoff amongst various criteria: price, stability, efficiency level, cavitation behaviour, lead time, etc. Currently there is not enough information within the KGS's document to make a choice. The evaluation criteria would be helpful in optimizing the proposed solution.

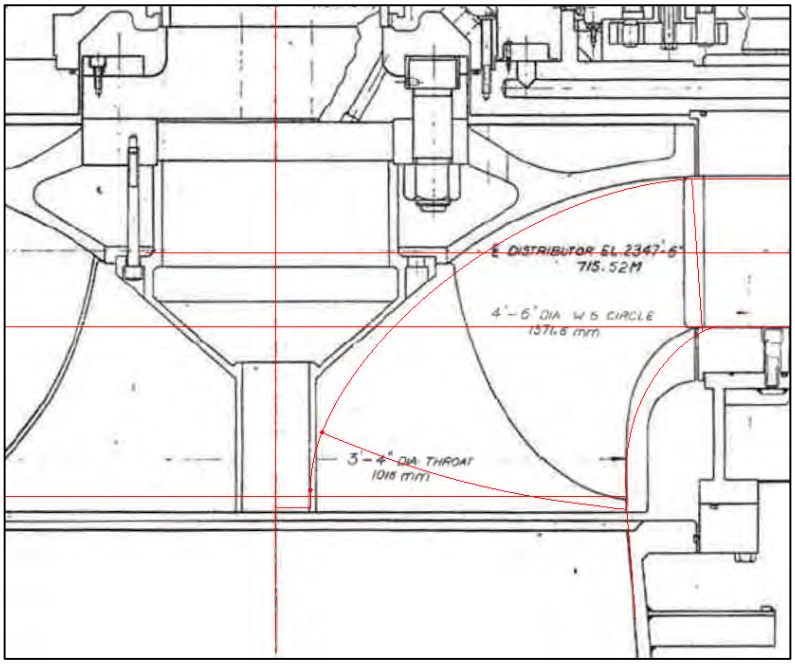

Figure 4: Alstom second possible reference for the Aishihik project

- Alstom will need drawings of gates and vanes with dimensions. For the purpose of the current performance estimate, rapid approximations were done. Refinement is required to narrow down the uncertainty;

- Volumetric losses through labyrinths for this head are important, Alstom needs to evaluate at best the expected leakage flow. The drawings supplied allowed us to see that the current configuration has both band and crown seals lengths shorter than our internal standards. Also, the radial gaps may be important and as a result the leakage flow is likely to be important. Further studies to determine if the current seal design is kept will need to be done following the reception of more complete information.

Alstom has already performed some rapid studies of the other components of the Aishihik turbine and brings attention to a potential refurbishment of the wicket gates. For instance, having gates cambered on the "opposite side" could give an estimated 0.4% to 0.8% gain in efficiency, see Figure 5 below. The efficiency gain would come from the greater inter-gates space which would allow a reduction of the water velocity and accompanying losses.

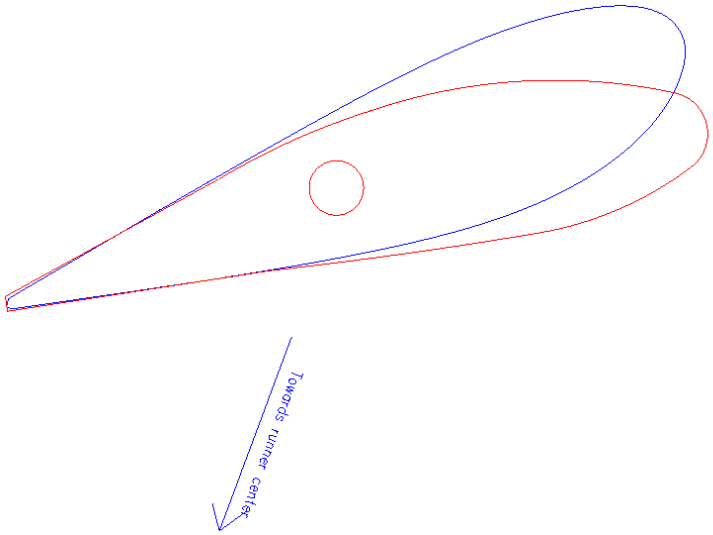

Figure 5: Comparison of the Aishihik gate (red) and a cambered gate (blue)

Alstom has a great expertise in vertical Francis turbines and we feel that our knowledge would be highly valuable for the Aishihik project. The preliminary studies performed indicate that at least two existing references would fit within Aishihik's configuration with minor adjustments required. More complete information is required to make a final choice between the two references. In both cases the proposed efficiency would provide an increase of the maximum power. As instance, using reference #1, we estimated that the maximum power would increase from the actual 15 MW to an expected 16.1 MW with the same amount of water of 9.72 m^3/s.

Regarding the axial thrust, further studies are required. Knowing the actual capacity of the thrust bearing would be useful to make an evaluation/verification.

Indeed, following the reception of complementary information during the firm RFQ, Alstom will perform further studies to ascertain the current assumptions and to propose a new runner and related components with the best characteristics for Aishihik power plant.

Work description

Alstom based their budget estimation on similar projects and on drawings supplied with the RFI, more details or a site visit will be necessary to firm up the budgets. For RFI purpose we have used a schedule of 6-1 days - 12/hrs per day for site works, it is considered that workers have to travel Haines Junction every days.

For the budget purpose we have calculated replacement parts directly related to the runner replacement, if other option are valuable to Yukon Energy we will be please to quote accordingly. Alstom also suggest to perform a condition assessment of the remaining turbine components this may identify if other components need to be replaced.

Table 1 – Site scope of work included in the budgetary price of **$250 500.00**

Scope of work	Included ✓
1. Turbine runner replacement.	
a) EHS site analyses.	✓
b) Turbine disassembly	✓
c) Parts inspections and recommandations.	✓
d) New runner and parts installation	✓
e) Turbine reassembly	✓
f) Commissioning	✓

Table 2 –Engineering scope of work included in the budgetary price of **$106 500.00**

Scope of work	Included ✓
2. Turbine Runner engineering	
a) Study for an adaptation of an Alstom runner profile to Aishihik turbine distributor and shaft.	✓
b) Drawings for fixed labyrinths adaptation to Alstom runner.	✓
c) Commissioning report.	✓

Table 3 – Parts for the project for a budgetary price of **$386 500.00**

Parts for project	Quantity	Parts total price
3. Replacement parts		
a) 1 Runner, cone and bolts.	1	$343 500.00
b) 1 Fixed labyrinths set and hardware.	2	$43 000.00

Included in this budgetary estimate

- 1 mobilization and 1 demobilization of ALSTOM SITCA INC;
- Transport of the parts to Aishihik Generating Station;
- Work and parts described in tables 1, 2 & 3;
- Standard required tooling;
- Travelling, meals and lodging expenses for required labour;
- Field report;

Excluded from this estimate

- Mobilization and demobilization of ALSTOM SITCA INC. labour and tooling in case of work interruption by others;
- Repairs, modifications, machining and all related costs deemed necessary for non-conform equipment and/or drawings;
- All damages, delays, or inconveniences resulting from work performed by other contractors, sub-contractors or employees provided by the Client;
- Special tools and lifting device required for this contract;
- Procedure, equipment, labour and costs associated to work in confined space;
- Dewatering and refilling of the power station unit(s);
- Overhead crane services;
- Any NDT testing;
- Absolute turbine effiency.
- Alignment correction work;
- All machining work (of other turbine parts and all generator parts) and the related costs;
- Waiting time and related costs;
- GST and PST

The Client also agrees to provide the following

- Procedure and lockout of equipment impacted by this contract;
- Adequately maintained access to reach working site allowing for equipment to be delivered by vehicle, for the duration of the contract;
- Sufficient opening (door, roof) to access the equipment;
- An easily accessible storing area on site for maritime-type containers;
- Containers for waste (components, waste oil and grease, soiled cloth, etc.) ensuing from ALSTOM SITCA INC. work and will be responsible for its disposal;
- Electrical and pneumatic power required for this contract;
- Asbestos-free environment;
- Valid inspection certificate for overhead crane and/or all permanent lifting devices on site;
- Adequate on-site facilities including but not limited to washrooms, lunchroom and office area;
- Scaffolding including drawings and installation procedure certified by an engineer;
- All drawings, maintenance manuals, procedures and specifications in his possession, at ALSTOM SITCA INC. request.

Ref: Budget quote for the manufacturing of one (1) replacement Francis Runner for Aishihik Generating Station. Norcan Reference #15-2215 Rev 0

Dear Joel,

Norcan Hydraulic Turbine Inc. is pleased to submit the following budget proposal for the manufacturing and installation of one replacement Francis Runner for Aishihik Generating Station Unit 2 based on the supplied data on February 17, 2015 file no. 14-1404-004.

Attached, please find a general summary, pricing and detailed scope of supply. I hope this proposal meets your requirements.

If you have any questions or require clarifications, please let us know.

Sincerely,
Norcan Hydraulic Turbine Inc.

Henk de Ridder

1.0 GENERAL SUMMARY

Pricing

Item	General Description	Qty	Amount (CAD/Dollar)
Equipment Supply	Manufacture one (1) 40.0" Dt Francis Runner.		(Itemized costs shall equal below sum):
	40.0" Dt Francis Runners	1 each	$268,033.00
	Delivery and Installation	1 each	$ 205,140.00
	Replacement Coupling Bolts	1 set	$ 8,600.00
	Blade Templates	1 set	$ 15,500.00
	Taxes *Not Included*		EXTRA if applicable

Notes

- Taxes are not included.
- Delivery time of 11-12 months from reception of P.O., receipt of down payment.
- Warranty for two (2) years from commissioning or thirty (30) months after delivery, whichever is sooner.
- Quote valid for 60 days.
- Quote based on existing runner removal from below. Existing removal equipment is present at site.
- Quote based on Norcan modifying existing runner removal and installation equipment to suit new runner.

2.0 DETAILED SCOPE OF SUPPLY

40.0" Dt Francis Runner 15 blade

Material
The Crown, Blades and Band components will be of cast ASTM A743 CA6NM or forged of A182 F6NM stainless steel or approved equivalent.

Construction
The Runners will be fabricated, machined, and ground in accordance with Norcan manufacturing design standards and tolerances stated in DWI050-Rev 3. The Runners will meet or exceed IEC standard publication 60193 1999-11.

For fabrication, the Crown and Band will be cast and/or forged and fully pre-machined. The Blades will be cast, pre-machined and hand ground. The Blades will be welded to the Crown and Band as follows:

The first 25% of the Blade length at the inlet and discharge will have 100% penetration. The remaining length of the Blade will have 1/3 of the Blade thickness V weld per side. A concave fillet weld will finish the Blade to Crown and Blade to Band. The fillet weld will be hand ground to the required finish with no permissible undercuts. The root weld filler material will be AWS No. 309 and the finish passes "cap" will be AWS No. E410 Ni Mo. All welders are qualified to QW-200.1, Section IX, ASME Boiler and Pressure Vessel Code or CSA W47.1. (Ref. DWI-059, DWI-013)

The Runner minimum finish will be as follows:

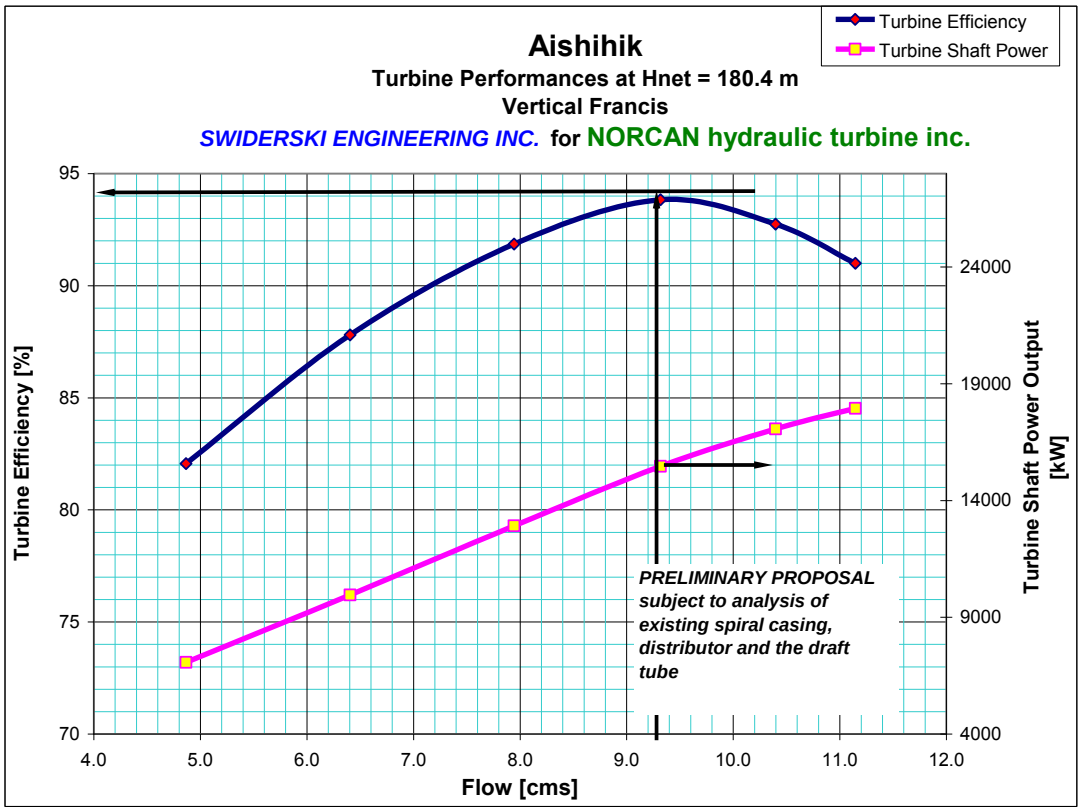
Water passages	
Upper two thirds of the Blade	125 finish
Lower one third of the Blade	63 finish
Runner	
Outside finish all over with axis	250 finish
Seal surfaces	125 finish
All other surfaces	125 finish

Balancing
The Runner will be dynamically balanced to meet or exceed the standards of ISO 1940 G2.5. Weights shall be added or removed in such a manner that there will be no projections or depressions from the finished surfaces. No eccentric machining will be performed.

3.0 PRELIMINARY PERFORMANCE

Hnet =	591.7	ft	=	180.40	m
Dth (nom) =	40.0	in	=	1.016	m
n =	720	rpm			

Turbine Efficiency	Flow	Flow	Turbine Shaft Power	Turbine Shaft Power	
[%]	[cms]	[cfs]	[kW]	[hp]	
82.06	4.87	171.7	7065	9474	
87.80	6.41	226.0	9950	13343	
91.86	7.94	280.3	12911	17314	
93.83	9.32	328.8	15466	20741	
92.74	10.40	366.9	17061	22879	
91.00	**11.15**	**393.4**	**17946**	**24066**	**CAVITATION LIMIT**



Performance above is based on best guess based on data supplied.

Analysis of existing hydraulic outline will be required to determine best runner fit using CFD.

Operational history will be required of existing performance of present runner.

Runaway speed and maximum thrust to be supplied upon completion of CFD and engineering.

4.0 COMMERCIAL TERMS

Delivery

Delivery will be 11-12 months after receipt of the contract, receipt of the down payment and supplied production drawings. All delivery times start from the date of acceptance of the order and receipt of the down payment.

Installation

Installation will be 6-8 weeks from time runner is delivered to site.

Project Schedule

A detailed schedule to be presented four (4) weeks after the award of the contract.

Payment Schedule

The following terms of Payment shall apply:

20% Down payment with the order.
10% Completion and approval manufacturing drawings and inspection test plan.
20% On receipt of construction materials (Castings, Forgings).
15% Completion of Runner fabrication.
15% Manufacturing complete, Runner ready to ship
10% Mobalized and on site old runner removed
10% New runner installed and commissioned

*Payment net 30 days from invoice issue date

5.0 GENERAL CONDITIONS OF CONTRACT

(Note: Any reference to "Norcan" is a reference to Norcan Hydraulic Turbine Inc.)

Indemnification

Norcan shall indemnify and hold harmless the Customer against all claims, demands, losses, damages and costs, all as finally judicially determined, excluding loss of profit and any punitive, exemplary, indirect, consequential or special losses or damages, whether in contract or in tort or otherwise, by third parties where such claims, demands, losses, damages and costs are:

(i) attributable to bodily injury, sickness, disease, or death, or to injury to or destruction of tangible property;

(ii) caused by negligent acts or omissions of Norcan or anyone for whose acts Norcan may be liable; and

(iii) made in writing within a period of two years from the date of delivery to the Customer of each Norcan supplied equipment.

The Customer expressly waives the right to indemnity for claims other than those stated above.

The obligations of Norcan to indemnify hereunder shall be limited to an aggregate amount no greater than the amount payable to Norcan under this Contract hereinafter referred to as the "total Contract price".

The Customer shall indemnify and hold harmless Norcan and Norcan's agents and employees from and against claims, demands, losses, costs, damages, actions, suits or proceedings arising out of Norcan's performance of the work under this Contract which are attributable to a lack of or defect in title or an alleged lack of or defect in title to the place where the Norcan supplied equipment is delivered and, or installed.

Force Majeure

Any delay or failure in the performance by Norcan hereunder shall be excused and no liability whatsoever will rest with Norcan where such delay or failure is caused by Force Majeure. For the purposes of this Agreement, Force Majeure shall mean an event or cause beyond Norcan's control and shall include, but is not limited to, acts of God, riots, wars, insurrection, acts of public enemy, sabotage, terrorism, vandalism, embargo, national emergency, accident, restraint of government, governmental acts, fires, floods and other natural disasters, explosions, severe weather including hurricanes and storms, injunctions, labour strikes or inability to obtain required labour, materials or manufacturing facilities from normal sources, acts of a customer and/or owner, wrecks or delays in transportation.

Warranty

The warranty period with respect to this Contract terminates on a date which is the sooner of:

(i) that day which is 12 months from the completion of the initial test runs of the installed Norcan equipment; and,

(ii) that day which is 18 months from the date of delivery of the Norcan supplied equipment.

Norcan shall be responsible for the proper performance of its work and for the work of those for whose acts Norcan may be liable to the extent that this Contract and related documents permits such performance, save that it is understood and agreed that:

(i) Norcan accepts no liability for the design of civil works, intake and trash racks, powerhouse or foundation stability, tail race or other associated water passages or for work improperly done by others, nor does Norcan accept liability for lack of or errors in water availability, flow duration studies or the condition of the water flowing into the turbine. Furthermore,

Norcan does not accept liability for damage to the turbine components due to debris (rock metal, lumber, etc.) passing through the turbine intake;

(ii) Norcan shall not be liable to remedy defects or deficiencies which have arisen as a result of the acts or omissions of those over whom Norcan does not exercise control;

(iii) This warranty is void and unenforceable unless Norcan is afforded the opportunity to complete a final inspection of the completed work within **14** (fourteen) days of installation of the Norcan supplied equipment.

Subject to the provisions of this clause Norcan shall correct promptly, at Norcan's expense, defects and deficiencies in its work which appear prior to and during the warranty period specified herein.

The Customer shall promptly give Norcan notice in writing of observed defects and deficiencies that occurred during the warranty period and Norcan shall be immediately afforded the opportunity to inspect and observe the alleged defects and deficiencies.

Where Norcan fails to correct defects or deficiencies brought to its attention for which it would otherwise be liable, it shall be liable to the Customer to pay for the reasonable costs incurred by the Customer in correcting such defects or deficiencies.

It is understood and agreed that Norcan's liability under this warranty is limited to an aggregate amount which shall not exceed 10 percent (10%) of the total Contract price.

Damages

It is agreed and understood that should turbine performance be within three percent (3%) of anticipated output, such shall not be considered a defect or deficiency in the work of Norcan and for the purposes of this Contract shall be

considered to be an acceptable outcome of the performance of the work by Norcan.

Norcan shall in no event be responsible for damages for loss of profit and other punitive, exemplary, indirect, consequential or special losses or damages, whether in contract or in tort or otherwise, including, without limitation, any business or commercial losses.

To the extent that Norcan is liable for damages as a result of the performance of its work or the performance of the work by those for whom it is liable, such damages shall not exceed, in the aggregate, an amount equal to 10 percent (10%) of the total Contract price.

The above is understood and agreed to by the following:

Signed and sealed this _____ day of _____ 20____.

In the presence of:

(Seal) (Seal)

NORCAN Hydraulic Turbine Inc.

6.0 NORCAN HYDRUALIC TURBINE INC. DIEM RATES AND TERMS.

(for the period of January 01, 2015 to December 31, 2015)

Description	Regular Rate per hour	Overtime per hour	Double time per hour
Turbine Engineering Technician	**$95.00**	**$125.00**	**$155.00**
Supervisor	**$95.00**	**$125.00**	**$155.00**
Turbine mechanic millwright	**$80.00**	**$120.00**	**$140.00**
Engineer	**$160.00**	**$210.00**	**$260.00**
Travel rate	**$60.00**	**$75.00**	**$75.00**
Drafting & Project Management	**$80.00**	**$120.00**	**$140.00**
Shop Machining (CNC)	**$105.00**	**$140.00**	**$170.00**
Shop General Machining	**$75.00**	**$110.00**	**$130.00**
Welder	**$75.00**	**$110.00**	**$130.00**
General Labour	**$55.00**	**$72.00**	**$88.00**
Field Machining: Rates as per equipment requirements			

Note: The above rates are for normal 8 hour days, Monday to Friday (Normal working hours are between 7:00 am to 6:00 pm. A 15% premium will apply to hours outside the normal hours)

Saturday - overtime for first 8 hours - double time
Sunday - double time
Statutory holidays - 2.5 * regular rate

Parts and materials **at cost plus 15%**

Meals & Accommodation	**$180.00 per day**
Mileage	**85¢ per Km**

General Terms:

1. Daily rates apply from the time the Norcan personnel leave the Office/Shop until their return to the Office/Shop. Should the Norcan personnel start from, return to, or proceed to a point other
than the office/shop, charges for travel expenses and per diem rates shall not exceed charges that normally would have been incurred from or to the Office/Shop. Travel time will be charged at the specific base rates for up to a maximum of "8" hours per day for each day
of travel.

2. Standby time: The time during which Norcan personnel are available for work, but are unable to do so because of circumstances beyond Norcan's control shall be considered as standby time and billing will be made as follows:
- At full applicable charges plus expenses for any weekdays (whether at site or not) and for any weekend days or holidays when the Norcan personnel is kept on standby at the jobsite or put on call off-site.

3. Unless otherwise specified and negotiated during the contract, weekdays, weekend, and holidays are defined as follows:
- Weekdays: Monday through Friday, working days
- Weekends: Saturday through Sunday
- Holidays: All recognized days that are celebrated in Canada
- A Workday is classified as an 8 hour day

4. For out of country work, the weekdays, weekends and holidays must be specified and agreed to during contract negotiation.

5. No additional charges will be made for the use of expendable small tools and test equipment normally carried by Norcan personnel. However, when additional expendable tools or hardware must be purchased for a particular job, then the charge for such tools or hardware will be billed to the customer at cost plus a 15% processing fee.

6. When special equipment is required a rental fee will be charged depending on the type of equipment and the length of time required. The customer will be billed for all special transportation costs plus a 15% processing fee. The customer is responsible for the safe storage at site, the timely return, and overall condition and function of said special equipment.

7. Subcontractors: Labour and material supplied through Norcan will be billed at cost plus a 15% processing fee.

8. The customer shall provide Norcan personnel with free and unobstructed access to the jobsite.

9. The customer shall provide safe and proper working conditions in accordance with all federal, provincial and local laws, rules and regulations.

10. The customer shall provide suitable required power, washroom facilities, and safe storage space for Norcan's equipment.

11. All oil, grease, water, and normal operating items required for the operation of the equipment will be provided by the customer. Disposal of above components is the responsibility of the customer.

12. All required permits and monitoring equipment are the responsibility of the customer

13. Technical Advisory Services:
These terms and conditions shall apply to Norcan's Technical Advisory Services incidental to the installation, overhaul, inspection, repair, modification or conversion of equipment which is located at the customers and/or owners location. Norcan's Technical Advisory Services function exclusively in an advisory capacity. The equipment, machinery and property shall be at all times in complete care, custody and control of the customer and/or owner. The buyer and/or customer will furnish qualified labour and supervisory personal to perform the required work.

14. Force Majeure:
Any delay or failure in the performance by Norcan hereunder shall be excused and no liability whatsoever will rest with Norcan where such delay or failure is caused by Force Majeure. For the purposes of this Agreement, Force Majeure shall mean an event or cause beyond Norcan's control and shall include, but is not limited to, acts of God, riots, wars, insurrection, acts of public enemy, sabotage, terrorism, vandalism, embargo, national emergency, accident, restraint of government, governmental acts, fires, floods and other natural disasters, explosions, severe weather including hurricanes and storms, injunctions, labour strikes or inability to obtain required labour, materials or manufacturing facilities from normal sources, acts of a customer and/or owner, wrecks or delays in transportation.

15. Limitation of Liability:
The remedies of the customer set forth herein are exclusive. The total liability of Norcan with respect to all claims under said services and contract, whether based on the services, contract, indemnity, tort, strict liability, or otherwise shall not exceed the purchase price of the services upon which such liability is based. Norcan shall in no event be liable for any consequential, incidental, or indirect damages arising out of said services (and the performance thereof) or out of any breach thereof, whether or not such loss or damage is based on the services, contract, indemnity, tort, strict liability, or otherwise.

APPENDIX C

ENERGY BENEFIT ANALYSIS

KGS GROUP CONSULTING ENGINEERS

MEMORANDUM

TO: **Dave Brown, P. Eng.**
Joel Lambert, P. Eng.

FROM: **Junying Qu, Ph.D., P. Eng.**
David Hinton, P. Eng.

DATE: **September 10, 2015**

FILE NO: **14-1404-04**

RE: **Aishihik Turbines Uprate Study – Energy Benefits Analysis**

1.0 INTRODUCTION

KGS Group was retained by Yukon Energy Corporation (YEC) to conduct a study into the potential upgrade options of the turbine runners on AH1 and AH2 at the Aishihik Generating Station (AGS). Alstom Power and Norcan Hydraulic Turbine Inc. provided the information for new runners that could be used for the potential upgrades of AH1 and AH2. These vendors will be referred to as Alstom and Norcan hereafter.

To help assess the benefits for the potential upgrades of AH1 and/or AH2 and compare the Alstom and Norcan proposed configurations, a hydro energy benefits analysis was conducted for the following seven scenarios using the YECSIM model.

- Existing condition
- Potential upgrades of AH1 only using the runners provided by Alstom
- Potential upgrades of AH1 only using the runners provided by Norcan
- Potential upgrades of AH2 only using the runners provided by Alstom
- Potential upgrades of AH2 only using the runners provided by Norcan
- Potential upgrades of both AH1 and AH2 using the runners provided by Alstom
- Potential upgrades of both AH1 and AH2 using the runners provided by Norcan

The YECSIM software is a detailed integrated power/water flow model operating on a weekly time step developed by KGS Group for YEC. It can be used for analysis of the operation and future expansion of the YEC electrical generating system including WAF (Whitehorse-Aishihik-Faro) and MD (Mayo-Dawson) systems. This model includes all assumed loads and load profiles, operating characteristics of each system power facility (e.g., unit efficiencies), licensed parameters for each plant as approved or proposed, and desired operating parameters for the system (such as reducing line losses or voltage stability) as well as the hydrological conditions. More information about the model can be found in the YECSIM User's Manual (Ref. 1).

This memorandum documents the detailed of energy benefits analysis for the potential upgrades of AH1 and/or AH2 at AGS.

2.0 TURBINE EFFICIENCY CURVES

For the energy benefits analysis using YECSIM model, the first step is to develop a combined turbine and generator efficiency curve for the entire power plant including AH1, AH2 and AH3 at the AGS for each of those scenarios.

The AGS consists of 3 turbines, including two 15 MW vertical Francis turbines installed originally in 1972 (AH1 and AH2), and a third 7 MW horizontal Francis turbine installed in 2011 (AH3). The two units AH1 and AH2 are very similar mechanically, except AH2 has a greater electrical capacity due to a rewind of the generator in 2006 (Ref. 2). Table 1 shows the unit efficiencies, including both turbine and generator efficiencies for AH1 based on the tests carried out on AH1 by Hatch in 2009 (Ref. 2). The existing AH2 operates similarly to AH1, and is assumed to be equal for this study. Table 2 shows the unit efficiencies for AH3 provided by YEC.

TABLE 1
CALCULATED UNIT EFFICIENCIES FOR THE EXISTING AH1

Station Load (kW)	Station Flow (m^3/s)	Unit Efficiency	Station Load (kW)	Station Flow (m^3/s)	Unit Efficiency	Station Load (kW)	Station Flow (m^3/s)	Unit Efficiency
2000	1.99	54.62	6700	4.61	79.229	11400	7.19	86.85
2100	2.04	55.71	6800	4.66	79.491	11500	7.25	86.93
2200	2.10	56.75	6900	4.72	79.749	11600	7.31	87.01
2300	2.16	57.74	7000	4.77	80.001	11700	7.36	87.08

Notes: Unit efficiencies include both Turbine and Generator efficiencies.

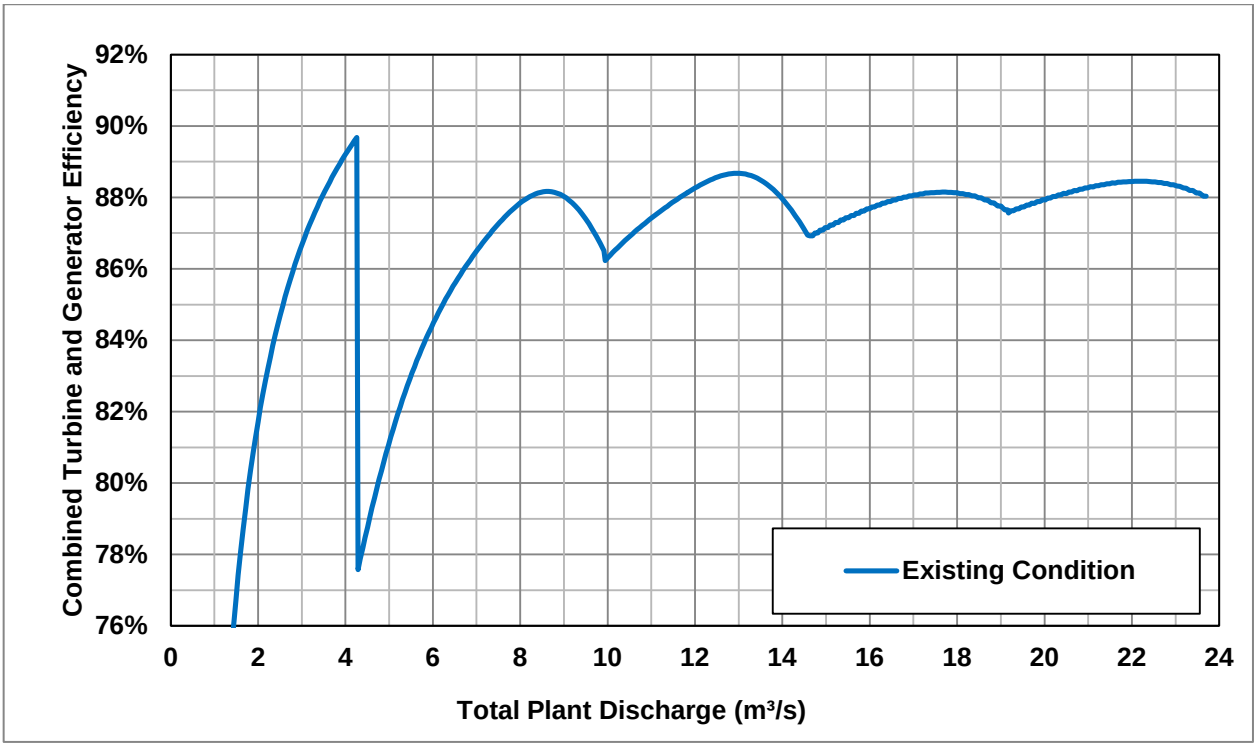
The best estimate optimized operation of AGS was determined based on the existing and proposed turbine characteristics provided by YEC. The plant was assumed to operate the most efficient combination of units for a given flow. To calculate plant output, typical net head was taken from Hatch's 2009 unit efficiency table according to Equation 1 (Ref. 3). This equation approximates net head as a function of plant output to account for increased tailwater level and headlosses with increased output.

$$Equation\ 1: \quad H_N = 187.91 - 0.12824P - 0.0012505P^2$$

Here H_N represents the net water head (m) and P represents the power output from the plant (W).

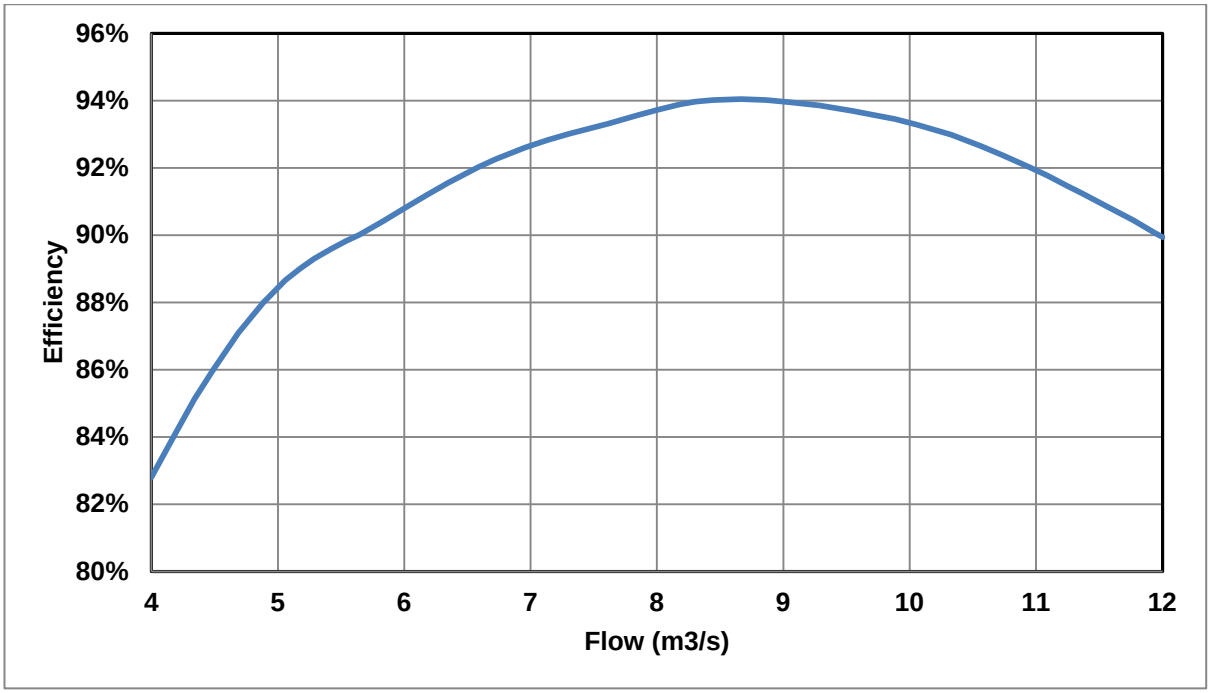
The combined turbine and generator efficiency curve for the entire existing 3 units at AGS were developed as shown in Figure 1.

FIGURE 1
COMBINED EFFICIENCY CURVE FOR EXISTING CONDITIONS



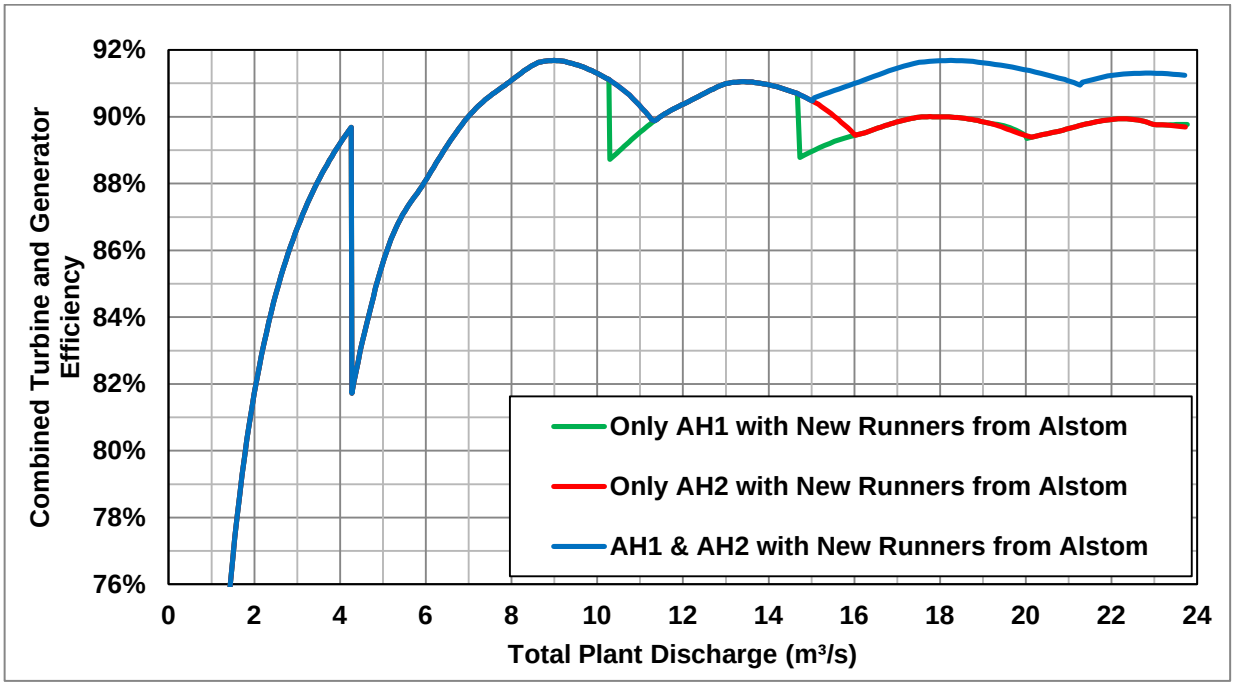
Alstom provided a preliminary performance curve for the proposed upgraded turbines as shown in Figure 2 (Ref. 3). The curve represents the best estimate efficiency at a constant head of 180.4 m but is subject to further study such as the analysis of the existing spiral casing, distributor and the draft tube. This efficiency curve was used in the model to calculate energy production using Equation 1 to approximate net head at given plant outputs.

FIGURE 2
ALSTOM EXPECTED PERFORMANCE FOR HNET = 180.4 M



A generator efficiency of 97.5% was assumed for AH1 and/or AH2 based on experience with similar generators. The AH2 generator is rated at 19,200 kVA and the AH1 generator is rated at 17,000 kVA. For the purpose of this study, a power factor of 1.0 was assumed to estimate plant operation. The developed efficiency curves for replacing AH1 and/or AH2 using Alstom runners are shown in Figure 3.

FIGURE 3
COMBINED EFFICIENCY CURVES FOR UPGRADES OF AH1 AND/OR AH2 USING ALSTOM RUNNERS



Similar to the development of efficiency curves for the upgrades using Alstom turbines, Norcan provided a preliminary performance curve for their proposed upgraded turbine as shown in Figure 4 (Ref. 4). The developed combined efficiency curves for replacing AH1 and/or AH2 using Norcan turbines are shown in Figure 5.

FIGURE 4
NORCAN PRELIMINARY PERFORMANCE FOR HNET = 180.4 M

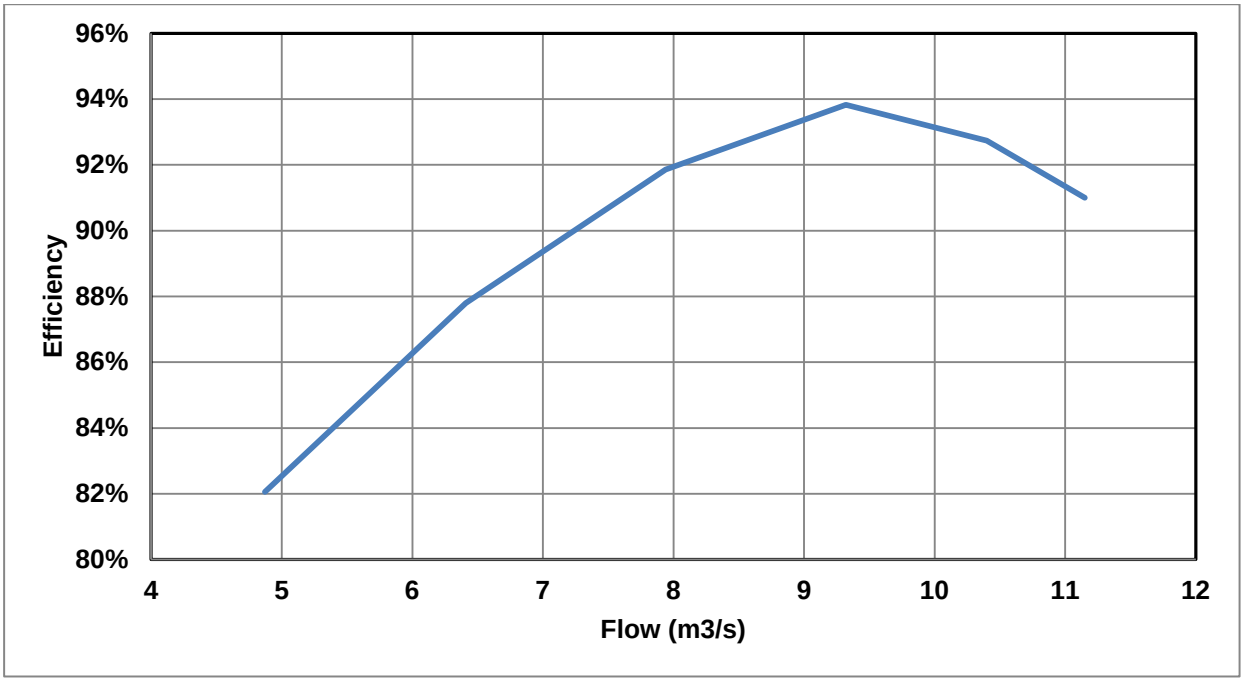


FIGURE 5
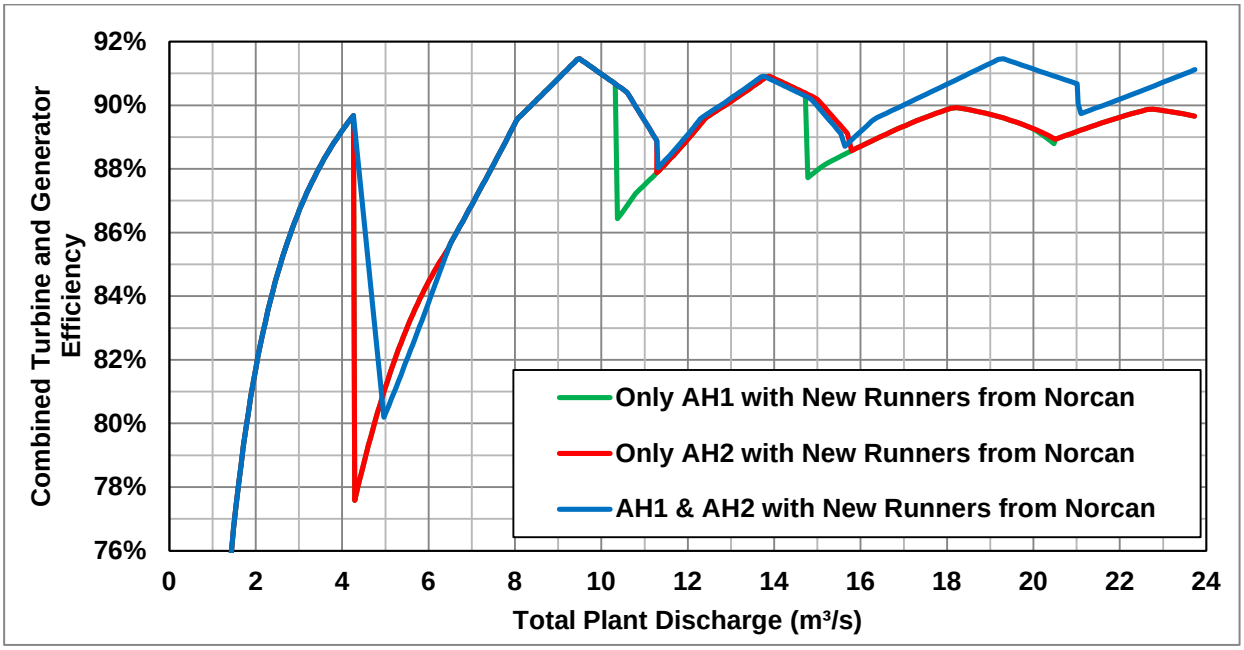
COMBINED EFFICIENCY CURVES FOR UPGRADES OF AH1 AND/OR AH2 USING NORCAN RUNNERS



For the purpose of this study, turbine efficiency curves for all three turbines were evaluated for the typical gross head and expected conveyance head losses. Plant operation was optimized for those seven scenarios based on the expected net head. Although the proposed replacement alternatives have higher flow capacity than the existing units, the total plant flow is still limited at the existing 23.7 m³/s, which is the summation of the original turbine capacity for AH1 and AH2 (19.46 m³/s in total) and the turbine capacity for AH3 (4.26 m³/s) based on the data provided by YEC. Without further study, it is not recommended to increase plant flow higher than the existing limit due to the possibility that emergency evacuation through the tailrace tunnel could be compromised, as described in KGS Group's Hydraulic Capacity Memo (Ref. 6).

3.0 THREE-TIER SYSTEM FOR SPECIFICATION OF EFFICIENCY

The 3-tier system for specification of efficiency is required in the YECSIM model to provide a reasonable representation of the range of efficiencies that may occur for the hydro energy generation from a powerhouse on weekly basis. The description of the 3 tiers can be found in the YECSIM User's Manual (Ref.1). The steps to calculate the 3 tiers for the AGS are described below:

- Estimation of the Minimum Flow through the AGS:

  The minimum flow through the powerhouse was estimated to be 2.8 m³/s at the AGS. According to the "Water Use License HY99-011, Correction to Clause 29" published by Yukon Territory Water Board in 2005, the minimum flow downstream of Canyon Pond is to be no less than 2.832 m³/s, including Giltana Creek flows (YECSIM User's Manual - Appendix E - Aishihik). The Water Use Licence HY99-011 - Clause 25 (2000) defines that the minimum flow over Otter Falls, which is located beside the AGS, is 0.142 m³/s from September 22 to April 30, 0.708 m³/s from May 19 to September 7, and 0.425 m³/s in the rest days. Usually the outflows from Aishihik Lake to Canyon Lake are greater than 2.832 m³/s in the spring and summer. Therefore, the flow through the powerhouse can be assumed no less than 2.8 m³/s.

- Calculation of the First Tier Efficiency:

  The first tier refers to a low range of total plant outflows. For the AGS, the low flow range was assumed from 2.8 m³/s to 4.26 m³/s with the operation Unit 3 only. The average energy efficiency of Unit 3 in this flow range is 0.880, which was assumed to be the first tier efficiency. The corresponding discharge for the first tier was defined as 3 m³/s in order to keep consistent with the flow used originally for the first tier in the YECSIM model.

- Calculation of the Second Tier Efficiency:

  The second tier efficiency, which represents the majority of operation wherein the plant outflow is less than the maximum, was estimated to be the average energy efficiency in the flow range from 3 m³/s to the maximum plant flow. The corresponding discharge for the second tier was defined as 6 m³/s in order to keep consistent with the flow used originally for the second tier in the YECSIM model.

- Calculation of the Third Tier Efficiency:

  The third tier efficiency, which represents the operation wherein the plant outflow is at the maximum, was estimated to be the average energy efficiency for the maximum flow and the second maximum flow with all units in operation. The corresponding discharge for the third tier was defined as the maximum allowable turbine flow with all units in operation. As mentioned in the previous section, the maximum plant discharge is limited to 23.7 m³/s.

Table 3 shows the estimated 3-tier systems for specification of efficiency for those seven scenarios including the existing condition and the proposed upgrade options. The coefficients for the first tier are the same for all of the scenarios since only AH3 at Aishihik GS was assumed to be running at the low flow range. For the second tier, the upgrades of both AH1 and AH2 using Alstom turbines provide the highest efficiency value. For the third tier, the upgrades of both AH1 and AH2 using Alstom turbines still provide the highest efficiency value. The efficiencies for all of the upgrade options are higher than the existing condition.

TABLE 3
THREE-TIER SYSTEMS FOR SPECIFICATION OF EFFICIENCY FOR AGS

3-Tier System	Station Flow (m³/s)	3-Tier System for Specification of Efficiency						
		Existing Condition	Turbine Upgrades (Alstom)			Turbine Upgrades (Norcan)		
			AH1 Only	AH2 Only	AH1 and AH2	AH1 Only	AH2 Only	AH1 and AH2
Tier 1	3	0.880	0.880	0.880	0.880	0.880	0.880	0.880
Tier 2	6	0.872	0.896	0.897	0.901	0.882	0.884	0.891
Tier 3	23.7	0.880	0.896	0.897	0.913	0.897	0.897	0.911

4.0 YECSIM MODEL

For the AGS, the new 3-tier system for specification of efficiency for each scenario and the maximum plant discharge (23.7 m³/s) were used in the YECSIM model. Since the maximum plant discharge is less than the plant capacity (approximate 25.5 m³/s for the existing units, 27.8 m³/s with the upgrade of Unit 2 using the Alstom turbine and 26.6 m³/s with the upgrade of Unit 2 using the Norcan turbine), the energy loss coefficient due to force outage at the AGS was assumed to be zero in the YECSIM model. Here the forced outages refer to the outages that occur unpredictably, or result from maintenance activities that exceed the length of time available in low-load periods (Ref.1).

For the input parameters for the other generating stations including Whitehorse GS, Mayo A and Mayo B GSs and the related lakes, the default values provided in the YECSIM model as listed in Appendix D of the YECSIM User's Manual (Ref.1) were used.

Two energy loads (468.1 GWh/year and 575.1 GWh/year) were used, which could reasonably be expected to occur or be surpassed within the future 20 to 30 years starting from 2009 as described in the report for the proposed Mayo Hydro Enhancement Project prepared by YEC (Ref. 2).

The simulation conditions that were used in the YECSIM model for those seven scenarios are summarized below:

- Simulation Period (or Energy Planning Period): 20 years
- Energy Systems: WAF/MD (including Mayo B GS)
- Energy load levels
  - Low Energy Demand: 468.1 GWh/year
  - High Energy Demand: 575.1 GWh/year
- Hydrologic water years from 1987 to 2007
- Water License Limits for Aishihik Lake
  - The minimum water level in a year is no lower than 913 m more than 2 in 5 years
  - The 10-year rolling average minimum water level is no lower than 913.3 m
  - The winter drawdown limit is 1.2 m
- Water License Limits for Mayo Lake
  - The water level difference between the beginning of the winter (Week 39) and the spring next year cannot be more than 2.5 m for 3 years in a row
- Marsh Lake Operation Policy
  - The change in flow from Marsh Lake is limited to +/- 20 m^3/s in the spring
- Operation Policy of Mayo A GS
  - The special turbine efficiencies were applied in the winter
  - The turbine capacity is increased up to 15 m^3/s when spilling water

5.0 PLANT CAPACITY

Incremental capacity represents an important benefit to the proposed turbine upgrade project. Although the proposed turbine capacity may exceed the existing turbine capacity, hydraulic conditions limit the effectiveness of this additional capacity. According to YEC, Aishihik GS is typically run at around 80% plant flow, so any excess turbine capacity requiring additional plant flow may not be realized. Therefore, the evaluation was based on plant capacity at 80% plant flow instead of the individual turbine capacity.

Plant capacity was estimated for each configuration based on the typical plant flow of 19 m^3/s. Net head at plant capacity was calculated using Equation 1. The estimated plant capacities for each proposed plant configuration are shown in Table 4.

TABLE 4
PLANT CAPACITY

Simulation Scenario	Plant Efficiency	Plant Capacity	Incremental Plant Capacity
	(%)	(MW)	(MW)
Existing Condition	87.8	29.8	-
New AH1 - Alstom	89.9	30.5	0.7
New AH1- Norcan	89.7	30.5	0.6
New AH2 - Alstom	89.9	30.5	0.7
New AH2 - Norcan	89.7	30.5	0.6
New AH1 and AH2 - Alstom	91.6	31.1	1.3
New AH1 and AH2 - Norcan	91.3	31.0	1.2

Incremental plant capacity varies depending how many units are upgraded. The selection of a turbine manufacturer is not a significant factor when comparing total plant capacity. Alstom units provide a marginal capacity benefit relative to Norcan units. Upgrading both AH1 and AH2 provides close to double the incremental capacity of upgrading only one unit.

For the purpose of designing electrical components, the plant capacity was evaluated at maximum flow and maximum expected net head using an optimistic estimate of conveyance system losses. For a plant flow of 23.7 m^3/s and net head of 182.2 m, the existing plant capacity is 37.2 MW. Proposed configurations range in capacity from 37.9 MW for the Norcan AH1 replacement to 38.6 MW for the Alstom 2 unit replacement.

6.0 YECSIM MODEL RESULTS

For each run, the results for the first 5 energy load years were abandoned to avoid the effects of the initial lake levels given at the start of the simulation as described in Section 6.1.4 in the YECSIM User's Manual (Ref.1). The last load year was also abandoned to avoid the effects of backwards calculation of lake operation rule curves during the YECSIM model simulation. Therefore the weekly average hydro energy generated from the AGS and the WAF + MD system was calculated for the remaining 14 energy load years. Then the annual hydro energy generated from the AGS or the WAF + MD system is the sum of the energy generated in 52 weeks of a year. Table 5 shows the model results at the low energy load level of 468.1 GWh/year and Table 6 shows the model results at the high energy load level of 575.1 GWh/year. Usually, the energy benefits to the WAF/MD system are of more interest than the energy benefits to the AGS itself. Here only the energy benefits to the system are discussed.

TABLE 5
ENERGY BENEFITS FOR AGS UPGRADES AT LOW ENERGY DEMAND

Simulation Scenario	Energy Generated at AGS	Total Hydro Energy Generated in the WAF/MD System	Net Energy Benefit to AGS	Net Energy Benefit to the WAF/MD System
	(GWh/Year)	(GWh/Year)	(GWh/Year)	(GWh/Year)
Existing Condition	114.30	429.05	-	-
New AH1 - Alstom	116.75	431.31	2.45	2.26
New AH1 - Norcan	115.34	430.01	1.05	0.96
New AH2 - Alstom	116.85	431.40	2.55	2.35
New AH2- Norcan	115.55	430.20	1.25	1.14
New AH1 and AH2 - Alstom	117.28	431.79	2.98	2.74
New AH1 and AH2 - Norcan	116.29	430.86	1.99	1.81

TABLE 6
ENERGY BENEFITS FOR AISHIHIK GS UPGRADES AT HIGH ENERGY DEMAND

Simulation Scenario	Energy Generated at AGS	Total Hydro Energy Generated in the WAF+MD System	Net Energy Benefit to AGS	Net Energy Benefit to the WAF+MD System
	(GWh/Year)	(GWh/Year)	(GWh/Year)	(GWh/Year)
Existing Condition	118.86	451.01	-	-
New AH1 - Alstom	121.27	453.20	2.41	2.19
New AH1 - Norcan	120.27	452.28	1.41	1.27
New AH2 - Alstom	121.34	453.26	2.47	2.25
New AH2- Norcan	120.41	452.41	1.55	1.40
New AH1 and AH2 - Alstom	122.17	454.05	3.31	3.04
New AH1 and AH2 - Norcan	121.45	453.38	2.58	2.37

As shown in Tables 5 and 6, the net energy contributions to the system with the upgrades using Alstom runners are always higher than the ones with the upgrades using Norcan runners at both the low energy demand and the high energy demand for the upgrades of AH1 and/or AH2 at AGS. The net energy benefits for the upgrades of AH2 are slightly higher than the benefits for the upgrades of AH1 because AH2 has a greater electrical capacity due to a rewind of the

generator in 2006. The net energy benefits for the upgrades of both AH1 and AH2 are higher than those for the upgrades of either AH1 or AH2 only.

Based on the net energy contributions provided in Tables 5 and 6, economic analysis related to the monetary values of energy benefits, capital costs and payback calculations becomes possible to assess the benefit values for the potential upgrades of AH1 and/or AH2 and choose a preferred turbine runner between Alstom and Norcan.

7.0 DISCUSSIONS AND CONCLUSIONS

Based on the energy benefits analysis, the following conclusions are made,

- For the upgrades of AH1 only, using Alstom runners would generate energy benefit from 2.19 GWh/year to 2.26 GWh/year to the system, while using Norcan runners would generate energy benefit from 0.96 GWh/year to 1.27 GWh/year to the system.
- For the upgrades of AH2 only, using Alstom runners would generate energy benefit from 2.25 GWh/year to 2.35 GWh/year to the system, while using Norcan runners would generate energy benefit from 1.14 GWh/year to 1.40 GWh/year to the system. The energy benefit for the upgrades of AH2 only is slightly higher than the one for the upgrade of AH1 only.
- For the upgrades of both AH1 and AH2, using Alstom runners would generate energy benefit from 2.74 GWh/year to 3.04 GWh/year to the system, while using Norcan runners would generate energy benefit from 1.81 GWh/year to 2.37 GWh/year to the system. The energy benefit for the upgrades of both AH1 and AH2 are higher than the one for the upgrades of either AH1 or AH2.

MEMORANDUM

TO: **JOEL LAMBERT**

CC:

FROM: **MONISH BHOWMIK**

DATED: **SEPTEMBER 18, 2015**

PROJECT NO: **14-1404-004**

RE: **AISHIHIK TURBINE UPGRADE - EXISTING EXCITATION CAPABILITIES**

1.0 BACKGROUND

Yukon Energy Corp. is currently considering a project to upgrade the turbine runner capacity to obtain uprated power from the existing Aishihik Unit 2. The Aishihik Unit 2 generator is equipped with a DC exciter and controlled by SR125E Basler AVR. Through a rewind project which was undertaken in 2006 the electrical capability of the generator was upgraded from 15.6 MVA to 19.2 MVA at 0.9 power factor. During the rewind project the unit was tested up to 16.5 MW as the available maximum mechanical power of the turbine is limited to 16.5 MW. As a part of the rewind project the generator rotor field poles were reinsulated, however, the DC exciter was not upgraded.

This memorandum is prepared to verify the capability of the existing exciter of the AH2 unit to produce 19.2 MVA at 0.9 p.f.

2.0 DOCUMENTS REVIEWED

The following documents were obtained from Yukon Energy Corp. and are used to estimate the exciter requirement for enhanced power:

1. Testing of Synchronous Unit Reactive Limits and Dynamic Testing/Model Validation for Yukon Energy Corporation, Aishihik Generating Station, prepared by Chaos electric Inc.
2. Aishihik Unit 2 Rewind & Protection Upgrade – 2006, Commissioning Report, Prepared by Ravindra P. Mutukutti, P.Eng.

3.0 FINDINGS

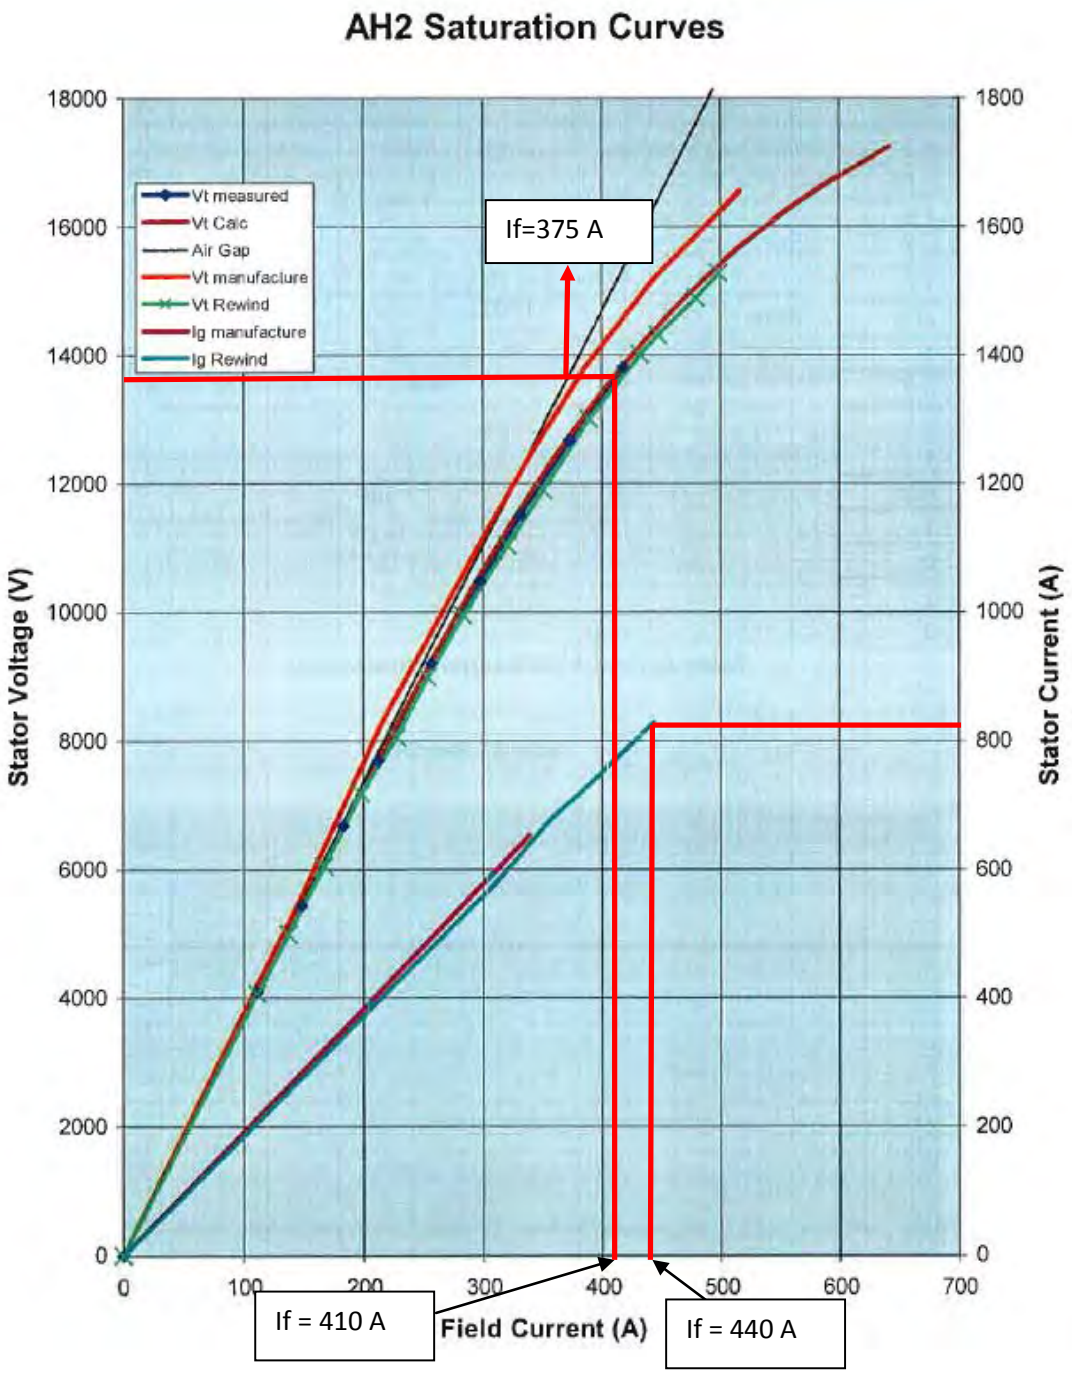
3.1 NAMEPLATE INFORMATION

The table below shows the comparison of the upgraded generator capacity and the DC exciter capacity:

Generator			
Items	**Before Upgrade**	**After Upgrade**	**Remark**
Field Voltage	75 V	75V	Stator rewind &
Field Current	630 A	720A	Rotor pole
Generator MVA	15.6 MVA	19.2 MVA	Re-insulation
Generator output current at rated condition	653 A	803 A	
Generator DC Exciter			
Volts at Full load	35 V	35 V	The DC exciter
Amps at Full Load	670 A	670 A	Was not upraded
KW	57 kW	57 kW	

3.2 OPEN CIRCUIT AND SHORT CIRCUIT SATURATION CURVE

From the review of the open circuit and short circuit saturation curve (Reference 1, Section 4.0) it was found that the field current required to produce the rated air gap line voltage (1 pu), rated open circuit terminal voltage (13.8 kV) and rated short circuit current (SCC test) is respectively 375A, 410A & 442A.

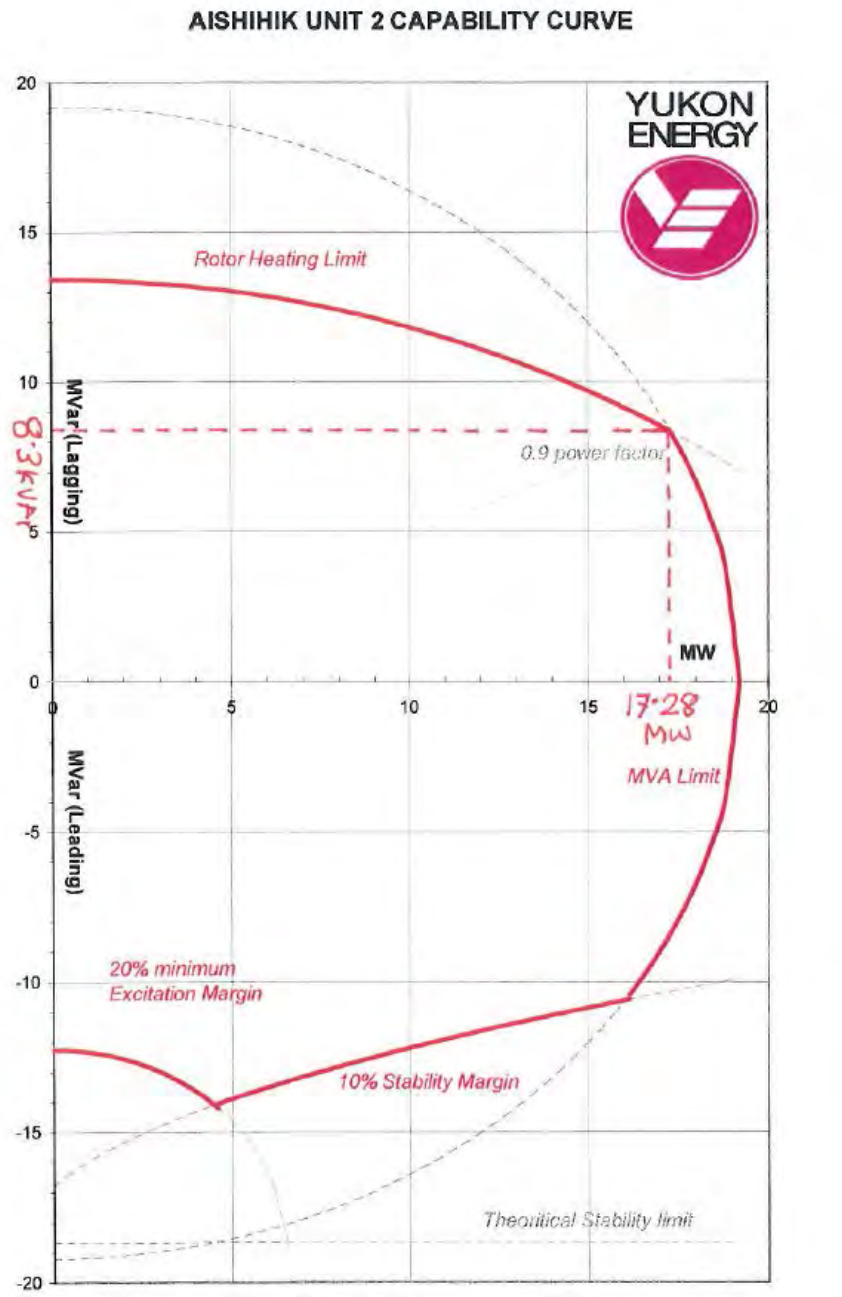


The above mentioned values were validated from the rewind commissioning report, which are provided in the following table:

Generator Short Circuit Condition			Generator Open Circuit Condition		
Field Voltage	**Field Current**	**Stator Current**	**Field Voltage**	**Field Current**	**Stator Voltage**
42 V	442 A	825 A	38 V	410 A	13.8 kV

3.3 GENERATOR CAPABILITY CURVE

The upgraded generator capability curve was reviewed, as provided in the generator rewind commissioning report (Reference 2, Section 2.0). According to the generator capability curve of the rewound, the generator will be able to produce 19.2 MVA at 0.9 power factor at the field voltage of 75 V and 720 A (Reference 1, section 3.2.2).



4.0 CONCLUSION

From the above information the following conclusions can be made:

- According to the rewind machine data provided by Voith-Siemens, to produce the rated power the generator rotor field voltage and field current requirement is 75 V and 720A respectively, while the DC exciter is rated at 670 A.
- The DC exciter will operate beyond its design limit to produce the rated voltage at 19.2 MVA, 0.9 power factor. This will cause rapid aging of the existing DC exciter.
- If Yukon Energy Corp. decides to operate the generator at 19.2 MVA at 0.9 power factor, a discussion with the OEM is requested to validate the impact on the DC exciter due to operation beyond its design ratings.
- If the existing exciter is operated at its maximum rating which is at 670 A, Voith-Siemens should be approached to obtained a new capability curve for the field limit of 670 A.

5.0 RECOMMENDATION

The following two alternatives are recommended related to the Aishihik Unit 2 exciter to accommodate enhanced power:

- **Alternative 1(Preferred):** The existing exciter is replaced with a static exciter to match the generator field requirement. The generator field leads and associated slip rings should be checked so that these are properly rated for enhanced power operation.
- **Alternative 2:** The rotating DC exciter is upgraded to meet the rewounded generator field requirement and the associated AVR should be replaced to meet the requirement of the upgraded exciter. The generator field leads and associated slip rings should be checked so that these are properly rated for enhanced power operation.

Notes: 1. Discount Rate to be used is the Blended Cost of Capital Rate for Yukon Energy

2. The simple payback period in years is the first year the the cumulative cash flow is positive in Column E

3. The discounted cash flow payback period is the first year that the Cumulative discounted cash flow (DCF) is positive in Column H

4. As the capital cost is a negative cash flow it should entered as a negative number

5. For paybacks exceeding 5 years the discounted payback should be used as the time value of money becomes more significant

Appendix E - 5.0

EXECUTIVE SUMMARY

This concept design report assesses four options for the future of the Mayo Hydro (MH0) facility. It presents a conceptual design, cost estimates and an economic assessment of each option. The four options considered are:

1. Option #1 – Replace the Mayo Hydro station.
2. Option #2 – Refurbish the Mayo Hydro station.
3. Option #3 – Remove the facility and return the site to a near greenfield condition.
4. Option #4 – Make safe and abandon in situ.

It is expected that, given appropriate maintenance and overhauls, Options 1 and 2 would provide 65 years or move of plant life.

The total present value was compared for all four options and found that Option 2 was the most economical with a total present value of $10,000,000 and a levelized cost of energy of $0.15/kWhr. Option 1 had the next highest total present value of $6,600,000 and a levelized cost of energy of $0.17/kWhr. These were followed by Option 4 and then Option 3 which had net present values of $2,950,000 and $1,250,000, respectively.

A 7.6 m/s design capacity for Option 1 and Option 2 was selected based on a combination of the minimum flow requirements of the Mayo Hydro tailrace (as per the water license), and maximum flows allowed while both Mayo B Hydro units are operating. Design capacities using higher flows were not financially attractive because they would result in very little additional energy and the additional capacity would only be usable when at least one of the Mayo B units is forced off-line, which occurs for a limited number of hours throughout a typical year.

Option 1 entails the replacement of the hydro facility, retaining the foundations and select embedded parts. It would provide one new turbine and generator unit, powerhouse, balance of plant systems, support systems, control room, powerhouse crane and surge tank. This option would include geotechnical work to stabilize slopes, and make repairs to the access road and tailrace.

Option 2 involves the refurbishment of the existing facility, retaining the foundations, embedded parts, powerhouse superstructure and the embedded spiral case, stay ring and discharge cone of the Unit 2 turbine. It would provide one new generator, new turbine components, other than those mentioned above, a new turbine inlet valve (TIV), balance of plant systems, support systems, control room and surge tank. Repairs/upgrades to the existing powerhouse superstructure and modernization of the crane were included. This option would include geotechnical work to stabilize slopes, and repair the roads and the tailrace.

Option 3 entails the complete demolition of the powerhouse (excluding the foundation) and the surge tank. It includes permanently plugging the tunnel upstream of the surge tank take-off and backfilling the powerhouse foundation and tailrace to return the site to a near greenfield condition.

Option 4 will abandon the powerhouse in place. The facility would be made safe for abandonment, the tunnel would be permanently plugged upstream of the surge tank, and the tailrace would be backfilled.

Complete cost estimates were prepared for each option and included all costs and a 30% contingency to account for unknowns given the level of design. An economic assessment was performed using a 65 year facility life span, 5.45% (nominal) weighted average cost of capital and 2% inflation for computing present value. Assumptions were made for the operating and maintenance cost, the capital expenditures cost, benefit of an increase in capacity and the benefit of an increase in annual energy production. Option 3 and 4 were assumed to be operational for an additional 10 years prior to removing the facility from service.

1.0 INTRODUCTION

Yukon Energy Corporation (YEC), established in 1987, is a publicly owned electrical utility which provides reliable electricity to almost 15,000 consumers. The hydro facilities at Whitehorse, Mayo, and Aishihik Lake provide 92 megawatts of power to the surrounding communities. With 31 megawatts produced by diesel generators (primarily used for back up), 8.8 megawatts by liquefied natural gas (used for back up), and .65 megawatts by a small wind turbine on Haeckel Hill near Whitehorse, Yukon Energy has the capacity to generate close to 132 megawatts.

The Mayo Hydro and Mayo B Hydro stations are located approximately 400 kilometers north of Whitehorse. Mayo Hydro started to produce power in 1952 and Mayo B Hydro in 2012. Mayo Hydro and Mayo B Hydro are fed from Wareham Lake and operate with a maximum total combined flow of 25 cubic meters per second (m^3/s) (19 m^3/s through Mayo B Hydro and 6 m^3/s through Mayo Hydro). Mayo Hydro has the capacity to pass up to 17 m^3/s; however, the design of the intake and penstocks restrict the combined flow to 25 m^3/s.

As per the water license for the Mayo River and Mayo Lake, in the channels downstream of the Mayo Hydro Powerhouse, a minimum instantaneous flow of 6 m^3/s is required from May 1 to September 30, and a minimum flow of 5 m^3/s is required for the remainder of the year. If Mayo Hydro is not operating, this minimum flow and potential energy must be passed through the spillway. Due to the higher water head available at Mayo B Hydro, the preference is to operate both Mayo B units and to operate Mayo Hydro at the minimum required flow.

The Yukon Energy Corporation is considering 4 options for the future of the Mayo Hydro facility.

- Option #1 – Replace the Mayo Hydro station.
- Option #2 – Refurbish the Mayo Hydro station.
- Option #3 – Remove the Mayo Hydro facility and return the site to a near greenfield condition.
- Option #4 – Make the facility safe and abandon in situ.

KGS Group was retained to assess each option at a conceptual level and recommend the most economical choice. The design life of Option 1 and Option 2 will be 65 years.

This Conceptual Design Report covers the economic assessment and cost estimates for the future options. The following sections summarize and explain the results of the analysis and a final recommendation is provided.

A condition assessment of the Mayo Hydro powerhouse was done in 2013/2014. This assessment and the associated report were updated by KGS Group in 2016. The study assesses the current condition of the facility and its components, prioritizes the required upgrades and presents costs estimates for the work required. It found that many of the systems have reached the end of their useful life and that extensive repairs/upgrades are required to maintain the facility in operation. The age and condition of the facility and the need for significant repairs or upgrades provide context for, and support, the recommendations of this report. Refer to the “Mayo Hydro (MH0) Asset Assessment Update” report for a detailed review of the facility’s condition.

2.0 THE FACILITY

Mayo Hydro is a two vertical Francis unit hydroelectric generating station located just north and outside of the town of Mayo, in the Yukon Territory. It has a maximum continuous rating of 5.1 MW. The facility was placed into service in 1952 with the commissioning of Unit MH1. Unit MH2 was placed into service in 1957.

The Mayo Hydro facility includes the following structures:

- One powerhouse building.
- One switchgear building (blue building).
- One surge tank.
- One tunnel.
- One substation/transformer yard.
- One intake structure.
- One spillway control structure.

The substation/transformer yard, intake structure and spillway control structure are not included in the scope of work for this project because these components are shared with Mayo B Hydro and will be required regardless of which option is chosen for the future of the Mayo Hydro facility. The switchgear building is not included in the scope of work because it will be relocated to the Mayo S249 substation as part of a separate project, regardless of which option is chosen.

3.0 OPTION 1 – REPLACE THE FACILITY

In accordance with the terms of reference, Option 1 entails replacement of the hydro facility, retaining only the foundations and other embedded parts. As discussed in Section 3.3, the surge tank will also be replaced. The hydro facility replacement will include a new powerhouse building, balance of plant systems and one new turbine/generator unit and its supporting equipment, complete with a new control room and powerhouse crane. Given appropriate maintenance and overhauls, it is expected that the life of the plant, post-replacement, would be 65 years or more.

3.1 PLANT CAPACITY

Prior to construction of Mayo B, Mayo Hydro had a plant design flow of 17 m^3/s. As detailed in the "Mayo A and Mayo B Generating Stations Optimizing Plant Operations Testing Results, May 2013" KGS Group (Appendix A), for most Wareham Lake levels, Mayo Hydro is restricted to operate at 6 m^3/s while two Mayo B units are running.

In order to determine a design capacity of a new turbine/generator unit for this study, Yukon Energy Corporation provided historical flow data for the Mayo Hydro plant. Flow data for the period of February 8, 2013 to February 18, 2016 was used, refer to Figure 1.

Because of the operational constraints of the Mayo Hydro/Mayo B Hydro complex (i.e. flow limitations at Mayo Hydro) and supported by the flow data in Figure 1, possible plant flows in the range of 6 m^3/s to 10 m^3/s were investigated. The four options that were considered are:

- Case 1: 1 unit sized for 9.7 m^3/s.
- Case 2: 2 units sized for 5 m^3/s each.
- Case 3: 1 unit sized for 6 m^3/s.
- Case 4: 1 unit sized so winter flow results in approximately 90% turbine efficiency.

To review the four cases, Andritz's Francis turbine efficiency curve data from the Mayo B bid was used. To estimate efficiencies using this efficiency curve, the axis with absolute flow values was converted to a percentage of rated flow and the efficiency for a given percentage of rated

flow was assumed to be the same, regardless of the rated flow. For example, the efficiency for a unit operating at 75% rated flow was the same regardless of the unit size.

The efficiency curve data is proprietary information that is closely guarded by the turbine suppliers. As such, the source curve has not been included in this report. However, Yukon Energy Corporation is in possession of this information from the Mayo B Hydro project.

Case 1: Single unit sized to maximize MH0 capacity (peak flow of 9.7 m^3/s).

This case coincides with the maximum possible flow that can be passed simultaneously through Mayo B Hydro and Mayo Hydro. This corresponds to 19 m^3/s through Mayo B and 9.7 m^3/s through Mayo Hydro. Note that this case is only reasonable if Wareham Lake is operated at or near the maximum license level of 574.5 masl.

In the winter, the single unit would run at 5 m^3/s (51.5% of rated flow). This results in a relatively low turbine efficiency (generator and transformer efficiency not considered here) of 82.5%. In the summer, the single unit would run at 6 m^3/s (61.8% of rated flow, with a turbine efficiency of approximately 89%). When needed, and the Wareham Lake levels and Mayo B operation allow, the flow could be ramped up to 9.7 m^3/s.

The current MH0 units are rated for 8.5 m^3/s each. Given newer technology, it is likely that the 9.7 m^3/s can be passed safely through the existing, or similar, water passage dimensions. This is an increase of 15% in the flow. Recent turbine upgrades have shown that flow increases on the order of 20% are usually possible without risking excessive cavitation, etc. The new manufacturing techniques in use today allow for more precise manufacturing and the increased flows.

Case 2: Two units sized for 5 m^3/s each.

- In winter, run one unit at rated flow for an approximate turbine efficiency of 94%.
- In summer, run two units at 60% flow with an approximate turbine efficiency of 88%.
- When conditions at Wareham Lake and Mayo B allow, run both units up to 97% flow.

This case is similar to Case 1, as it provides the installed capacity to fully utilize the capacity at the site, except that two units are provided instead of one. This would allow for the plant to produce electricity with a higher efficiency. Again, this capacity is only available when Wareham Lake is operated at the maximum license limit or when at least one Mayo B unit is off line.

A disadvantage of this option is that both units would be required to pass the minimum riparian flows in the summer.

Case 3: One unit rated for 6 m^3/s.

- In winter, run one unit at 83.3% of rated flow for an approximate turbine efficiency of 93%.
- In summer, run the unit at 100% of rated flow with an approximate turbine efficiency of 94%.
- With this case, the unit would always operate at very high efficiency. It would essentially be base loaded. It would contribute only limited spinning reserve in the winter and none in the summer.

Case 4: One unit sized so winter flow results in 90% turbine efficiency.

On the representative turbine efficiency curve used, 90% efficiency occurs at approximately 66% of rated flow, resulting in a unit sized for a maximum flow of 7.6 m^3/s.

- In winter, run the unit at 66% of rated flow for an approximate turbine efficiency of 90%.
- In summer, run the unit at 80% of rated flow with an approximate turbine efficiency of 92%.
- With this case, the unit would always operate at relatively high efficiency. It would essentially be base loaded. It would contribute limited spinning reserve in both winter and summer.

3.2 SELECTION OF CAPACITY

After reviewing the options, Case 4 was selected. That is, one unit rated for a maximum flow of 7.6 m^3/s.

Cases 1 and 2 were discounted because with these options, the plant would seldom run at rated load because of the flow limitations of the combined Mayo Complex. The full capacity can only be used when at least one Mayo B unit is off-line or when Wareham Lake is operated at or very near its maximum licence level. Wareham Lake is not usually operated at or very near the maximum license limit level because doing so causes some flooding upstream, reduces the time available for staff to react in the event of a load rejection (need to operate the spillway faster) and there is limited freeboard at the spillway gates which prevents raising the lake level too much. Also, Mayo B units are offline for a limited number of hours throughout the year.

Although a two unit arrangement (Case 2) provides redundancy and some increased capacity that could be used when Mayo B Hydro is shut down or running with a single unit, it significantly increases cost and given the very limited operating time a second unit would run, it is not financially justifiable. To illustrate this, a rough costing exercise was undertaken and it was determined that providing two units instead of one would increase the total project cost by approximately $9,000,000 to $14,800,000, depending on size of the units and if they are new or refurbished. Since the total annual production for Mayo Hydro will remain nearly the same, due to the 6 m^3/s flow limitation most of the time, a second unit will account for an approximate increase of $0.044/kW.h to $0.073/kW.h in the levelized cost of energy. Furthermore, since Mayo B Hydro operates at much higher head (approx. 60 m net head versus 34.6 m for Mayo Hydro), more energy is produced by a given amount of water at Mayo B.
Case 4 was chosen over Case 3 because it provides minimal additional capacity and spinning reserve and it more closely matches the recent historical plant flows shown in Figure 1.

Andritz Hydro, a turbine and generator supplier provided a preliminary unit selection (Appendix B). Selection was limited to vertical units that could re-use the existing foundation and water passages. The setting elevation of the turbine runner was considered given the constraints of the existing foundation.

The following sections detail the concept design to replace the Mayo Hydro facility.

3.3 DEMOLITION

The demolition will include the removal of:

- The existing powerhouse superstructure.
- Turbine/generators, TIVs and their related components.
- There are no electrical systems with sufficient value to justify retaining for reuse. To be re-used, a component would have to be carefully removed, packaged, stored and re-installed in a new installation. It is expected that the added complexity in design, construction and commissioning would negate any cost savings associated with the reuse of the components. Therefore, all electrical systems (generator, balance of plant, building systems) should be demolished and replaced with new.
- Asbestos abatement (generators, roof panels).
- Disposal of any PCBs, lead, oil, and potentially small amounts of mercury.
- Spiral cases and both TIV pedestals.
- The powerhouse mechanical systems, including: domestic, sanitary, compressed air, fire protection, HVAC systems.
- Surge tank superstructure.
- Surge tank mechanical and electrical.

The existing septic field will be abandoned in place.

The existing draft tube sectional gates and guides will be re-used for Unit 1.

The replacement of the surge tank is included in this study as its interior condition is unknown. If inspections during later phases of the project show that the surge tank is in good condition, it may be reused to reduce costs.

3.4 MECHANICAL AND ELECTRICAL

3.4.1 Turbine and Generator

The new turbine/generator will be placed in Unit 1's current location since this allows for a larger service bay on the access road side of the powerhouse (Figure 2 and Figure 3). A service bay

incorporating the space formerly occupied by Unit 2 will allow trucks to back directly into the powerhouse to unload/load. The penstock feeding the unused turbine pit will be permanently plugged and its TIV pit modified to suit the needs of the new facility. The new unit will be:

- Vertical Francis turbine.
- 7.6 m^3/s at 34.6 m of net head.
- 2300 kW, 6.9 kV synchronous generator with static excitation, 600 rpm.
- 986 mm runner diameter.

The turbine and generator will be supplied with a new electronic governor system.

At this concept stage, the design details of the equipment were not specified, but it is assumed that the new turbine and generator equipment would consist of:

- Generator:
    a. Standard catalogued air-cooled generator. That is, the generator would not be a custom design.
    b. Global VPI type insulation with resins that do not support combustion when energy sources are removed.
    c. Inertia would consist of the natural inertia of the unit only.
    d. Capable of withstanding runaway speeds for extended periods.
- Turbine:
    a. Stainless steel runner and wicket gates.
    b. Greaseless bushings throughout.
- Turbine Inlet Valve (TIV):
    a. New butterfly valve, complete with new hydraulic actuator and counterweight closure capability, rated for single point of isolation.
- Governor:
    a. Digital PLC-based governor.
    b. High pressure HPU with a backup pump and motor.
    c. Nitrogen charged bladder-type accumulators sized to provide stored energy for two close strokes and one open stroke of the wicket gates and one open stroke of the TIV.
- Excitation:

a. No redundant bridge.
b. Ceiling voltage capability: 2 pu.

- The unit will be provided with vibration monitoring equipment.
- Unit control and monitoring systems and SCADA systems.
- Neutral grounding resistor cubicle and a new phase (power lead connection) cubicle, complete with surge arrestors and capacitors.
- A cooling water filtering skid will be provided to filter cooling and shaft seal water.

The above parameters have been assumed at this time. The detailed design phase should include appropriate grid and hydraulic transient studies to determine generator and excitation system requirements. For example, these studies should include an assessment of whether brushless excitation would be acceptable instead of the more expensive static excitation included herein and ceiling voltage requirements, as well as the required generator inertia and electrical parameters.

The concept design includes the capability to restart the unit using on site stored energy (in accumulators and DC battery banks), in a fashion that is similar to the current plant and no diesel generator has been allowed for at this time. This would allow staff to restart the unit to power the station service, etc. Given the smaller size of the unit, it is unclear at this time what line charging and grid restoring capabilities this unit would have. This would have to be determined at the beginning of the detailed design phase following the results of the above-mentioned grid and hydraulic transient studies.

3.4.2 Balance of Plant

The powerhouse will require the following new mechanical balance of plant systems:

- Domestic water.
- Sanitary waste (including holding tank).
- Station drainage (including an oil/water separator).
- Compressed air.
- HVAC (including surge tank).
- Fire protection.

- Powerhouse crane.
- Draft tube crane.

Due to the powerhouse's proximity to the river, a new septic field is not feasible. Instead, a sewage holding tank will be provided. The holding tank will be buried and be equipped with heat tracing for the drain lines.

The TIV pit of Unit 2 will be converted into an oil/water separator, complete with coalescing filters/plate pack and drainage pumps (Figure 3). The oil-water-separator will be housed in a concrete pit and sized to accommodate normal station drainage and fire protection water flows.

The fire protection system will be fed from the penstock and will be comprised of listed strainers, piping, hose stations and a fire detection and alarm system. The new generators will be fabricated with self-extinguishing insulating materials; therefore a generator deluge system will not be required.

The powerhouse crane will be an overhead top running bridge crane. The draft tube crane will be an electric monorail crane.

The powerhouse will require the following electrical balance of plant systems:

- Grounding systems.
- Lighting and emergency lighting.
- Fire alarm system.
- Telephone system.
- Control and corporate data networks.
- Security and card access systems.
- Station service distribution panels and convenience transformer.
- Communication relocation.
- New cables and cable trays.
- DC power system.
- Station service transformer (SST) with an automatic transfer scheme.

- 15 kV arc-proof metal-clad switchgear (with unit protections).

All communications from Mayo B, Mayo Hydro, the Wareham spillway and the intake have fibre communication which route through Mayo Hydro. Prior to performing demolition, the communications/fibre will need to be relocated to the switchyard or otherwise bypassed. It is proposed that this equipment and cabling be permanently relocated to a new communications building in the switchyard.

3.5 STRUCTURAL

A new insulated metal clad powerhouse superstructure will be installed on the existing foundation. The powerhouse will be designed to current design standards to withstand seismic loads and loads from the cranes, wind, snow, etc.

The new spiral case and discharge cone will be anchored/grouted in place of the removed Unit 1. Unused openings within the generator and turbine floors will be filled with concrete. If additional laydown space is required on the turbine floor, the concrete that supported the Unit 2 generator may be removed and the floor reinforced as required; it is expected that the cost of this rework would be significant. Minor concrete rehabilitation is likely required over the concrete foundation.

Unit 2's draft tube will be sealed with a structural wall immediately behind the gate guides and then infilled with lean concrete to the generator floor level for improved structural stability. Unit 2's penstock will be plugged and a blanking plate will be installed in the powerhouse.

In addition to the added mass from infilling the decommissioned draft tube, allowances have been included for the installation of post-tensioned rock anchorage to improve powerhouse stability (powerhouse anchors) for updated seismic loading.

A new control room, complete with fire rated wall separations will be provided. The switchgear will be located on the generator floor.

As discussed in Section 3.3, a new surge tank superstructure will be provided. The concrete foundation has been assumed to be suitable for reuse; however, a detailed inspection will be required to confirm this assumption.

3.6 GEOTECHNICAL

3.6.1 Slope Above Powerhouse

The stability of the slope immediately behind the powerhouse structure has been, and continues to be, of concern due to the possibility of a slope failure damaging the critical infrastructure (surge tank, powerhouse, electrical, etc.) that is supported on the slope. The rock mass behind the powerhouse structure will need to be stabilized in order to reduce the risk for damage to the building and/or injury to employees. This is achieved by:

- Scaling and removal of loose rock and debris through hand removal (using rope access) or mechanical means (using long arm backhoe or jackhammer).
- Installation of rockfill catch ditches and catch fences to impede rockfall from traveling onto the back of the powerhouse
- Flatten the top of the slope area and grade it such that positive drainage is achieved in order to reduce the potential for erosion and surface water infiltration into the rock mass.
- Reinforce the excavated rock faces to prevent any loose rock from potentially damaging the structures by installing new wire mesh and rock anchors.

3.6.2 Tailrace

The bottom row of gabion baskets and the underlying gabion mattress below the tailrace water level has failed due to the constant wear of high velocity streams and ice on the galvanized wire baskets. The gabion wall will be repaired.

3.6.3 Access Road

There is a steep section of the road immediately east of the 69 kV substation where runoff water has been allowed to flow directly down the shoulder of the road resulting in gully erosion which also affects the access road to Mayo Hydro. The shoulder area where the gully has formed will

need to be repaired and an appropriately sized rip-rap lined ditch will be designed and constructed at the location of the gully to convey surface run-off. The access road to the surge tank location will also require upgrading to facilitate demolition and re-construction of the new structure.

3.7 COST ESTIMATE

Table 1 provides a summary of the total project costs. For a detailed contractor direct cost estimate, refer to Appendix C.

TABLE 1
TOTAL PROJECT COST - OPTION 1 – REPLACEMENT

ITEM			COST
Contractor Direct Costs			**$13,284,000**
Site Work			$120,000
Slope, Tailrace & Access Road Stabilization			$1,897,000
Decommissioning and Demolition			$799,000
Structure Rehabilitation (Concrete, Anchoring, Repairs)			$1,014,000
New Structures (Powerhouse and Surge Tank)			$1,062,000
New Turbine, Generator & TIV			$4,416,000
Electrical and Mechanical Balance of Plant			$3,976,000
General Contractor Indirect Costs	**35%**	**of Directs**	**$4,650,000**
Travel and Camp Costs (or accommodations)	**6%**	**of Directs**	**$800,000**
Subtotal			**$18,734,000**
Contingency	**30%**	**of Subtotal**	**$5,620,000**
Total Construction Cost			**$24,354,000**
Contractor Markups			**$4,920,000**
Profit	*12%*	*of Const.*	$2,922,000
Head Office Overhead	*7.0%*	*of Const.*	$1,705,000
Bonding & Insurance	*1.2%*	*of Const.*	$292,000
Total Contractor Price			**$29,274,000**
Owner Costs			**$2,710,000**
Environmental Licencing/Consulting	*3.0%*	*of Directs*	$399,000
Final Design	*7.0%*	*of Directs*	$930,000
Site Assistance & Quality Assurance	*6.0%*	*of Directs*	$797,000
Owner's Administration	*2.0%*	*of Contract*	$585,000
Total Project Cost			**$32,000,000**

The total project cost of $32,000,000 is expected to be inclusive of all project costs. Given the limited amount of design work performed to date, a contingency of 30% has been included. Also, the allowances for contractor indirect costs, travel and accommodation, profit, overhead, etc. are based on KGS Group's recent experience on hydroelectric development projects in various remote locations in Canada (including the Mayo B Hydroelectric project).

3.8 SCHEDULE

A preliminary design and construction schedule is shown on Figure 7 (end of report). A pre-design phase includes the environmental licensing and would begin immediately. The detailed design phase would include inspections of the surge tank and spiral cases, multiple studies to refine the turbine/generator selection, hydraulic transient study, grid/electrical study, and drawings and specifications.

Turbine and Generator procurement will commence during detailed design and span into the construction schedule.

During construction, a total of three Mayo B plant outages are expected (1 month, 2 months, 2 weeks). The total process from pre-design to commercial operation is expected to span 2.25 to 2.5 years in duration.

4.0 OPTION 2 – REFURBISH THE EXISTING FACILITY

Option 2 involves the refurbishment of the existing facility. The work entails the refurbishment of Unit 2 only, replacement of the powerhouse mechanical and electrical balance of plant systems, replacement of the surge tank, and the removal of Unit 1. Unit 2 will be refurbished since its embedded spiral case and stay ring will be reused and they are newer (1969 compared to 1952) than Unit 1. Additionally, Unit 2 has a slightly higher capacity than Unit 1 (2.9 MW vs 2.7 MW). At the beginning of the detailed design phase, both units should be inspected and a final decision should be made as to which unit is to be refurbished.

The intent is to essentially replace all of Unit 2, with the exception of the embedded spiral case, stay ring and discharge cone. These embedded components would be refurbished in situ, thereby eliminating the need to cut them out of the concrete substructure. Although the existing turbine runner is only approximately 15 years old, a new runner is contemplated at this time. This allows for the selection of a higher synchronous speed, thereby requiring a less expensive generator; resulting in a lower overall cost along with a new runner. A new TIV, certified for use as a single point of isolation, will also be provided, as it is not expected that the existing one will provide reliable service for the life of the station (assumed to be 65 years from the date of refurbishment).

Given appropriate maintenance and overhauls, it is expected that the life of the plant, post-refurbishment would be 65 years or more.

The Unit 1 penstock will be plugged and its TIV pit modified to suit the needs of the facility. The proposed refurbished unit will have the same capacity as the unit described in Option 1. The service bay will be placed in the current location of Unit 1 (Figure 4). The powerhouse crane will be used to hoist loads off of trucks that are backed into the powerhouse. Clearances between the truck and new generator will be limited, but there is sufficient space. Loads will be lifted and moved over the new unit into the service bay.

This option is similar to Option 1, with the exception that the powerhouse building superstructure, the powerhouse crane, and embedded components will be retained and refurbished. All other systems will be replaced with new systems. Most of the mechanical and

electrical balance of plant systems have reached the end of their life and require either replacement or refurbishment. Given the extent of work proposed, the replacement of the balance of plant systems is warranted. It is expected that this option will provide similar reliability and service as Option 1.

The arrangement of the refurbished powerhouse is shown in Figure 4 and Figure 5. The following sections further detail the concept design to refurbish the Mayo Hydro facility.

4.1 DEMOLITION

The demolition will include the removal of:

- Unit 1 generator and associated equipment.
- Unit 2 generator and governor, turbine bearing, head cover.
- There are no electrical systems with sufficient value to justify retaining for reuse. To be re-used, a component would have to be carefully removed, packaged, stored and re-installed in a new installation. It is expected that the added complexity in design, construction and commissioning would negate any cost savings associated with the reuse of the components. Therefore, all electrical systems (generator, balance of plant, building systems) should be demolished and replaced with new.
- Disposal of any PCBs, lead, oil, and potentially small amounts of mercury.
- Unit 1 spiral case and TIV pedestal.
- The powerhouse balance of plant mechanical systems, including: domestic water, sanitary sewer, fire protection, and HVAC systems.
- Compressed air system excluding the compressors and receiver tank. Re-use of the relatively new compressors has been assumed.
- Surge tank superstructure.
- Surge tank mechanical and electrical.

The existing septic field will be abandoned in place.

The existing draft tube sectional gates and the Unit 2 guides will be re-used.

The replacement of the surge tank is included in this study as its interior condition is unknown. If inspections during later phases of the project show that the surge tank is in good condition, it may be reused to reduce costs.

The existing governor has been problematic ever since an upgrade to an electronic Woodward 505 governor was performed. The supplier's prior attempts to correct the problems have failed. For this reason, a new electronic governor and HPU will be provided.

4.2 MECHANICAL AND ELECTRICAL

4.2.1 Turbine and Generator

As discussed above, the Unit 2 will be refurbished. The refurbished unit would entail:

- New vertical Francis turbine runner (to match existing spiral case).
- Rated 7.6 m^3/s at 34.6 m of net head.
- New 2300 kW, 6.9 kV synchronous generator with static excitation, 600 rpm.
- New head cover, wicket gates, servo and bearings.

The spiral case, discharge cone and stay ring will be sandblasted, inspected and, if required, repaired in situ, then repainted.

The turbine and generator will be supplied with a new electronic governor system.

A service bay incorporating the space formerly occupied by Unit 1 will allow for sufficient lay down and maintenance space. The penstock feeding the unused turbine pit will be permanently plugged and its TIV pit modified to suit the needs of the new facility.

At this concept stage, the design details of the equipment were not specified, but it is assumed that the new/refurbished turbine and generator equipment would consist of:

- Generator:

a. Standard catalogued air-cooled generator. That is, the generator would not be a custom design.
b. Global VPI type insulation with resins that do not support combustion when energy sources are removed.
c. Inertia would consist of the natural inertia of the unit only.
d. Capable of withstanding runaway speeds for extended periods.

- Turbine:

  a. Stainless steel wicket gates.
  b. Greaseless bushings throughout.

- Turbine Inlet Valve (TIV):

  a. New butterfly valve, complete with new hydraulic actuator and counterweight closure capability, rated for single point of isolation.

- Governor:

  a. Digital PLC-based governor.
  b. High pressure HPU with a backup pump and motor.
  c. Nitrogen charged bladder-type accumulators sized to provide stored energy for 2 close strokes and one open stroke of the wicket gates and one open stroke of the TIV.

- Excitation:

  a. Static excitation.
  b. No redundant bridge.
  c. Ceiling voltage capability: 2 pu.

- The unit will be provided with vibration monitoring equipment.
- Unit control and monitoring systems and SCADA systems.
- Neutral grounding resistor.
- A cooling water filtering skid will be provided to filter cooling and shaft seal water.

The above parameters have been assumed at this time. The detailed design phase should include appropriate grid and hydraulic transient studies to determine generator and excitation system requirements. For example, these studies should include an assessment of whether brushless excitation would be acceptable instead of the more expensive static excitation included herein and ceiling voltage requirements, as well as the required generator inertia and electrical parameters.

The concept design includes the capability to restart the unit using on site stored energy (in accumulators and DC battery banks), in a fashion that is similar to the current plant and no diesel generator has been allowed for at this time. This would allow staff to restart the unit to power the station service, etc. Given the smaller size of the unit, it is unclear at this time what line charging and grid restoring capabilities this unit would have. This would have to be determined at the beginning of the detailed design phase following the results of the above-mentioned grid and hydraulic transient studies.

4.2.2 Balance of Plant

The following new mechanical balance of plant systems will be provided:

- Domestic water system.
- Sanitary waste (including holding tank and heat traced piping).
- Station drainage (including an oil/water separator).
- Compressed air system.
- HVAC (including surge tank).
- Fire protection.

Due to the powerhouse's proximity to the river, a new septic field is not feasible. Instead, a sewage holding tank will be provided. The holding tank will be buried and be equipped with heat tracing for the drain lines.

The TIV pit of Unit 1 will be converted into an oil/water separator, complete with coalescing filters/plate pack and drainage pumps (Figure 5). The oil/water separator will be housed in a concrete pit and will be sized to accommodate normal station drainage and fire protection water flows.

The fire protection system will be fed from the penstock and will be comprised of listed strainers, piping, hose stations and a fire detection and alarm system. The new generators will be fabricated with self-extinguishing insulating materials; therefore a generator deluge system will not be required.

The powerhouse and draft tube cranes will be modernized.

The powerhouse will require the following electrical balance of plant systems:

- Unit control and monitoring systems and SCADA systems.
- Neutral grounding resistor and phase cubicle (c/w surge arrestors and capacitors).
- Lighting and emergency lighting.
- Fire alarm system.
- Telephone system.
- Control and corporate data networks.
- Security and card access systems.
- Station service distribution panels and convenience transformer.
- Communication relocation.
- New cables and cable trays.
- DC power system.
- Station service transformer (SST) with an automatic transfer scheme.
- 15 kV arc-proof metal-clad switchgear (with unit protections).

All communications from Mayo B, Mayo Hydro, the Wareham spillway and the intake have fibre communication which route through Mayo Hydro. Prior to performing demolition, the communications/fibre will need to be relocated to the switchyard or otherwise bypassed. It is proposed that this equipment and cabling be permanently relocated to a new communications building in the switchyard.

Grounding for the Mayo Hydro plant appears to be provided embedded into the structure itself and where exposed, appears to be in reasonable condition. The grounding will require a ground resistivity measurement and potential upgrade.

The neutral grounding resistor will need to be replaced due to its age and to better suit the new generator. The new generator would be provided with a phase cubicle for connection of the power leads.

It has been assumed that all of the electrical balance of plant systems will be replaced. Most of the systems are at the end of their useful lives and the amount of effort and cost to reuse select components or subsystems greatly outweighs the cost of its replacement. This will apply to security and card access systems, communications, lighting, etc.

4.3 STRUCTURAL

The existing structure will need reinforcements and anchoring to meet current design codes, particularly for seismic load conditions. The existing powerhouse roof reportedly contains asbestos and would need to be encapsulated in place or removed. A new roof membrane will be installed on top of the existing structure. All windows and doors will be replaced with maintenance-free and energy efficient products.

The powerhouse block walls will need to be repointed and a new fire-rated control room will be constructed. Insulation for the roof and walls will be added. Any openings within the generator and turbine floors will be filled with concrete. If additional laydown space is required on the turbine floor, the support concrete that supported the Unit 1 generator may be removed and the floor reinforced as required; it is expected that the cost of this rework would be significant. Minor concrete rehabilitation is likely required over the concrete foundation.

Unit 1's draft tube will be sealed with a structural wall immediately behind the gate guides and then infilled with lean concrete to the generator floor level for improved structural stability. Unit 1's penstock will be plugged and a blanking plate will be installed in the powerhouse. In addition to the added mass from infilling the decommissioned draft tube, allowances have been included for the installation of post-tensioned rock anchorage to improve powerhouse stability (powerhouse anchors) for updated seismic loading.

As discussed in Section 4.1, a new surge tank superstructure will be provided. The concrete foundation has been assumed to be suitable for reuse; however, a detailed inspection will be required to confirm this.

4.4 GEOTECHNICAL

The geotechnical considerations for this option are the same as they are for Option 1. Refer to Section 3.5 for details.

4.5 COST ESTIMATE

Table 2 below outlines the total project costs. For a detailed contractor direct cost estimate, refer to Appendix C.

TABLE 2
TOTAL PROJECT COST - OPTION 2 – REFURBISHMENT

ITEM			COST
Contractor Direct Costs			**$11,870,000**
Site Work			*$120,000*
Slope, Tailrace & Access Road Stabilization			*$1,897,000*
Decommissioning and Demolition			*$497,000*
Structure Rehabilitation (Concrete, Anchoring, Repairs)			*$1,559,000*
New Structures (Powerhouse and Surge Tank)			*$266,000*
New Turbine, Generator & TIV			*$3,142,000*
Electrical and Mechanical Balance of Plant			*$4,389,000*
General Contractor Indirect Costs	**35%**	**of Directs**	**$4,150,000**
Travel and Camp Costs (or accommodations)	**6%**	**of Directs**	**$710,000**
Subtotal			**$16,730,000**
Contingency	**30%**	**of Subtotal**	**$5,020,000**
Total Construction Cost			**$21,750,000**
Contractor Markups			**$4,390,000**
Profit	*12%*	*of Const.*	*$2,610,000*
Head Office Overhead	*7.0%*	*of Const.*	*$1,523,000*
Bonding & Insurance	*1.2%*	*of Const.*	*$261,000*
Total Contractor Price			**$26,140,000**
Owner Costs			**$2,420,000**
Environmental Licencing/Consulting	*3.0%*	*of Directs*	*$356,000*
Final Design	*7.0%*	*of Directs*	*$831,000*
Site Assistance & Quality Assurance	*6.0%*	*of Directs*	*$712,000*
Owner's Administration	*2.0%*	*of Contract*	*$523,000*
Total Project Cost			**$28,600,000**

4.6 SCHEDULE

A preliminary design and construction schedule is shown on Figure 8 (end of report). A pre-design phase includes the environmental licensing and would begin immediately. The detailed design phase would include inspections of the surge tank and spiral cases, multiple studies to refine the turbine refurbishment, the generator selection, transient study, grid/electrical study, and drawings and specifications.

Turbine and generator procurement will commence during detailed design and span into the construction phase.

During construction, a total of three Mayo B plant outages are expected (1 month, 2 months, 2 weeks). The total process from pre-design to commercial operation is expected to span 2.25 to 2.5 years in duration.

5.0 OPTION 3 – REMOVE THE FACILITY AND RETURN SITE TO NEAR GREENFIELD CONDITION

Option 3 consists of returning the site to a near greenfield condition. This includes the removal of the surge tank and powerhouse, but the foundations would remain in place and be backfilled.

The following sections detail the concept design to return the site to a near greenfield condition.

5.1 DEMOLITION

The demolition will include the removal of:

- The existing powerhouse superstructure.
- Turbine/generators and their components.
- Disposal of any PCBs, lead, oil, and potentially small amounts of mercury.
- Both TIVs.
- All powerhouse mechanical and electrical systems.
- Surge tank.
- Surge tank mechanical and electrical systems.
- Draft tube gates.

The existing septic field will be abandoned in place.

5.2 COMMUNICATIONS

All communications from Mayo B, Mayo Hydro, the Wareham spillway and the intake have fibre communication which route through Mayo Hydro. Prior to performing demolition, the communications/fibre will need to be relocated to the switchyard or otherwise bypassed. It is proposed that this equipment and cabling be permanently relocated to a new communications building in the switchyard.

5.3 STRUCTURAL

The penstock upstream of the surge tank take-off would be plugged and sealed with a concrete wall.

5.4 GEOTECHNICAL

The powerhouse foundation will be backfilled, topped with topsoil, graded and potentially seeded with grass. The topsoil will extend into the existing parking lot area. The tailrace will be infilled with rockfill.

The slope stabilization, the tailrace gabion basket repair and the road repairs that are described in Section 3.5 will not be required for this option.

Following the completion of the work, the road down to Mayo Hydro will be barricaded with a barrier and a fence to prevent access.

5.5 COST ESTIMATE

Table 3 below outlines the total project costs. For a detailed contractor direct cost estimate, refer to Appendix C.

TABLE 3
TOTAL PROJECT COST - OPTION 3 – DEMOLISH AND RETURN TO GREENFIELD

ITEM			COST
Contractor Direct Costs			**$1,675,000**
Site Work			*$60,000*
Slope, Tailrace & Access Road Stabilization			*$0*
Decommissioning and Demolition			*$1,040,000*
Structure Rehabilitation (Concrete, Anchoring, Repairs)			*$0*
New Structures (Powerhouse and Surge Tank)			*$0*
New Turbine, Generator & TIV			*$0*
Electrical and Mechanical Balance of Plant			*$575,000*
General Contractor Indirect Costs	**35%**	**of Directs**	**$590,000**
Travel and Camp Costs (or accommodations)	**6%**	**of Directs**	**$100,000**
Subtotal			**$2,365,000**
Contingency	**30%**	**of Subtotal**	**$710,000**
Total Construction Cost			**$3,075,000**
Contractor Markups			**$620,000**
Profit	*12%*	*of Const.*	*$369,000*
Head Office Overhead	*7.0%*	*of Const.*	*$215,000*
Bonding & Insurance	*1.2%*	*of Const.*	*$37,000*
Total Contractor Price			**$3,695,000**
Owner Costs			**$330,000**
Environmental Licencing/Consulting	*3.0%*	*of Directs*	*$50,000*
Final Design		*	*$100,000*
Site Assistance & Quality Assurance	*6.0%*	*of Directs*	*$101,000*
Owner's Administration	*2.0%*	*of Contract*	*$74,000*
Total Project Cost			**$4,000,000**

* For options 3 & 4, design cost would be more than 7%. An allowance of $100,000 was used.

5.6 SCHEDULE

A preliminary design and construction schedule is shown on Figure 9 (end of report). A pre-design phase includes the environmental licensing and would begin immediately. The detailed design phase would include demolition, drawings and specifications detailing the work.

During construction, one Mayo B plant outage is expected (2 months) to plug the tunnel upstream of the surge tank. The total process from pre-design to project completion is expected to span 1 to 1.25 years in duration.

6.0 OPTION 4 – ABANDON THE FACILITY IN PLACE AND MAKE SAFE

Option 4 will abandon the powerhouse in place and make the site safe as required. The following sections detail the concept design to render the station safe for abandonment.

6.1 DEMOLITION

The demolition will include the removal of:

- Access ladders on the surge tank and powerhouse.
- Disposal of any PCBs, lead, oil, and potentially small amounts of mercury.
- Electrical feeds to the powerhouse.

6.2 COMMUNICATIONS

All communications from Mayo B, Mayo Hydro, the Wareham spillway and the intake have fibre communication which route through Mayo Hydro. Prior to performing demolition, the communications/fibre will need to be relocated to the switchyard or otherwise bypassed. It is proposed that this equipment and cabling be permanently relocated to a new communications building in the switchyard.

6.3 STRUCTURAL

The penstock upstream of the surge tank take-off will be plugged and sealed with a concrete wall.

The windows and doors in the powerhouse will be boarded and sealed to prevent access into the powerhouse. Access hatches to confined spaces (spiral case, surge tank, etc) will be welded shut.

6.4 GEOTECHNICAL

The slope stabilization, the tailrace gabion basket repair and the road repairs that are described in Section 3.5 will not be required for this option. The tailrace will be infilled with rockfill. Following the completion of the work, the road down to Mayo Hydro will be barricaded with a barrier and a fence to prevent access.

6.5 COST ESTIMATE

Table 4 below outlines the total project costs. For a detailed contractor direct cost estimate view Appendix C.

TABLE 4
TOTAL PROJECT COST - OPTION 4 – ABANDON IN SITU

ITEM			COST
Contractor Direct Costs			**$945,000**
Site Work			*$60,000*
Slope, Tailrace & Access Road Stabilization			*$0*
Decommissioning and Demolition			*$290,000*

Final Design		*	*$100,000*
Site Assistance & Quality Assurance	*6.0%*	*of Directs*	*$57,000*
Owner's Administration	*2.0%*	*of Contract*	*$42,000*
Total Project Cost			**$2,300,000**

* For options 3 & 4, design cost would be more than 7%. An allowance of $100,000 was used.

6.6 SCHEDULE

A preliminary design and construction schedule is shown on Figure 10 (end of report). A pre-design phase includes the environmental licensing and would begin immediately. The

detailed design phase would include demolition, drawings and specifications detailing the greenfield site.

During construction, one Mayo B plant outage is expected (2 months) to plug the tunnel upstream of the surge tank. The total process from pre-design to project completion is expected to take less than one year.

7.0 ECONOMIC ASSESSMENT

The economic assessment of the options is summarized in Table 5 and the detailed economic assessment for each Option is detailed in Appendix D. The economic assessment of Option 1 and Option 2 was performed using the following:

- 65 year life span.
- 5.45% (nominal) weighted average cost of capital.
- 2% inflation for computing the present value.
- An assumed $7.10/MWhr operating and maintenance cost.
- $1.15/MWhr capital expenditure costs were taken from similar KGS Group projects.
- No water rental cost.

For Option 3 and 4, it was assumed that the hydro plant would continue in operation until the plant could no longer be operated. During that period regular maintenance activities would continue, however no dollars will be spent on capital expenditures. By operating only 1 unit at a time, it is assumed that:

- A 10 year remaining life span could be achieved with the hydro plant.
- 2% inflation for computing the present value.
- An assumed $7.10/MWhr operating and maintenance cost.
- No water rental cost.

YEC provided the energy benefit per MWhr for all four Options for years 2006 to 2035. The economic analysis performed in this study started at year 2016 in the provided data, and the 2035 projection was taken and extended for years 2036 to 2081 (Options 1 and 2 only).

The existing station switchgear is operating well beyond its expected life. The switchgear may operate for another 10 years of service, but proper consideration of safe working distances and operating boundaries should be incorporated into the work procedures for the site to limit potential for worker hazard in case of unexpected failure.

For all options it was assumed that the units will operate at a maximum of 2.3 MW. This reduces the power rating of Options 3 and Option 4, however with the max flow rate of 6 m^3/s (while both Mayo B units are running) this is assumed to be an accurate assumption that allows a more direct comparison between options.

To aid in comparing all options on a total present value basis, KGS Group incorporated costs of construction, operation, capital expenditures, produced energy benefit and the benefit of an increase in capacity. The energy and capacity benefit were taken from an email sent by YEC (Appendix E). The email pertains to the "Aishihik Rerate and Assessment" project performed by KGS Group, which assessed a comparable project and was assumed to be acceptable for this analysis. The email states the following:

- Benefit of an increase in capacity - $2.5M per MW based on avoided capital cost of new natural gas generation.
- Benefit of an increase in annual energy - $200,000 per GWh based on avoided operating (i.e. variable cost) cost of natural gas.
- Sensitivity analysis for energy benefit going from $100,000 (best possible natural gas operating cost) to $300,000 (diesel operating cost).

These options do not increase the total capacity of YEC system, however Option 3 and 4 will reduce the capacity and the "benefit of an increase in capacity" will act negatively to those options.

TABLE 5
ECONOMIC ANALYSIS SUMMARY

	OPTION 1 REDEVELOPMENT	OPTION 2 REFURBISHMENT	OPTION 3 DEMOLITION	OPTION 4 ABANDON IN SITU
Assessment Factors				
Total Project Cost	$32,000,000	$28,600,000	$4,000,000	$2,300,000
Plant Size (MW)	2.3	2.3	2.3	2.3
Annual Energy (GWhrs/yr)	10.4	10.4	7.2	7.2
Life Cycle Costs - Present Value				
Total Operating Costs	$2,100,000	$2,100,000	$500,000	$500,000
Total Capital Expenditures	$400,000	$400,000	$0	$0
Energy Benefits - Present Value				
MWhr Produced - Year 1 to 10 (Present Value)	98,771	98,771	57,278	57,278
MWhr Produced - Year 11 to 65 (Present Value)	106,528	106,528	0	0
Total MWhr Produced (Present Value)	205,300	205,300	57,278	57,278
Total Energy Benefit (@ $200/MWhr)	$41,100,000	$41,100,000	$11,500,000	$11,500,000
Increased Capacity Benefit - Present Value				
Capacity Increase (MW)	0	0	-2.3	-2.3
Total Benefit (@ $2.5M/MW)	$0	$0	-$5,750,000	-$5,750,000
Cost Indicators				
Total Present Value	$6,600,000	$10,000,000	$1,250,000	$2,950,000
Installed Project Cost ($/kW)	$13,910	$12,430		
Levelized Cost ($/kWhr)	$0.17	$0.15		
Levelized Cost ($/MWhr)	$166	$150		

The assessment in Table 5 shows that Option 2 has the greatest total present value and lowest levelized cost. Both Option 1 and 2 have a large present value compared to Option 3 and 4. Option 1 and 2 do have a large initial cost, however this cost does contain a 30% contingency and would need to be developed further to achieve a cost estimate with an improved accuracy. Option 2 is more viable than Option 1 mainly due to costs associated with demolition and construction of a new powerhouse, new cranes, new embedded components (spiral case and stay ring) and additional concrete work. Otherwise, Option 1 and 2 will have the same produced

energy benefit, maintenance costs and capital expenditures. The success of Option 1 and 2 may be highly dependent on the assumed energy benefits, so a sensitivity analysis was performed and the results are summarized in Table 6 below and they are graphically represented in Figure 6.

TABLE 6
ENERGY BENEFITS SENSITIVITY ANALYSIS

	OPTION 1 REDEVELOPMENT	OPTION 2 REFURBISHMENT	OPTION 3 DEMOLITION	OPTION 4 ABANDON IN SITU
Total Present Value (@ $100/MWhr)	-$14,000,000	-$10,600,000	-$4,600,000	**-$2,900,000**
Total Present Value (@ $125/MWhr)	-$8,900,000	-$5,500,000	-$3,100,000	**-$1,400,000**
Total Present Value (@ $150/MWhr)	-$3,800,000	-$400,000	-$1,700,000	**$100,000**
Total Present Value (@ $175/MWhr)	$1,500,000	**$4,900,000**	-$300,000	$1,500,000
Total Present Value (@ $200/MWhr – Reference Price)	$6,600,000	**$10,000,000**	$1,300,000	$3,000,000
Total Present Value (@ $225/MWhr)	$11,700,000	**$15,100,000**	$2,700,000	$4,400,000
Total Present Value (@ $250/MWhr)	$16,900,000	**$20,300,000**	$4,100,000	$5,800,000
Total Present Value (@ $275/MWhr)	$22,000,000	**$25,400,000**	$5,600,000	$7,300,000
Total Present Value (@ $300/MWhr)	$27,100,000	**$30,500,000**	$7,000,000	$8,700,000

Note 1: Bolded cells indicate the highest present value for each energy benefit rate.
Note 2: Shaded cells indicate a positive present value.

Table 6 shows that Option 2 has the best total present value at energy benefits slightly above $150/MWhr and higher, and that Option 1 becomes more viable than Option 3 and 4 for an energy benefit of approximately $175/MWhr and higher.

The economics of Option 3 and 4 are highly dependent on the assumed increased capacity benefits, so a sensitivity analysis was performed using a constant energy benefit of $200,000 per GWHr and the results are summarized in Table 7.

TABLE 7
INCREASED CAPACITY BENEFITS SENSITIVITY ANALYSIS

	OPTION 1 REDEVELOPMENT	OPTION 2 REFURBISHMENT	OPTION 3 DEMOLITION	OPTION 4 ABANDON IN SITU
Total Present Value (@ $2.5M/MW – Reference Benefit)	$6,600,000	$10,000,000	$1,250,000	$2,950,000
Total Present Value (@ $4.5M/MW)	$6,600,000	$10,000,000	-$3,350,000	-$1,650,000
Total Present Value (@ $6M/MW)	$6,600,000	$10,000,000	-$6,800,000	-$5,100,000

Table 7 shows that the economics of Option 3 and 4 become progressively worse as the increased capacity benefit increases.

8.0 RECOMMENDATION

Based on the results of the economic assessment, the refurbishment of the existing plant (Option 2) is recommended as it has the highest present value and lowest levelized cost of energy for energy benefit rates slightly in excess of $150,000 per GWHr and higher, for all capacity benefit rates studied.

Should this project proceed, the following is a list of activities that will be required:

- Environmental Approval and Licensing.
- Inspection of surge tank and spiral cases.
- Study on whether to replace or reuse the runner.
- Refinement of runner/turbine rating (if runner is replaced).
- Hydraulic transient study.
- Grid/electrical parameters study.
- Detailed design, drawings and specifications.
- Equipment procurement.
- Construction.
- Commissioning.

9.0 STATEMENT OF LIMITATIONS AND CONDITIONS

9.1 THIRD PARTY USE OF REPORT

This report has been prepared for the Yukon Energy Corporation to whom this report has been addressed and any use a third party makes of this report, or any reliance on or decisions made based on it, are the responsibility of such third parties. KGS Group accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions undertaken based on this report.

9.2 CAPITAL COST ESTIMATE STATEMENT OF LIMITATIONS

The cost estimates included with this report have been prepared by KGS Group using its professional judgment and exercising due care consistent with the level of detail required for the stage of the project for which the estimate has been developed. These estimates represent KGS Group's opinion of the probable costs and are based on factors over which KGS Group has no control. These factors include, without limitation, site conditions, availability of qualified labour and materials, present workload of the Bidders at the time of tendering and overall market conditions. KGS Group does not assume any responsibility to the Client, in contract, tort or otherwise in connection with such estimates and shall not be liable to the Client if such estimates prove to be inaccurate or incorrect.

ATTENTION: Mr. Ron Gee
Water Management Engineer

RE: Mayo A and Mayo B Generating Stations
Optimizing Plant Operations Testing Results, May 2013

Dear Mr. Gee:

The Mayo B Hydroelectric Project was designed to operate with a total combined Mayo A and Mayo B flow of 25 m^3/s (19 m^3/s through Mayo B and 6 m^3/s through Mayo A). Yukon Energy Corporation (YEC) has indicated their wish to maximize the capacity of the Mayo complex by increasing these combined flows. The purpose of this letter is to describe the findings of the testing done in May 2013 and the subsequent analysis that was carried out to investigate the extent to which this can be achieved, while ensuring that adequate pressures are maintained in the penstock to Mayo B. Operating the Mayo A and B plants outside of the original design flow conditions can augment energy production; but it also carries increased risk to the penstock unless the acceptable operating conditions are maintained.

The analysis and recommendations are presented in detail in Appendix A.

P:\Projects\2009\09-1404-01\02.FinalDesign\300.DC-Iss\08.Letters\SOURCE\02.08.DN300.44.0_LTR_MayoA-B GS OptimizingPlantOpsTestResults_2014-05-09_JCL FGC.doc

Recommended maximum Mayo A flows for given Wareham Lake levels and Mayo B flows are presented in the following table:

RECOMMENDED ALLOWABLE MAYO A FLOWS

Wareham Lake Water Level (m)	Mayo A Maximum Flows (m^3/s)						
	One Mayo B Unit Running at Any Flow	Two Mayo B units Running at:					
		8.0 m^3/s Total	10.0 m^3/s Total	12.5 m^3/s Total	15.0 m^3/s Total	17.5 m^3/s Total	20.5 m^3/s Total
573.5	8.7	**Wareham Lake below Minimum Level for Operation of 2 Mayo B Units**					
573.6	10.0						
573.7	11.2

574.4	17.0	6.0	6.0	6.0	6.0	8.3	8.3
574.5	**17.0**	**6.0**	**6.0**	**6.0**	**7.5**	**9.7**	**9.7**

MAXIMUM ALLOWABLE MAYO A FLOWS

The effect of limiting wicket gate openings at Mayo B to 83% was investigated and calculated values for maximum allowable Mayo A flows are presented in Table 4 of Appendix A. The flows shown in that table are theoretically acceptable if the Mayo B wicket gates are limited to 83% or less. However, there is a risk that wicket gate limits which are not physically imposed could be inadvertently removed or defeated in the future, putting the penstock at risk.

The following limits are recommended for pressure levels at the air vent shaft at the tunnel intake:

- Minimum with two Mayo B units in operation: El. 573.4 m
- Minimum with one Mayo B unit in operation: El. 572.9 m

It is recommended that the overall head losses along the intake and conveyance system be monitored and reviewed periodically (suggest minimum of every 3 years) and if/when an event occurs that raises concerns about the integrity of the system, and that the water levels at PI2 and at the air vent shaft be monitored continuously.

If monitoring data shows increased head losses with respect to those obtained during the May 2013 tests, it is recommended to assess the situation and adjust the plant flows to maintain the

levels at PI2 stipulated in the plant operational limits. Increased head losses are indication of changes in the conveyance system, possibly debris accumulation or ice blockage at the trashracks or along the tunnel or penstock. These would need to be corrected to restore the allowable flows indicated in this letter.

Other operational conditions at the Mayo plants are recommended to be maintained. These are:

Mayo B Flows:

- Minimum: 4 m^3/s per unit

Mayo A Flows:

- No limits when Mayo B not operated

Levels at PI2 (highest point in the Mayo B penstock):

- Low Alarm: El. 572.5 m
- Low-Low Alarm (Shutdown): El. 572.2 m

In preparing this letter, KGS Group has assumed that YEC will confirm that intake flows in excess of 25 m^3/s are in full accordance with the environmental license for the tunnel intake at Wareham Lake and its trashrack, and that YEC will undertake any regulatory requirements, if necessary, to modify the terms and conditions of the license to allow these flows. This report addresses only the technical aspects of increasing the maximum flow at the plants beyond the design values and the implications with respect to penstock pressures.

This letter has been prepared for Yukon Energy Corporation to whom it has been addressed and any use that a third party makes of this report, or any reliance on or decisions made based on it, are the responsibility of such third parties. KGS Group accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions undertaken based on this report.

Should you have questions regarding this assessment, please contact the undersigned.

APPENDIX A

MAYO A AND MAYO B GENERATING STATIONS
OPTIMIZING PLANT OPERATIONS TESTING RESULTS, MAY 2013
DETAILED ANALYSIS AND RECOMMENDATIONS

1.0 BACKGROUND INFORMATION

The operational limits for Mayo B (range of forebay levels and flows) have been revised using data obtained during the first two years of operation of the plant and are summarized in the KGS Group letter: *Mayo B Hydroelectric Project – Operational Conditions for the Mayo B Plant (Ref. 1)*. The conditions indicated in that letter are as follows:

Forebay Levels at Wareham Lake:

- Maximum: El. 574.5 m
- Minimum with two Mayo B units in operation: El. 573.9 m
- Minimum with one Mayo B unit in operation: El. 573.5 m

Mayo B Flows:

- Minimum: 4 m^3/s per unit
- Maximum: 9.5 m^3/s per unit

Mayo A Flows:

- Maximum: 6 m^3/s with two Mayo B units in operation: El. 573.9 m
- No limits when Mayo B not operated

Levels at PI2 (highest point in the Mayo B penstock):

- Low Alarm: El. 572.5 m
- Low-Low Alarm (Shutdown): El. 572.2 m

Levels downstream of the trashracks:

- Minimum with two Mayo B units in operation: El. 573.7 m
- Minimum with one Mayo B unit in operation: El. 573.3 m

The stipulated minimum level at PI2 ensures that at this point the design safety margins will be maintained in all operation conditions considered during the design.

2.0 TEST DATA COLLECTED

The data collected from tests conducted on May 28 and 29 of 2013 allowed the review of the operational limits described in this letter. The recommendations here provided are based on the status of the system during these tests. Conditions could arise in the future that could cause exacerbated head losses at any point in the system. For instance, the trashracks could become severely blocked by debris or, with time, there is algae growth or physical deterioration of the tunnel, or corrosion of the penstock. Should any factor change with time to increase the system head losses observed, the allowable flows presented in this letter would need to be reduced to maintain operation of the plants within the specified limits.

Overall monitoring of pressure levels and the alarms at PI2 is required to allow early detection of conditions within the conveyance system that exceed the specified design conditions. It is recommended that the overall conveyance system head losses be reviewed periodically (every 3 years would be a reasonable guide) and/or if an event occurs that raises concerns about the integrity of the system. The water levels at PI2 and at the trashrack shall continue to be monitored continuously.

2.1 CONVEYANCE SYSTEM FLOWS, PRESSURES AND POWER AT THE PLANTS

The measurements obtained during the tests included flows at Mayo B, Wareham Lake levels, pressures at PI2, pressures at the inlet of the Mayo B turbines as well as generated power and wicket gate openings at the Mayo A and Mayo B turbines. These were obtained for various conditions of flows in Mayo A and Mayo B and are summarized in Table 1.

TABLE 1: SUMMARY OF COLLECTED DATA IN MAY 2013

Time Frame		Average Wareham Lake Level (m)	Average PI2 Level (m)	Average Flow (m^3/s)		Power (MW)		Gate Opening % (Mayo A)		Gate Opening % (Mayo B)		Piezometric head difference Lake - PI2 (m)

2.2 WATER LEVEL CHANGES AND HEAD LOSSES AT THE TRASHRACK AND INTAKE

The water level changes between the reservoir and various locations in the intake were measured in order to confirm the estimated head losses in the intake entrance and trashrack. The water levels were measured on site during the tests (at the forebay, the intake gate slot and the air vent shaft) and they form the baseline for this analysis. The measured elevation differentials from the lake to the intake gate slot and the air vent comprise not only intake and trashrack head losses but also what is termed the “velocity head” at each point. The latter is not a head loss but rather corresponds to the kinetic energy in the flow. Both head losses and velocity head were considered in the verifications summarized in Table 2 below. The table shows the level differentials measured during the tests and the corresponding values that were estimated during the design for the location of the air vent, based on the design assumptions for head losses and velocities and the reported conditions at the intake. The table includes a range of values that were calculated during the design. These include the “best estimate” as well as a range of low (optimistic) and high (conservative) head loss values. The best estimate values most closely match the level differences that were measured up to the air vent shaft.

TABLE 2: MEASURED LEVELS AT THE INTAKE OF THE MAYO GS TUNNEL WITH RESPECT TO WAREHAM LAKE

Total Intake Flow [m^3/s]	Mayo A Flow [m^3/s]	Mayo B Flow [m^3/s]	Difference in Level with Respect to Wareham Lake (m)				
			Measured up to the Intake Gate Slot	Measured up to the Air Vent Shaft	Estimated for the Entire Intake Structure		
					Optimistic	Best Estimate	Conservative
26.4	6	20.4	Not measured	0.52	0.49	0.55	0.62
30.4	10	20.4	0.52	0.71	0.65	0.73	0.83
32.8	12.5	20.3	0.60	0.82	0.76	0.85	0.96
35.2	15	20.2	0.73	0.99	0.88	0.98	1.11

Note: These measurements were taken on May 29, 2013, directly by Ron Gee and Joel Lambert. These values are not based on SCADA data.

It must be noted that the measurements summarized in Table 2 were performed with a relatively clean trashrack. Significant debris blockage of the trashrack in the future will increase the measured differences from those observed at the various flows. Any increase in excess of 0.3 m from the intake water levels measured would warrant review of the combined plant operation as well as inspection of the trashrack.

2.3 MAYO B FLOWS

The combined flows at Mayo B were measured by instrumentation and collected through SCADA. The flows at Mayo A are estimated based on the measured power and with relationships used by YEC in the past. These relationships have not been reviewed in detail by KGS Group but result in flows that are within the expected range of values. The recommendations provided in this letter are based on application of those relationships for estimation of Mayo A flows and should be revised if these were modified.

The May 2013 tests results showed that a combined flow of 20.5 m^3/s for the two Mayo B turbines was required to obtain full plant capacity (close to 10 MW). This flow exceeded the maximum of 9.5 m^3/s per unit used in the project design as indicated in the Operational Condition Letter. This greater than expected flow was consistent with the findings of the performance testing conducted by Accusonic which suggest that the efficiency of the turbines and generators would not meet the guaranteed level.

The greater flow needed by Mayo B to produce maximum plant capacity limited the amount of flow that could be concurrently passed through Mayo A while maintaining the pressures in the system above the required minimum values.

The efficiency shortfall of the Mayo B units was rectified by closing the draft tube air admission valves. With the air admission valves closed Mayo B now produces the rated plant capacity closer to the expected flow. YEC has now implemented a wicket gate limit at Mayo of 83% in the plant's control system software.

3.0 DATA ANALYSIS AND DISCUSSION

3.1 ALLOWABLE MAYO A FLOWS

Based on the data listed in Table 1, a relationship was developed between the Mayo A and Mayo B flows and the resulting pressure head difference between Wareham Lake and PI2. That relationship in metric units is as follows:

$$\textit{Pressure Head Difference} = 0.00396\ Q_A^2 + 0.00387\ Q_B^2$$

Where: Q_A= Total flow through the Mayo A powerhouse (m^3/s)

Q_B = Total flow through the Mayo B powerhouse (m^3/s)

Figure 1 shows the values of pressure head difference between Wareham Lake and PI2 according to the above relationship, compared with the values obtained from the tests.

As was noted above, it cannot be over-emphasized that the above relationship reflects the conditions found during the tests, including a relatively clean trashrack, and could change if these conditions were altered. For instance, if there is debris or ice blockage at the trashracks, these would need to be cleaned to restore the assumed losses. Otherwise, the relationship would need to be modified.

It must also be noted that at times the levels at PI2 can oscillate within a 0.5 m range. This has been observed (through the instrumentation as well as with direct measurements using a string line and a float) at several instances during the first two years of operation of Mayo B, and occurs even when the Mayo B units are shut off and there is only flow through Mayo A. This fact confirms the need to monitor the water levels at PI2 and to maintain the safe margins reflected in the recommended alarm levels.

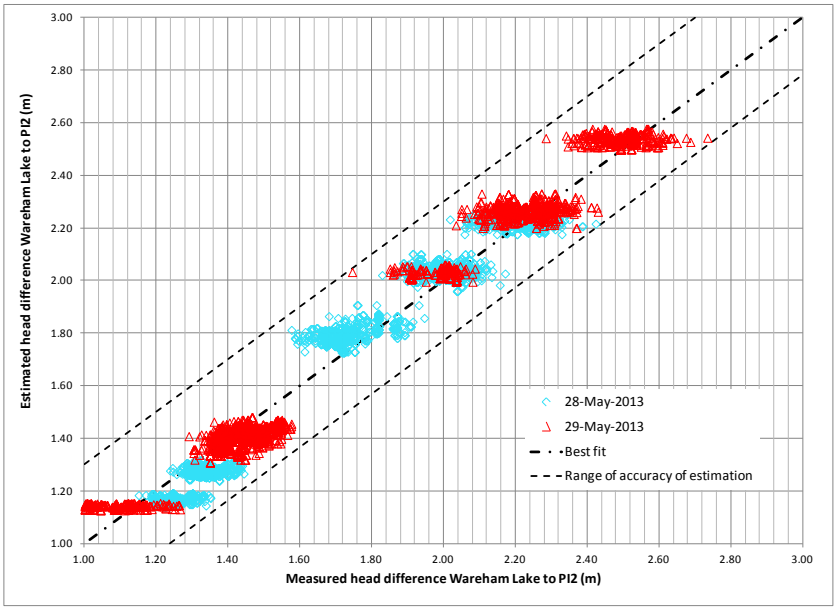

Figure 1: Piezometric Head Difference Wareham Lake to PI2 (estimated vs. measured)

Based on the test results and the relationships derived from them, the maximum allowable flows at Mayo A, for various conditions at Mayo B and Wareham Lake are indicated in Tables 3 and 4. These tables show the amount of water that can be safely directed to Mayo A, given the water level in Wareham Lake and the steady-state flow through Mayo B. The first column in the tables shows the Wareham Lake level and the title row shows the total steady state flow (two units combined) at Mayo B. For example, if Wareham Lake is at El. 574.2 m and Mayo B is operating with a total flow of 12.5 m^3/s, Mayo A can safely be operated up to a maximum of 6.0 m^3/s (Table 3) for unrestricted opening of the Mayo B units. If the wicket gates at Mayo B are physically limited to 83% opening under all operating modes (Table 4), then Mayo A can safely be operated up to a maximum of 8.4 m^3/s.

TABLE 3: ALLOWABLE MAYO A FLOW
IF MAYO B WICKET GATES ARE ALLOWED TO OPEN TO 100%

Wareham Lake Water Level (m)	Mayo A Maximum Flows (m^3/s) with No Limit on Mayo B Wicket Gate Opening						
	One Mayo B Unit Running at Any Flow	Two Mayo B units Running at:					
		8.0 m^3/s Total	10.0 m^3/s Total	12.5 m^3/s Total	15.0 m^3/s Total	17.5 m^3/s Total	20.5 m^3/s Total
573.5	8.7	Wareham Lake below Minimum Level for Operation of 2 Mayo B Units					
573.6	10.0						
573.7	11.2						
573.8	12.3						
573.9	13.3	6.0	6.0	6.0	6.0	6.0	
574.0	14.2	6.0	6.0	6.0	6.0	6.0	
574.1	15.1	6.0	6.0	6.0	6.0	6.0	
574.2	15.9	6.0	6.0	6.0	6.0	6.0	
574.3	16.7	6.0	6.0	6.0	6.0	6.7	6.7
574.4	17.0	6.0	6.0	6.0	6.0	8.3	8.3
574.5	**17.0**	**6.0**	**6.0**	**6.0**	**7.5**	**9.7**	**9.7**

The criteria used for determining the allowable Mayo A flow rates was to maintain a safety margin for the water level at PI2 in the event that Mayo B was loaded from the steady state condition (shown in the title row in the tables) to full load, at the maximum wicket gate opening rate. The shaded areas indicate that the safety margin on the water level at PI2 is less than what was originally adopted for the design (2 m in transient conditions). Mayo B should not be continuously operated in this region, except for when restoring the grid.

Table 3 is based on a full capacity of 10.25 m^3/s for each unit at Mayo B, which is more than the previously stipulated 9.5 m^3/s but corresponds to the test measurements for maximum power at the plant with the draft tube air admission valves open.

Table 4 takes into account a physical limit to the wicket gate opening at Mayo B of 83%. Table 4 can only be used if the wicket gates at Mayo B are limited to a maximum 83% opening.

**TABLE 4: ALLOWABLE MAYO A FLOW
IF MAYO B WICKET GATES LIMITED TO 83%**

Wareham Lake water level (m)	Mayo A Maximum Flows (m^3/s) with Mayo B wicket gates limited to 83% opening						
	One Mayo B Unit Running at any flow	Two Mayo B units Running at:					
		8.0 m^3/s Total	10.0 m^3/s Total	12.5 m^3/s Total	15.0 m^3/s Total	17.5 m^3/s Total	19.5 m^3/s Total
573.5	9.7	Wareham Lake below Minimum Level for Operation of 2 Mayo B Units					
573.6	10.9						
573.7	12.0						
573.8	13.0						
573.9	13.9	6.0	6.0	6.0	6.4	7.3	
574	14.8	6.0	6.0	6.0	8.1	8.9	
574.1	15.6	6.0	6.0	6.7	9.5	10.2	6.0
574.2	16.4	6.0	6.0	8.4	10.8	11.4	7.6
574.3	17.0	6.0	7.0	9.7	11.9	12.4	9.1
574.4	17.0	6.2	8.6	11.0	12.9	13.4	10.4
574.5	17.0	8.0	10.0	12.0	13.8	14.3	11.5

The basis for Tables 3 and 4 includes:

- A rate of Mayo B wicket gate opening limited to 100% per 45 seconds.
- The assumption that Figure 1 represents, and will continue to represent, actual conditions in the Mayo A / Mayo B water conveyance. Increased losses in the water conveyance will invalidate Tables 3 and 4.

The largest factor contributing to the limits shown in Tables 3 and 4 is the potential transient effect of accepting load at Mayo B. The magnitude of this transient effect is less pronounced when the initial steady state flow at Mayo B is closer to its full capacity; as a result, more flow can be passed through Mayo A.

When the initial steady-state flow at Mayo B is near 17.5 m^3/s the head losses in steady state condition increase to the point where the allowable flows at Mayo A need to be reduced to maintain the steady state pressure at PI2 above current alarm levels.

3.2 TRASH RACK HEAD LOSSES

Divers have previously reported that rock rubble is partially blocking the trashrack at the intake by 20% to 30% of the opening. Removing this rubble was not considered prudent as it was not evident to the divers that the removal could be done in safe manner. There was potential that this would lead to further deterioration of the slope adjacent to the intake. The differences in water levels from Wareham Lake to the air vent shaft, shown in Table 2, correspond closely to the values estimated by KGS Group at the design stage, when adjusted to include a 20% blockage in front of the trashracks. The measured and estimated values are shown in Figure 2.

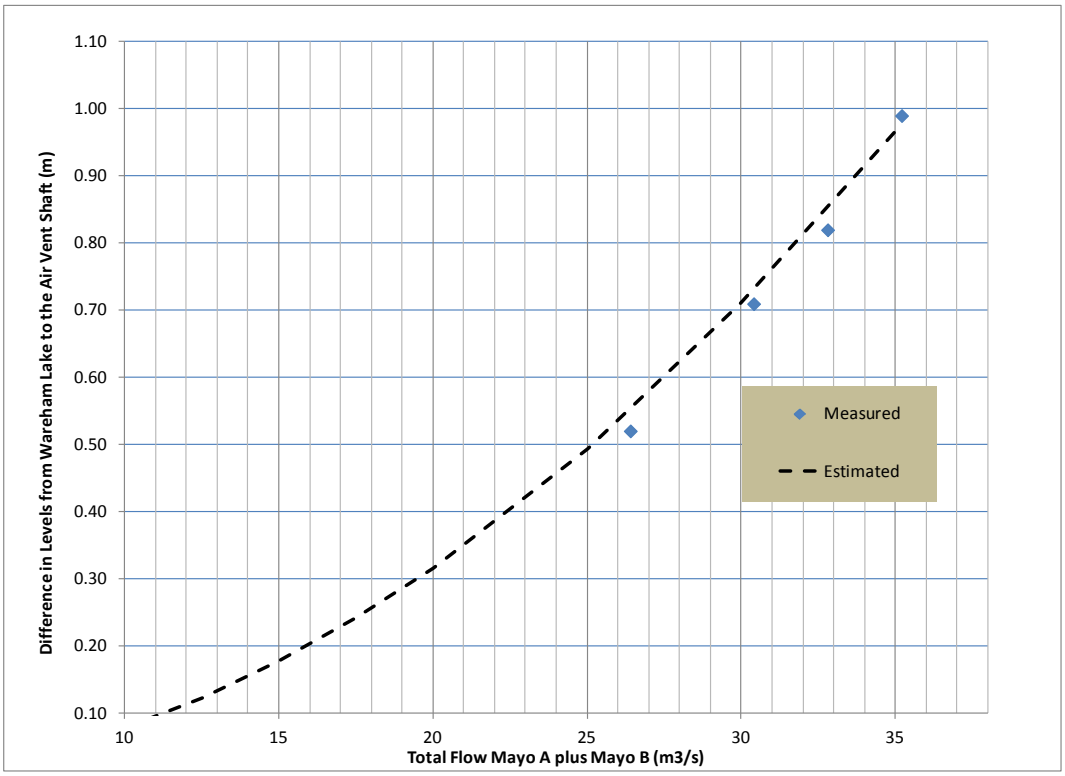

Figure 2: Level Difference between Wareham Lake and Intake Air Vent Shaft

The values provided in Figure 2, and the corresponding minimum levels at PI2, suggest that the following levels at the air vent shaft could be adopted:

- Minimum with two Mayo B units in operation: El. 573.4 m
- Minimum with one Mayo B unit in operation: El. 572.9 m

These are lower than those indicated in Ref.1. The water levels at the air vent shaft are currently collected through SCADA. It is important that these levels and the levels at Wareham Lake are monitored and that YEC maintains a record of the corresponding readings before and after cleaning and/or inspecting the trashracks, as well as a record of the conditions encountered there. This data can then be used as a basis for early detection of debris blockage and for possible future modification to the operational limits.

4.0 RECOMMENDATIONS

KGS Group recommends that the flows through the Mayo A and Mayo B powerhouses be limited to the levels listed in Table 3 as these flow rates provide the design margin of safety on the water levels at the penstock high point vent (PI2) even if the Mayo B wicket limit is not in place. The values listed in Table 4 are only safe if the Mayo B wicket gate opening is limited to 83% or less.

The following limits are recommended for pressure levels at the air vent shaft at the tunnel intake:

- Minimum with two Mayo B units in operation: El. 573.4 m
- Minimum with one Mayo B unit in operation: El. 572.9 m

Other operational conditions at the Mayo plants are recommended to be maintained. These are:

Mayo B Flows:

- Minimum: 4 m^3/s per unit

Mayo A Flows:

- No limits when Mayo B not operated

Levels at PI2 (highest point in the Mayo B penstock):

- Low Alarm: El. 572.5 m
- Low-Low Alarm (Shutdown): El. 572.2 m

It is recommended that the overall head losses along the conveyance system be reviewed periodically (suggest minimum of every 3 years) and if/when an event occurs that raises concerns about the integrity of the system, and that the water levels at PI2 and at the air vent shaft be monitored continuously.

If monitoring data shows increased head losses with respect to those obtained during the May 2013 tests, it is recommended to assess the situation and adjust the plant flows to maintain the levels at PI2 stipulated in the plant operational limits. Increased head losses are indication of changes in the conveyance system, possibly debris accumulation at the trashracks or along the tunnel or penstock. These would need to be corrected to restore the allowable flows indicated in this letter.

APPENDIX B

EMAIL: ANDRITZ – FRANCIS TURBINE/GENERATOR REDEVELOPMENT STUDY (APRIL 11, 2016)

From: Broadhurst Gary
To: Joel Lambert; Daniel Giesbrecht
Cc: Taylor Thomas
Subject: 2016.04.11 / YEC / Mayo A GS / KGS - Redevelopment Study / Francis Turbine+Generator Budget Price Request / Q&A"s
Date: April-11-16 4:41:52 PM
Attachments: image002.png
image001.png

Hi Joel,

Find below our responses to your questions

1. Turbine full load efficiency is 91.7% giving turbine output = 2366 KW. With generator eff = 97% you get generator output = 2295 rather than 2200. Initial offer was rounded down to 2200 KW. Though, same price.
2. There would be cost premiums rather than savings to go with generator voltage of 6.9KV. In addition to extra cost for generator there would also be need for 15KV switchgear rather than 5KV, which would result in cost increase due to change in voltage class. For such small generator outputs, the 4.160 kV voltage is a better solution.

We trust these responses answer your questions appropriately.

Kind regards,
Gary

Subject: RE: YEC / Mayo A GS / KGS - Redevelopment Study / Francis Turbine+Generator Budget Price Request

Thank you very much for the budget pricing Gary. This is very useful.

I just have a few questions about this. What would the peak efficiency of the turbine be? You show a 2200 kW generator, but even at 90% turbine efficiency and 97.5% generator efficiency, I get an output slightly above 2200 kW. I am trying to firm up what the output would be to use in the economic analysis.

Also, would changing to a 6900 V generator change the cost significantly?

Regards,
Joel

Subject: RE: YEC / Mayo A GS / KGS - Redevelopment Study / Francis Turbine+Generator Budget Price Request

Hi Joel & Rudy,

Andritz Hydro is pleased to provide you with our budget offer as requested for the Mayo A Redevelopment Study.

The turbine runner diameter is 986 mm. Setting elevation is 0.75 M above TWL. Generator would be 600 rpm; 2200 KW 4160 V.

Scope is:

- Vertical Francis turbine with steel spiral case and steel draft tube elbow
- 4160 V Synchronous generator with brushless excitation
- Turbine generator controls including governor function
- 5 KV metal clad switchgear
- DC power system
- 150 KVA Station Service transformer
- Installation advisor
- Commissioning and start-up

Budget price is $3,300,000 Taxes extra DDP site in the Yukon

Attached are the following documents:

- Preliminary turbine hydraulic outline
- Compact Francis Turbine brochure

Your assumption regarding the Andritz Hydro A CAT (Compact Axial Turbine) turbine is correct, as it would probably not be a good fit for the Mayo A GS Redevelopment concept of utilizing the existing powerhouse, because of the need for a deep setting with such a high head. In the event a completely new powerhouse would be considered then it might be applicable to consider our A CAT type turbines.

We trust this budget offer is of service to KGS in performing your Mayo A GS, Redevelopment Study. We'd appreciate if KGS could keep us abreast of developments of your study to YEC.

Subject: RE: YEC / Mayo A GS / KGS - Redevelopment Study / Francis Turbine+Generator Budget Price Request

Hi Gary,

Here are a few drawings for the Mayo A Powerhouse and one of the site. Feel free to explore other options, but do not feel obliged to "optimize" at this stage. The deadlines are quite short so it doesn't leave much time.

I did not look at this in detail, but I would have thought that a Kaplan or your CAT turbines would have needed a much deeper setting than the existing substructure would allow. I strongly suspect that a francis machine will win out, but I have been wrong before.

Best regards,
Joel

Hi Joel,

We'd appreciate obtaining some of the existing Mayo A powerhouse drawings as we'd like to explore the possibility of other turbine types such as Kaplan or our Compact Axial Turbines (CAT).

Cheers,
Gary

Hi Joel,

Thank-you for reaching out to Andritz Hydro regarding your Mayo A Redevelopment Study.

We'll endeavour to provide you with a budgetary estimate for a new vertical Francis turbine and generator for the Mayo A project. As you mentioned a horizontal Francis turbine & generator perhaps could be considered if we had more details regarding existing powerhouse.

I look forward meeting you during my next trip to Winnipeg or perhaps if you are coming thru / to Vancouver.

Kind regards,
Gary

Subject: Mayo A - New unit pricing

Hi Gary,

As we discussed on the phone yesterday, I would like to get some pricing on a new for the Mayo A

facility at Yukon Energy. We are currently conducting a study to help YEC determine what to do with the facility (Replace, refurbish, remove, etc.). For various reasons, we are looking at removing the two existing units and installing a single unit.

Also, we have a very short timeline for this work, therefore, I would not have time for you to prepare a very detailed estimate, but any opinion on pricing that you could provide in the next two weeks would be very helpful.

The details of the installation is:

Arrangement: Vertical Francis. We could consider a horizontal arrangement, but that would require extensive concrete changes and I think it would be cost prohibitive.
Gross Head: 36.8 metres
Net Head: 34.6 metres
Max Q: 7.6 cms
Setting (centerline of distributor): 0.76 metres above TWL
Inertia constant (H): minimum of 2
All ancillary equipment (switchgear, transformers, cabling, etc.) will be replaced, therefore, use whatever generator voltage is optimal.
There is a surge chamber a short distance from the powerhouse. Existing water starting time is on the order of 1 second (assuming that both units react in tandem).

I mention the setting above as the hope is to reuse the same powerhouse substructure for both the "Replace" and the "Refurb" options. A report I have from about 15 years ago lists the spiral case as being in poor condition, so for this stage of the project, we will assume that the spiral case, stay ring, and discharge ring all need to be replaced.

If possible, I would be interested in pricing for a complete package, including:

- Turbine
- Generator
- TIV
- Governor/HPU
- Unit P&C

If certain items are not available, just let me know.

Best regards,
Joel Lambert, P.Eng.
Senior Mechanical Engineer
KGS Group
865 Waverley Street
Winnipeg, Manitoba, R3T 5P4

MAYO HYDRO DETAILED DIRECT COSTS

APPENDIX C: MAYO A DETAILED DIRECT COSTS
KGS PROJECT: 16-1404-002
MAYO HYDRO (MH0) FUTURE FACILITY OPTIONS
CONCEPT DESIGN REPORT
FINAL – REV 0

ITEMS	Unit	Unit Cost (2016 $)	OPTION 1: Replace		OPTION 2: Refurbish		OPTION 3: Greenfield		Option 4: Make Safe	
			Quantity	Cost (2016 $)	Quantity	Cost (2016 $)	Quantity	Cost (2016 $)	Quantity	Cost (2016 $)
SITEWORK				**$120,000**		**$120,000**		**$60,000**		**$60,000**
Clearing	-	-		-		-		-		-
- Misc.	ha	$20,000	0	$0	0	$0	0	$0	0	$0
Dewatering Allowance	months	$15,000	4	$60,000	4	$60,000	4	$60,000	4	$60,000
Access road maintenance	months	$5,000	12	$60,000	12	$60,000	0	$0	0	$0
SLOPE STABILIZATION				**$1,897,000**		**$1,897,000**		**$0**		**$0**
Powerhouse/Surge Slope										
- Phase 1: Mapping/Survey/Assessment	LS	$80,000	1	$80,000	1	$80,000	0	$0	0	$0
- Phase 2: Bench cut/ Flatten Top Slope / New Rock Support	LS	$1,700,000	1	$1,700,000	1	$1,700,000	0	$0	0	$0
Tailrace										
- Gabion Basket Repair	LS	$80,000	1	$80,000	1	$80,000	0	$0	0	$0
Access Road Alignment										
- Repair of the shoulder area where gully has formed near the sub-station	LS	$12,000	1	$12,000	1	$12,000	0	$0	0	$0
- Surface grading and minor granular fill placement	LS	$25,000	1	$25,000	1	$25,000	0	$0	0	$0
DECOMISSIONING AND DEMOLITION				**$799,000**		**$497,000**		**$1,040,000**		**$290,000**
Demo Mobilization/Demobilization	LS	$150,000	1	$150,000	1	$150,000	1	$150,000	0	$0
Powerhouse Superstructure Removal	LS	$250,000	1	$250,000	0	$0	1	$250,000	0	$0
Surge Tank Removal (includes improving access)	LS	$300,000	1	$300,000	1	$300,000	1	$300,000	0	$0
TG and Assoicated Equipment Removal	per unit	$60,000	2	$120,000	2	$120,000	2	$120,000	0	$0
Selected Concrete Demolition	m^3	$3,200	20	$64,000	10	$32,000	0	$0	0	$0
Blanking Plate	LS	$5,000	1	$5,000	1	$5,000	0	$0	0	$0
Plug Tunnel										
- Rock Excavation (from tunnel)	m^3	$1,000	0	$0	0	$0	10	$10,000	10	$10,000
- Rock Support	m^2	$260	0	$0	0	$0	25	$7,000	25	$7,000
- Concrete	m^3	$3,300	0	$0	0	$0	25	$83,000	25	$83,000
Backfill Powerhouse and Tailrace	m^3	$100	0	$0	0	$0	2000	$200,000	1500	$150,000
Secure Powerhouse (remove ladders, weld hatches)	LS	$10,000	0	$0	0	$0	0	$0	1	$10,000
Block Powerhouse Road and Signage	LS	$10,000	0	$0	0	$0	1	$10,000	1	$10,000
Hazardous Materials Disposal Allowance	LS	$10,000	6	$60,000	4	$40,000	6	$60,000	2	$20,000
REHABILITATION				**$1,014,000**		**$1,559,000**		**$0**		**$20,000**
New Roofing	LS	$106,000	0	$0	1	$106,000	0	$0	0	$0
Modernize Crane (allowance)	LS	$50,000	0	$0	1	$50,000	0	$0	0	$0
Concrete work for Generator / OWS Install	m^3	$3,300	40	$132,000	20	$66,000	0	$0	0	$0
Seismic Improvements										
- Anchoring Design and Install Allowance	LS	$800,000	1	$800,000	1	$800,000	0	$0	0	$0
- Bracing Design and Install Allowance	LS	$175,000	0	$0	1	$175,000	0	$0	0	$0
Lean Concrete Infill	m^3	$1,000	18	$18,000	18	$18,000	0	$0	0	$0
Asbestos Encapsulation (roof)	LS	$20,000	0	$0	1	$20,000	0	$0	1	$20,000
New Overhead Door	LS	$63,000	0	$0	1	$63,000	0	$0	0	$0
Concrete Remediation Allowance	LS	$53,000	1	$53,000	1	$53,000	0	$0	0	$0
Insulation Upgrade	LS	$160,000	0	$0	1	$160,000	0	$0	0	$0
Diving Inspection (Draft Tube Concrete / Guides)	LS	$11,000	1	$11,000	1	$11,000	0	$0	0	$0
Additional fall restraint measures	LS	$11,000	0	$0	1	$11,000	0	$0	0	$0
Repair Flashing, weather stripping, wall penetrations	LS	$10,625	0	$0	1	$11,000	0	$0	0	$0
Repoint Block Walls	LS	$15,000	0	$0	1	$15,000	0	$0	0	$0
NEW STRUCTURES				**$1,062,000**		**$266,000**		**$0**		**$0**
Powerhouse										
- Superstructure steel (based off building volume)	m^3	$120	1,450	$174,000	0	$0	0	$0	0	$0
- New Powerhouse Crane	LS	$100,000	1	$100,000	0	$0	0	$0	0	$0
- New Monorail Crane for Draft Tube Gates	LS	$30,000	1	$30,000	0	$0	0	$0	0	$0
- Steel Cladding	m^2	$450	670	$302,000	0	$0	0	$0	0	$0
- Architectural Finish	LS	$200,000	1	$200,000	0	$0	0	$0	0	$0
- Control Room	LS	$10,000	0	$0	1	$10,000	0	$0	0	$0
- Tailrace steel deck w/ guard rail	LS	$11,000	1	$11,000	1	$11,000	0	$0	0	$0
Surge Tank										
- Superstructure steel (based off tank volume)	m^3	$120	500	$60,000	500	$60,000	0	$0	0	$0
- Steel Cladding	m^2	$450	350	$158,000	350	$158,000	0	$0	0	$0
- Mechanical and Electrical	LS	$26,500	1	$27,000	1	$27,000	0	$0	0	$0
TURBINE AND GENERATOR				**$4,416,000**		**$3,142,000**		**$0**		**$0**
New Turbine, generator, governor, switchgear, DC system, SST (supply)	per unit	$3,550,000	1	$3,550,000		$0	0	$0	0	$0
New Turbine, generator, governor, switchgear, DC system, SST (Install)	per unit	$600,000	1	$600,000		$0	0	$0	0	$0
Refurbish Turbine	per unit	$492,000		$0	1	$492,000	0	$0	0	$0
New Generator (Includes Excitation and Install)	per unit	$2,100,000		$0	1	$2,100,000	0	$0	0	$0
New Turbine Inlet Valve (TIV)	per unit	$250,000	1	$250,000	1	$250,000	0	$0	0	$0
New Governor	Each	$209,000		$0	1	$209,000	0	$0	0	$0
Cooling Water Sediment Separator and Replace Shaft Seal	Each	$15,938	1	$16,000	1	$16,000	0	$0	0	$0
Sandblast, Inspect, Paint Stay Ring and Spiral Case	Each	$74,200		$0	1	$75,000	0	$0	0	$0
ELECTRICAL & MECHANICAL BALANCE OF PLANT				**$3,976,000**		**$4,389,000**		**$575,000**		**$575,000**
Mechanical Balance of Plant				$308,000		$327,000		$0		$0
Electrical Balance of Plant				$3,388,000		$3,782,000		$575,000		$575,000
TOTAL DIRECTS				**$13,284,000**		**$11,870,000**		**$1,675,000**		**$945,000**

APPENDIX D

ECONOMIC ASSESSMENTS

APPENDIX D: OPTION 1 ECONOMIC ASSESSMENT - NEW POWERHOUSE
KGS PROJECT: 16-1404-002
MAYO HYDRO (MH0) FUTURE - FACILITY OPTIONS - CONCEPT DESIGN REPORT - REV B

Assumptions:			
1	Capacity	2.3	MW
2	Annual Capacity Factor		
3	Annual Energy Production	10.43	GW.h
4	Annual Fuel Costs per MW.h	$0.00	
5	Annual O and M Costs per MW.h	$7.10	(Reference Project: Pehonan Estimated costs)
6	Annual CAPEX Costs per MW.h	$1.15	(Reference Project: Tazi Twé Estimated costs)
7	Capacity Cost	32,000	x1000$
8	Principal Payment	492	x1000$ (Using even principle payments method)
9	Project Life	65	Years
10	Nominal Interest Rate	5.45%	(From YEC)
11	Escalation Rate	2.0%	(From YEC)

Result Summary			
1	Total Energy Production	205,300	MW.h
2	Total Loan Payments	31,762	x1000$
3	Total Operating Cost (Fuel & O & M)	2,073	x1000$
4	Total CAPEX Cost (major maintaince)	335	x1000$
5	Total Cost	34,170	x1000$
6	Levelized Cost	16.64	Cents/KW.h
		166.44	Dollars/MW.h

Calculation Details

Year	Energy Production (MW.h)		Unpaid Balance	Loan Payments ($000) Current Value		Fuel & O & M ($000)	CAPEX ($000)	Total ($000)	
	Current Value	Present Value	Current Value	Principal	Interest	Current $ Value	Current $ Value	Current $ Value	Present $ Value

APPENDIX D: OPTION 3 AND 4 ECONOMIC ASSESSMENT - DEMOLITION AND RETURN TO GREENFIELD/ABANDON IN SITU
KGS PROJECT: 16-1404-002
MAYO HYDRO (MH0) FUTURE FACILITY OPTIONS
CONCEPT DESIGN REPORT
FINAL – REV 0

Assumptions:			
1	Capacity	2.3	MW
2	Annual Energy Production	7.18	GW.h
3	Annual Fuel Costs per MW.h	$0.00	
4	Annual O and M Costs per MW.h	$7.10	(Reference Project: Pehonan Estimated costs)
5	Annual CAPEX Costs per MW.h	$0.00	
6	Project Life	10	Years
7	Nominal Interest Rate	0	(From YEC)
8	Escalation Rate	0	(From YEC)

Option 3 - Demolition and Return to Greenfield

Result Summary			
1	Total Energy Production	57,278	MW.h
2	Total Capital Cost	4,000	x1000$
3	Total Operating Cost (Fuel & O & M)	458	x1000$
4	Total CAPEX Cost (major maintaince)	0	x1000$
5	Total Cost	4,458	x1000$

Option 4 - Abandon in Situ

Result Summary			
1	Total Energy Production	57,278	MW.h
2	Total Capital Cost	2,300	x1000$
3	Total Operating Cost (Fuel & O & M)	458	x1000$
4	Total CAPEX Cost (major maintaince)	0	x1000$
5	Total Cost	2,758	x1000$

Calculation Details

Year	Energy Production (MW.h)		Capital ($000)		Operating ($000) (Fuel & O & M)		CAPEX ($000) (Major Maintaince)		Total ($000)

APPENDIX E

EMAIL: AISHIHIK RERATE STUDY (APRIL 13, 2015)

The following correspondence from Yukon Energy Corporation was used as a basis for a Present Value analysis of the Mayo A Future Options. The attached email contains assumptions provided by Yukon Energy Corporation to analyze the benefit of an increase in capacity ($/MW), and the benefit of an increase in annual energy ($/GWh). The information was provided for the Aishihik Rerate and Assessment Project and is assumed to be applicable to the analysis of Mayo A.

Attachments: TAB-2012-05-08-Business Case Templates.xlsm

Joel,
You should assume the following:
1/ benefit of an increase in capacity - $2.5M per MW based on avoided capital cost of new natural gas generation.
2/ benefit of an increase an annual energy - $200,000 per GWh based on avoided operating (i.e. variable cost) cost of natural gas.

It would be worthwhile doing some sensitivity analysis based on capacity benefits of between $1M (high speed diesel gensets) and $10M (wind or higher cost new hydro).
Similarly for energy benefit going from $100,000 (best possible natural gas operating cost) to $300,000 (diesel operating cost).

For paybacks longer than 5 years, we use discounted payback – see attached economic spreadsheets – use 5.2% as YEC's discount rate.

Note that both of the larger turbines (AH1 and AH2) at Aishihik have had their generators rewound in the 1990's that would allow a modest increase in capacity to be an option or part of an option (combination of capacity and efficiency gains) with rerunnering.
The units were rewound in different years by different vendors resulting with different ratings on the new insulation. I can't recall the final revised generator ratings. I believe one was increased to about 16 MVA and the other one to about 16.5 MVA from their original 15.5 MVA ratings.

Goran/Lawrence/Bill/Guy – any comments?

Hector,
I am away for a couple weeks starting Monday. I was wondering if could respond to the question below by sending any answer you have to Joel Lambert of KGS. Please copy me so that I can stay in the loop.

Thanks.

Hector,
Would you be able to answer the question below. It pertains to a study being performed on the potential rerunnering of the Aishihik turbines.

Subject: FW: Aishihik rerate study,

Hi Ron,

The original question I sent is below. This is the value that YEC assigns to the additional energy produced by the new runner.

Say for example that the upgrade costs $1,000,000 and that the uprated machine produces an additional 2 GWhr/year. If the value of energy is $300,000 / GWhr, the simple payback would be 3.3 years. The value of energy may depend greatly if it reduces diesel consumption or not. Presumably it will since Aishihik has a lot of storage.

If it helps, we can have a call to discuss further. If so, I would likely include someone else from KGS that has a lot of experience in these matters.

Regards,
Joel

Subject: Aishihik rerate study,

Hi Ron,

What value of energy should we be using in our payback calculations for the Aishihik Rerate Study? Presumably this would be a $/GW-h value.

Knight Piésold CONSULTING

EXECUTIVE SUMMARY

Yukon Energy Corporation (YEC) commissioned Knight Piésold Ltd. (KP) to conduct a desktop review of potential small hydroelectric projects in the Yukon and northern British Columbia. The objectives of the study were to compare technical and economic development criteria and to establish a ranking that provides YEC with the basis for further studies.

This study utilized a four stage screening process to identify the best development options from a list of forty five sites:

- Screen 1: Removal of Redundant Sites and Sites Located in Parks (44 reduced to 40 Sites)
- Screen 2: Removal of Sites with Excessive Transmission Lengths (40 reduced to 23 Sites)
- Screen 3: Unit Cost of Energy Screening (23 reduced to 5 Sites), and
- Screen 4: Focused Assessment of Preferred Options (Top 5 Sites).

The screening process yielded the following results:

- The most attractive (preferred) projects, based on a desktop level assessment of location, project layout, site characteristics, capacity, energy, and cost, are Drury Lake, Finlayson River, Anvil Creek, Tutshi – Windy Arm, and Wolf River.
- The Levelized Cost of Capacity (LCOC) for the preferred sites ranges from $700 to $1,200/kW-yr at the YEC real interest rate of 3.38 percent.
- The Levelized Cost of Energy (LCOE) for the preferred sites ranges from $0.13 to $0.21/kWh at the YEC real interest rate of 3.38 percent.
- Based on a stand-alone assessment of hydropower development and interconnection to the closest existing or proposed transmission line, the most attractive small hydro sites are the Finlayson River, Wolf River, and Tutshi – Windy Arm. Drury Lake and Anvil Creek appear to be more expensive on a cost of energy basis.
- The optimal installed capacities for the Finlayson River, Tutshi – Windy Arm, and Wolf River Projects are likely in the order of double those used in the present study. 20 MW was the upper bound cap for this study based on the purpose set out in the RFP (to evaluate sites of 20 MW or less).
- The Tutshi – Windy Arm Project has the additional benefit of increasing the winter generation at the Yukon Generating Station downstream.
- If the Moon Lake – Tutshi Lake pumped storage project is developed, it may have material synergies with development of the Tutshi – Windy Arm small hydro project.

The optimal small hydro site will depend on a number of factors, including capital costs, desired capacity, development of proposed transmission lines, environmental impacts, and social conditions. Further evaluation of the preferred sites is recommended to improve the understanding of engineering, economic, environmental, and social factors impacting project development. Should such assessment indicate that there are no technical or environmental showstoppers, further evaluation of the sites through pre-feasibility and feasibility studies should be pursued to prove economic viability.

The table below summarizes the key financial and technical attributes for the five preferred sites.

ATTRIBUTES	Drury Creek	Finlayson River	Anvil Creek	Tutshi - Windy Arm	Wolf River
TECHNICAL:					
Installed Capacity (MW)	8.1	17.6	9.8	7.2	20.0
Net Annual Generation (GWh)	31.7	138.9	41.3	56.6	95.6
Mean Annual Discharge (m^3/s)	4.9	16.5	4.1	16.1	40.3
Design Flow - Qd (m^3/s)	9.3	13.3	8.2	15.0	37.7
Gross Head (m)	99	150	135	54	60
Transmission Line Length (km)	1	5	11	1	23
FINANCIAL:					
Estimated Capital Cost	$ 97,250,000	$ 265,990,000	$ 109,210,000	$ 125,400,000	$ 220,170,000
O&M Costs - Fixed ($/yr)	$ 1,945,000	$ 5,320,000	$ 2,184,000	$ 2,508,000	$ 4,403,000
O&M Costs - Variable ($/yr)	$ 158,000	$ 695,000	$ 207,000	$ 283,000	$ 478,000
YEC Rate Scenario (3.38%)					
Levelized Cost of Energy ($/kWh)	$ 0.19	$ 0.12	$ 0.17	$ 0.14	$ 0.14
Levelized Cost of Capacity ($/kW-yr)	$ 700	$ 1,000	$ 700	$ 1,100	$ 700
IPP Rate Scenario (4.61%)					
Levelized Cost of Energy ($/kWh)	$ 0.23	$ 0.14	$ 0.20	$ 0.17	$ 0.17
Levelized Cost of Capacity ($/kW-yr)	$ 900	$ 1,100	$ 800	$ 1,300	$ 800
High Interest Rate Scenario (8.82%)					
Levelized Cost of Energy ($/kWh)	$ 0.24	$ 0.15	$ 0.21	$ 0.18	$ 0.18
Levelized Cost of Capacity ($/kW-yr)	$ 900	$ 1,200	$ 900	$ 1,400	$ 900

1 – GENERAL

1.1 INTRODUCTION

Yukon Energy Corporation (YEC) commissioned Knight Piésold Ltd. (KP) to conduct a desktop review of potential small hydroelectric projects in the Yukon and northern British Columbia. The objectives of the study were to compare technical and economic development criteria and to establish a ranking that provides YEC with the basis to plan further studies on the more favorable sites.

1.2 SCOPE

This study was undertaken in response to a two part Request for Proposals (RFP) issued by YEC, to identify potential pumped-storage sites within a 25 km radius of existing or proposed transmission infrastructure and to review a number of previously identified small hydro resources with capacities of 20 MW or less. The intention was to compare the cost of energy and installed capacity with other potential fossil fuel and renewable options that may be available to YEC, including wind, diesel and natural gas-fired generation.

The requirements for the small hydro study, as stated in the RFP, were:

- Review existing information for the various sites
- Update existing cost estimates
- Update power generation profiles
- Evaluate size of reservoirs and inundation areas for small hydro sites with storage, and
- Evaluate potential hydro sites against financial and technical attributes.

This desktop assessment covered proposed sites and reports dating back more than fifty years. Previous studies have varied in scopes and objectives, and not all existing information was available to KP for this review. No new geotechnical or physical data has been collected, and the assessment does not weigh environmental and societal impacts or the regulatory permitting process, with the exception that projects located in parks have been eliminated due to perceived regulatory barriers. The assessment is high level in nature and relies upon data, mapping, and project information from various sources with variable quality.

1.3 METHODOLOGY

This study utilized a four stage screening process to determine the preferred run of river and storage hydroelectric projects within the scope of this study:

- Screen 1: Removal of Redundant Sites and Sites Located in Parks
- Screen 2: Removal of Sites with Excessive Transmission Lengths and Associated Costs
- Screen 3: Unit Cost of Energy Screening, and
- Screen 4: Focused Assessment of Preferred Options (Top 5 Sites).

Each screening stage is detailed in subsequent sections of this report. The process has been developed to eliminate sites that are indeterminate, fundamentally flawed, and comparatively expensive or technically unviable, with the overriding objective of providing a focus for future studies on the better development options.

1.4 OVERVIEW OF HYDROELEC POWER GENERATION

Conventional hydroelectric power stations utilize the water in a river and the elevation drop in its channel (often at rapids and waterfalls) to generate electrical energy, which is transmitted to domestic and/or industrial consumers using powerlines. Hydropower is a renewable source of energy with a low carbon footprint. It is a long standing, proven technology that is prevalent worldwide and particularly in regions with high annual precipitation and mountainous terrain.

Conventional hydroelectric power projects can be subdivided into two general types:

- Run of River Hydro

Run of river hydroelectric plants utilize the available flow in a river at any given time, with minimal upstream headpond/reservoir storage. Water is typically diverted at a weir into a water conveyance system (canal, tunnel, and/or penstock), to a powerhouse, and then back into the natural river channel. Very little alteration is made to the natural hydrograph downstream of a run of river project.

Electric output is a function of short term (hourly or daily) river discharge, varying daily and seasonally in parallel with the river discharge hydrograph. In the Yukon, run of river generating potential occurs predominantly from May until August, during spring freshet and summer glacial melt.

- Storage Hydro

Storage hydroelectric plants utilize an upstream lake or reservoir to store water and to control the outflow and energy output on a daily, monthly, or seasonal basis. This allows for load shaping and winter generation, a time at which run of river generation is very low.

Storage hydropower configurations vary, from lake/reservoir controlled run of river style projects (with configurations as described above), to large dams with built in generating units where all elevation head is derived from the dam itself, to a combination of both.

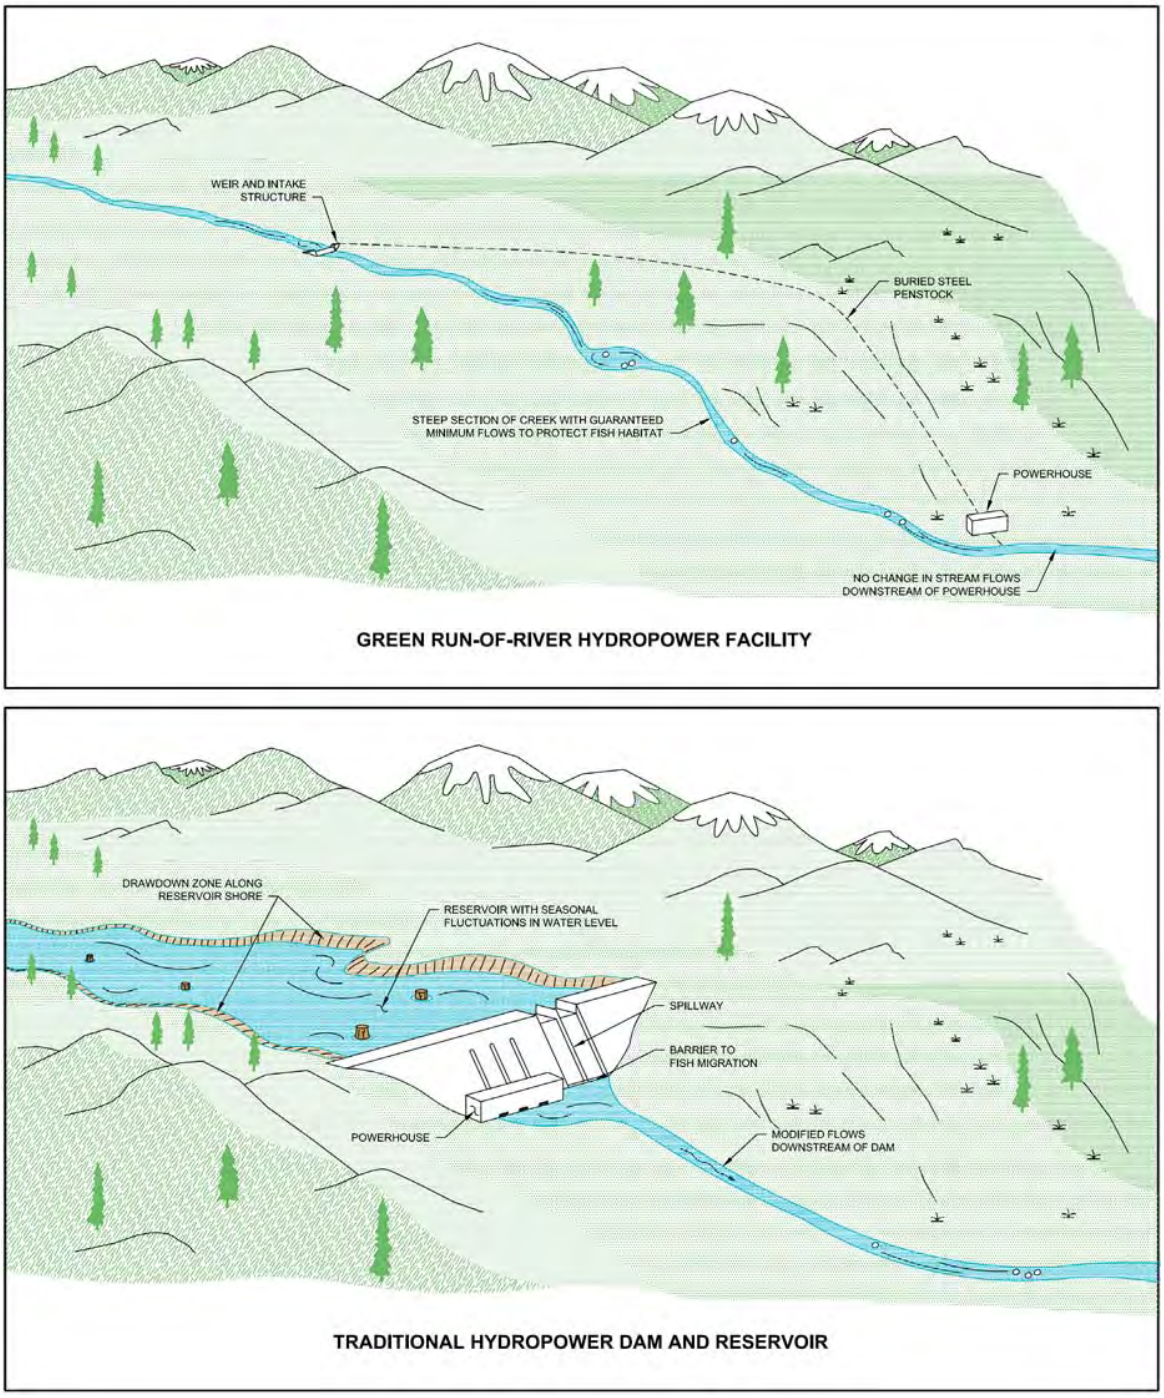

Figure 1.1 Conceptual Hydropower Project Layouts

1.5 YUKON'S ELECTRICITY SYSTEM

1.5.1 Current Capacity

YEC currently owns and operates approximately 131 MW of installed capacity, consisting of 92 MW of hydro, 0.8 MW of wind, and 37.8 MW of thermal (diesel and natural gas). Yukon Electrical Company Ltd. (YECL), owned by ATCO, supplies approximately 1.3 MW of hydroelectricity and 6.8 MW of diesel power.

YEC's hydroelectric generating capacity is comprised of:

- 37 MW Aishihik Generating Station, 150 km west of Whitehorse
- 15 MW Mayo Generating Station, 450 km north of Whitehorse
- 40 MW Whitehorse Generating Station, located on the Yukon River at Whitehorse, and
- 1.3 MW Fish Lake Generating Station (YECL).

1.5.2 Power Grid

The Yukon power grid is shown on Figure 1.2 and comprises the following major components:

- 138 kV Whitehorse / Aishihik / Faro (WAF) grid
- 69 kV Mayo / Dawson transmission line, and
- 138 kV Carmacks / Stewart transmission line, connecting the WAF grid and the Mayo / Dawson transmission line.

The Yukon electricity network is an isolated grid, with no connection to other jurisdictions (BC, Alaska or Northwest Territory). The Yukon grid currently services all Yukon communities except for Watson Lake, Burwash Landing/Destruction Bay, Beaver Creek, and Old Crow [YDC, 2015].

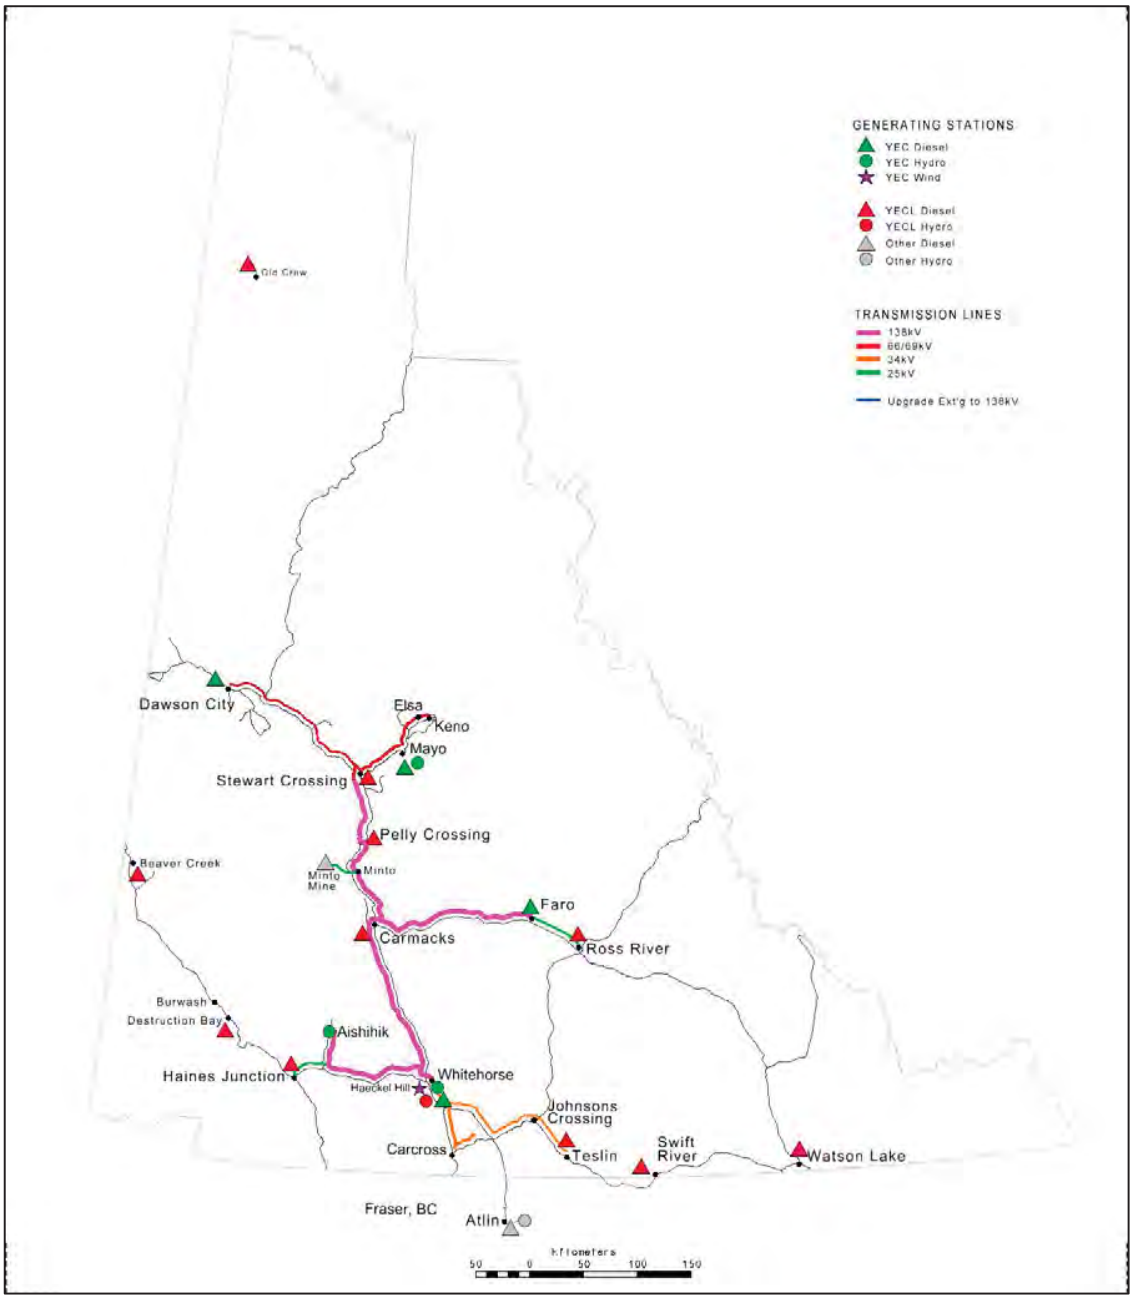

Figure 1.2 Yukon Electricity Network (YEC, 2016)

1.5.3 Proposed Transmission Lines

The following major transmission line extensions have also been considered by YEC:

- Aishihik to Destruction Bay
- Skagway (AK) to Whitehorse
- Atlin (BC) to Whitehorse, and
- Faro to Watson Lake, to connect Watson Lake to the Yukon grid.

1.6 INITIAL SITE LIST

In the RFP, forty nine projects were listed for review under the scope of the small hydro study. Upon project award, YEC requested that five sites be removed from the list. Table 1.1 provides a full listing of the forty four projects included in this study, along with their previously considered installed capacities and annual energy outputs as provided by YEC.

1.7 SMALL HYDRO SITE LOCATIONS

Figure 1.3 shows the location of the forty five sites, as well as existing and proposed transmission lines, communities, and existing hydropower plants.

Table 1.1 Initial Site List

2 – INFORMATION REVIEW AND PRELIMINARY SCREENING

2.1 RECONCILIATION OF EXISTING INFORMATION

Many hydro studies have been completed for YEC, Yukon Electrical Company Ltd. (YECL), Yukon Development Corporation (YDC), and other entities in the Yukon, dating back over fifty years. The initial phase of this study was to review these reports and to compile project information.

The level of detail and quality in the available information was highly variable, with some sites having been studied numerous times, and others only having been identified as potential resources. Studies have varied, from desktop studies and high level reconnaissance to site investigations and feasibility designs.

A complete listing of the reports that were reviewed for the small hydro study, either having been provided to KP directly by YEC or found online through public sources, is provided in Section 6. It should be noted that this information was not comprehensive, and a number of historic reports were missing or otherwise unavailable for this study.

2.2 PRELIMINARY EVALUATION – SCREEN 1

The first screen targeted the removal of redundant projects and sites located in national or territorial parks. This level of screening resulted in the elimination of five sites.

2.2.1 Redundant Sites

From the information review, it appears that the site list included the following redundancies:

- Sites 15 and 16: Kluane Canyon – Although recorded with a different installed capacity, both sites are in the same location and represent only one resource potential (regardless, Kluane Canyon is located in a national park and is eliminated in Section 2.2.2).
- Site 23: Middle Canyon (Small) – Documentation revealed that the Lower Canyon on the Frances River (Site 9) is also known as Middle Canyon, and mapping investigations confirmed these sites to be interchangeable.

2.2.2 Sites Located in Parks

A review of project locations identified the following sites to be located in national or territorial parks:

- Sites 15 and 16: Kluane Canyon
- Site 36: Rose Lake to Kusawa Lake, and
- Site 44: Upper and Lower Primrose.

2.2.3 Sites Passing Screen 1

Table 2.1 provides the site list after Screen 1. Thirty nine sites were successful in progressing to the Screen 2 evaluation.

Table 2.1 Sites Passing Screen 1

2.3 TRANSMISSION LINE LENGTH – SCREEN 2

Transmission line length and the associated costs of interconnection, along with access road lengths and costs, are significant factors impacting the viability of hydroelectric project development. With transmission costs estimated in the order of $500,000/km to $1,000,000/km, the economics of small hydro projects can be substantially eroded as transmission distance increases.

For this assessment, transmission lengths exceeding 25 km to an existing or proposed future transmission line were considered to be too great, and these projects were eliminated from further consideration at this time. Future grid expansions may warrant further consideration of sites outside of the 25 km buffer used in this study.

Project clustering may significantly improve the economics of more distant project groupings if they are developed concurrently, and this may render some of the more distant projects viable. However, it is outside the scope of this study to consider project clusters.

2.3.1 Distance to Existing and Proposed Transmission Lines

Table 2.2 provides a summary of the estimated shortest linear length to interconnect to existing and proposed future transmission lines. This table only includes the thirty nine sites passing Screen 1.

Table 2.2 Distance (km) to Existing and Proposed Transmission Lines

Site #	Project	Distance to Existing Transmission	Distance to Proposed Transmission

3 – COST TO BENEFIT ASSESSMENT - SCREEN 3

3.1 GENERAL

The Screen 3 evaluation was based on consideration of capital costs, capacity, and the energy potential of each site. Six run of river and sixteen small hydro with storage sites underwent the following sequence of tasks:

- Hydrology review and assessment
- Review of project layouts
- Energy Modelling
- Indicative cost estimating, and
- Cost to benefit analyses (Unit Cost of Energy, Unit Cost of Capacity).

3.2 HYDROLOGY

A hydrology review was conducted on all sites passing Screen 2. The purpose of this review was to determine the suitability of hydrological values previously developed for various projects, and to develop hydrological estimates for those sites where no historically reported information could be obtained.

3.2.1 Regional Hydrology

Data from a total of forty six Water Survey of Canada (WSC) gauges with catchment areas between 10 km^2 and 7,000 km^2 were reviewed to develop an understanding of regional trends in measured runoff for catchments of varying sizes and regions. The data were used to develop estimates of Mean Annual Discharge (MAD) and Mean Annual Unit Discharge (MAUD) at all project sites that passed Screen 2. The data were also used to produce typical hydrographs to estimate the distribution of flow throughout the year.

3.2.2 Discharge

Table 3.1 provides the estimated MAUD and MAD values for all sites passing Screen 2. Where no previous hydrology information could be obtained, KP developed estimates on the basis of the MAUD values from the WSC gauges in the region. These gauges are dispersed across the majority of the Yukon and provide a reasonable means of assessing hydrologic patterns throughout the region. Some of the basic trends evident in the data are as follows:

- MAUD appears to decrease in a south-westerly direction along the border between the Yukon and the Northwest Territories, with lower unit discharge values evident in the dry, lower relief interior zones versus the mountainous terrain along the eastern provincial border.
- In the south-western corner of the Yukon, MAUD appears to be relatively high due to the onshore movement of moist maritime air from the Pacific Coast. The effects of this moisture influx extends slightly beyond the Coastal Mountain Range, and then drops off markedly due to a ‘precipitation shadow’ effect that results in a progressive reduction in MAUD moving east.

MAUD values were selected for the project sites on the basis of proximity and similarity of catchment size to the WSC stations. Commonly, there are two to three local gauge stations that provide a basis for estimating unit discharge. Where applicable, consideration was also given to the MAUD values reported for various project sites.

Additional regional considerations when determining a site's MAUD included:

- Glaciers in a watershed, which generally increase MAUD due to melt during the warm summer months
- Lakes in a watershed, which generally decrease MAUD due to greater evaporation, and
- The local relief, with higher elevation watersheds generally having higher precipitation and correspondingly higher MAUD.

Table 3.1 Unit Runoff and Discharge

Site #	Project	Catchment Area (km^2)	MAUD, Reported ($L/s/km^2$)	MAUD, KP Estimate ($L/s/km^2$)	MAD (m^3/s)
1	Anvil Creek	513		8.0	4.1
3	Campbell Creek	611		9.0	5.5
5	Drury	550	9.0		4.9
8	Finlayson	1,542	10.7		16.5
9	Frances River (Lower Canyon)	12,969		7.5	97.3
11	Homan Lake	150		12.0	1.8
12	Hoole River	738		9.0	6.6
14	Kathleen Canyon	904		15.5	14.0
17	Lapie	1,293	10.1		13.1
22	Mica Creek	543		4.5	2.4
25	North Fork Klondike River	1,100	12.6		13.9
26	North McQuesten	2,010		7.5	15.1
27	Orchay	390	7.5		2.9

29	Pleasant Cr with Rogue	3,272		9.0	29.4
33	Reid Lakes and Lake Creek	1,024	5.4		5.5
34	Rock Creek	424	12.6		5.3
39	Squanga Creek	838	3.6		3.0
43	Tutshi-Windy Arm	992	16.2		16.1
47	Watson Lake & McDonald	330	3.4		1.1
48	Watson River	97		9.0	0.9
49	Wolf River	3,500		11.5	40.3

3.2.3 Hydrographs

Using the available WSC gauge data, hydrographs were generated and grouped according to watershed size in an effort to determine if any consistent and pronounced differences in annual hydrograph shape could be related to catchment size in the Yukon. The catchment sizes of the forty six WSC gauges that were considered range from 10 km^2 to 7,000 km^2. A variety of size groupings were plotted for comparison purposes and it appeared that there are two basic groups of hydrographs of similar shape: those for areas less than 500 km^2 and those for areas greater than 500 km^2. There does not appear to be sufficient variation in hydrograph shape to merit further division by basin size. The two basic hydrograph shapes, which were delineated according to the average monthly values for the indicated basin sizes, are shown on Figure 3.1.

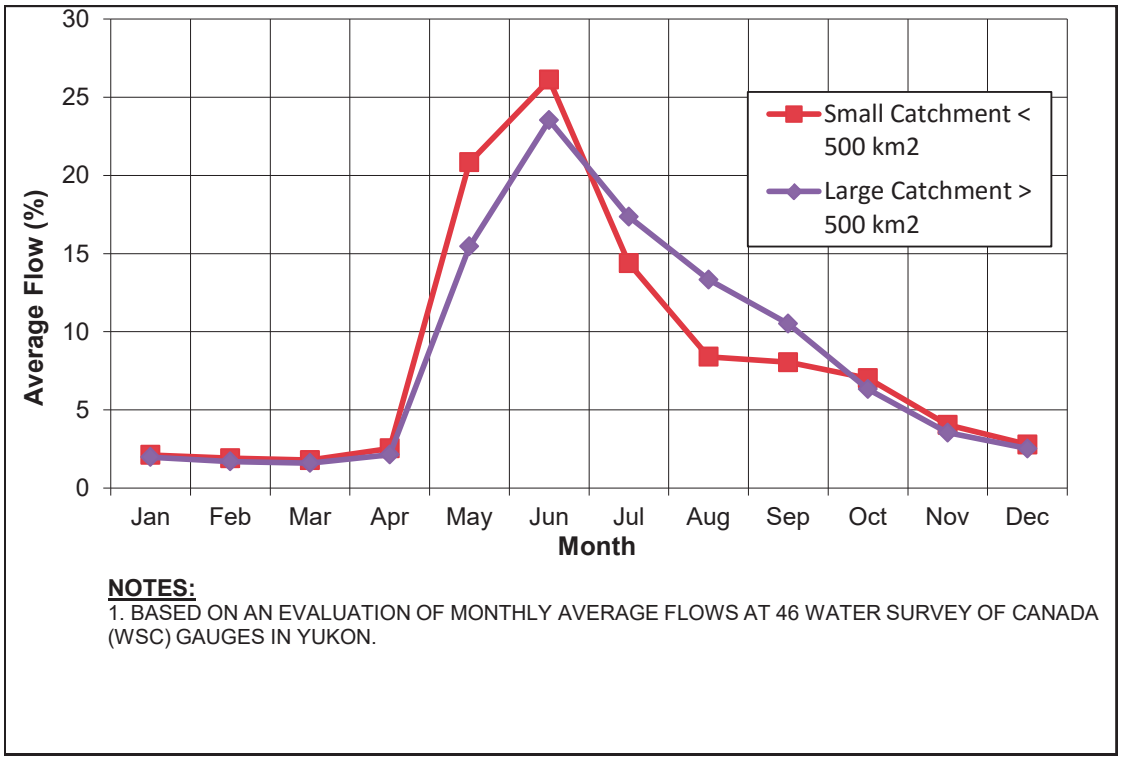

Figure 3.1 Typical Hydrograph

For relatively small basins, the peak freshet flow period is more pronounced but of shorter duration than for large basins, which tend to sustain flows at higher levels through the summer months. This pattern is consistent with the tighter elevation range characteristic of smaller basins (with snowmelt occurring more rapidly and more consistently throughout the basin) and the higher likelihood of glacier content in the large basins (which supply late summer flows through melting).

3.2.4 Dependable Capacity (Flow)

Dependable Capacity is defined by BC Hydro to be the maximum capacity that a generating station can reliably produce when required, with an 85 percent level of confidence and assuming that all generating units are in service (BC Hydro, 2005). In the context of hydropower plants, capacity synonymous with availabile flow and storage upstream of the intake.

In line with the 85 percent confidence level described above, Dependable Flow is herein defined to be the monthly flow that will be available for a given month in 85 percent of calendar years (P85). P85 values will vary between different drainages and river systems based on site specific climate and hydrology conditions.

0 22APR16 ISSUED FOR INFORMATION SBR JGC SHM
REV DATE DESCRIPTION PREP'D CHK'D APP'D

The hydrological estimates described in Sections 3.2.1 – 3.2.3 screening level assessments based on regional climatic and hydrographic trends. The WSC gauge data that was reviewed represents average flow data (P50 conditions). Long term site specific data was not available and 'true' site specific percentile values, such as P85, were not determined. However to support YEC's assessment of potential small hydro resources relative other generation technologies, KP assessed select regional data to provide indicative P85 values for each project as follows.

Based on the assumption that annual discharge follows a normal distribution (example shown on Figure 3.2), the P85 Dependable Flow will occur approximately one standard deviation below the P50 level (-1σ). The size of the standard deviation is dependent on the spread of the data for any particular river system, which is influenced by catchment area, elevation, and regional climatic trends.

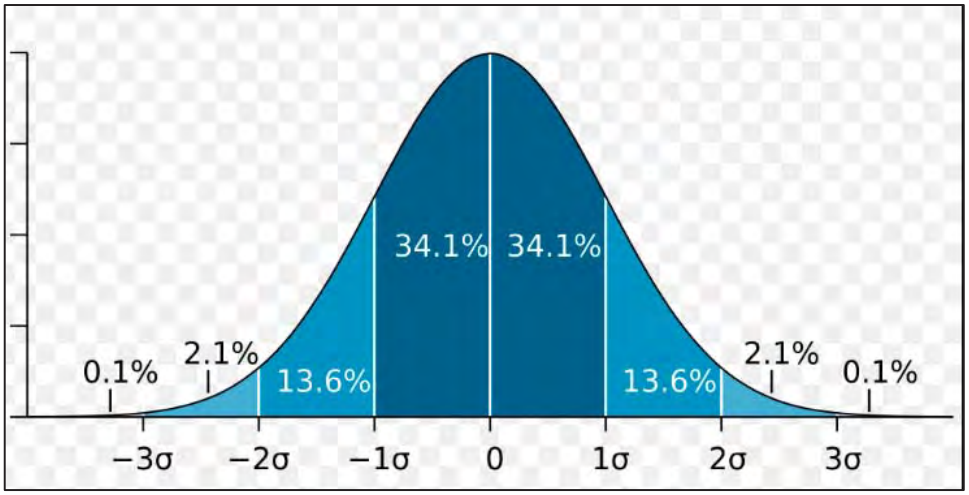

Figure 3.2 Normal Distribution

In order to provide YEC with a rough approximation of the dependable capacity for the small hydro sites, KP has reviewed the standard deviation and coefficient of variation observed in a small sample of long term WSC gauge data. This review indicates that the coefficient of variation is higher during the freshet and summer period than it is during the shoulder seasons and winter months. It also indicates that the coefficient of variation for smaller catchment areas is higher than that for larger catchments. Both of these observations align with expectation.

For the small hydro sites, and especially for sites that operate on a run of river basis, the Dependable Capacity will vary significantly from month to month, and during winter, dependable capacity is close to zero in some cases. The estimated indicative monthly dependable capacity and energy output values are included in Appendix A.

3.3 RUN OF RIVER PROJECTS

3.3.1 Design Basis

Run of river hydroelectric plants utilize the available flow in a river at any given time, with minimal headpond/reservoir storage, and electric output is a function of short term (hourly or daily) yield. The optimal installed capacity depends on numerous factors, including constructability, environmental requirements, and the need for and ability to sell seasonal power.

As illustrated in Figure 3.1, the majority of the electric generating potential for run of river projects in the Yukon occurs between May and August, from the onset of the spring freshet through summer as snow and glacial melt feed the river systems. Winter flows tend to be very low, as surface water is frozen and rivers are fed predominantly from lakes and groundwater sources. As such, run of river

projects do not offer good base load and are more beneficial for peak energy production in the spring and summer seasons.

Assuming that all energy output can be utilized, the optimal design flow for a run of river plant tends to be in the order of 2 times the Mean Annual Discharge (MAD). If peak power during the spring and summer is not desired and base load is more highly valued, a lower design flow and a correspondingly higher capacity factor should be targeted, such as 0.5 times MAD.

For the purpose of assessing and fairly comparing the run of river projects, it is assumed that all energy output can be utilized and, accordingly, design flow has been set at 2 times MAD. The exception is Site 49 – Wolf River, which is considered with a lower design flow to not exceed the 20 MW upper limit for this small hydro assessment. It appears that a much higher design flow for this site is an optimization worth considering in a future study.

3.3.2 Energy Models

Energy models were developed for the six run of river hydro sites evaluated in Screen 3. The energy models used the monthly hydrology data developed for this study and a number of assumptions:

- Instream Flow Requirements (IFR) equal to 5 percent of MAD.
- 10 percent head losses through intake and conveyance to the turbine, at maximum design flow, and a linear decrease in head loss with decreasing flow.
- Average efficiency of 90 percent from turbine to the point of sale, to account for turbine – generator losses, transformer losses, transmission losses, station usage, and outages.
- Turbine types auto selected for optimal performance according to design flow and head.

3.3.3 Indicative Costs

Basic indicative cost estimates were developed for each project using KP's in-house experience and cost estimating database for projects with comparable characteristics. Where the level of detail in the existing design was insufficient to permit an accurate assessment of site specific conditions, facility layouts, sizes, and costs were scaled according to head, flow, installed capacity, and other key project costing metrics. Cost estimates included the following major components:

- Task 100: Mobilization, Demobilization, Insurance, Bonds, Overheads, and Contractor's Profits
- Task 200: Access and Site Preparation
- Task 300: Intake, Forebay, Headrace, and Tailrace
- Task 400: Water Conveyance System
- Task 500: Powerhouse and Ancillary Services
- Task 600: Power Generation Equipment (Water to Wire)
- Task 700: Switchyard, Transmission, and Interconnection
- Task 800: Dam(s) and Reservoir(s)
- Engineering, Procurement, and Construction Management (EPCM): 8 %, and
- Contingency: 30 %.

3.3.4 Cost to Benefit Analysis

The fair evaluation of alternative hydropower development options requires an assessment of project costs and benefits. The Screen 3 assessment was based on the comparative values for two financial metrics, the Unit Cost of Capacity and the Unit Cost of Energy:

- ***Unit Cost of Capacity = Net Present Cost at Commissioning ($) / Installed Capacity (MW)***
  This unit of measurement can be useful for gauging project costs in relation to other proposed or existing power projects. For instance, YEC's Mayo B Hydroelectric Project was constructed for a cost of roughly $120 million, and added 10 MW of power to the Yukon's energy system (YEC, 2016), equating to a unit capacity cost of roughly $12 million/MW. The unit capacity cost of the better options in this study are in this order of magnitude, providing some confidence in the underlying quantities and unit rates that have been assumed.
  While unit capacity cost does have its usefulness, it is not a good measure of the overall project value since capacity is not directly correlated to energy production and revenues.
- ***Unit Cost of Energy = Net Present Cost at Commissioning ($) / Average Annual Energy Production (GWh/yr).***
  Unit energy cost is a useful financial metric for the determination of a project's value and relative ranking of sites with different installed capacities and hydrology characteristics. Provided that all energy can be sold, unit energy cost is directly correlated with revenue. The Screen 3 assessment and selection of preferred sites was based on the unit cost of energy.
  Unit energy costs in the order of $2.5 million/GWh/yr or less are considered to be favorable development costs and projects with this value may warrant further consideration.

Table 3.2 provides a summary of the major design outputs for the run of river projects, along with the estimated (indicative) costs and cost to benefit metrics. The values presented are based on a net present cost at commissioning that assumes a construction duration of 3 years and a real interest cost of 4.61 percent (IPP development rate provided by YEC).

Table 3.2 Run of River Screen 3 Summary Table

Site #	Name	Design Flow	Gross Head	Installed Capacity	Net Avg. Energy	Net Present Cost	Unit Capacity Cost	Unit Energy Cost
		m^3/s	m	MW	GWh/yr		$/MW	$/GWh/yr
14	Kathleen	28.0	15.0	3.7	12.6	$ 61,323,000	$ 16,537,000	$ 4,857,000
17	Lapie	26.2	36.0	8.3	29.6	$ 92,078,000	$ 11,057,000	$ 3,116,000
25	North Fork Klondike	27.8	69.0	16.9	60.0	$ 180,170,000	$ 10,638,000	$ 3,004,000
34	Rock Creek	10.6	40.0	3.7	12.6	$ 97,531,000	$ 26,053,000	$ 7,722,000
39	Squanga Creek	6.0	54.0	2.9	10.2	$ 30,248,000	$ 10,574,000	$ 2,980,000
49	Wolf River	28.3	80.0	20.0	104.9	$ 271,023,000	$ 13,559,000	$ 2,584,000

NOTES:
1. Net Average Energy is based on P50 hydrology estimates as described in Section 3.2.
2. Estimated monthly energy output values are provided in Appendix A.
3. Net Present Cost assumes a three year construction period and an interest rate of 4.61 percent.

3.4 SMALL HYDRO WITH STORAGE PROJECTS

3.4.1 Design Basis

Storage hydroelectric plants utilize an upstream lake or reservoir to store water and to control the outflow and energy output on a daily, monthly, or seasonal basis. This allows for load shaping and winter generation, provided the reservoir has sufficient storage in relation to MAD and the design flow of the plant. Storage capacity is of particular value during the low flow fall, winter, and early spring months, when run of river output is low and reliance on costly diesel power generation is high.

The available storage in an upstream reservoir is a significant factor to be considered in the sizing of storage hydro plants. While this study does not specifically address environmental considerations, lake level changes may impact the environment and private land, and technical constraints may further hinder the construction of high dams for large lake raises. The design basis for the storage hydro plants considered in this assessment was discussed with YEC during this study and was agreed as follows:

- For sites where storage is possible on a natural lake or lakes, lake level increases have been limited to 5 m.
- Where no upstream lake is available and/or where minimal viable elevation drop has been identified, a dam sized to store 20 m of water has been provided for both water storage and head (Site 9 – Frances River, Site 12 – Hoole River, Site 26 – North McQuesten River).

The selection of the optimal design flow and the corresponding installed capacity is a function of the reservoir storage capacity and MAD. The general approach used for the selection of design flow is:

- Where the available lake storage capacity exceeds the annual yield of a river system, reservoir size was reduced to roughly the volume of annual average yield, and the annualized flow through the plant was adjusted to match the man annual yield (flow approaches MAD, less IFR releases).
- Where the available lake storage capacity is substantially less than the annual yield of a river system, the design flow was set at 2 times MAD and the plant was assumed to operate as a run of river style project when the reservoir is near full, with the added benefit of an improved capacity factor due to reservoir draw down in the low flow months.

3.4.2 Reservoir Flooded Areas

Table 3.3 provides a summary of the reservoir storage characteristics for all of the small hydro with storage sites evaluated in Screen 3. These reservoir characteristics coupled with the hydrology conditions (Section 3.2) are the basis for the Screen 3 energy and cost estimating for the small hydro with storage sites.

For each of the options listed in Table 3.3, the area upstream of the dam that will be inundated when the dam is filled has been estimated using the available topography and a standard depth – area interpolation. Flooded areas are calculated as the estimated new lake area minus the natural lake area. These are best guess values based on the coarse mapping interval that was available.

Table 3.3 Storage Hydro Reservoir Characteristics

Site #	Project	Natural Lake Area (km^2)	Lake Level Increase (m)	New Lake Area (km^2)	Estimated Available Storage (m^3)
1	Anvil Creek	5.3	5.0	5.9	27,875,000
3	Campbell Creek	2.5	5.0	3.2	14,250,000
5	Drury Lake	26.0	5.0	27.9	134,750,000
8	Finlayson (Wolverine Lake)	8.2	5.0	10.6	47,000,000
8	Finlayson (Finlayson Lake)	20.0	5.0	23.0	107,500,000
9	Frances River (Lower Canyon)	2.8	20.0	15.5	70,625,000
11	Homan Lake	5.2	5.0	7.1	30,625,000
12	Hoole River	0.0	20.0	2.3	10,063,000
22	Mica Creek	32.6	2.0	35.0	71,400,000
26	North McQuesten	0.0	20.0	9.0	38,375,000
27	Orchay (Lake B)	0.7	5.0	0.9	3,875,000
27	Orchay (Orchay Lake)	5.5	5.0	6.3	29,375,000

43	Tutshi Lake	51.9	5.0	55.0	267,125,000
47	Watson Lake	13.9	2.5	14.5	35,438,000
48	Watson River	0.2	5.0	0.6	2,000,000

3.4.3 Cost to Benefit Analysis

Energy models were developed for each small hydro with storage site, using the design basis described in Section 3.4.1 and the energy model assumptions described in Section 3.3.2. Indicative cost estimates were developed as described in Section 3.3.3.

Table 3.4 provides a summary of the major design outputs for the small hydro with storage projects, along with the estimated (indicative) costs and cost to benefit metrics. The values presented are based on a net present cost at commissioning, assuming a construction duration of 3 years and a real interest cost of capital of 4.61 percent (IPP development rate provided by YEC).

Table 3.4 Small Hydro with Storage Screen 3 Summary Table

Site #	Name	Design Flow	Gross Head	Installed Capacity	Net Avg. Energy	Net Present Cost	Unit Capacity Cost	Unit Energy Cost
		m^3/s	m	MW	GWh/yr		$/MW	$/GWh/yr
1	Anvil	8.2	135.0	9.8	41.3	$ 120,502,000	$ 12,329,000	$ 2,918,000
3	Campbell	11.0	77.0	7.5	29.0	$ 145,101,000	$ 19,403,000	$ 5,010,000
5	Drury	9.3	99.0	8.1	31.7	$ 84,993,000	$ 10,484,000	$ 2,682,000
8	Finlayson	13.3	150.0	17.6	138.9	$ 280,698,000	$ 15,932,000	$ 2,021,000
9	Frances	129.5	17.5	20.0	88.7	$ 281,896,000	$ 14,089,000	$ 3,178,000
11	Homan	3.6	77.0	2.4	13.5	$ 84,507,000	$ 34,529,000	$ 6,277,000
12	Hoole	13.2	17.5	2.0	7.7	$ 145,368,000	$ 71,276,000	$ 18,982,000
22	Mica	4.6	35.0	1.4	5.6	$ 123,257,000	$ 86,654,000	$ 22,165,000
26	North McQuesten	30.2	17.5	4.7	18.0	$ 156,324,000	$ 33,502,000	$ 8,675,000
27	Orchay	2.7	132.0	3.1	24.6	$ 89,740,000	$ 28,798,000	$ 3,653,000
28	Pleasant	5.4	40.0	1.9	14.9	$ 154,622,000	$ 81,554,000	$ 10,344,000
29	Pleasant & Rogue	56.7	40.0	20.0	77.9	$ 536,734,000	$ 26,804,000	$ 6,889,000
33	Reid Lakes & Lake Creek	5.2	90.0	4.1	32.4	$ 163,807,000	$ 39,830,000	$ 5,052,000
43	Tutshi - Windy Arm	15.0	51.0	6.8	53.4	$ 136,411,000	$ 20,141,000	$ 2,555,000
47	Watson Lake & McDonald	2.1	60.0	1.1	4.4	$ 56,326,000	$ 49,947,000	$ 12,776,000
48	Watson River	1.8	50.0	0.8	2.9	$ 28,593,000	$ 35,984,000	$ 10,009,000

NOTES:

1. Net Average Energy is based on P50 hydrology estimates as described in Section 3.2.
2. Additional capacity and energy values are provided in Appendix A; average capacity and average energy, and dependable capacity and firm energy.
3. Net Present Cost assumes a three year construction period and an interest rate of 4.61 percent.

3.5 SHORTLIST OF PREFERRED SITES

The five preferred sites were selected based on the lowest unit energy costs presented in Tables 3.2 and 3.4. Table 3.5 presents a summary of the shortlisted sites; which include one (1) run of river project (Wolf River) and four (4) small hydro with storage projects.

Table 3.5 Shortlist of Preferred Sites

Site #	Name	Design Flow	Gross Head	Installed Capacity	Net Avg. Energy	Net Present Cost	Unit Capacity Cost	Unit Energy Cost
		m^3/s	m	MW	GWh/yr	$	$/MW	$/GWh/yr
1	Anvil	8.2	135.0	9.8	41.3	$ 120,502,000	$ 12,329,000	$ 2,918,000
5	Drury	9.3	99.0	8.1	31.7	$ 84,993,000	$ 10,484,000	$ 2,682,000
8	Finlayson	13.3	150.0	17.6	138.9	$ 280,698,000	$ 15,932,000	$ 2,021,000
43	Tutshi - Windy Arm	15.0	51.0	6.8	53.4	$ 136,411,000	$ 20,141,000	$ 2,555,000
49	Wolf River	28.3	80.0	20.0	104.9	$ 271,023,000	$ 13,559,000	$ 2,584,000

It should be noted that, while the costs and costing metrics were assessed in an unbiased manner, a significant variable is accuracy of project reference information and quality of data for each sites; which induces inaccuracy into the assessment model. With more comprehensive site specific data (i.e. hydrology, topography and foundation conditions) the economics of preferred projects could deteriorate while other sites could improve, and therefore the comparative rankings would change.

Four (4) additional sites ranked closely to the five preferred sites and may warrant further consideration when site specific is available, including:

- Squanga Creek $M 2.980/GWh/yr
- North Fork Klondike River: $M 3.004/GWh/yr
- Lapie River $M 3.116/GWh/yr, and
- Frances River $M 3.178/GWh/yr/.

4 – EVALUATION OF PREFERRED SITES

4.1 PROJECT LAYOUTS

For the preferred sites, reference information and project layouts were reviewed in finer detail than was possible for the full list of sites evaluated in Screen 3. This involved detailed reconnaissance of historic reports, old and current mapping, and other pertinent site specific considerations.

4.1.1 Drury Lake

Reference Reports: *1989, 1990, 1991 Hydro Investigations* [S. Demers], *Assessment of Potential Hydro Sites* [KGS Group, 2008]

The Drury Lake Project is located on Drury Creek between Drury Lake and Little Salmon Lake, in the Yukon River watershed. The site is approximately 170 km north of Whitehorse and is situated within 1 km of the Robert Campbell Highway and the existing WAF transmission line.

A variety of studies have previously been commissioned, including high level reconnaissance, geotechnical investigations, and design studies, and these have resulted in a number of alternative design concepts. The most recent study was completed by KGS in 2008 and provides basic site layouts, design and geotechnical considerations, and cost estimates for different options.

While earlier studies considered a low gradient canal and a short penstock, geotechnical risk and the presence of permafrost were noted by KGS. At this desktop level, the conveyance alignment and specific constructability concerns cannot be addressed in any detail beyond that reported by KGS, and so the selection of a buried low pressure penstock instead of a canal has been adopted by KP.

A preliminary general arrangement of the project layout is shown on Figure 4.1. Key project parameters and characteristics for this layout are as follows:

- Q_d = 9.3 m^3/s.
- Gross Head = 99 m.
- Installed Capacity = 8.1 MW.
- 5.3 km of access roads from the Robert Campbell Highway to the powerhouse, along the water conveyance, and upstream to the outlet of Drury Lake.
- Concrete Faced Rockfill Dam (CFRD) or earthfill control dam at the outlet of Drury Lake to provide 5 m of storage (operating storage of 135 Mm^3). The dam would be constructed with an IFR discharge system and a spillway to Drury Creek for flood water management.
- Intake weir across Drury Creek, approximately 4 km downstream of the lake outlet (El. 729 masl)
- 4.8 km penstock located on the south side of Drury Creek (alignment as previously indicated by KGS), comprising 3.6 km of low pressure pipe (LPP) and 1.2 km of high pressure pipe (HPP).
- Powerhouse (El. 630 masl) and substation at the edge of Drury Creek, upstream of the Robert Campbell Highway and the river mouth at Little Salmon Lake.
- 0.5 km transmission line, with t-tap interconnection to the existing WAF grid.

There does not appear to be much value in increasing the capacity of the Drury Lake Project. As designed, all available water (after IFR) on an average annual basis would be used for six months of reservoir filling and six months of generation; such that an increased capacity would only decrease the generating period.

4.1.2 Finlayson River

Reference Reports: *1990 Hydro Investigations* [S. Demers, 1990]

The Finlayson River is a major tributary to Frances Lake and the Frances River, in the Liard River watershed. The Finlayson River Project is located adjacent to the Robert Campbell Highway and just upstream of Frances Lake, approximately 300 km to the northeast of Whitehorse.

The only available study for this project was the 1990 Hydro Investigations by S. Demers. This study is outdated and high level in nature, and little is known of site specific geotechnical conditions. However, it is assumed that the locations of the intake dam, canal, penstock, and powerhouse are the most suitable and have therefore been used for this desktop level study.

The design concept involves lake storage and flow regulation on Finlayson Lake and Wolverine Lake, and an intake diversion dam on Finlayson River downstream of the Wolverine River confluence. In its previously envisioned configuration, the intake dam on Finlayson River would be 66 m high at the head of a canyon, and reservoir flooding would require rerouting approximately 3 km of the Robert Campbell Highway. The highway is gravel, and the anticipated costs and technicalities of rerouting this highway are not anticipated to be difficult. However, should rerouting of the highway be impractical for permitting or other reasons, it is likely that a smaller dam and a modified water conveyance alignment could be found.

A basic general arrangement for the proposed project layout is shown on Figure 4.2.Key project parameters for this layout are as follows:

- Q_d = 13.3 m^3/s.
- Gross Head = 150 m.
- Installed Capacity = 17.6 MW.
- 17 km of access roads, to reach the outlets of Wolverine and Finlayson Lakes, the intake diversion dam, water conveyance and powerhouse.
- Relocation of 3 km of the Robert Campbell Highway (due to dam flooding).
- Control dams at the outlets of Wolverine and Finlayson Lakes to provide 5 m of lake storage (combined operating storage of 155 Mm^3). The dams would be constructed with IFR release systems and spillways for flood water management.
- 66 m high CFRD or structured earthfill intake diversion dam located at the head of a canyon on the Finlayson River, upstream of Frances Lake.
- Spillway at the south abutment to route flood flows safely downstream to Finlayson River.
- Water conveyance canal at the north abutment, extending 4.7 km to a forebay (El. 885 masl).
- 1.35 km penstock.
- Powerhouse and substation, located at the shore of Frances Lake (El. 735 masl).
- 5.1 km transmission line, with t-tap interconnection to the proposed Ross River – Watson Lake transmission line paralleling the Robert Campbell Highway.

In its present configuration, the Finlayson River Project is sized for firm power of 17.6 MW, operating at a 100 percent capacity factor all year. It is anticipated that the optimal project in terms of a cost to benefit assessment would be much larger, perhaps in the order of 40 to 45 MW. Site investigations and a more detailed review of site specific data would be required to confirm project viability.

4.1.3 Anvil Creek

Reference Reports: *Nil*.

The Anvil Creek Project is located on Anvil Creek, approximately 205 km northeast of Whitehorse and 16 km east of Faro. The project is located in the Pelly River watershed, a tributary to the Yukon River. Very little previous information could be obtained for the data review of this site.

The KP concept involves lake storage and flow regulation on Anvil Lake and a buried penstock following the Anvil Creek valley to a powerhouse location upstream of the Anvil Creek – Blind Creek confluence. An alternative configuration involves a tunnel and penstock combination that offers a shorter overall water conveyance length. This option is envisioned to be more costly than the full penstock option, however should surficial conditions prove difficult in the Anvil Creek valley, it may become a viable alternative.

A basic general arrangement for the proposed project layout is shown on Figure 4.3, including both water conveyance options. Key project parameters for this layout are assumed as follows:

- Q_d = 8.2 m^3/s.
- Gross Head = 135 m.
- Installed Capacity = 9.8 MW.
- 3.5 km of new access road to access the powerhouse site from the Blind Creek Road. An allowance of 5 km of existing road upgrades for the Blind Creek access road have been allotted.
- 11 km of transmission line service access roads.
- Concrete Faced Rockfill Dam (CFRD) or earthfill control dam at the outlet of Anvil Lake to provide 5 m of storage (operating storage of 27.9 Mm^3). The dam would be constructed with an IFR discharge system and a spillway to Anvil Creek for flood water management.
- Intake weir at the dam and lake outlet (El. 905 masl)
- 4.7 km penstock located adjacent to Anvil Creek.
- Powerhouse (El. 770 masl) and substation at the edge of Anvil Creek.
- 11 km transmission line crossing the Pelly River and interconnecting to the WAF grid at the Robert Campbell Highway (Highway 16).

Very limited reference information was available for the Anvil Creek hydropower site. The project layout was developed using Google Earth and publicly available mapping on the Yukon Government website (GeoYukon). Site characterisation of terrain hazards, bedrock and surficial geology, access, and technical viability of the project should be determined through site visits and acquisition of topographic data and aerial photos.

4.1.4 Tutshi – Windy Arm

Reference Reports: *1990, 1991 Hydro Investigations* [S. Demers, 1990, 1991], *Assessment of Potential Hydro Sites* [KGS Group, 2008].

The Tutshi – Windy Arm Project is a proposed storage hydropower development located between Tutshi Lake and Windy Arm of Tagish Lake in northern British Columbia. Tutshi and Tagish Lakes are tributaries to the Yukon River. The project site is approximately 45 km to the south of Carcross, Yukon, and the proposed powerhouse location is within 1 km to the east of the Klondike Highway.

A number of studies have previously been completed for this site, including geotechnical investigations, design, and cost estimates, resulting in a number of alternative design concepts. This desktop study is based on the most current concepts, presented in the 2008 KGS report.

A basic arrangement for the proposed project layout is shown on Figure 4.4. Key project parameters for this layout are as follows:

- Q_d = 15.0 m^3/s.
- Gross Head = 54 m.
- Installed Capacity = 7.2 MW.
- 23.5 km of access roads, to reach the powerhouse, surface conveyance, tunnel intake, and outlet control dam on Tutshi Lake.
- Tutshi Lake outlet control dam to provide 5 m of lake storage (operating storage of 267 Mm^3), equipped with IFR release system and spillway for flood water management.
- Tunnel intake and 1.7 km tunnel through the hill separating the north end of Tutshi Lake from Windy Arm of Tagish Lake (Intake El. 707 masl).
- 2.7 km long penstock.
- Powerhouse on the south shore of Windy Arm, Tagish Lake (El. 656 masl).
- Substation and 0.5 km long transmission line, with t-tap interconnection to the proposed transmission line alongside the Klondike Highway.

In its present configuration, the Tutshi – Windy Arm Project is sized for firm power of 7.2 MW, operating at a 100 percent capacity factor all year. It is anticipated that the optimal project in terms of a cost to benefit assessment would be larger, perhaps in the order of 15 MW. At this larger installed capacity and higher design flow (Q_d = 30 – 32 m^3/s), the project would utilize more of the annual inflow to Tutshi Lake that would be spilled for a smaller project.

Site investigations and a more detailed review of site specific data would be required to confirm project viability and the optimal project size.

4.1.5 Wolf River

Reference Reports: *1990, 19911 Hydro Investigations* [S. Demers, 1990, 1991].

The Wolf River is a tributary of the Nisutlin River upstream of Teslin Lake, in the headwaters of the Yukon River. The Wolf River Project site is located near the river mouth and approximately 22 km to the northeast of the community of Teslin and the Alaska Highway.

The only available studies for this project were the 1990 and 1991 Hydro Investigations by S. Demers. Little is known of site specific geotechnical conditions and cannot be confirmed at the desktop level. It is assumed for the purpose of this study that the location of the powerhouse, penstock, and conveyance alignment was the most suitable based on the site visit by S. Demers.

The project was envisioned to comprise a water conveyance approximately 11 kilometres in length. A review of Google Earth and regional mapping have led to a decision to move the intake further downstream, shortening the conveyance without a significant reduction in head. However, actual head will need to be confirmed with more accurate mapping.

A basic general arrangement for the proposed project layout is shown on Figure 4.5. Key project parameters for this layout are as follows:

- Q_d = 37.7 m^3/s.
- Gross Head = 60 m.
- Installed Capacity = 20 MW.
- 23 km of access roads to reach the project facilities.
- An intake diversion weir across Wolf River, diverting water to a 5.9 km long canal on the north side of the river (Intake El. 789 masl).
- Forebay (El. 780 masl) and 800 m long penstock.
- Powerhouse (El. 720 masl) and short tailrace channel to Wolf River.
- Substation and 23 km transmission line to Teslin, with a t-tap interconnection to the YEC proposed upgraded transmission line to Teslin.

This project has good power generating potential, and there may be an opportunity to target a higher installed capacity, in the order of 40 to 45 MW, for optimal project economics. However, for this study, an upper bound capacity of 20 MW was set as a cap for small hydro, in line with the scope described in the RFP.

The 1991 study also noted the potential opportunity for storage in Wolf Lake, which could improve winter generation and the plant capacity factor. This has not been considered in this study but may be a worthwhile design consideration in the future.

4.2 TURBINE SELECTION

The selection of the optimal turbine and major equipment type and configuration is a function of design flows, installed capacities, and operating criteria. Conceptual turbine selections for the preferred sites described in this section generally conform to the typical equipment operating ranges illustrated on Figure 4.6. The preliminary turbine selections for the preferred sites are:

- Drury Creek: Francis
- Finlayson River: Pelton
- Anvil Creek: Pelton
- Tutshi-Windy Arm: Francis, and
- Wolf River: Francis.

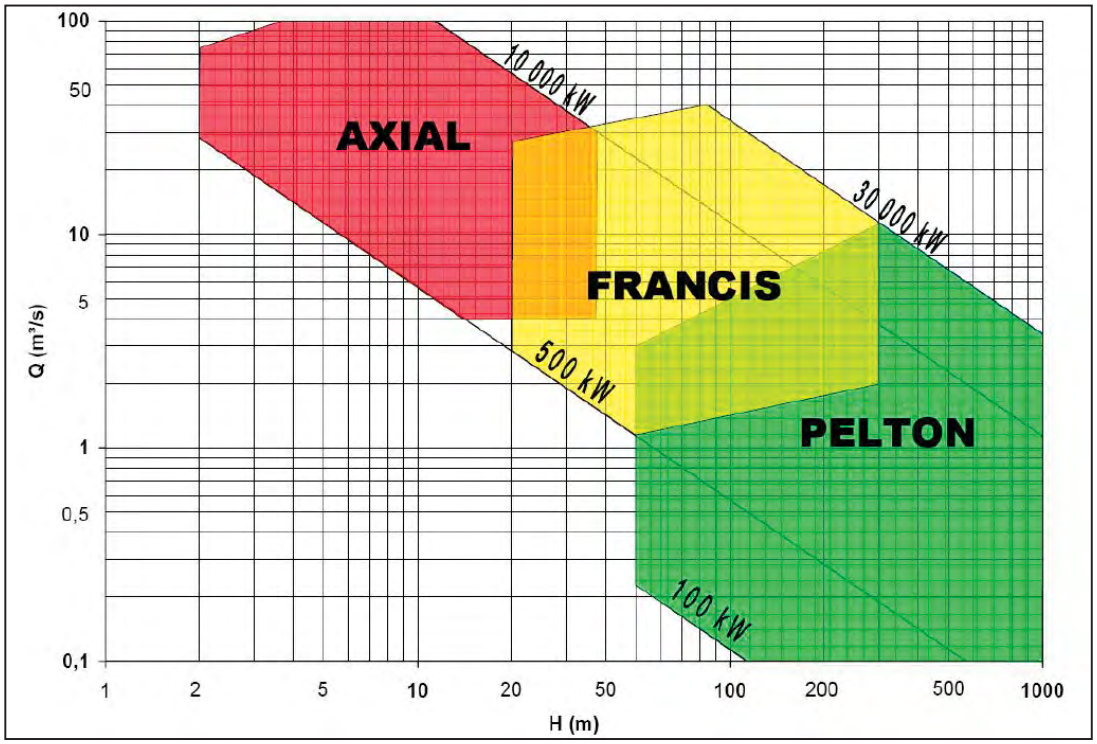

Figure 4.6 Turbine Selection Guideline

4.3 CAPITAL COST EVALUATION

Capital cost estimates have been developed based on the project configurations outlined in Section 4.1. Site specific data were used to establish project size, quantities and constructability. These attributes were used to estimate approximate material volumes for excavation, backfill, embankment material and reinforced concrete. Electrical and mechanical equipment requirements were estimated based on empirical data from KP's prior projects and published in industry technical reports.

The capital cost estimate includes an allowance for the Contractor's preliminary and general costs (overheads, insurance, bonus and profit etc.), an allowance for EPCM costs, and contingency.

Unit rates for material production, equipment procurement and installation costs relied on KP's internal costing database including recent, relevant experience with similar sized hydroelectric

projects in Western Canada and the Yukon. KP's hydro project cost database also offered an order of magnitude check of total estimated costs for individual facility components and complete facilities, based on projects with comparable characteristics such as design flow, penstock pipe characteristics (length, diameter, pressure rating), gross head, generating capacity, powerhouse area, excavation quantities, reinforced concrete volumes, backfill quantities, switchyard capacity and transmission line capacity and length. Where a project interconnection is via "Tee-Tap" type interconnection it is assumed the transmission line interconnects to the closest possible point along an existing or future proposed transmission line; requiring expensive substation and/or switching station infrastructure. There may be sites where a cheaper option exists to extend the transmission line slightly further to interconnect at an existing substation. In this case the avoided costs of building a new substation or switching station could outweigh the cost of extending the transmission line. This was not considered in this study, but should be in the next level of study. An indicative interconnection arrangement is depicted in Figure 4.7 below:

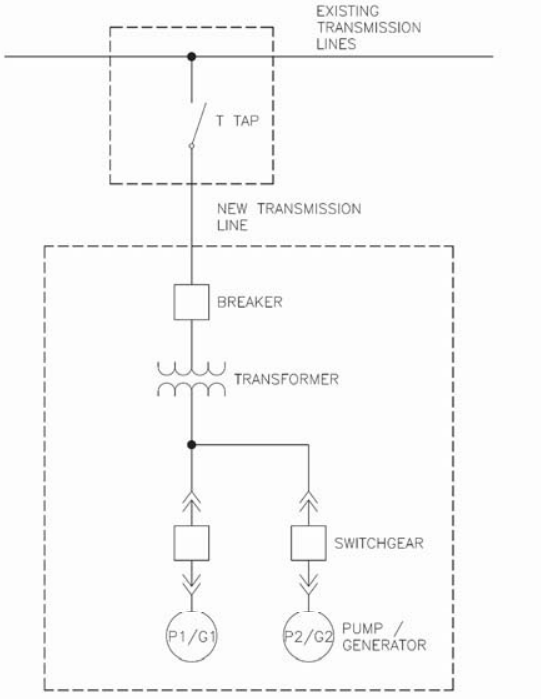

Figure 4.7 Indicative T-tap Interconnection Arrangement

Generating equipment costs were based on installed capacity, head and flow, while switchyard costs were estimated based on installed capacity. Adjustments to reflect the higher construction costs in the Yukon were included where appropriate. All dollars are shown in 2015 Canadian Dollars (CAD).

Capital costs were considered at a screening level, and costs will vary as more site specific assessments are undertaken and project designs are refined. The estimates have been prepared with sufficient detail for a preliminary AACE Class 5 estimate (±50%). These costs should be used as comparison of sites rather than as a reliable indication of the actual construction costs for any single project.

The overall estimated costs for the preferred sites are shown in Table 4.1.

4.4 FINANCIAL EVALUATION

KP has developed a financial model to assess the Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for the five preferred sites. The basic parameters used in the financial model include:

- Capital Cost Estimate — Varies by alternative
- Fixed Operating Costs — 2.0% of initial capital cost per year
- Variable Operating Costs — $0.005/kWh for power generation
- Net Annual Generation — Varies by option
- Construction Period — 3 years, and
- Project Life — 65 years.

No escalation/inflation is included in the financial evaluation. Interest rates are assumed for the real cost of capital as provided by YEC:

- YEC resource options — 3.38%
- IPP resource options — 4.61%, and
- High interest scenario — 8.82%.

The loaded capital cost, or net present cost at Commercial Operation Date (COD) is accounts interest accrued during construction, using the following formula:

$$C = \sum_{\mathrm{yr}=0}^{\mathrm{n}} \mathrm{c}(1+i)^{\mathrm{n-yr}}$$

Where:

$$C = loaded\ capital\ cost$$
$$c = construction\ cost\ in\ given\ year\ of\ interest$$
$$yr = construction\ year\ of\ interest$$
$$n = total\ number\ of\ years\ of\ construction\ (4)$$
$$i = interest\ rate$$

Next, the levelized capital cost per year is calculated using the capital recovery factor formula:

$$LC = \frac{iC(1+i)^N}{(1+i)^N - 1}$$

Where:

$$LC = levelized\ capital\ cost\ per\ year$$
$$N = total\ project\ life$$

A summary of the project financial attributes for the preferred sites is included in Table 4.2. The summary provides levelized cost results for the YEC development real cost of capital rate, IPP rate, and high interest scenario rates provided by YEC.

4.5 OTHER CONSIDERATIONS

The cost estimates and financial attributes described in Section 4.2 and 4.3 are appropriate for a stand-alone approach to project evaluation. Two additional potential synergies have been identified: benefits to downstream generation at other hydroelectric facilities, and benefits from potential pumped-storage developments. These benefits are described below.

4.5.1 Benefits to Downstream Generation

In the KGS 2008 study, it was noted that the Tutshi – Windy Arm Project would offer potential increases in winter generation at the Whitehorse Generating Station, due to the increased available winter flows in the Yukon River that will result from attenuation of the Tutshi Lake outflows. In the KGS study, the estimated magnitude of the increase was 6 GWh/yr.

This is an advantage that should improve the economics and relative merit of developing the Tutshi – Windy Arm Project. No other preferred site will improve the winter generation of the Whitehorse Generating Station or the three other existing hydropower facilities in the Yukon.

4.5.2 Benefits from Pumped-Storage Development

In parallel with this study, KP also completed an assessment of potential pumped-storage hydropower sites that could provide winter power to the Yukon. The study (KP Reference VA103-556/2-1) investigated a number of sites, many of which are located within the same watersheds as the small hydro sites considered in this report.

Of particular note, the best pumped-storage site for all scenarios assessed is located between Moon Lake and Tutshi Lake. Development of both the pumped-storage scheme and the Tutshi – Windy Arm small hydro project could have significant advantages, including shared cost of access to the Tutshi Lake outlet control dam, and additional flow control on Tutshi Lake, with the potential for compounded increases in winter generation. Additionally, it may provide significant logistical and construction related advantages if both sites were to be developed concurrently or in sequence.

The optimal project configuration for the combined Moon Lake – Tutshi Lake pumped-storage project and Tutshi – Windy Arm small hydro project would require a more detailed study encompassing both of these projects.

4.6 DEVELOPMENT SCHEDULE

A high level development schedule has been created to illustrate the relative timelines for completing critical tasks associated with developing small hydro projects in the Yukon. The relative timelines for completing the major development tasks is similar for each option described above, and this schedule should be considered as generic and indicative only. The major development tasks and timelines are listed below.

1. Feasibility Study – 1 year
   - Will require detailed mapping and site specific hydrology data for a minimum of one year of data collection
2. Environmental Assessment (Permitting and Baseline Studies) – 2 years (will start concurrent with Feasibility Study)
   - Will include fisheries, hydrological and wildlife/terrestrial studies that will be inputs to the Environmental Assessment for each project
   - First Nations and stakeholder consultation will also be included in this stage
3. EPC Tendering Process – 1 year
   - EPC tender design can start immediately after Feasibility Study
4. Construction – 3 years
   - Will commence once Environmental Assessment Certificate is received and EPC contractor is selected
5. Commissioning – 4-6 months
   - Commences after Construction
6. Operations – 65 years

The best case scenario for duration of project development is 5.5 years; from the start of the Feasibility Studies through to the end of Commissioning. Actual project development schedules are site specific and may be influenced environmental baselines studies, consultation with first nations and broader public opposition to development of the project.

5 – CONCLUSIONS AND RECOMMENDATIONS

5.1 CONCLUSIONS

A screening assessment of previously identified small hydro sites in the Yukon was completed to identify the better development options for future studies. A total of forty-four potential sites were assessed in a multi-stage screening process.

The most attractive (preferred) projects, based on a desktop level assessment of location, project layout, site characteristics, capacity, energy, and costs, are Drury Lake, Finlayson River, Anvil Creek, Tutshi – Windy Arm, and Wolf River. Summary of results for preferred sites is as follows:

- LCOC ranges from $700 to $1,200/kW-yr at the YEC real interest rate of 3.38 percent.
- LCOE ranges from $0.13 to $0.21/kWh at the YEC real interest rate of 3.38 percent.
- Based on a stand-alone assessment of hydropower development, the most attractive small hydro sites are the Finlayson River, Wolf River, and Tutshi – Windy Arm. Whereas, Drury Lake and Anvil Creek appear to be more expensive on a cost of energy basis.
- The optimal installed capacities for Finlayson River, Tutshi – Windy Arm, and Wolf River Projects are likely higher than reported in the present design and should be explored further. The purpose of this study was to evaluate sites of 20 MW or less based on the requirements, as such the optimal installed capacities were not determined.
- The Tutshi – Windy Arm project has the added benefit of increasing potential winter generation at the Yukon Generating Station downstream.
- If the Moon Lake – Tutshi Lake pumped storage project is developed, it may have material synergies with development of the Tutshi – Windy Arm small hydro project.

A summary of the Financial and Technical attributes of the preferred sites is presented in Table 5.1 below:

SMALL HYDRO ASSESSMENT

SUMMARY OF TECHNICAL & FINANCIAL ATTRIBUTES
PREFERRED SITES

10/6/2016 19:25

ATTRIBUTES	Drury Creek	Finlayson River	Anvil Creek	Tutshi - Windy Arm	Wolf River
TECHNICAL:					
Installed Capacity (MW)	8.1	17.6	9.8	7.2	20.0
Net Annual Generation (GWh)	31.7	138.9	41.3	56.6	95.6
Mean Annual Discharge (m^3/s)	4.9	16.5	4.1	16.1	40.3
Design Flow - Qd (m^3/s)	9.3	13.3	8.2	15.0	37.7
Gross Head (m)	99	150	135	54	60
Transmission Line Length (km)	1	5	11	1	23
FINANCIAL:					
Estimated Capital Cost	$ 97,250,000	$ 265,990,000	$ 109,210,000	$ 125,400,000	$ 220,170,000
O&M Costs - Fixed ($/yr)	$ 1,945,000	$ 5,320,000	$ 2,184,000	$ 2,508,000	$ 4,403,000
O&M Costs - Variable ($/yr)	$ 158,000	$ 695,000	$ 207,000	$ 283,000	$ 478,000
YEC Rate Scenario (3.38%)					
Levelized Cost of Energy ($/kWh)	$ 0.19	$ 0.12	$ 0.17	$ 0.14	$ 0.14
Levelized Cost of Capacity ($/kW-yr)	$ 700	$ 1,000	$ 700	$ 1,100	$ 700
IPP Rate Scenario (4.61%)					
Levelized Cost of Energy ($/kWh)	$ 0.23	$ 0.14	$ 0.20	$ 0.17	$ 0.17
Levelized Cost of Capacity ($/kW-yr)	$ 900	$ 1,100	$ 800	$ 1,300	$ 800
High Interest Rate Scenario (8.82%)					
Levelized Cost of Energy ($/kWh)	$ 0.24	$ 0.15	$ 0.21	$ 0.18	$ 0.18
Levelized Cost of Capacity ($/kW-yr)	$ 900	$ 1,200	$ 900	$ 1,400	$ 900

M:\1\03\00556\02\A\Report\2 - Small Hydro\Rev 0\Tables\[Preferred Sites Rev0.xlsx]Table 4.2

NOTES:

1. DOES NOT INCLUDE UPFRONT ENVIRONMENTAL, PERMITTING AND OWNERS COSTS.
2. DOES NOT INCLUDE APPLICABLE SALES TAXES.
3. EPCM COSTS INCLUDE DETAILED ENGINEERING, TENDERING OF CIVIL AND WATER-TO-WIRE CONTRACTS, SITE SUPERVISION, OVERALL PROJECT MANAGEMENT AND ENVIRONMENTAL MONITORING.
4. COSTS ARE PRELIMINARY AND ARE CONSIDERED EQUIVALENT TO AN AACE CLASS 5 ESTIMATE.

REV	DATE	DESCRIPTION	PREP'D	CHK'D
0	6OCT'16	ISSUED WITH REPORT VA103-556/2-	SDR	KLA

To determine the optimal small hydro site will require further assessment of a number of factors, including desired capacity, development of proposed transmission lines, environmental impacts, political/societal conditions and capital cost estimates based on site quantities. Consideration of these factors, in conjunction with detailed site investigations and engineering studies on the preferred sites, will be required.

5.2 RECOMMENDATIONS

Further evaluation of the preferred sites is recommended, to improve the design basis, project configurations, and understanding of hydrological and geotechnical conditions. The following activities are recommended:

- Preliminary site visits to the following projects to further evaluate technical viability:
  - Drury Lake
  - Finlayson River
  - Anvil Creek
  - Tutshi – Windy Arm, and
  - Wolf River.
- Obtain accurate mapping (such as PhotoSat satellite topography) for the proposed project areas to confirm project configurations and details including dam sizes, water conveyance routings, powerhouse locations, access roads, and transmission lines.
- Implement hydrological data collection programs at the preferred sites.
- Update energy estimates based on hydrology data and accurate depth-area-capacity curves for reservoirs.
- Update quantity and cost estimates.
- Undertake a screening assessment of social and environmental permitting constraints at each of the five preferred sites.

Should the above assessment indicate that there are no technical or environmental showstoppers, detailed evaluation of the sites through pre-feasibility and feasibility studies should be pursued to prove economic viability.

MORRISON HERSHFIELD

June 23, 2016 MH ref. 5151214

Stuart Simpson, General Manager,
Atlin Tlingit Economic LP
PO Box 408,
Atlin, BC
V0W1A0

Dear Mr. Simpson:

Re: Prefeasibility Study for Atlin Hydro Expansion Project – 2016 Update

Morrison Hershfield is pleased to provide our report on the above noted project. This is an updated version of the prefeasibility report completed in 2015. This 2016 update now includes the transmission line options assessment for connection to the Yukon electrical system and addresses Yukon Energy Corporation's comments. It continues to be a privilege to work with ATELP on this exciting and interesting renewable energy project.

We look forward to any opportunity to support you and your team in developing this important project. In the meantime, if we can be of further service, please do not hesitate to contact me at (867) 456-4747.

Yours truly,
Morrison Hershfield Limited

Forest Pearson, P.Eng.,
Geological Engineer / Project Manager

1 PROJECT OVERVIEW

1.1 Background and Project Objective

On April 1st, 2009 the 2.1MW Atlin Hydro Project began commercial power production. The hydropower facility is owned by Xeitl Limited Partnership which is 100% owned by Taku River Tlingit First Nation. The project is located on Pine Creek and is approximately 4 km east of the community of Atlin, BC. Atlin is an isolated community located approximately 50 km south of the Yukon-British Columbia border. Atlin is only road accessible from the Yukon Territory.

Atlin is not connected to a regional electrical power grid and therefore all electrical needs of the community are generated locally. Power created by the current Atlin hydro project is sold to BC Hydro on a 25-year energy purchase agreement. Under this agreement, Xeitl has an obligation to provide up to 8.3 GWh/yr by 2032. The Atlin hydro project now meets all of the community's electrical power needs and has additional unutilized generating capacity. Backup power in case of outage is provided by diesel electric generation owned and operated by BC Hydro.

The current hydropower project only develops a portion of the hydropower potential of the site. The existing project utilizes approximately 107 m of head (drop) on Pine Creek. There remains another 55 m of head between the current powerhouse (located at the confluence of Pine and Spruce Creeks) and Atlin Lake. There is also additional undeveloped head upstream of the current head pond. As such, the existing project only utilizes a portion of the flow available in Pine Creek. There is then significant additional energy potential on Pine Creek that could be developed.

The Yukon Territory has an isolated electrical system that is largely supplied by hydroelectricity. Atlin is not currently connected to the Yukon's electrical grid. The Yukon is nearing capacity of its renewable energy system. Most recently public available forecasts suggest that the Yukon will have a renewable energy shortfall of over 80 GWh/yr by 2030[1]. Shortfalls in renewable energy will be met with fossil-fuel based electrical generation (diesel or natural gas fired generation).

In summer of 2014 the Taku River Tlingit First Nation's economic development corporation, the Atlin Tlingit Economic Limited Partnership (ATELP), secured funding from the Aboriginal Affairs and Northern Development Canada's ecoENERGY for Aboriginal and Northern Communities Program to conduct a pre-feasibility study of expanding the hydropower project. The current study provides a preliminary assessment of increasing hydropower production for export to the Yukon electrical grid. This study has been updated in 2016 to include a transmission connection assessment.

The community of Atlin, British Columbia is located on the Yukon Plateau physiographic region of northern BC, just east of the Coast Mountains. Pine Creek originates from Surprise Lake and then flows westward approximately 20 km to discharge into Atlin Lake. Much of the creek has been extensively mined for placer gold since the 1900's. A road from Atlin to Surprise Lake parallels the creek. Surprise Lake (32 km^2) is the headwaters for the creek and provides storage for the hydropower project. The current hydropower project has developed 107.6 m of head by conveying water through a penstock

[1] Yukon Energy Corporation, 2013:Yukon Energy Corporation Application for an Energy Project Certificate and Energy Operation Certificate Regarding the Proposed Whitehorse Diesel – Natural Gas Conversion Project. December 9, 2013.

over a distance of approximately 3.9 km around a set falls in a short canyon. The current powerhouse lies just upstream of the confluence with a significant tributary stream called Spruce Creek. Below the current powerhouse, Pine Creek flows another 4 km, dropping approximately 55 m before discharging to Atlin Lake.

The current study envisions expanding the current powerhouse with two additional turbines of 1.45MW each (bring the total powerhouse capacity to 5MW). A second, or lower, powerhouse could be developed on Atlin Lake, providing an additional 2.5 to 3MW of capacity. The capacity of the lower powerhouse is a function of available flows and head (see Section 4.3 of this report); the specific installed capacity will need to be refined during the next phase of study. A new transmission line of approximately 100 km would be required to connect the project with the Yukon Territory's electrical grid.

1.1.1 Project Objective

In general terms the goal of the project is twofold:

1. Estimate the scale of the hydropower opportunity readily available for development on Pine Creek. How much power could be generated if the full potential of the site was developed?

2. Is the expanded development of the site, for sale to the Yukon electrical grid, potentially economically viable?

The study is to determine the scale of the opportunity and if whether it is worthwhile to pursue. At this stage the development concepts have not taken into consideration environmental and social mitigations and only limited work has been done to optimize the project design. The design concepts presented in this study are preliminary in nature for the purpose of estimating project costs and are not necessarily representative of the ultimate design or layout of the project.

1.2 Scope of Work

The scope of work for the Atlin Hydro Expansion Project pre-feasibility study is as follows. The level of detail of the study is limited by the available budget; however the objective is to generate a preliminary project concept and a cost estimate at +/-30%. Power and energy estimates are evaluated based on available historical flow data on both Pine Creek and nearby rivers. The project work consists of two main phases:

1. Project conceptualization, to define the proposed layout and energy estimates:
    a. Project initiation, including review of previous work and previous studies and an initial site visit by the project team;
    b. Site definition including initial project layout concepts and acquisition of new 1-m contour mapping of the project study area;
    c. Hydrological and power studies including development of an updated synthetic flow series, power production estimates and a simplified flood frequency analysis.

2. Pre-feasibility engineering and design

    a. Preliminary design of the major works including dams, intake structures, control structures and spillways, water conveyance and powerhouse;

    b. Preparation of cost estimate (+/-30%) estimated from bill of quantities derived from the preliminary design drawings (class IV or better based on AACE framework). Also a preliminary construction schedule is presented.

    c. Completion of a transmission assessment to estimate electrical transmission and connection requirements to the Yukon's electrical system, including cost estimates.

    d. Preparation of this prefeasibility design report and a presentation.

Two other related phases of work are being conducted concurrently with this prefeasibility study:

a. A hydrometric monitoring program was established in late 2014 to determine actual water levels and stream flows in key water bodies relevant to the hydro expansion project. This consists of continuous monitoring of lake levels in Surprise Lake and flow in Pine and Spruce Creeks;

b. An environmental scoping is being completed consisting of an existing environmental data review, gap analysis and an assessment of regulatory approvals likely to be required.

1.3 Previous Work and Available Data

This study builds upon previous work and existing information. Some of the most relevant data includes:

- Surprise Lake Hydroelectric Project: Proposal for Supply of Electricity to BC Hydro at Atlin, prepared by Canadian Utilities, Limited, Synex Energy Resources Ltd and Yukon Development Corporation. 1990.
- Atlin Hydroelectric Project Hydrology Report. Prepared for Taku Land Corporation by Sigma Engineering Ltd. March, 2006.
- Stage-discharge data for Surprise Lake and Pine Creek. Spot flow and lake measurements collected between 1990 and 2005 for Yukon Energy Corporation.
- Stream flow data for Pine Creek collected at Water Survey of Canada (WSC) station (09AA008) which operated at the mouth of Pine Creek. This station has only 10 years of complete discharge data between 1956 and 1969 (1956-1961, 1966-1969).
- Presentation on Biological Assessment of the Atlin Small Hydro Project, Progress Report September 2005 prepared by Richard Erhardt for Taku Land Corp.
- Atlin Hydroelectric Project Environmental Impact Statement prepared by Taku Land Corporation August 2006.
- Atlin Hydroelectric Project As-Built Drawings by Sigma Engineering. Prepared for Taku Land Corporation, July 2009.

- Atlin BC to Yukon Interconnection Costing Study. Prepared by BBA Engineering for Yukon Energy Corporation. August 2011.
- BC Land Tenure from DataBC including: TANTALIS Crown Tenures, Crown Land Rights-of-way, Surveyed Parcels and Surveyed Right-of-way Parcels.
- Confidential construction data provided by Atlin Tlingit Economic Development Corporation for the existing hydroelectric project completed in 2009. This includes access to construction contracts and project cost details for the original project construction between 2007 and 2009.

1.3.1 Topographic Mapping

New 1-meter topographic mapping was obtained for the project and is used as the topographic base for the preliminary design. Underhill Geomatics of Whitehorse, Yukon was retained to generate the mapping. The mapping was created from 2010 1:20,000 scale aerial photography. The mapping includes 1 meter contour data, water bodies and an orthophoto. The extent of the mapping generally follows Pine Creek and extends from the current intake head pond down to Atlin Lake. Mapping data was provided digitally to ATELP in AutoCAD format and cartographic version of mapping is provided in Appendix B.

2 SITE VISIT & OBSERVATIONS

An initial site visit was conducted by the project team on September 24 and 25th, 2014. Forest Pearson (project manager / geological Engineer), David Morissette (hydrotechnical engineer) and Shaun Beatty (civil engineer) were part of the visit and were accompanied for portions of the visit by Stuart Simpson, ATELP General Manager. The site visit included a brief helicopter over flight of the potential project site followed by on the ground reconnaissance. A copy of the site visit memorandum is provided in Appendix C and a representative photo log is provided in Appendix D. The location of features described herein are shown on Figure 2-1.

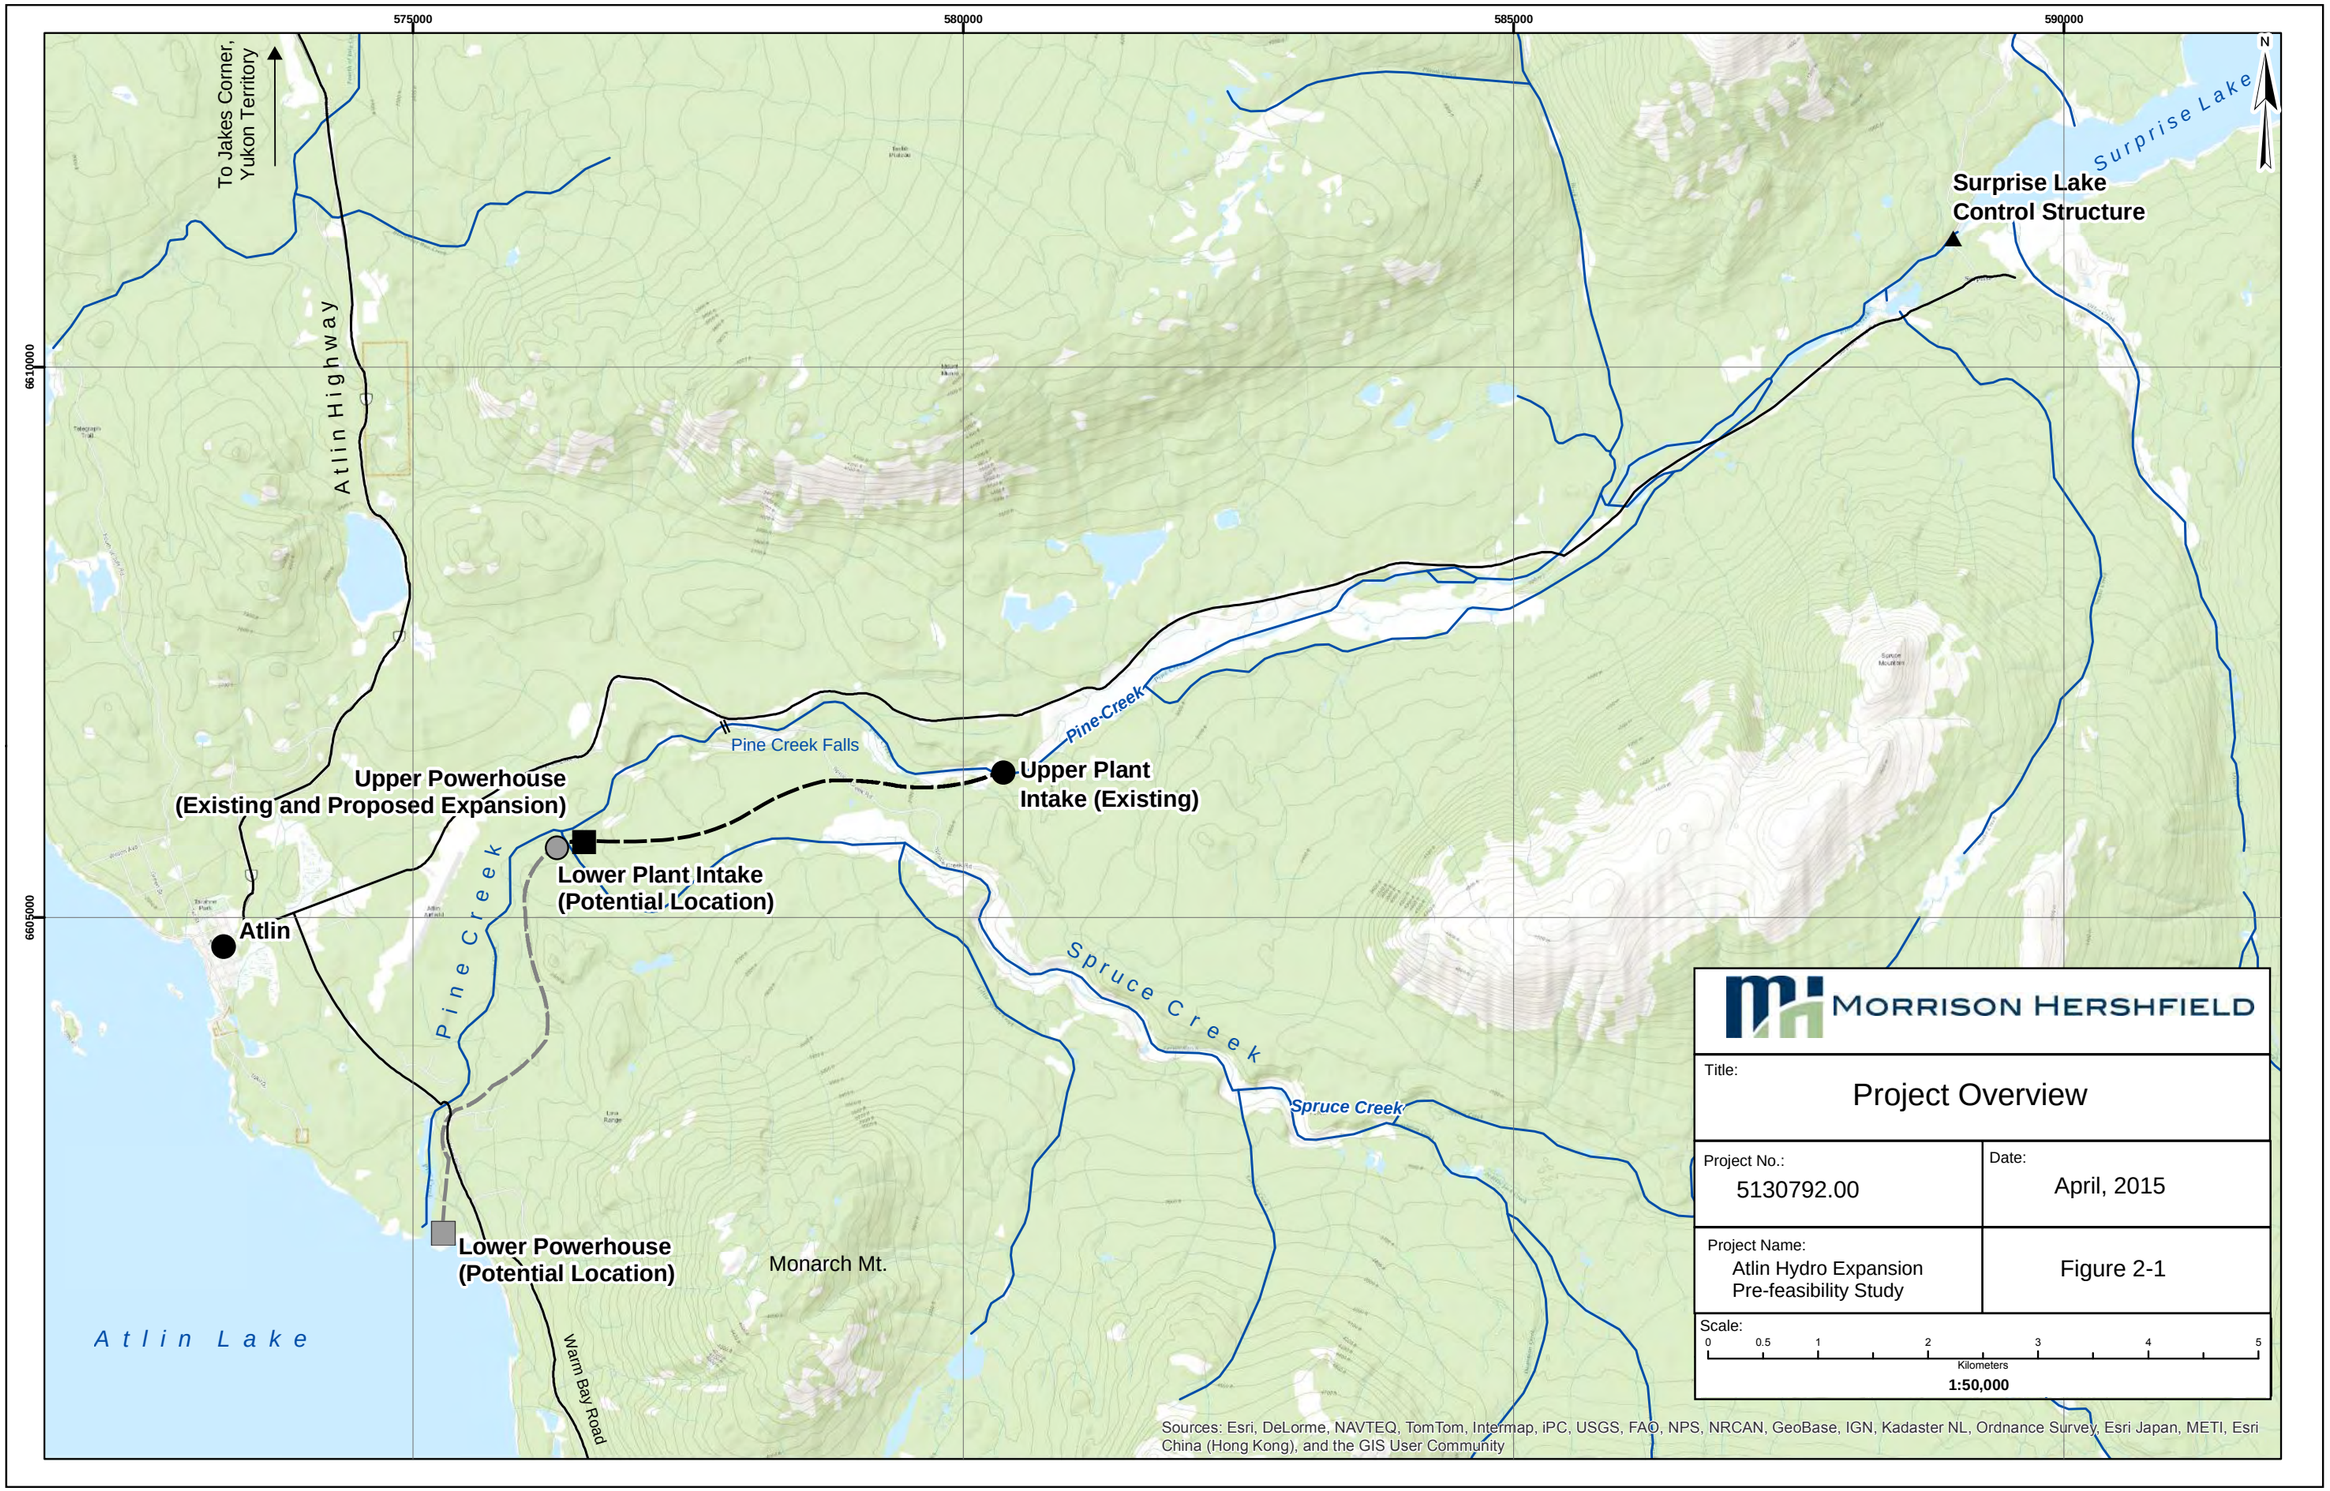
The site visit included:

- Ground inspection of the Surprise Lake outlet and control structure with access via Surprise Lake road;
- Ground inspection of the existing Pine Creek intake structure. This included a brief visual reconnaissance of Spruce Creek for consideration of diversion into the existing head pond;
- Visual reconnaissance of the existing penstock and associated right of way;
- Site visit to the inside and outside of the existing powerhouse. This also included the bridge and potential new headpond area downstream of the existing powerhouse;
- A detailed on the ground reconnaissance of a potential lower powerhouse location on Atlin Lake, just south of the Monarch Mountain Trail parking lot. The hill-slope above this site was also inspected for ground and terrain conditions for the penstock route;
- A road-based reconnaissance from both the Art Centre Road and South Pine Drive of a potential higher penstock alignment to Atlin Lake;
- A ground traverse of the upper 1.5 km of the lower penstock alignment to assess potential intake locations, ground conditions and to determine topographic constraints to a penstock alignment.

The following main conclusions were gathered from the site visit:

Surprise Lake Control Structure

- The control structure at Surprise Lake can be readily modified to increase storage range on the lake by raising the existing sheet pile and rock fill control weir (see Photo 1). Work will need to be done to assess the suitability of the current outlet structure and fish way under higher and lower lake conditions.
- The channel between the lake and the control structure appears to be relatively shallow. It is likely the channel would need to be deepened to extract water from the lake at lower lake levels.



K:\Internal\Environmental_Services\GIS_Environment_Services\GIS_Project_Work\Yukon\5143079\GIS_5143079\GIS_Maps\Atlin_Hydro_Expansion_Location_Plan.mxd

Photo 1: Surprise Lake control structure with rock fill and sheet pile weir on the right.

Existing (Upper) Power Plant

- There appears to be adequate space at the existing head pond to accommodate a second intake structure to feed the powerplant expansion. The head pond is contained by bedrock outcrops on both sides of the creek (see Photo 2).
- The head pond itself is created by a concrete weir founded on bedrock. The weir appears to be in good condition, however has some minor leaks through the south abutment. These leaks do not appear to be problematic at this time.
- The head pond is reported to have issues with frazil ice accumulation in the winter. It is thought that this problem may be compounded by the presence of a submerged rockfill berm between the main pond area and the intake. This creates a depositional area that may exacerbate the accumulation of frazil ice. Furthermore, there is a reach of rapids on the creek immediately upstream of the head pond. These rapids not only limit the size of the head pond but are also likely to increase frazil ice generation in this reach..
- The existing clearing for the penstock is quite wide and should be able to accommodate a second penstock for most of the alignment with any further clearing. Ground conditions appear

to be glaciofluvial gravel for most of the route which is suitable for excavation and installation of a penstock (see Photo 4).

- Expanding the existing powerhouse appears reasonable. There is adequate space on the south side assuming some excavation of the hill side. Soils at the powerhouse are primarily sand and gravel with no bedrock outcrops anticipated near surface (see Photo 3).
- Sand and course gravel is abundant throughout the area and is readily available due to the extensive placer gold mining of the creeks.

Photo 2: Existing head pond and intake structure, looking west.

Photo 4. Existing penstock right of way, looking downstream (west). Penstock in on the left, service road on the right side of the clearing.

Photo 3. Existing powerhouse looking south towards Spruce Creek. Pine Creek is in foreground.

Lower Power Plant

- No obvious or natural containment for a head pond was identified. Topography is fairly flat and no deep natural pools near the desired intake location were observed. In the absence of any natural features, it is proposed that an excavated head pond be created immediately downstream of the existing powerhouse access road bridge (see Photo 3). Potential for tail water effects from a lower head pond on the existing powerhouse will need to be considered. Soils at this location are coarse alluvial gravel with no bedrock in the vicinity. This suggests that soils will be fairly porous should an impoundment be created in this area.
- The alignment for the lower penstock is significantly more complicated that the upper alignment. This is due to steep side slopes, varying terrain conditions (bedrock outcrops, wetland areas) and topographic constraints (see Photo 5).
- The upper 1.5 km of the potential penstock alignment is primarily alluvial sand and gravel terraces. A saddle between the mountain side and a bedrock hill was located and provide a convenient topographic feature for the penstock alignment approximately 1.5 km south of the head pond area.

Photo 5. View of lower penstock alignment terrain conditions looking north towards existing powerhouse.

- There are a number of titled properties along the lower segment of the potential penstock alignment (within the first kilometer upstream of the powerhouse). These are located along Warm Bay Road, Arts Centre road and either side of Pine Creek at the bridge. These properties conflict with some potential penstock routes.
- There appears to be adequate space for a powerhouse on the shore of Atlin Lake. Pine Creek itself has created a large alluvial fan extending out into Atlin Lake. The shallow gravel deposits extend out into the lake making the lake quite shallow near the mouth of the creek. The lake drops off more quickly from the shoreline south of the fan (see Photo 6). Sediment disposition from the creek affecting the potential tailrace should be considered.
- The hillside above the potential powerhouse location rises steeply to the east of the Warm Bay Road. The hillside is open rolling bedrock outcrop with very little tree cover.

Photo 6. View of potential lower powerhouse locations on Altin Lake. Pine Creek fan is on the left. Note exposed bedrock hillside above Warm Bay road.

3 PROPOSED LAYOUT

3.1 Project Components Overview

Multiple new hydro project components are required to maximize power production at Pine Creek. For the purposes of this study, the hydro expansion project layout is assumed to consist of the followings (see Figure 2-1):

1. Increased water storage range on Surprise Lake to increase water storage for seasonal power production. It will require modifications to the existing Surprise Lake control structure and weir.
2. Expanding the upper power house with additional generating capacity. It will require an additional penstock and intake structure to convey the additional water to the added turbine(s). It is not anticipated that the existing head pond will require modification other than the addition of a second intake structure for the new penstock. Modifications to help prevent frazil ice accumulation in the head pond are however warranted, especially with the proposed increase in winter flows.
3. A new powerhouse on or near Atlin Lake. It will require a new conveyance (penstock) and associated head pond and intake structure downstream of the existing powerhouse.
4. A transmission line from Atlin to the Yukon Territory's electrical grid. It has been assumed that the new transmission line would terminate at Jakes Corner based in the preliminary transmission options assessment completed as part of this study.

3.1.1 Spruce Creek Diversion

Spruce Creek is the largest tributary to Pine Creek. It joins Pine Creek immediately below the current powerhouse. Like Pine Creek, Spruce Creek has been extensively modified and affected by placer gold mining over the past century. Placer mining on both creeks continues to occur.

Flows from Spruce Creek can be utilized for power production at either the new lower power project or potentially by both power plants if the creek was diverted into the upper (existing) head pond. The current head pond has a normal water elevation of about 832.5 m. Diverting Spruce Creek would require intercepting the creek at approximately elevation 835 m and approximately 1.7 km of conveyance (ditch or pipe) to convey the water to the head pond. Given this topography there are a number of considerations that make diverting Spruce Creek into the upper head pond challenging:

- Construction of the conveyance may be challenging due to steep side-slope topography at the required intake elevation.
- Soils are very permeable gravels which would make a diversion ditch relatively porous and may even require a liner.
- An intake structure on Spruce Creek may be challenging due to high sediment load and frequent floods and variable flows resulting from upstream placer mining operations.

Preliminary estimates suggest that diverting Spruce Creek into the upper head pond could create an additional 2 to 3 GWh/yr of summer energy. Summer energy is of limited to low value to Yukon. Therefore the economic case for an upper diversion of Spruce Creek is difficult to envision at this time under conventional development approaches.

For the purposes of this study, it will be assumed that Spruce Creek will be utilized for the lower power plant only. A small diversion ditch will divert Spruce Creek into the new lower headpond just upstream up the mouth of the creek into Pine Creek.

3.2 Lower Powerhouse Alternatives

Several layout alternatives for the lower power plant were considered to determine the optimal arrangement and to address the physical constraints of the site. Specifically lower powerhouse locations and associated penstock alignment options were evaluated. The potential layout alternatives were developed based on on-site observations, topographic mapping and land ownership. Five potential powerhouse locations were identified jointly by the project team and ATELP. These options are shown on Figure 3-1.

Table 3-1 provides a qualitative evaluation of the project layout options for the lower power plant for a number of considerations. Location “E”, located on the Pine Creek fan near the Monarch Mountain trail parking lot was selected for preliminary design. This location was selected for the following reasons:

- Develops the maximum head for the site (maximize power potential)
- Penstock alignment largely avoids land tenure conflicts and powerhouse location largely avoids other potential land use conflicts.
- Site appears to be technically suitable from a construction perspective
- The hillside above the selected site provides opportunity for development of the required surge facility.

Figure 3-1: Lower Powerhouse & Penstock Alternatives

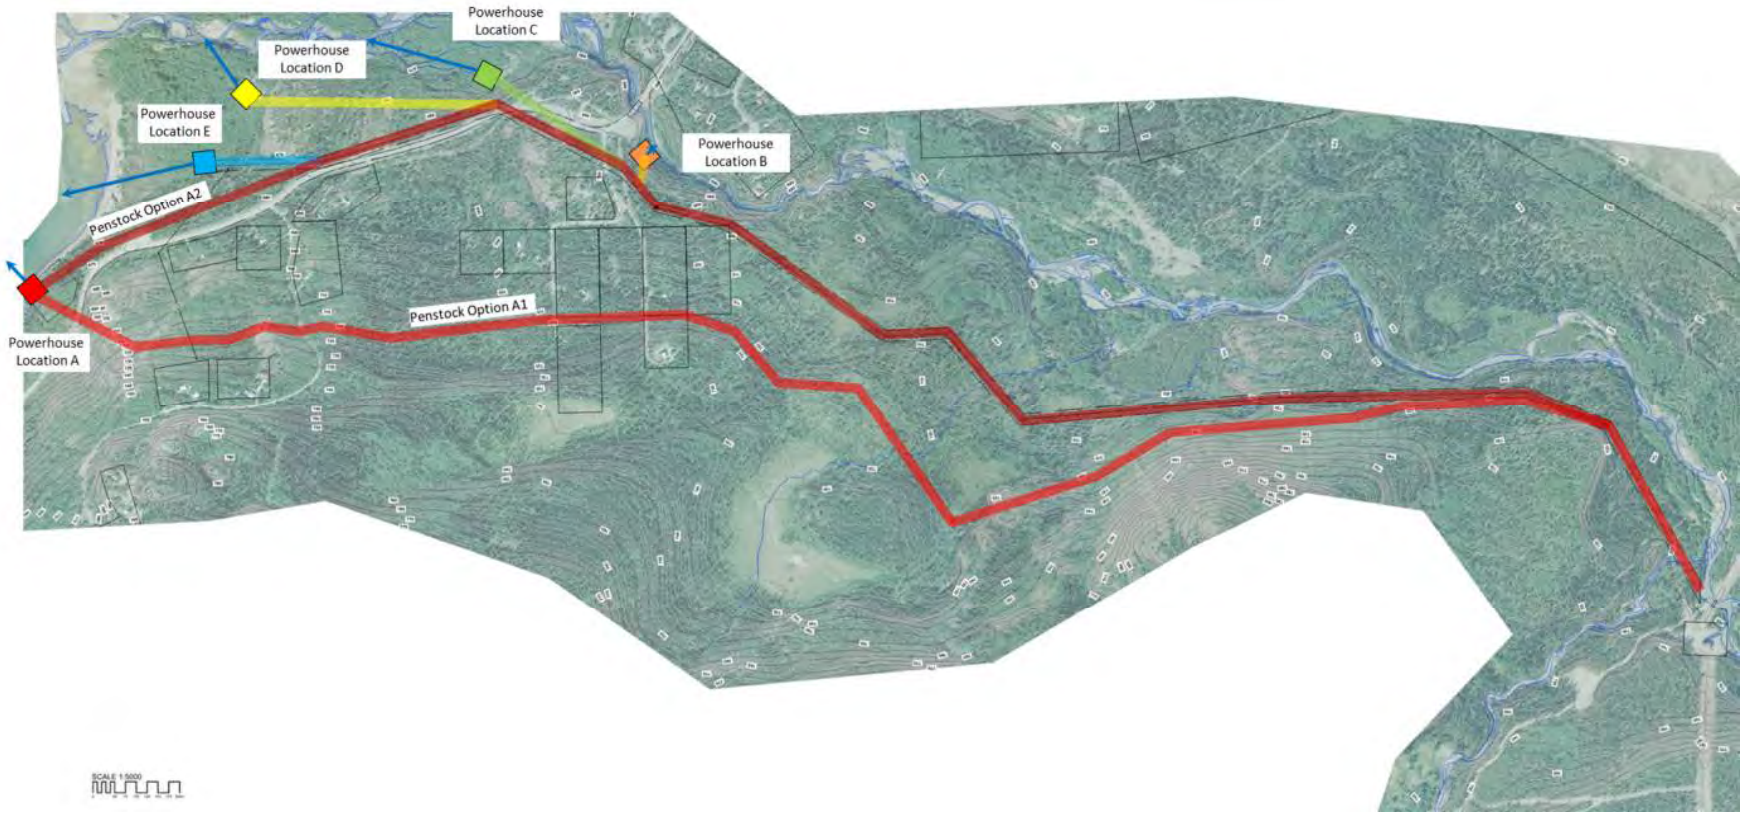


Table 3-1: Lower Powerhouse & Penstock Alignment Options

Green indicates Best for parameter, Red indicates Worst for parameter. **Bold** indicates preferred option.

Powerhouse Location	A. Atlin Lake		B. Pine Creek Above Bridge	C. Pine Creek Below Bridge	D. Upper Pine Creek Fan	E. Lower Pine Cr. Fan
Penstock Alignment	A1. Upper Alignment	A2. Lower Alignment along Warm Bay Road	B. Lower Alignment to Pine Creek Bridge	C. Lower Alignment to below Campground.	D. Lower Alignment to Pine Cr. fan	**E. Lower Alignment to Pine Cr. fan**
Penstock Length	4.4 km	4.4 km	3.0 km	3.4 km	3.8 km	**4.0 km**
Penstock Constructability	• Greatest length of potentially poorly drained/swampy soil • Significant lengths of side hill construction in rock • Significant rock work at end of alignment (Monarch Mt. Trail area)	• Less side hill & rock construction • Less poorly swampy areas crossed • Requires construction of 1.0 km along Warm Bay Road (either in ditch or under road surface)	• Less side hill & rock construction • Less poorly swampy areas crossed. • Does not cross Warm Bay Rd.	• Less side hill & rock construction • Less poorly swampy areas crossed.	• Less side hill & rock construction • Less poorly swampy areas crossed.	• **Less side hill & rock construction** • **Less poorly swampy areas crossed.**
Penstock Alignment Land Ownership	Likely land conflicts both at S. Pine Creek Drive and potentially along Art Centre Rd.	Avoids land conflicts – route pass below (north) of S. Pine Creek Dr. properties. Possible issues with constructing in Warm Bay Rd. right of way.	Avoids land conflicts – route pass below (north) of S. Pine Creek Dr. properties	Avoids land conflicts – route pass below (north) of S. Pine Creek Dr. properties	Avoids land conflicts – route pass below (north) of S. Pine Creek Dr. properties	**Avoids land conflicts – route pass below (north) of S. Pine Creek Dr. properties**
Gross Head	57.5 m (Lake elev. 667.5)		42 m (Creek elev. 683)	47.5 m (land surface elev. 676.5)	52.5 m (land surface elev. 671.5)	**56m (land surface elev. 669)**
Powerhouse Constructability	Hillside, sand and gravel over bedrock. Site is small but likely adequate.		Site is very small and difficult to access. Will likely require building powerhouse into hillside and bedrock excavation	Adequate space, extensive sand and gravel, well drained. Possible near-surface bedrock at base of hill.	Adequate space, extensive sand and gravel, well drained. No bedrock. May require creek deflection berm to prevent migration of creek into powerhouse area.	**Adequate space, extensive sand and gravel, well drained.** **Possible near-surface bedrock at base of hill.**
Tailrace Considerations	Excavation of tailrace in lake required (to accommodate lake level fluctuations		Negligible – direct discharge to creek	Requires 270 m long excavated tailrace in sand and gravel to Pine Creek.	Requires 100 m long excavated tailrace in sand and gravel to Pine Creek.	**Requires 200 m long excavated tailrace in sand and gravel to Atlin Lake**
Proximity of Private Property	Nearest residence: 400m.		160 m to campground and 110m nearest residence on S. Pine Drive and	100 m to campground. 320 m to nearest residence on Pine Dr. and S. Pine Dr.	330 m to nearest residence on Warm Bay Rd. 680 m to campground.	**220 m to nearest residence on Warm Bay Rd.**
Recreational Impacts	Likely conflicts/issues with crossing Monarch Mt. Trail		Potential construction noise/visual impacts to campground & neighbors	Potential construction noise/visual impacts to campground	No significant conflicts identified.	**Tailrace constructed through Pine Creek beach**

3.2.1.1 Upper Powerhouse Alternate Arrangement

There is a set of rapids on Pine Creek immediately upstream of the current head pond. Further upstream of the rapids, Pine Creek has been heavily disturbed and flows through approximately 5 km of placer gold mine workings. Between the upper end of the placer mining area and the existing head pond, the creek drops approximately 65 m. Therefore additional head potential exists upstream of the current plant. An alternative arrangement for the upper powerhouse has been identified as described below, but this option has not been assessed in detail as part of the current study. Generally, components of this alternate arrangement are described as follows:

There is an old diversion canal that at some time in the last century intercepted Pine Creek upstream (east) of the placer mining area and diverted the creek around the mines. Remnants of the diversion channel are clearly visible on the south side of the valley and the former canal comes within 1.5 km of the current head pond.

An alternative arrangement could be developed that would utilize the additional 65 m of head. This alternative arrangement could consist of intercepting Pine Creek upstream of the placer mines, building a 7.5 km long power canal following the old canal, plus a new 4.3 km penstock from the end of the power canal to the existing powerhouse (see Figure 3-2). This arrangement would require an entirely new penstock (the existing penstock could not be used due to higher pressures associated with the additional head) plus entirely new turbines to utilize the full flow and higher head. This would result in the existing infrastructure (head pond, penstock and powerhouse) being largely un-utilized.

Figure 3-2: Upper powerhouse alternate arrangement

There are two advantages to the alternate arrangement:

1. Increased annual energy production—depending on the specific installed capacity, it could produce on the order of an additional 17 GWh/yr of energy (on top of the energy production of the proposed layout); and
2. A potential reduction in frazil-ice related issues by avoiding the set of rapid upstream of the current head pond. It is suspected that this reach is generating most of the frazil ice that reaches the existing upper headpond.

The drawback of this alternate arrangement is the existing investment would not be well utilized. The existing plant would only be used for limited generation during late summer/fall months if there is surplus water in the creek and if there are outages on the new power plant.

The costs and technical challenges of this alternate arrangement, plus financial implications should be assessed at the next phase of study before advancing the final scheme for the hydro expansion project to feasibility level study.

4 HYDROLOGICAL AND POWER STUDIES

This section presents an analysis of the hydrology of Pine Creek watershed for the purpose of expanding hydroelectric generation in Pine Creek. The goal of the project is to increase energy generation by (1) developing additional head below the existing powerhouse (including the Spruce Creek catchment), and (2) optimize storage in Surprise Lake to maximize winter energy generation that is highly valuable to the Yukon.

The Atlin Tlingit Economic Limited Partnership (ATELP) currently owns and operates a 2.1 MW hydroelectric generation facility that utilizes flows in Pine Creek. The Atlin Hydro Expansion Project considers the possibility of increasing power generation on Pine Creek by developing additional head, expanding the existing facility and optimizing the storage in Surprise Lake to maximize winter generation. Surplus energy would be delivered to Yukon via a transmission line connecting Atlin to Jakes Corner.

The outflows of Surprise Lake are controlled by an overflow rock fill weir and a low level outlet operated with a slide gate. Water from Surprise Lake seasonally overtops the weir at the outlet. Otherwise, minimum flows are maintained in Pine Creek year-round with a fishway.

4.1 Hydrological Study

4.1.1 Geographic Setting and Climate

Pine Creek is located near Atlin in north western British Columbia. The regional climate of the catchment spans three different Biogeoclimatic Zones (Boreal White and Black Spruce, Spruce-Willow-Birch and Alpine Tundra). The nearest and continuously active meteorological station is located in Atlin (Environment Canada Station #1200560). This station is located approximately 7 km from the Pine Creek catchment at an elevation of 673.6 m ASL.

The Atlin station has records of daily temperature and precipitation beginning in August, 1905 to the present day. According to the 1980-2010 Canadian Climate normal set by Environment Canada, the station receives 365 mm of annual precipitation, with 201 mm falling as rain. Mean monthly temperatures fluctuate seasonally between -12.8°C (January) to 13.4°C (July) with a mean annual temperature of 1.1°C. The total monthly precipitation and mean temperature for Atlin are shown in Figure 4-1.

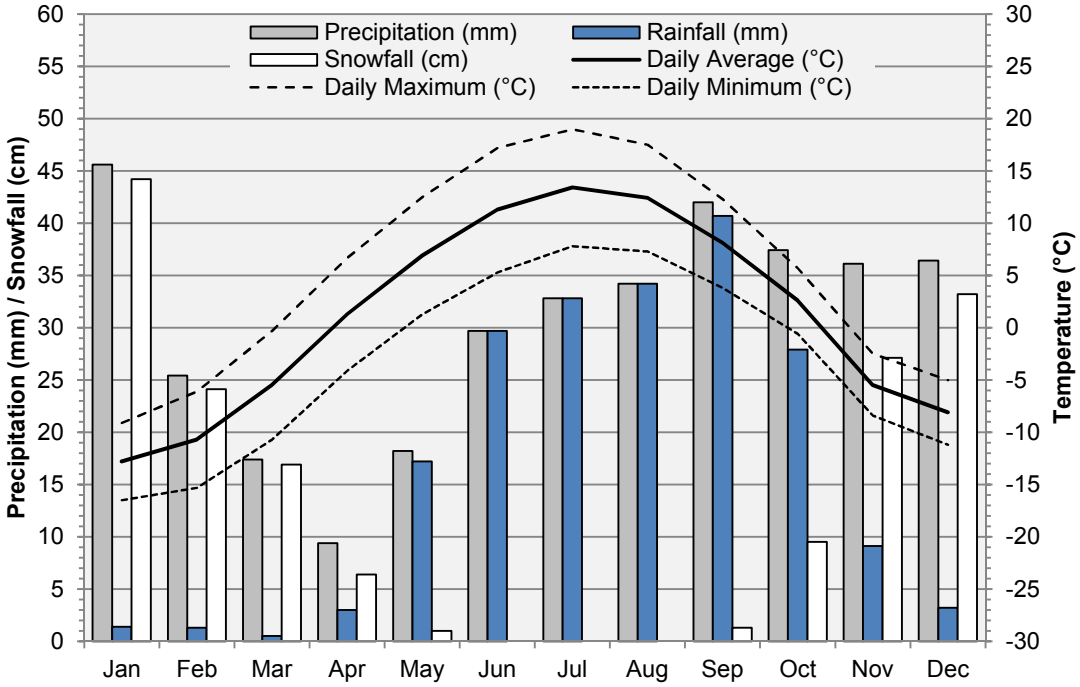

Figure 4-1: 1981 to 2010 climate normals for Atlin, BC (Environment Canada Station #1200560).

4.1.2 Previous Studies

A hydrological study was completed by PO Sjoman Hydrotech Consulting in 2003. This report was referenced in Sigma Engineering Hydrology Report (2006). The findings of this report were the basis for selecting the Gladys River WSC station as a representative data set for developing a long-term synthetic flow series for Pine Creek for the purpose of estimating the power potential of the existing power plant. This study included an assessment of eight Water Survey of Canada (WSC) stations proximal to the region. Due to an inability to retrieve PO Sjoman report, the report was not reviewed or evaluated as part of this assessment.

Sigma Engineering Ltd. completed a Hydrology Report for the Atlin Hydroelectric Project (2006). This report used a comparison of common period of record flows at the Gladys River and Pine Creek to determine a 'calibration factor' of 0.97. This was used to convert flows measured at the Gladys River to flows on Pine Creek at selected points within the catchment. The ratio of average annual unit discharge was used to synthesize flows at the intake location and outlet of Surprise Lake using a scaling factor based on the size of each catchment area. Using this data, the mean annual flow (MAF) was estimated at 4.06 m^3/s at the existing upper intake and 3.4 m^3/s at the outlet of Surprise Lake.

The flow series used by Sigma to estimate the power and energy potential of the site could not be retrieved. Verifications were made in the current study to confirm the selection of Glady's River as the reference hydrometric station to develop a flow series for Pine Creek.

4.1.3 Regional Stations

Five Water Survey of Canada (WSC) stations in proximity of Pine Creek were evaluated for suitability as surrogate flow records of Pine Creek. The catchment areas had to be no greater than four times that of Pine Creek, to be considered representative to develop a long term flow series. Table 4-1 summarizes the WSC stations considered, along with the number of complete years of record, mean annual flows and unit flows. Unit flows per square kilometer provides a way to compare watersheds of different sizes, by comparing flows on a common basis (over one kilometer square). A general description of each WSC station considered in this assessment and its ability to represent flow in Pine Creek is presented hereafter.

Table 4-1: Summary of nearby Water Survey of Canada hydrometric gauging stations.

Station	Name	Drainage Area (km^2)	Period	Complete years of record	Mean yearly flows (m^3/s)	Unit flows ($m^3/s/km^2$)
09AA008	Pine Creek near Atlin	697	1956-1969	10	5.1	0.0074
09AE004	Gladys River at outlet of Gladys Lake	1,910	1961-1993	32	14.8	0.0078
09AA012	Wheaton River near Carcross	864	1966-2011	41	7.9	0.0091
09AA009	Watson River near Carcross	1,150	1956-1973	9	5.1	0.0044
09AB008	McClintock River near Whitehorse	1,700	1957-1994	28	9.8	0.0058

Pine Creek

The Pine Creek station (09AA008) has a catchment area of 697 km^2 and operated near the mouth of Pine Creek on Atlin Lake from 1956 to 1969. There is 10 years of complete data between 1956-1961 and 1966-1969. Daily discharge records from this station represent all flows that originate within the project area. Daily mean discharges were selected from complete-year records and used as the basis for evaluating the ability of other regional stations to represent flows within this catchment. Mean annual discharge for the complete-year record is 5.1 m^3/s, representing an area-unit flow of 0.0074 $m^3/s/km^2$.

Gladys River

The Gladys River station (09AE004) is the catchment located immediately to the east of the Pine Creek basin. The record from this gauge location extends from 1961 to 1993 and contains 30 years of complete daily records. The station is located near the outlet of Gladys Lake and has mean annual flow of 14.8 m^3/s, with a unit flow of 0.0078 $m^3/s/km^2$. The Gladys River's catchment contains a similar percentage of surface water area as Pine Creek.

Wheaton River

The Wheaton River station (09AA012) is located approximately 90 km to the northwest of Atlin. Continuous daily flow measurement began at this station in 1966 and continues to the present. The station has a drainage area of 864 km^2 comprised primarily of high elevation terrain. Annual

discharge at this gauge is dominated by snowmelt and rain events during the spring. No lakes, ponds or other surface water features that provide storage are present within the Wheaton River catchment.

Watson River

Also located to the northwest of Atlin, the record from the Watson River station (09AA009) spans 20 years between 1956 and 1973. This station represents a drainage area of 1,150 km^2 and has a mean annual discharge of 5.1 m^3/s. Similar to the Wheaton River, the Watson river catchment is dominated by upper elevation terrain but represents a much larger catchment area.

McClintock River

The McClintock River is located approximately 92 km to the north of Atlin, BC, with daily flow data collected between 1957 and 1994. The station represents a drainage area of 1,700 km^2 and has a mean annual flow of 9.8 m^3/s. This station was primarily considered as an alternative to represent flows from parts of the Pine Creek catchment that are not affected by the storage of Surprise Lake. This includes the areas that drain into Spruce Creek and the inflows into Surprise Lake.

A comparison was made between the five gauging stations over the common period of record from 1966 to 1969. Unit hydrographs averaged over the four years were plotted to compare the behavior of each catchment over the year.

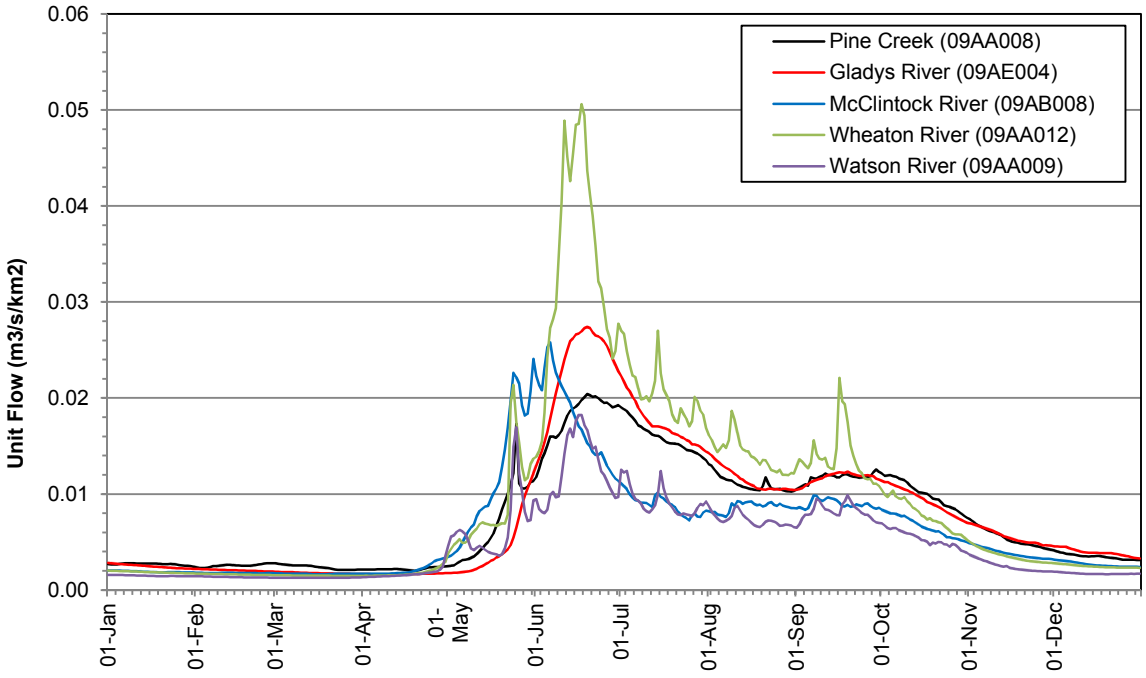

Figure 4-2: Mean daily unit flow comparison for selected regional WSC stations over the common period of record, 1966-1969.

The McClintock and Watson Rivers were rejected since their unit flow is significantly lower than the reference Pine Creek station's unit flow. A comparison of the Wheaton River flows with the Pine

Creek and Gladys River flows was made to determine if it is a suitable reference station for the inflows to Surprise Lake (i.e. un-routed flows to the lake). Figure 4-3 shows the unit yearly hydrographs for the three stations over the common period of record.

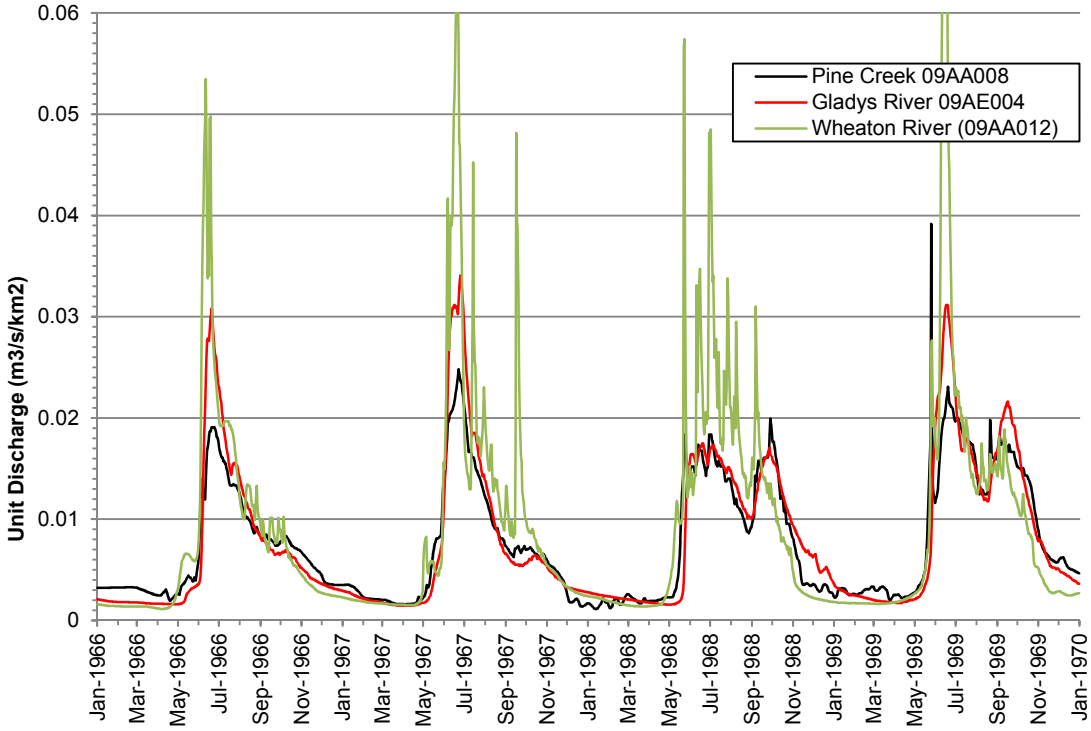

Figure 4-3: Daily unit flows for the period-of-record, 1966-1969

The Gladys River station is considered the most suitable station to develop long-term synthetic flow series in Pine Creek. Although the Wheaton River could also have been suitable to develop and inflow series to Surprise Lake based on the previous comparison, the Gladys River is retained for the following reasons:

- Use of Gladys River in previous hydrometric assessment for the purposes of electrical generation;
- Similarity of unit flows for Pine Creek and Gladys River (see Table 4-1);
- Both Gladys River and Pine Creek gauging stations capture water discharging from large surface water body at a similar elevation (Surprise Lake and Gladys Lake);
- Gladys River catchment is located adjacent to Pine Creek with the gauging stations located approximately 60 km from one another. Each station also demonstrates a similar timing of freshet and response to regional precipitation events.

4.1.4 Development of the flow series

A long-term flow series for Pine Creek was developed using the Gladys River flow record as described above. Flows from Gladys River were transferred directly to the various sub catchments of Pine Creek based on a ratio of catchment areas. Gladys River has generally higher summer flows

than Pine Creek over the 4 years of common record (Figure 4-3) while flows during the fall and winter are generally lower. This is likely due to the larger percentage of the catchment that Surprise Lake represents compared to Gladys Lake, thus providing more significant routing of inflows. Continuous flow gauging on Pine Creek will allow to improve the quality of the inflow series and firm up power estimates. Overall Gladys River has a unit flow per kilometer square that is about 5% higher than Pine Creek. The Gladys River flow record is however more recent thus may capture better the potential effects of climate change on the catchment. At this stage of study and based on the available data, Gladys River represents the best proxy station to use to determin the power and energy potential of the Atlin Hydro Expansion Project.

Inflows to Surprise Lake were first determined, following by inflows from the different intermediate sub-catchments. This approach is consistent with the one taken in previous hydrological studies of the Pine Creek catchment.

The proposed layout of the Atlin Hydro Expansion Project is presented in detail in Sections 3 and 5, as well as on the drawings in Appendix A. Based on the proposed layout, flows were determined at the following locations along Pine Creek to simulate the power and energy generation potential of the project:

- Surprise Lake at its outlet;
- Upper head pond/intake (existing, for the upper power plant);
- Lower head pond/intake (new, for the lower power plant);

Figure 4-4 illustrates the contributing catchments to each location. Inflows to Surprise Lake will be regulated based on the selected management scheme, while flows originating downstream of Surprise Lake will be unregulated. Both head ponds have minimal storage capacity and as a result is neglected in the power generation analysis.

The total catchment area at the outlet of Surprise Lake is 470 km^2. The upper and lower plants respectively have catchment areas of 553 and 678 km^2 at their intake

Surprise Lake

Synthetic flow records of Pine Creek at the outlet of Surprise Lake were determined by scaling daily flows in the Gladys River between 1963 to 1993 (complete years only) to the Surprise Lake catchment area (470 km^2). This data was then reverse-routed through Surprise to determine an inflow series to Surprise Lake this is used to simulate reservoir operations. The reverse routing exercise was based on methods described by Zoppou (1999) for reverse routing of flows through a surface water body. Corresponding Surprise Lake elevations were determined by a stage-discharge relationship for the outlet of Surprise Lake that is based on measurements made by Yukon Energy Corporation (YEC) at the lake outlet between 1990 and 2006 (by Monty Alfred). Daily inflow volumes were determined by subtracting the outflows from changes in Surprise Lake storage (estimated area of 32 km^2). Daily inflow flow series to Surprise Lake were then routed through Surprise Lake to develop an outflow series. The two outflow series (synthetic and routed) compared well.

The resulting Surprise Lake inflow series does not reflect the effect of storage in the lake and is therefore considered representative of flows in other reaches of the Pine Creek catchment (i.e. Spruce Creek and intermediate catchment between the different structures) not affected by surface water bodies.

The average monthly inflows and outflows of Surprise Lake are presented in Figure 4-2. Average monthly inflows were calculated from daily inflows to Surprise Lake as a result of the reverse-routing exercise. Surprise Lake outflows were calculated from daily average inflows routed through Surprise Lake considering a natural outlet (without any outlet structure) for verification purposes. A graphical presentation of unregulated average daily flows and Surprise Lake water levels is shown in Figure 4-5.

Table 4-2: Mean monthly inflows and outflows of Surprise Lake, 1963 to 1993 (unregulated).

Month	Inflow (m^3/s)	Outflow (m^3/s)

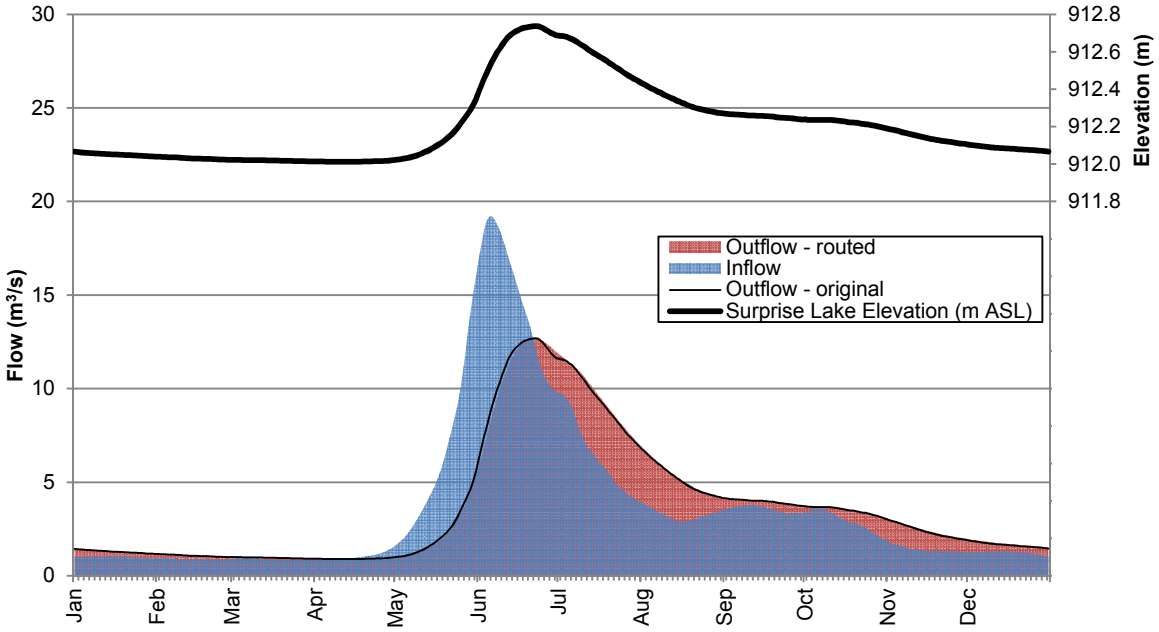
Figure 4-5: Surprise Lake synthetic hydrology (unregulated) based on reverse-routing of scaled Gladys River (WSC 09AE004) 1963-1993 hydrometric record.



Intermediate catchments below Surprise Lake

Flow series from the various intermediate sub-catchments below Surprise Lake were determined by scaling the synthetic inflow series to Surprise Lake to each of those catchments. The basin area for the intermediate catchments are presented in Table 4-3 below.

The intermediate catchment of Pine Creek between the Surprise Lake outlet and the upper head pond has a surface area of 83.2 km^2. The resulting average yearly inflows is estimated at 0.7 m³/s, resulting in a total average yearly inflow of 4.4 m³/s at the upper power plant intake.

Average yearly flows in Spruce Creek (catchment area of 107 km^2) were estimated at 0.8 m³/s. Flows were also calculated for the intermediate catchment of Pine Creek between the existing intake and the mouth of Spruce Creek (catchment area of 19 km²), yielded an average yearly flow of 0.2 m³/s. The resulting total flow at the lower power plant intake is then of 5.4 m³/s.

Table 4-3: Contributing catchments for the Upper and Lower Power Plant.

	Catchment	Basin area (km²)	Mean flow (m³/s)
Upper Plant	Surprise Lake	470	3.7
	Intermediate catchment above upper intake on Pine Creek	83	0.7
	Total	**553**	**4.4**
Lower Plant	Intermediate catchment below upper intake on Pine Creek	19	0.2
	Spruce Creek	107	0.8
	Total	**678**	**5.4**

4.1.5 Low Flow Analysis

Minimum flows occur in the late winter and are associated with base flow in the channel. A 7-day low flow analysis of the 2, 5, 10, and 25-year return periods was calculated for the synthetic Surprise Lake inflow and outflow (unregulated) series. This analysis is based on fitting the annual minimum flows for any seven consecutive days to a Log-normal Pearson Type III distribution function. This function is then solved for the associated recurrence probability (0.5, 0.2, and 0.1, 0.05, respectively) to estimate the 7-day low flows. Table 4-4 presents the low flows for Surprise Lake inflows, Pine creek at the outlet of Surprise Lake, Spruce Creek and Intake structures.

The 7-day low flows for the upper intake are slightly greater than previously reported by Sigma Engineering Ltd. (2006). Sigma estimated 1.1 m^3/s, 0.93 m^3/s, 0.85 m^3/s and 0.78 m^3/s for 2, 5, 10 and 25-year return periods using a slightly different methodology. It is expected that differences with the results presented in this report are a function of the different methods applied.

Table 4-4: Summary of 7-day low flow analysis for 2, 5, 10 and 25 year return periods, based on the Surprise Lake synthetic inflow and outflow series.

Return Period (years)		Empirical Probability	Surprise Lake Inflow (m³/s)	Surprise Lake Outlet (m³/s)	Upper Intake (m³/s)	Spruce Creek (m³/s)	Lower Intake (m³/s)
7Q2	2	50 %	1.3	1.0	1.2	0.3	1.6
7Q5	5	20 %	1.1	0.9	1.1	0.25	1.4
7Q10	10	10 %	0.9	0.9	1.1	0.22	1.3
7Q25	25	4 %	0.8	0.9	1.0	0.20	1.3

4.1.6 Flood Analysis

A simplified flood frequency analysis of Pine Creek was conducted to determine floods of different return period at various key locations for the project. Floods were determined at the following locations:

- Surprise Lake control structure (lake outlet)
- Upper head pond/intake
- Lower head pond/intake

The maximum flows at the outlet of Surprise Lake are dependent on the water level management scheme. Two sets of maximum daily annual flows over the duration of the flow series were retrieved: one from the synthetic Surprise Lake inflows and a second from the simulated outflows from Surprise Lake which occur prior to controlled releases from the reservoir (maximum flow between early May and end of October). Each set of maximum annual flows were fit to a Gumbel, Log Normal and Log-Pearson III type probability model. The average flow predicted by all three distribution models was taken as a representative flood flow for the respective return periods.

The flood frequency developed for the Surprise lake inflow series was scaled to the Spruce Creek and intermediate segments of the catchment below Surprise Lake using the respective catchment area ratios. Flood flows from the outlet of Surprise Lake were then combined with intermediate catchment and Spruce Creek flows to determine flood sizes at the Upper and Lower Intakes. The size, probability and return periods of flood flows are summarized in Table 4-5.

The 1: 100 year flood at the Surprise Lake outlet is estimated at 16.4 m^3/s. This flood translates to a 25.5 m^3/s and 39.3 m^3/s flow at the Upper and Lower Intakes, respectively. A number of similarly-sized flows (i.e. 0.8 m^3/s) at the outlet of Surprise Lake were excluded from the analysis since these values more strongly reflect the reservoir management scheme rather than actual peak flood flows at the Surprise Lake outlet.

Table 4-5: Summary of Flood Frequency Analysis for the Pine Creek catchment at the Surprise Lake control structure, Upper and Lower Intakes.

Return Period (years)	**Surprise Lake Control Structure** (*m^3/s*)	**Upper Intake** (m^3/s)	**Lower Intake** (m^3/s)
2	5	9	15
10	10	17	26
20	12	19	30
50	15	23	35

4.2 Power and Energy Simulations

Simulations were run to estimate the long-term power and energy potential of the Atlin Hydro Expansion Project. The proposed layout of the project is discussed in more detail in Section 3 and 5. The layout is composed of two power plants:

1) The ***upper power plant,*** which includes the existing 2.1 MW facility augmented with a new 2.9 MW plant for a total installed capacity of 5 MW. The upper plant operates under a gross head of 107.6 m.

2) The ***lower power plant*** has an installed capacity of 2.8 MW. It operates under a gross head of 55.5 m. Its head pond is located approximately 200 m downstream of the tailrace of the upper plant.

4.2.1 Surprise Lake Storage

Surprise Lake is the reservoir for the existing power plant on Pine Creek and is currently managed within a 1.05 m operating range. The Atlin Hydro Expansion Project considers an increase in the storage range at Surprise Lake in order to increase and maximize winter energy generation from the system.

It is proposed to increase the Surprise Lake storage range to 2.5 m. Based on an approximate surface area of 32 km^2 for Surprise Lake, it would provide up to 80 Mm^3 of storage. This volumes stores most of the inflows to the lake (except for the summer releases for power generation and for minimum flow requirements), which were estimated to be on average 132 Mm^3 per year over the duration of the flow series.

Modifications to the Surprise Lake Control Structure would be required to accommodate the increase in storage range (discussed in Section 5.1). Table 4-6 summarizes the configuration of the existing and proposed control structure at the outlet of Surprise Lake.

Table 4-6: Parameters of Surprise Lake Control Structure

	Existing Configuration	Proposed Configuration
Overflow weir crest elevation (m)	913.1	913.85
Weir crest width (m)	32	32
Outlet control structure	1.8 m diameter culvert	1.8 m diameter culvert
Full Pond Level (m)	913.15	913.85
Low Pond Level (m)	912.10	911.35
Operational Range	1.05	2.5

The power simulation considers two new power plants. The upper power plant will be located adjacent to the existing generating station and will utilize all of the water available for generating at that site. The location of the lower power plant will be near Atlin Lake and utilize flows from the Pine Creek catchment below the upper Intake and outflows from the upper power plant. The location and layout of the proposed power plants are illustrated in Drawings 01 to 03 in Appendix A. Contributing catchment areas to each plant are presented on Figure 4-4 in Section 4.1.4.

Consideration was also given to a 2 m storage option (911.85 m to 913.85 m) in Surprise Lake for the power simulations. Results for this option are presented for the purpose of evaluating the benefits and environmental challenges of the 2.5 m storage range. The detail methodology for the 2 m storage option is not presented in the report, but similar operation rules as the 2.5 m storage range apply.

4.2.2 Surprise Lake Management

A model was created to simulate the management of Surprise Lake. The following rules and assumptions were incorporated into the model:

1) Maximize winter generation, where the majority of freshet and summer inflows are stored in Surprise Lake and released later in the winter for hydro generation. Summer releases are only to meet the Atlin electrical load (baseline taken as the 20 years forecast) and minimum flow requirements. The Atlin electrical load can be met with power production at both power plants (existing and expansion to upper power plant and new lower power plant). Unregulated inflows from the intermediate sub-catchments below Surprise Lake also provide additional water to both power plants during the summer months;

2) Regulated flow releases for the winter begin on November 1st and last until May 10th. Releases are kept as constant as possible during the winter period, except during the spring when power demand from the Yukon is expected to be lower. The objective is to discharge flows of approximately 6 m³/s on average from Surprise Lake.

   The objective of the schedule of releases is to draw down Surprise Lake as close as possible to the LSL without going below this level in any of the simulated years. Gate operation rules were developed based on the water level in the lake to meet that objectives. The following gate openings are retained (in % opening):

Lake Elevation > than	% Open
913.85 m	*55 %*
913.60 m	*60 %*
912.10 m	70 %
911.45 m	80 %
911.35 m	25 %

3) The gate opening is set at a 10 % (18 cm) when the reservoir fills in the summer and fall. This opening maintains a minimum flow in Pine Creek of a least 10% of the mean annual discharge (MAD) of 3.7 m³/s at the outlet of Surprise Lake. Inflows from the intermediate catchment areas below Surprise Lake and above the intake structures contribute additional flow to Pine Creek.

4) Floods are managed as close as possible to the full pond level by opening the low level outlet gate when the water level is above 913.75 m in Surprise Lake (10 cm below the full

pond level). Most floods can be managed without exceeding the full pond level by more than 10 cm.

Surprise lake water levels were simulated for the 2.5 m operational range as a result of the regulated flow releases for 30 years of synthetic flow records (1963 to 1993). Figure 4-6 and Table 4-7 presents the average yearly Surprises Lake water levels, inflows and outflows over the duration of the flow series. Maximum storage occurs in late October. The lake is drawn down to within 10 cm of the low pond level typically in early May, prior to lake infilling. Surprise Lake water levels for the entire simulation period are illustrated in Figure 4-7.

Surprise Lake reaches the full pond level in 23 of the 31 years of simulation. In the years when lake levels do not reach the full pond level, they are at least within 0.2 m with the exception of 1978 (the driest year). Management of Surprise Lake causes water levels to be drawn down in the spring to a level close to the low pond level and varies between 911.35 m and 911.5 m, depending on the timing of the start of reservoir infilling during the freshet. Water spills above the crest of overflow weir during the late summer and early fall in approximately one-half of the simulated years. This is a result of Surprise Lake reaching the proposed full supply elevation of 913.85 m.

Figure 4-6: Average yearly Surprise Lake operations for the proposed 2.5 m operational range.

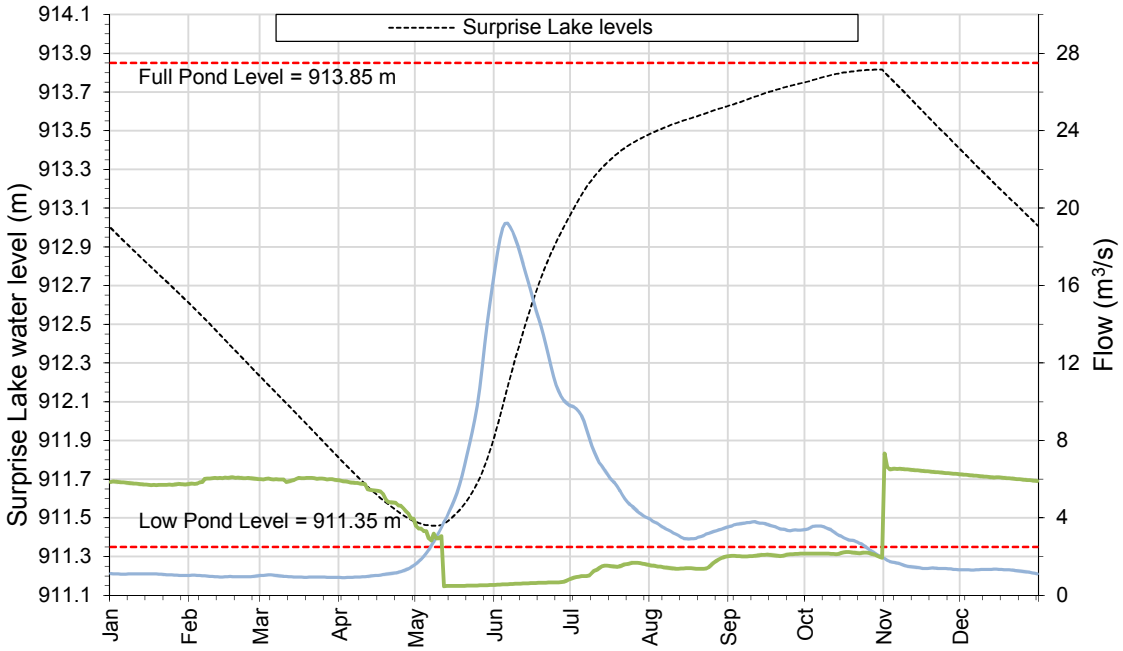

Table 4-7: Mean monthly Surprise Lake water levels, inflows and outflows during the simulated period

Month	Surprise Lake Level (m)	Inflows (m³/s)	Outflows (m³/s)
January	912.8	1.1	5.8
February	912.4	1.0	6.0
March	912.0	1.0	6.0
April	911.6	1.1	5.2
May	911.6	6.4	1.4
June	912.6	14.9	0.6
July	913.3	6.4	1.4

4.3 Power Generation

A power generation model was created to estimate the power and energy potential of the Atlin Hydro Expansion Project. The results that are presented in this section are for the total installed capacity on Pine Creek, including the existing 2.1 MW power plant.

Upper power plant

The existing 2.1 MW power plant is located approximately 10 km downstream of Surprise Lake on Pine Creek. The upper power plant has a gross head of 107.6 m and bypasses a reach of Pine Creek with a steep gradient containing several waterfalls. The proposed development is to construct an additional power plant adjacent to the existing 2.1 MW plant. A new penstock will convey water from the existing upper head pond to the new power plant adjacent to the existing plant and will operate under the same head. A new intake structure will be constructed in the existing upper head pond.

The power simulations for the upper plant include the operation of the existing and proposed power generation facilities. The power simulation of the upper power plant is a function of the synthetic

flow series and management of the reservoir (Surprise Lake), with an additional contribution from the intermediate catchment between the outlet of Surprise Lake and the Upper Power Plant intake. The average yearly inflow to the upper intake is estimated at 4.4 m^3/s. A flow duration curve is also presented in Figure 4-8.

The existing plant is currently operated with a 1.22 m (48 inches) diameter high-density polyethylene (HDPE) diameter penstock that conveys water to the 2.1 MW power plant that operates under a turbine flow of 2.45 m^3/s. Based on the flow duration, a total turbine flow of 6 m^3/s is selected for the upper plant (existing and new plant combined) which corresponds to a flow with approximately 30% exceedance. The new upper plant will then have a turbine flow of 3.55 m^3/s which leads to an installed capacity of 2.9 MW. A new 1.52 m (60 inch) diameter HDPE penstock will convey water from the upper head pond to the new upper plant. Head losses were estimated for both friction along the penstock and at various singularities along the system. A Manning's coefficient of 0.010 was selected for the HDPE penstock.

A conservative constant 85% turbine efficiency was used for the power simulations. Higher turbine efficiency can however be achieved under optimal operating flows especially for Francis and Pelton turbines. The proposed Turgo turbines for the upper power plant expansion will however have a slightly lower efficiency. Detail turbine efficiency curves will be obtained from suppliers in the feasibility study and power simulations will be conducted with varying efficiency based on the operating flows to firm up the power estimates.

Power production simulation parameters and assumptions for the upper power plant are summarized in Table 4-8.

Lower power plant

The lower power plant will have a new intake constructed approximately 200 m downstream of the upper power plant tailrace. It will capture the inflows coming from Spruce Creek through a small diversion of the creek into the new lower head pond. A new penstock will convey water approximately 4 km to the lower power plant located adjacent to Pine Creek approximately 200 m upstream of its mouth on Atlin Lake.

Power simulations for the lower power plant utilized the regulated flows from the upper power plant (turbine flow and residual spill), and the unregulated flows from the intermediate catchment between the upper head pond and Spruce Creek, and from Spruce Creek itself. The average yearly flow at the lower intake is estimated at 5.4 m^3/s. A flow duration curve for flows at the lower power plant intake is presented in Figure 4-8.

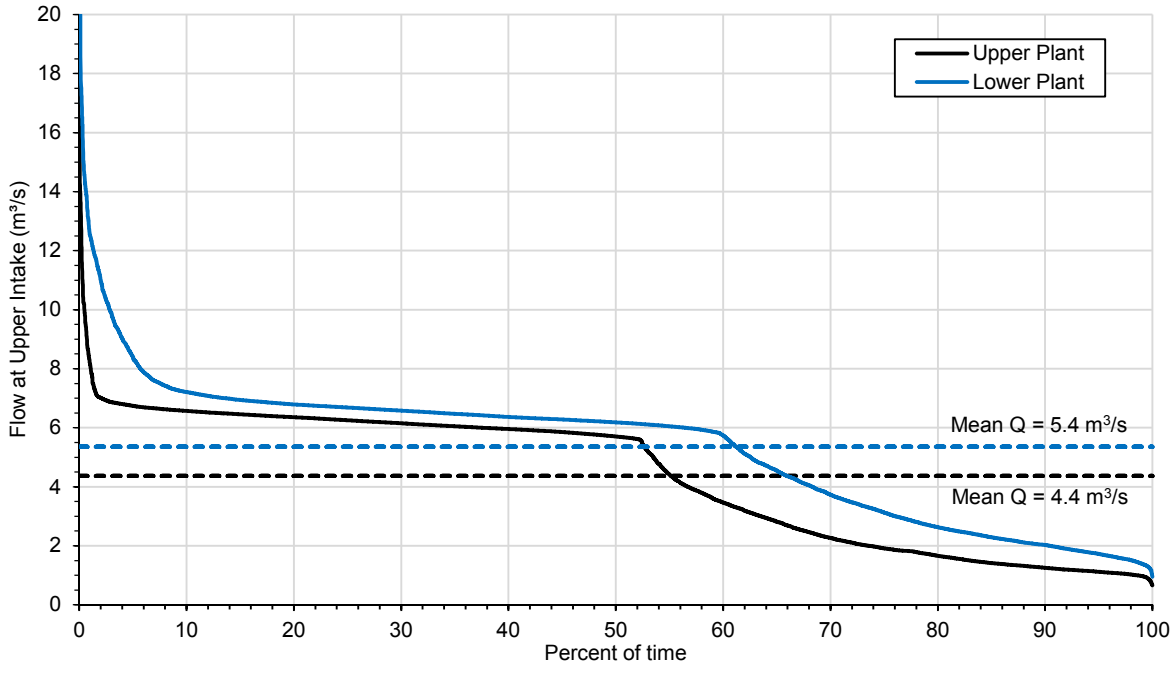
Based on the flow duration curve a turbine flow of 7 m^3/s is selected, which corresponds to a flow with approximately 20% exceedance. The new lower power plant will operate under a gross head of 55.5 m, which leads to an installed capacity of 2.8 MW. Two 1.52 m (60 inches) diameter HDPE penstock will convey water from the new lower head pond to the lower power plant. Head losses were estimated for both friction along the penstock and at various singularities along the system. A Manning's coefficient of 0.010 was selected for the HDPE penstock.

Power production simulation parameters and assumptions for the lower power plant are summarized in Table 4-8.

Table 4-8: Design Parameters and Assumptions for the Upper and Lower Power Plant.

Element	Upper Plant	Lower Plant
Gross Head	107.6 m	55.5 m
Penstock Size	1.5 m diameter (HDPE)	2 x 1.5 m diameter (HDPE)
Maximum Flow Velocity	2 m/s	2 m/s
Head Losses	Friction: 4.3 m Singularities: 3.0 m Total: 7.3 m	Friction: 4.2 m Singularities: 3.0 m Total: 7.2 m
Average yearly flow	4.4 m^3/s	5.4 m^3/s
Environmental Flow (10% MAF)	0.44 m^3/s	0.54 m^3/s
Turbine Flow	Existing Plant: 2.45 m^3/s New: 3.55 m^3/s Total: 6 m^3/s	New: 2 x 3.5 m^3/s Total: 7 m^3/s
Installed Capacity	Existing: 2.1 MW New: 2.9 MW Total: 5.0 MW	New: 2 x 1.4 MW Total: 2.8 MW
Turbine Efficiency	85%	85%

Figure 4-8: Flow duration curve for Upper and Lower Power Plant.



4.4 Simulation results

Power and energy generations were estimated on a daily basis at each power plant. A minimum flow of 10% of the mean annual flow at each plant is discharged from the head pond year-round. Monthly results were compiled for presentation in the report.

Figure 4-9 and Table 4-9 presents monthly power and energy generation for each plant. Figure 4-10 presents the total yearly generation over the duration of the 31-year synthetic flow series. This flow series does provide indication of the variability of power generation relative to the average power production. A low-flow assessment is also provided in Section 4.5 which gives indication of the firm power production. A more comprehensive percentile assessment of generation will be completed as part of the feasibility study and will be supported by flow data collected on Pine Creek since 2014.

Upper power plant

The mean annual power for the upper power plant is estimated 3.2 MW for an average capacity factor of 63%. The mean monthly capacity factor varies between close to 100% in November and December to as low as 30% in August. This corresponds with the timing and magnitude of controlled releases and infilling of the Surprise Lake reservoir.

Using the simulated flow series for Pine Creek (1963 to 1993), the total mean annual energy generation for the upper power plant is 28.2 GWh and varies between 23.7 GWh and 34.9 GWh over the simulated period.

Lower power plant.

The mean annual power for the lower power plant is 1.9 MW for an average capacity factor of 66%. The average monthly capacity factor varies on average between as high as 90% in November and December, and as low as 35% in August. The capacity factor of the lower plant is generally between 80% and 90% during the winter months.

The mean annual energy generation for the lower power plant is based on the synthetic flow records (1963 to 1993). Simulated mean annual energy generation for the Lower Power Plant is 16.3 GWh and varies between 13.6 and 20.3 GWh over the simulation period. Figure 4-10 presents the yearly total energy generation at the lower plant over the duration of the flow series. The spike in generation that is observed in June is a result of the freshet of the various intermediate sub-catchments below Surprise Lake (between power plants and Spruce Creek).

Figure 4-9: Upper and Lower Power Plant mean monthly power production (MW).

Comparison with the 2 m storage option

The power and energy generation potential of the Atlin Hydro Expansion Project was estimated for a 2 m storage range in Surprise Lake as a potential alternative to the 2.5 m storage base case presented in this study. A 2 m storage range could either be implemented by raising the new proposed low pond level (thus reducing the required river excavation to accommodate the lower level) or by lowering the proposed new full pond level (thus reducing the increase in the overflow weir height and the increase in the maximum lake level). Average monthly energy generation for the 2 m storage range for both the upper and lower power plants is presented in Table 4-10. The difference in energy generation between the 2.5 m storage option is presented for comparison purposes.

Table 4-10: Average monthly power and energy generation for the Upper and Lower plants (2 m storage)

Month	Upper Plant			Lower Plant			Total		
	Power (MW)	Energy (GWh)	Diff. (GWh)	Power (MW)	Energy (GWh)	Diff. (GWh)	Power (MW)	Energy (GWh)	Diff. (GWh)
January	4.6	3.4	0	2.3	1.7	0	7.0	5.1	0

Average	**3.1**	**27.3**	**-0.9**	**1.7**	**15.3**	**-1.0**	**4.9**	**42.6**	**-1.9**

The 2 m storage range option in Surprise Lake produces on average 1.9 GWh less energy per year, which only represents a 4.5% drop in generation potential. The main effect of implementing a 2 m storage range compared to a 2.5 m storage range a reduction in the winter energy generation (when most needed by Yukon) and an increase summer generation. The reduction in winter energy is estimated at 4.7 GWh on average, being observed mostly from February to April based on the operation scheme that was defined for the purpose of the simulations.

Further optimization work should be done in the next project phase to determine the benefits of the additional winter energy associated with the 2.5 m operational range compared to the regulatory challenges that may result from a larger storage range on Surprise Lake.

4.5 Power Production Summary

The proposed Atlin Hydro Expansion Project power simulations are a function of synthetic flows developed for Pine Creek that are based on historical hydrometric records scaled from the Gladys River between 1963 and 1993. The simulation maximizes the storage available in Surprise Lake, optimizes generation potential at existing facilities and incorporates additional flows from Spruce Creek and intermediate catchments below the existing intake structures. Two additional power plants were incorporated into a power production simulation of the hydroelectric expansion. This resulted in a total 7.8 MW installed capacity on Pine Creek.

The storage range of 2.5 m in Surprise Lake is considered the most optimal range at this preliminary stage to maximize winter energy generation on Pine Creek. Such a range allows maximum storage of the inflows to the lake during an average hydrological year. The simulations were intended to

maximize winter energy generation for the purpose of distributing to Yukon Energy during periods of greater energy demand. Consequently, this operation mode reduces generation in the summer months during the reservoir infilling period. Minimum energy delivery obligation for the community of Atlin (forecast 2032 load) are still met every month of the year over the duration of the synthetic flow series.

Figure 4-11 illustrates the average total monthly generation for the project while Figure 4-12 illustrates the minimum total monthly generation from both power plants combined over the duration of the flow series. It is important to note that careful adjustment of flows from Surprise Lake can be performed to meet, at a minimum, the future energy delivery obligation. Maximum energy generation is achieved in winter months (November through March) and minimum generation occurs in summer months (May through October) during reservoir infilling.

Total average yearly energy generation for the upper and lower power plants combined amounts to approximately 44.6 GWh with an average capacity factor close to 65%. This power simulation represents represent the upper range of generation from Pine Creek.

Figure 4-11: Simulated average monthly generation for the Upper and Lower Power Plant.

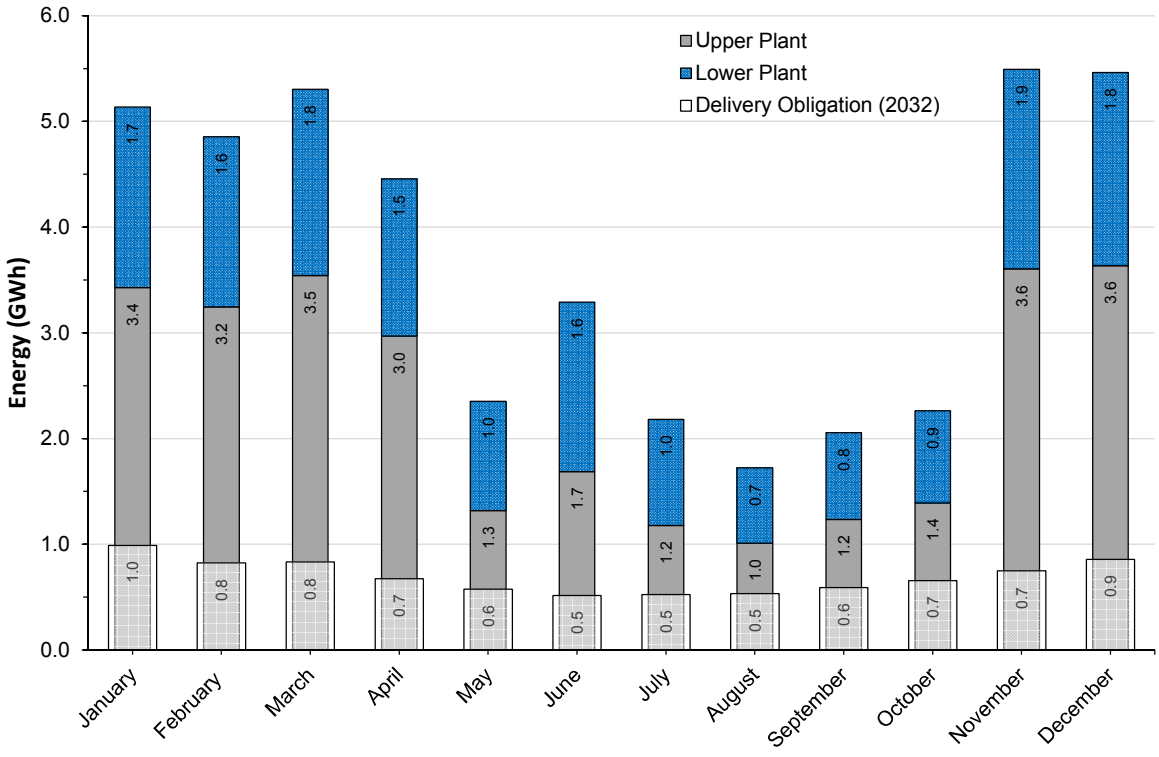

Figure 4-12: Simulated minimum monthly generation for the Upper and Lower Power Plant.

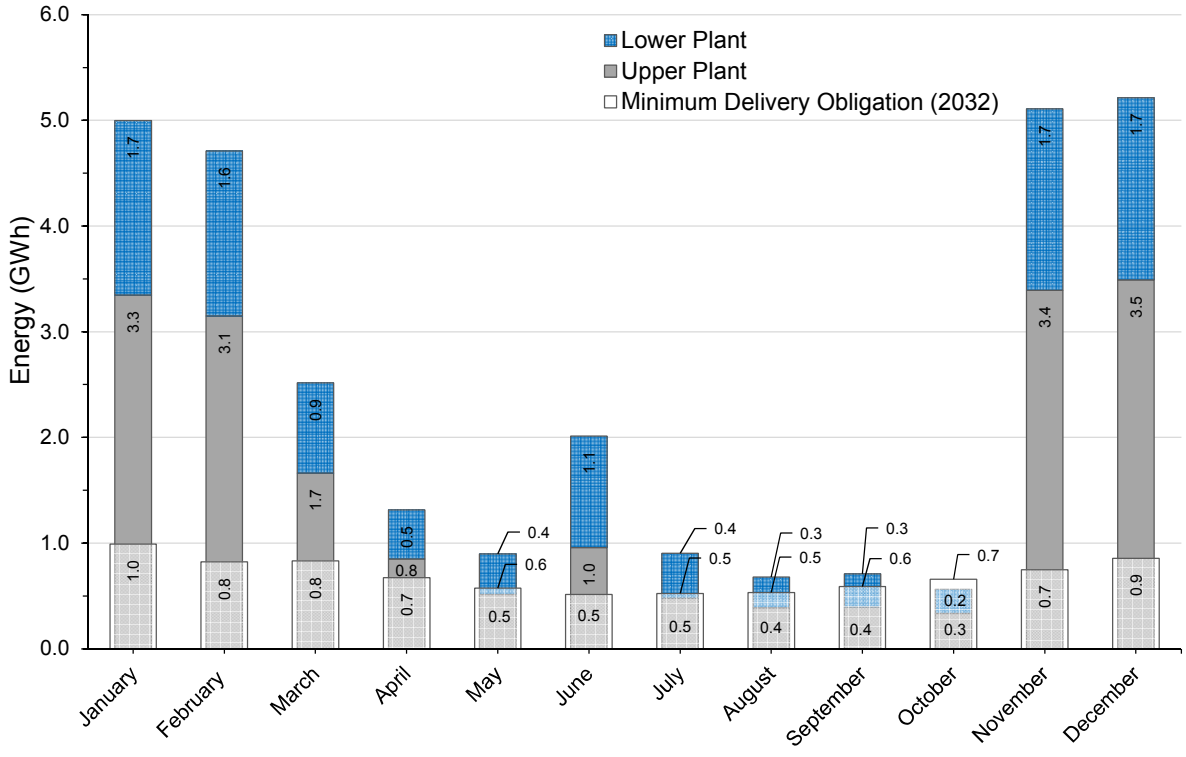

5 PRELIMINARY DESIGN

5.1 Design Criteria and Assumptions

The 1:100 years flood is selected as the design flood for the project at this stage. This corresponds to the inflow design flood recommended by the Canadian Dam Association for dams with a Low level of consequence in case of dam failure (no potential loss of life). Due to the small impoundment volume of both head ponds, it is expected that the effects of a potential dam break would be minimal and would dissipate rapidly as the flood wave migrates down river. This assumption will need to be confirmed in the feasibility study.

A preliminary flood study was conducted and is presented in detail in Section 4. The design flood flows retained for the hydraulic design of the spillway at each works are presented in Table 5-1.

Table 5-1: Design flood flows

Location	Design flow (m^3/s)
Surprise Lake control structure	16
Upper head pond	26
Lower head pond	39

It should be noted that the design flow at the Surprise Lake control structure represents the maximum outflow that can be expected at the lake outlet, considering the routing of inflows through the lake. Design flows for the upper and lower head pond are also based on the maximum outflows from Surprise Lake, with additional unregulated inflows coming from the various intermediate sub-catchments below Surprise Lake. If a smaller storage range at Surprise Lake was to be selected for the project, design flows would likely be increased due to increased spill at the Surprise Lake control structure resulting from the smaller storage volume being held in the lake.

Each of the three locations above will be designed to safely pass the inflow design flood.

Additional design criteria are selected for the water retaining structures.

- Minimum freeboard (embankment dam): 0.5 m (no wave action)
- Minimum freeboard (embankment dam): 1.0 m (potential wave action – Surprise Lake)
- Minimum freeboard (concrete dam): 0.5 m
- Minimum side slope (rock fill): 2H:1V

The Isbash equation was used to determine the appropriate size of rip rap/cobbles that is required to resist flow velocities, at different locations for the project (overflow weir at Surprise Lake control structure and lower head pond, stilling basin at lower head pond, Spruce Creek diversion ditch, etc.). Large quantities of cobbles are readily available near Pine Creek due to extensive placer mining that has taken place in the area. Cobbles can be used in location where fairly flat erosion protection is required. In sloped areas, riprap will need to be produced in order to stay in place. Cobbles would be at risk of rolling compared to angular rock.

The Isbash equation is widely used in engineering applications and relates the mean diameter of rip rap (D_{50} in mm) required to resist a given flow velocity:

$$D_{50} = \frac{V^2}{2g\,C^2\left(\frac{\gamma_r - \gamma_e}{\gamma_e}\right)\cos\alpha}$$

Where,

V is the flow velocity in m/s;
g is the gravitational constant of 9.81 m²/s;
C is the Isbash coefficient for turbulence (0.86 for low turbulence, up to 1.2 for high turbulence where hydraulic jumps form);
γ_r is the specific weight of rock, approximately equal to 2.65 x 9,810 N/m³;
γ_e is the specific weight of water, approximately equal to 1 x 9,810 N/m³;
α is the angle of repose of rip rap (based on side slope of channel).

Figure 5-1 presents curves for different turbulence coefficients for given velocities. A side slope of 2H:1V was used to determine the angle α, which is the slope proposed for the rip rap.

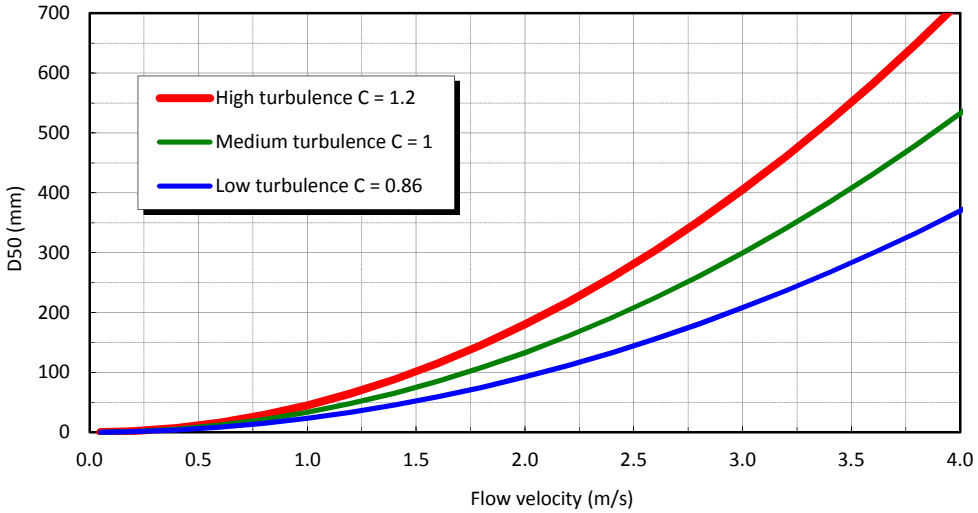

Figure 5-1: Required Rip Rap D_{50} to Resist a Given Flow Velocity

5.2 Surprise Lake Control Structure

The Surprise Lake control structure currently allows the management of water levels in the lake and to control outflows, especially during the winter period. Water is being stored during the summer and fall, and then being released during the winter months for power generation at the existing Upper Plant. The lake is currently managed between the following water levels:

- Existing full pond level: 913.15 m
- Existing low pond level: 912.10 m

1.05 m of storage is currently licensed in Surprise Lake, which is expected to be sufficient to meet the Atlin's electrical load for the next 20 years or more. The hydro project also currently includes a lake storage permits that allows flooding up to 913.85 m on Surprise Lake, which is not currently being fully utilized.

It should be noted that Surprise Lake uses a local datum derived from elevation on top of the concrete wall at the low level outlet intake (elevation of 913.75 m shown on Sigma Engineering as-built drawings). It is believed that this local datum was derived from old benchmarks left by Monty Alfred when doing water surveys more than a decade ago. For consistency between the existing works and operating water levels, it is decided to maintain the local datum at this stage. All licensed water levels refer to this local datum.

It was previously identified in Section 4 that a storage range of 2.5 m would provide an optimal storage range to maximize winter energy generation and store the vast majority of the yearly inflows. Based on a preliminary qualitative assessment of environmental constraints, it was decided to set the new pond level at the 913.85 m value that is current licensed and to develop additional top and bottom storage. The Lake Storage Permit will not require modification; only the Water License will need to be modified or appended to account for the larger storage volume that is being utilized.

The existing Surprise Lake control structure is composed of the following works:

- A ***rock fill overflow weir*** with a crest elevation of 913.15 m. A sheet pile cut-off wall and membrane provide seepage control for the structure. The weir is closed on each side with a higher secondary crest at elevation 914.15 m (1 m higher) than the main overflow section. Large riprap (D_{50} > 500 mm) is protecting the bridge abutments immediately downstream from the overflow weir;

Photo 7: Existing weir at Surprise Lake

- A ***low level outlet*** of 1.8 m diameter pipe on the left embankment, in the small head pond. It is closed with an Armtec vertical sliding gate (operated manually with a gearbox) mounted on a vertical concrete headwall of 0.5 m thickness and approximately 4 m in height. The headwall is founded on a concrete footing of 0.3 m thickness. The current invert elevation of the pipe is at elevation 909.80 m.

Photo 8: Existing outlet structure at Surprise Lake

- A ***fishway*** located on the left embankment, in the small head pond. The fishway is composed of a 1 m diameter culvert that travels under the road embankment. Downstream is a concrete fish passage structure with a total of six basins. Each basin is separated by a baffle that allows the fish to swim through each drop, which are estimated to have an approximate height of 20 to 30 cm. The culvert is permanently open but the fish passage concrete structure can be dewatered by closing the opening in the baffles and/or the downstream gate (operated with a hand wheel). The current invert elevation of the culvert is at elevation 911.10 m.

Photo 9: Existing fishway downstream of Surprise Lake control structure

The change in the full and low pond levels (increase in storage range in Surprise Lake) will require some modifications on the existing structures to effectively retain the water in the lake and discharge water downstream of the structure. The overflow weir will need to be raised, while the low-level outlet may require modification to be operational at higher and lower water levels. The fishway in its current state will remain operational for part of the year, when water levels in the lake vary between the existing storage limits. Additional studies will need to be done to determine the effectiveness of the fishway for higher and lower water levels and if it needs to be operational at all during that period. If required the fishway could be modified to accommodate the new operating water levels. Details about the proposed changes on each the structures are presented below and on Drawing 04 in Appendix A.

Overflow rockfill weir

It is proposed to raise the crest elevation of the rock fill weir from 913.15 m to 913.85 m (0.7 m increase). Additional class 1 riprap (D_{50} of 300 mm) will be placed on the downstream face of the weir while additional cobbles (D_{50} of 200 mm) will be placed on the upstream face of the weir, matching the materials of the existing structure. Class 1 riprap can resist flow velocities up to 3.5 m/s based on Isbash equation, which will be adequate under the inflow design flood scenario. The crest width of the overflow section will remain at 32 m and the longitudinal slopes will also remain the same as for the existing structure (4H:1V) downstream slope and 2.5H:1V upstream slope). To reduce seepage through the raised portion of the weir, it is proposed to extend the sheet-pile cut-off up to the new crest-elevation, by bolting on new sheet-pile onto the existing one. Additional membrane is not deemed necessary at this time. It was installed to prevent against internal erosion (piping) of the structure, and the small increase in the full pond level is not likely to modify significantly seepage flow under the structure.

Modifications to the overflow weir will take place in the dry as much as possible, with the flow being diverted through the low level outlet. Surprise Lake should be near its current low pond level at the time of construction.

Low level outlet

At this stage, it is assumed that the low level outlet will remain operational in its current configuration, with only a few minor modifications. The access catwalk will however need to be raised to accommodate the higher full pond level. The current gearbox will remain in place but will sit lower relative to the water level compared to current conditions but will still remain above the full pond level thus remaining operational.

A cursory verification of the existing vertical slide gate (Armtec) specifications was made. It was determined that the gate can adequately resist the increased pressure head (by up to 70 cm), and can operate adequately also under higher water levels.

The maximum hydraulic capacity of the low level outlet was estimated using the sluice gate equation to confirm that it can discharge the flows required for the project (on average 6 m^3/s during the winter season – see Section 4) for the range of operating water levels. Verification was made first to confirm that friction through the pipe was not controlling the discharge capacity of the low-level outlets. It is assumed that there is no downstream submergence effect at this stage. It will

likely require downstream excavation in Pine Creek to lower the downstream water level and ensure an adequate hydraulic capacity near the low pond level. The equation is as follow:

$$Q = C_d A\sqrt{2gH}$$

Where,

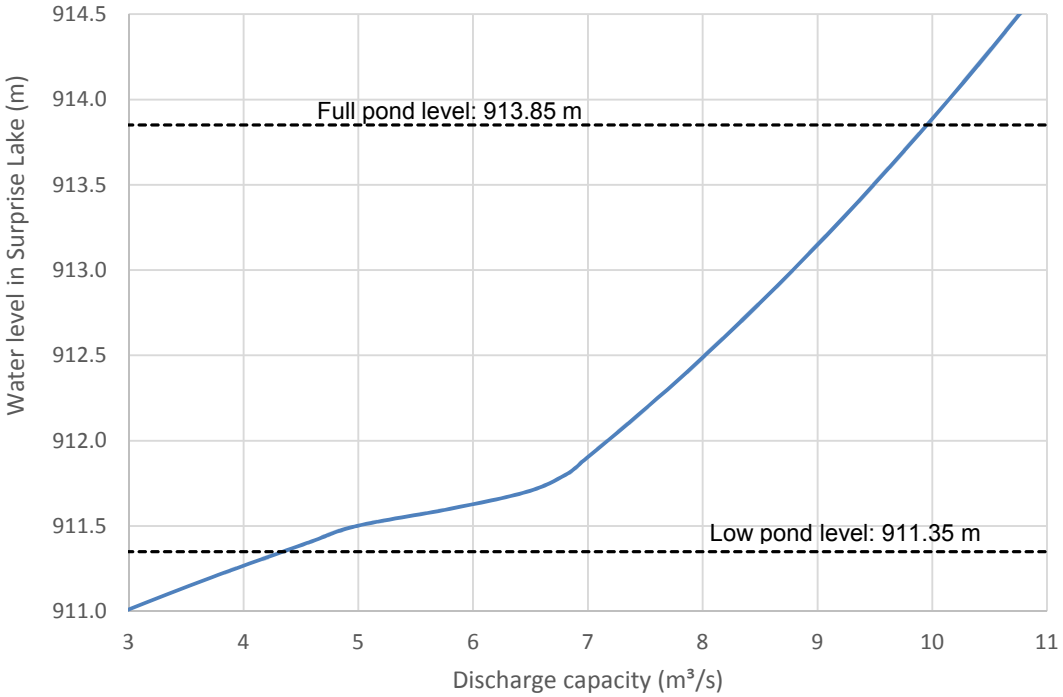
C_d is the discharge coefficient, taken as 0.5;
A is the cross-sectional area of the hydraulic passage;
g is the gravitational constant of 9.81 m²/s;
H is the head above the invert elevation of the low level outlets (equal to the water surface elevation minus the invert elevation).

Figure 5-2 presents the discharge capacity curve of the low level outlet at full-opening. It should be noted that when water levels dip below 911.6 m (top of culvert), the conduit becomes partially submerged and behaves as open channel flow.

At the full pond level of 913.85 m, the low level outlet has a discharge capacity of approximately 10 m³/s. Such a discharge capacity will allow for the effective management of floods near the full pond level with minimal increase in water level above the full pond level. With a design flow of 16 m³/s (1:100 years flood), it means that only 6 m³/s would pass over the rock fill weir assuming that the gate of the low-level outlet is fully open. This would translate to a maximum water level of approximately 914.1 m.

Near the low pond level of 911.35 m, approximately 4.5 m³/s could be discharged from the low level outlet assuming no submergence effects. This will require river excavations downstream from the structure. In this case, the low level outlet would be partially submerged and open channel flow equations do apply.

Figure 5-2: Discharge capacity of low level outlet at full opening



Fishway

It is expected that the fishway culvert will be partially dewatered from mid-March to early-June due the proposed new low pond levels (911.35 m, or 0.75 m lower than in current conditions). There will however always be water conveying through the fishway (minimum depth at entrance of 0.25 cm). The fishway would also experience higher discharge and flow velocities when the lake level is above the current full pond level of 913.15 m due to the increased head. Surprise Lake water levels are expected to be higher than this value from early July to early December on average, when the lake is filled to the new full pond level of 913.85 m

At this stage it is assumed that the fishway will remain operational with only a few minor changes to the existing geometry. Modifications of the cross-sectional area of the openings between the basins and/or of the height of the sills are proposed at this stage to improve the efficiency of the fishway. Additional studies will need to be completed to determine if further changes are warranted based on the operation water levels.

Channel excavation

In order to accommodate the new low pond level of 911.35 m, channel excavations will be required both upstream and downstream of the Surprise Lake outlet structure.

In the current configuration, it was reported by ATELP that there is a head difference between the water level in Surprise Lake and immediately upstream of the control structure, when the lake is near its current low pond level of 912.10 m. That head difference is believed to vary between 10 and 20 cm, suggesting that there is a hydraulic control upstream of the structure. This control occurs in

the shallow section that is easily seen from shore approximately 60 m upstream of the structure. Remnants and old wooden structure are also seen in the water at this location, contributing to the reduction in the conveyance capacity at this location at low water. The picture below shows this shallow section.

Photo 10: Remains of old wooden control structure at Surprise Lake outlet

An exploratory bathymetric survey was conducted by ATELP in the spring of 2015 to determine the elevation of the river bed at that location. Results showed that at numerous locations the water depth is on average only 0.8 to 1.0 m in the shallow sections (when the lake was approximately at elevation 912.80 m) thus suggesting that the river bed elevation is approximately 912.0-911.8 m. In order to adequately convey the flows in future conditions down to the low pond level of 911.35 m, it is recommended to excavate the lake outlet to elevation 910.35 m to provide a minimum of 1 m water depth. Excavation could take place mostly from shore. If a longer reach is required, either in-water excavation or access with a temporary rock fill berm is possible.

The following approximate ***upstream excavation*** dimensions are selected based on the available information:

- Length: 180 m
- Width: 10 m (assuming limited reach from the excavation equipment)
- Average depth: 2.0 m (1.5 m depth and 0.5 m additional excavation for erosion protection)

The riverbed is believed to be silty at this location such that protection against erosion will be warranted. Maximum flow velocities up to 1.5 m/s can be expected at that location under critical low water conditions. Cobbles with a minimum D_{50} of 100 mm will be adequate at this location. Such cobbles should be readily available in close proximity to the site.

It has also been identified that current water levels downstream of the structure will be too high in future conditions to accommodate the new low pond level. The current tailwater levels are believed to vary between 911.5 m and 912.0 m on average. It is expected water levels below 911.0 m are require to adequately discharge water from the lake when near the low pond level of 911.35 m. River excavations will be required downstream from the structure to lower the tailwater levels by up to 1 m. The picture below shows Pine Creek downstream of the outlet structure, with some riffles in the far end (approximately 100 m downstream of the structure).

Photo 11: Pine Creek looking downstream from Surprise Lake control structure

At this stage, the following preliminary ***downstream excavation*** dimensions are assumed for costing purposes.

- Length: 150 m
- Width: 10 m (assuming access from one shore or over-ice)
- Average depth: 1 m

As for the upstream excavation, erosion protection will be required for the downstream excavation if the river substrate following the excavations is too small. Maximum flow velocities between 2 and 2.5 m/s can be expected at this location, such that cobbles with a minimum D_{50} of 200 mm is required.

A bathymetric survey of Pine Creek below the structure will be required to further assess the downstream water levels at the control structure. Hydraulic modelling should be conducted to determine the extent of excavation that is required to adequately convey water out of the lake at the new low pond level. Environmental effects of river excavations on Pine Creek will also need to be assessed.

5.3 Upper Power Plant Expansion

The upper power plant expansion will be adjacent to the existing power plant. It will make use of the existing infrastructure, more specifically the headpond and clearing for the existing penstock and powerhouse. Details about the new infrastructures required for the expansion are described below.

5.3.1 Intake

A second concrete intake box is selected for the intake structure, located west of the current intake structure. The intake will utilize the existing head pond. The existing intake structure was assessed for suitability to supply both penstocks (existing and proposed new penstock) but was determined to have insufficient capacity. The proposed new intake structure will be identical to the current structure due to good reported operator experience with the existing structure. Furthermore using identical designs will facilitate ease of maintenance, parts and servicing of the two structures.

The proposed location is to take advantage of the former diversion channel that had been previously excavated through bedrock during the construction of the head pond weir (see Photo 12). It has since been backfilled. The new intake structure would be set back from the existing structure to allow for a small cofferdam/plug to remain, isolating the work area from the existing head pond and allow the head pond to remain operations during most of the construction.

Photo 12: Existing intake under construction with diversion channel to the right

The intake structure would be founded on bedrock. Its dimensions are approximately 2.1 m wide by 4m deep with an approximate height of 6 m. The walls and the floor of the structure will be 0.4 m thick, made of reinforced concrete.

The intake will be closed with a vertical sliding gate mounted on the upstream face of the wall of the intake box. The gate will be operated using a mechanical screw hoist. For winter operations a portable steam boiler can be used for potential de-icing operations, if required. Trashracks will be installed upstream of the gate, inside the intake box, to prevent debris from entering the penstock. Embedded steel guides in the concrete walls just downstream of the face of the structure will allow stoplogs to be inserted to dewater the intake box and remove debris when maintenance of the structure is required.

Concrete Wing Wall

A concrete wing wall is proposed to extend upstream from the east face of the new intake box. The wing wall can be constructed as part of the new intake box works. A sheet pile wall would then be installed connecting the wing wall to the west upstream end of the existing intake structure. The area between contained by these structures would then be backfilled to provide a work surface for mechanized removal of frazil ice from the vicinity of the intakes.

The concrete wing wall would be 0.8 m thick reinforced concrete with an approximate height of 6 m by 6 m long. The wall will be constructed on a concrete footing that will be founded on bedrock. Use of a sheet-pile retaining wall between the wing wall and the existing intake structure will allow the retaining wall to be installed without needing to dewater the headpond or existing intake.

A detail assessment of the frazil ice accumulation issue in the upper headpond will need to be conducted in the feasibility study. It will allow to determine potential mitigation solutions to reduce the accumulation of frazil ice in the headpond that currently require substantive maintenance activities each winter. The new proposed operational scheme at Surprise Lake will lead to higher winter flows in Pine Creek which could increase frazil ice generation.

5.3.2 Penstock

The proposed second penstock will parallel the existing penstock. It is proposed to install the penstock on the north side of the current penstock for ease of construction. As the current penstock is located on the southern half of the existing cleared right of way with a service road located on the north side. Installing the penstock on the north side will allow it to be installed without needing to routinely cross the existing penstock during construction.

A cross-over will be required near the powerhouse. Because there is insufficient space near the river to expand the existing powerhouse to the north. It is suggested that the new penstock cross the existing penstock where it is cut into the crest of the hill-slope above the powerhouse. This location allows the proposed new penstock to be readily installed above the existing pipe at this location.

The total length of the penstock is approximately 4 km with all but approximately 330 m (being sections for bedrock) running through sand and gravel. A trench will be excavated along the

proposed route between the access road and the existing penstock. A typical cross-section is proposed through overburden as presented on Drawing 02 of Appendix A.

The cross-section through overburden will be excavated with side slopes of 1.5H:1V with a minimum horizontal clearance of 0.4 m on each side to facilitate compaction of backfill. It is proposed to install the penstock over a minimum layer of 0.15 m thickness of granular fill to ensure good drainage at the bottom of the trench. The penstock will then be backfilled first with select granular fill around and over the penstock. A minimum of 0.7 m of random fill will then be placed above the granular fill to reduce risk of freezing of the penstock in case of extended winter shut-down. The random fill will be graded to cover the whole width of the trench and prevent ponding of water at surface. It is expected that a large portion of the overburden materials excavated from the penstock trench will be used as random fill.

Penstock Selection Considerations

For the proposed arrangement, approximately 4 km of penstock will be required to convey flows to the powerhouse from the intake structure at the head pond. Typical head losses within a conveyance system are usually in the order of 5 to 10% of the total gross head, with this value usually being more critical for sites with relatively low elevation changes. In order to minimize friction losses that will occur over the length of the penstock, flow velocities are typically kept between 1.8 and 2.4 m/s.

Based on the design flows for the upper powerhouse expansion, a nominal 5 ft. (1.52 m) inner diameter penstock size was selected as most appropriate. At this diameter penstock is available in steel or in high-pressure HDPE alternatives, while steel is the only high-pressure alternative at larger diameters (2 m or more). Both steel and HDPE penstock is available in lengths of up to 15 m. When comparing supply costs, HDPE is a more cost effective alternative than steel and has some installation advantages due to lighter weight for handling and flexibility during installation and welding. In general the installation methods are very similar in terms of backfill and connection requirements. On this basis, plus considering the existing owner's experience, HDPE penstock has been selected for the majority of the upper power plant conveyance system.

For the HDPE penstock option lighter wall weight would be used for the upper portion of the route, getting progressively thicker until the penstock elevation dropped to the point where transition to steel pipe would be required due to higher water pressures. Based on the existing penstock configuration, the following quantities of HDPE penstock are assumed (outside diameters are presented here):

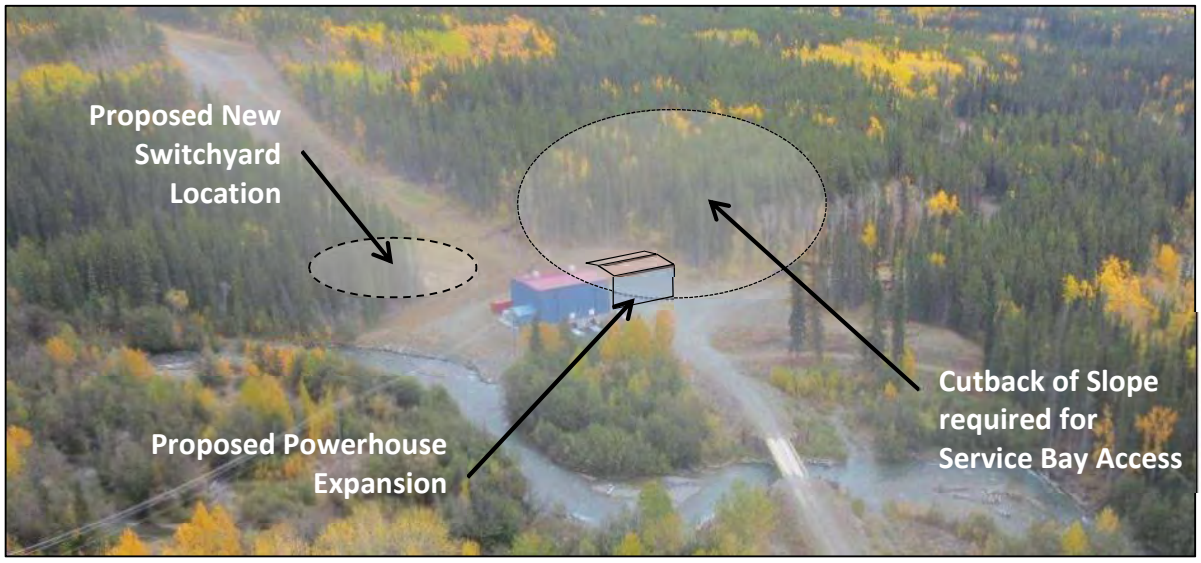
- 1,828 m of 63" DR41
- 256 m of 63" DR32.5 (50 PSI)
- 713 m of 63" DR26 (64 PSI)
- 768 m of 63" DR21(80 PSI)

As this site has 107 m of gross head, the lower 440 m of penstock would need to be steel pipe to resist the higher pressures. The steel penstock would then bifurcate to small steel pipes sections immediately upstream of the powerhouse expansion to feed the two new units.

5.3.3 Upper Powerhouse Expansion

The proposed powerhouse expansion will be located on the south side of the existing upper powerhouse and be constructed within the existing granular parking and turn around area. The powerhouse is expected to be constructed in the dry, with an overburden plug remaining within the tailrace to exclude the creek water from the foundation excavation during construction. This plug would be removed after the powerhouse had been completed, and the remainder of the tailrace would be completed in the wet. Limited inflows were experienced during the construction of the existing powerhouse. The powerhouse excavation was advanced to what was reported as a "hardpan" layer (likely glacial till). Based on this previous experience it is anticipated that only limited dewatering will be required. .

Figure 5-3: Layout of Upper Powerhouse Expansion



The powerhouse extension would be located on the south side of the existing powerhouse, as seen in the Figure 5-3 above and Drawing 06, and will require a cutback into the adjacent hill slopes to the southeast to facilitate adequate access into the service bay from the south side. The Pine Creek water elevation at this location will be regulated to approximately 723.5 m by the proposed lower headpond for the new lower power plant. The anticipated tailrace elevation would be approximately the same elevation as the creek with the existing tailrace channel widened to facilitate the increased flow.

The existing upstream head pond and intake structure maintains the forebay level at the penstock intake to approximately El. 832.5 m during normal operations, which provides a gross available head of approximately +/- 107 m for both the existing plant and the proposed expansion.

5.3.3.1 Foundation Considerations

Subsurface conditions at the proposed powerhouse extension are known with some confidence due to the construction of the previous powerhouse. Foundation conditions are expected to be course alluvial gravel similar to what can be observed at the surface in the area. The new powerhouse will

be marginally deeper than the existing structure at the location of the draft tube and it is not expected that bedrock will be encountered. Due to the existing proximity of the powerhouse to Pine Creek, foundation dewatering may become an issue during construction. Currently sheet pile retaining walls have been shown along the downstream side of the new powerhouse to either side of the draft tubes to prevent washout or movement of fill from beneath the structure into the tailrace. A sheet pile cut off wall may be required around the perimeter of the structure if groundwater conditions prove difficult. Further analysis will be required to determine the appropriate foundation design and soil parameters at the powerhouse location moving forward.

5.3.3.2 Turbine / Generator Equipment Considerations

Turbine Selection

At this level of study, turbine design flows are typically selected for an exceedance of approximately 25% to 35%, which corresponds to a flow of approximately 6.2 m^3/s. As the existing 2.1 MW plant currently uses up to 2.45 m^3/s, a design flow of 3.6 m^3/s was selected to maximize the plant capacity providing an additional 2.9 MW with a gross head of approximately 107 m. When accounting for riparian flows these design values correspond to an exceedance of approximately 25% which was desired to provide as much power as was reasonable possible from the powerhouse expansion alone. The selected design flow and capacity of the expansion would require further analysis and refinement at later stages of study in order to optimize the cost of annual energy generation.

Pelton and Francis units were initially considered for the powerhouse expansion due to their ability to efficiently operate with lower flows and medium to high gross head, and their typical use in small hydro developments. Turgo units were also considered for this application as they overlapped the operational ranges of Pelton and Francis units considered for this application.

Turgo units are very similar to Pelton units in that they are impulse type turbines with the advantage that they can operate at higher flows than a similarly sized Pelton machine. Similar to a Pelton unit, the impulse energy from jets of water are used to drive the turbine wheel, except that in a Turgo unit the jets comes in at an angle to the wheel instead of perpendicular to the axis of rotation. For the same power produced a Turgo unit will typically have a runner half the size of a comparable Pelton unit and therefore twice the specific speed, which will in turn require a smaller, less expensive generator. Similar to Pelton units, a Turgo unit uses deflectors to prevent upsurge on a load rejection therefore eliminating the need for surge facilities.

Francis units were discarded from the selection process as the remaining flow available from Surprise Lake did not allow for efficient operation year round at lower flow levels. Due to their slower rotation speed, Francis units would require much larger and more expensive generators than what would be required for Pelton or Turgo units. Additionally, the selection of Francis units would have required a surge facility which would be difficult and costly at this powerhouse location.

As expected, Turgo and Pelton units were both acceptable solutions given the relatively low design flows and medium to high gross head. The combination of operational flow and head at this site are near the lower limit of Pelton operation, but Turgo units are well suited to the site conditions and operate at higher RPM than a comparable Pelton unit, and therefore require a smaller and less costly generator. Pelton units considered would have had to incorporate multiple jets or conversely operate at a slower speed, increasing the cost for either the turbine and/or generator respectively.

The preferred option utilizes two Turgo units to reduce equipment size and cost, and allows the existing powerhouse crane at the upper plant to be utilized to carry out installation and repairs. Although not necessary given the existing plant contains two units, the addition of two Turgo units provides additional generation reliability and better plant efficiencies over a wider range of flows. Additional studies of greater detail should revisit and confirm the selection of dual Turgo units.

The selected unit parameters of the 1.45 MW Turgo Turbines proposed are summarized below:

- Normal Head Pond Level: 832.5 m
- Tailwater Level: 724.0 m to 723.5 m
- Rated head: 107 m
- Penstock: Single 1.52m I.D. diameter HDPE penstock with a bifurcation to 0.9 m diameter steel penstocks at the powerhouse.

Layout Considerations

The powerhouse has been located immediately adjacent to the existing powerhouse to facilitate use of the existing powerhouse crane for maintenance and repairs. The service bay has been located on the south side of the new structure similar to the existing powerhouse as it provides the best means of access without extending the proposed building further than necessary beyond the expanded tailrace.

5.3.3.3 Transient Analysis and Surge Facility

A surge facility is not required as the design of Turgo units utilizes deflectors to prevent upsurge on a load rejection and allows for the dissipation of surge pressures without damage to the units, which is similar to the Pelton units installed in the existing powerhouse.

5.3.3.4 Powerhouse Configuration

Details for the development scheme for the expanded powerhouse with two Turgo units have been provided in Drawings 06, 07 and 08. A service bay for the powerhouse would be constructed on the south (access) side of the powerhouse at ground level and contain the new electrical and mechanical systems associated with the plant within an insulated, metal clad steel superstructure. It has been assumed that the existing control room can be modified to allow for operation of the units; however, there is additional room available in the new service bay to include a new control room if necessary.

The service bay has been sized such that the generating equipment can be brought in to the powerhouse on flatbed trucks and unloaded using the existing overhead crane running on extensions of the existing rails and crane supports. There is also room to work on the major unit components in the service bay during the initial installation and for any future maintenance work. The existing 23 tonne overhead bridge crane will be retained as it is sufficient for the heaviest lift associated with the new turbines which is the generator assembly. The existing crane will perform loading, unloading, insertion and removal of the generator rotor or the assembled generator stator onto or from a truck.

The new superstructure for the powerhouse building will be designed to match the envelope of the existing structure with crane rails extended to cover the new portions of the powerhouse. Modifications to the existing pre-engineered building will be required, including the removal of the end column and bracing on the south side to facilitate the travel of the existing crane into the new building. Further study will be required to verify that modifications can be made to the existing pre-engineered structure without compromising its integrity as the designs of pre-engineered structures are typically highly efficient and leave little room for changes in loading or load path.

Immediately upstream of the powerhouse expansion the single HDPE penstock would bifurcate into two steel penstocks. Turbine flows would enter the concrete powerhouse substructure through short sections of steel penstock and then exit through individual draft tubes to the tailrace and then into Pine Creek. A turbine inlet valve (TIV) would be provided immediately upstream of each turbine as a means of shutting off the flow in an emergency and for use as an isolation device during maintenance activities, in addition to the intake structure slide gate.

Floor elevations have been selected based on the assumed tailwater level and the setting of the Turgo unit. The centerline of the penstock bifurcation is dictated by the turbine setting, with the lower powerhouse levels designed to provide adequate clearances around the turbine inlet valves immediately upstream of the units. The service bay elevation is set to match the existing powerhouse and the surrounding parking and turnaround area. Unit settings would need to be confirmed following detailed hydraulic analysis and turbine selection in the next project phase.

5.3.3.5 Electrical Equipment Considerations

General Configuration

The basic proposed configuration is a 2.9 MW, two unit plant expansion which is anticipated to require two 1.81 MVA generators. The two generating units will be of the synchronous type, with a nominal rating of 1.81 MVA at 0.8 power factor (pf).

The remainder of the electrical systems will generally follow the electrical configuration with the following main characteristics:

- Static excitation systems.
- One generator step up transformer (GSU) for the entire plant, with voltage and power ratings matching the generating units.
- 15kV class, vacuum generator circuit breakers and arc resistant switchgears.
- Redundant station service system.
- Energy would be sent to the proposed switchyard located adjacent to the expanded powerhouse which would then distribute power north through a 69 kV transmission system to the Yukon's electrical grid or have power stepped down for distribution to the community of Atlin.

Medium Voltage System

Each generating unit will have arc resistant switchgear that will feature draw out generator vacuum circuit breakers. As well, switchgear sections will house generator side Potential and Current

Transformers (PTs and CTs) and surge suppression equipment, tie off for the excitation system and GSU side PTs and CTs and will also include a tie off for the SSLC.

Interconnection between the generating units and the switchgear and between the switchgear and GSU will be by 15kV cable. The generator neutral leads will be connected to the neutral grounding equipment.

AC Station Services

Power for all auxiliary services and AC equipment required at each facility will be provided from the Powerhouse AC station service system.

Under normal operation, the station service power will be provided by the station's own generators. The station service system will allow power to be maintained during several types of equipment outages. The generator step-up transformer can energize the station service transformer from the high voltage network. The Generator circuit breaker will isolate the generator excitation transformers for this case.

If the units are shut down and power is not available from the HV network, the existing 50 kW generator that ATELP owns for the station service of the existing plant could be connected to the station service system. At this time we anticipate that a portable diesel generator would be available locally or from Whitehorse if needed, and the cost for purchasing one to keep at site has not been included in our estimates.

Dry-type transformers, switchgear line-ups, main breakers and tie breakers will be sized for the full load of the station.

The main incomings and tie-circuit breakers on each load center will be remotely controlled from the main control room and locally at the switchgear.

The AC distribution system will have a single 600V MCC, a single 600V panel, and a single 120/208V panel for both generating units and their auxiliaries, and at this time no redundancy has been provided.

Unit and GSU Protection

Generators and generator step up transformers will be protected by single multifunction digital relays. These relays, which will be powered by a single 125 VDC system, will provide the following minimum protections:

- Generator Reverse Power (32).
- Generator Thermal Protection (49).
- Inadvertent Energization (50/27).
- Breaker Failure Protection (50BF).
- Generator Turn Fault Protection (51SP).
- Generator Stator Ground Fault (59G).
- 100% Generator Stator Ground Fault (64S).
- Generator Field Ground (64F).
- Generator Under-frequency (81).
- Generator Differential (87G).

- Generator V/Hz (96G).
- Transformer Oil Temperature (26T).
- Transformer Winding Temperature (49WT).
- Transformer Overcurrent (50/51).
- Transformer Differential (87T).
- Transformer Restricted Ground Fault (87G).
- Transformer V/Hz (96T).

There will also be other standalone protection for mechanical generator or governor faults, such as overspeed and for GSU, such as oil level, oil temperature, etc.

Controls will be Programmable Logic Controller (PLC) based.

5.3.4 New Switchyard and Transmission

A new 4 km long 69 kV transmission system would be used to transmit energy from the proposed lower powerhouse to the new proposed switchyard located at the upper Atlin powerhouse. From this switchyard power would then be transmitted north to connect with the Yukon Territory's electrical grid or be stepped down for distribution to the community of Atlin. The new switchyard has been proposed to be located to the northeast of the upper powerhouse on slightly higher ground than the parking and turn around area adjacent to the upper powerhouse. A preliminary layout of the substation is provided in Appendix F.

Figure 5-4: New Switchyard Location

The generator step up transformers would be located in a switchyard adjacent to the Upper powerhouse. The high side voltage would be 69kV. A 69kV disconnects would also be located downstream of the transformer to provide isolation.

The switchyard would have a 69 kV SF6 circuit breaker and motorized disconnect with ground switches, potential transformers, current transformers and associated bus work and steel structures. This breaker would feed a single transmission line.

5.4 Lower Power Plant

5.4.1 Intake and Head Pond

An artificial head pond will need to be excavated for the intake structure of the lower powerhouse. A reconnaissance of lower Pine Creek (downstream of the existing powerhouse) was conducted both by air and foot to locate potential locations for the head pond. Pine Creek is mostly a shallow braided gravel-bed creek with some deeper pools that generally do not exceed 2 to 3 m in depth. The floodplain of the creek is also quite flat limiting the options to potentially raise the water level to form the head pond. It was determined that the optimal location to build the new head pond would be immediately downstream of the bridge located near the existing (upper) powerhouse. The following photo shows the location where it is proposed to excavate the lower head pond, as seen from the bridge when looking downstream.

Photo 13: Proposed location of lower head pond on Pine Creek, looking downstream

At this location, Pine Creek takes a sharp bend towards the north (to the right if looking downstream) and widens slightly over a short distance. Higher ground is located on the left bank (up to elevation 725 m) and the road closes the right bank at least to elevation 723.5 m. The headpond could then be naturally contained at least to elevation 723.5 m at this location, and

higher if needed with only small closing dam being required. Spruce Creek enters Pine Creek about 50 m downstream of that location such that a small diversion will be required to have Spruce Creek connecting with the head pond. The approximate dimension of the proposed head pond will be 50 m by 60 m, which is limited by the space available.

The following works will composed the head pond:

- A concrete intake structure located on the left side of the head pond;
- A concrete wingwall adjacent to the intake structure;
- A rock fill overflow spillway, located over the natural creek bed, to control the head pond water levels;
- An rock fill closing dam on either side of the overflow spillway;
- An excavated slope on the upstream end of the head pond;

Diversion of Pine Creek during construction of the head pond will take place with a diversion channel on the right side of the creek. The diversion channel will be excavated through the existing access road to the upper power plant. Crossing of the road (if deemed necessary for access from the north side of the creek) could either be done by installing culverts or by moving the existing bridge Since filling of Surprise Lake will occur during the construction period of the lower head pond (summer season) flows are expected to be low. Spruce Creek diversion will only be built once all other works of the head pond are completed. For the purpose of preliminary sizing of the diversion channel, a maximum diversion flow of 10 m^3/s was assumed. A diversion channel with a base width of 5 m and a maximum depth of 2 m (1.5 m flow depth and 0.5 m freeboard) is selected. The diversion channel will need to be protected with rock fill (or cobbles) with a D_{50} of at least 100 mm.

The depth of the head pond was determined based on the minimum submergence criteria for the intake. Two 1.52 m diameter penstocks are proposed for the lower plant (discussed in more detail in Section 5.4.2). The following parameters were estimated for each penstock:

- Maximum flow: 3.5 m^3/s (total turbine flow 7 m^3/s)
- Maximum flow velocity: 2 m/s

The minimal submergence of the intake was determined based on Gordon equation (1970) developed based on observations on numerous existing generating stations in Quebec.

$$S_{min} = CVd^{0.5}$$

Where,

S_{min} is the minimum submergence
C is a coefficient to account for approach flow conditions (0.55 for linear and 0.72 for asymmetric)
V is the flow velocity in the penstock (in m^3/s)
d is the penstock diameter (in m)

A C coefficient of 0.72 was selected since approach flow conditions at the intake are not linear, thus increasing the risk of vortex formation. The resulting minimal submergence was calculated as 1.8 m.

In order to establish the head pond depth and the invert elevation of the intake (for each penstock), a minimum pond level was set based on the topographical constraints as well as based on the proposed geometry for the spillway (discussed further). The objective is also to maximize the head at the site without adversely impacting tailwater levels at the upper plant. . A minimum pond level of 723.0 m was selected. With a 1.52 m inside diameter (I.D.) diameter penstock and a minimum submergence of 1.8 m, the invert elevation of the intake has to be at least 3.4 m below the minimum pond level. The invert elevation of the intake was set at elevation 719.2 m which provides an additional 0.4 m of safety margin against submergence against potential entrainment of debris and ice in the small head pond. The bottom of the head pond is set at elevation 718.2 m, which is 1 m below the invert of the intake. It will reduce sediments from filling the bottom up to the intake elevation.

Intake structure and concrete retaining wall

A concrete intake box for the intake structure will be located on the left side of the overflow spillway, adjacent to the concrete wingwall. Since no bedrock is present at the site, it will be founded on overburden materials, such that a concrete pad will be required. Its dimensions will be approximately 6 m wide by 4 m deep, with an approximate height of 7 m. The structure should extend up to elevation 725 m to close the head pond. The walls and the floor of the structure will be 0.4 m thick, made of reinforced concrete.

The intake will be closed with a vertical sliding gate mounted on the upstream face of the downstream wall of the intake box. At this stage, it is expected that the gates will be operated using a mechanical screw hoist. For winter operations, a portable gas generator and steam boiler can be used for potential de-icing operations, if required. Power could also be easily provided to the lower head pond since the existing upper powerhouse is located within 300 m of the site. Thrash\racks will be installed upstream of the gate, inside the intake box, to prevent debris from entering the penstock. Embedded steel guides in the concrete walls just downstream of the upstream face of the structure will allow the insertion of stop-logs to dewater the intake box to remove debris or if maintenance of the structure is required.

A concrete retaining wall will be built on the left side of the intake box to close the south end of the head pond. The retaining wall will allow mechanized equipment to operate adjacent to the intake structure for removal of frazil ice, if needed. The wall will be 0.8 m thick reinforced concrete with an approximate maximum height of 7 m. It will be approximately 18 m long. The wall will be constructed on a concrete footing that will be founded on overburden materials. Rock fill will be used to backfill the wall on the downstream side, where a parking/turn-around area for access will be established.

Overflow spillway

Due to the small size of the head pond and for ease of operations, an overflow spillway is selected to pass the design flood without the need for any gate operations. The overflow spillway will also allow maintaining the minimum pond level. Since the head pond is mostly excavated into the ground, the spillway will only have a maximum height of approximately 3 m. An overflow rock fill weir was selected with a sheet pile cut-off wall to reduce seepage through and under the structure. It is proposed to extend the cut-off wall at least 6 m below the bottom elevation of the head pond to prevent internal erosion and seepage.

Two different crest elevations are proposed:

1. A lower crest at elevation 723.0 m, with a width of 4.5 m. This crest will pass normal summer excess flows and provide the minimum environmental flow;
2. A higher crest at elevation 723.7 m, with a width of 15 m. This crest will allow the passage of larger floods.

Side slopes of 4H:1V are selected along the crest of the overflow weir to provide vehicle access on the crest for maintenance activities, including mechanized frazil ice removal and sediment removal in the head pond if required. A 5 m crest width is selected to accommodate potential machinery traffic.

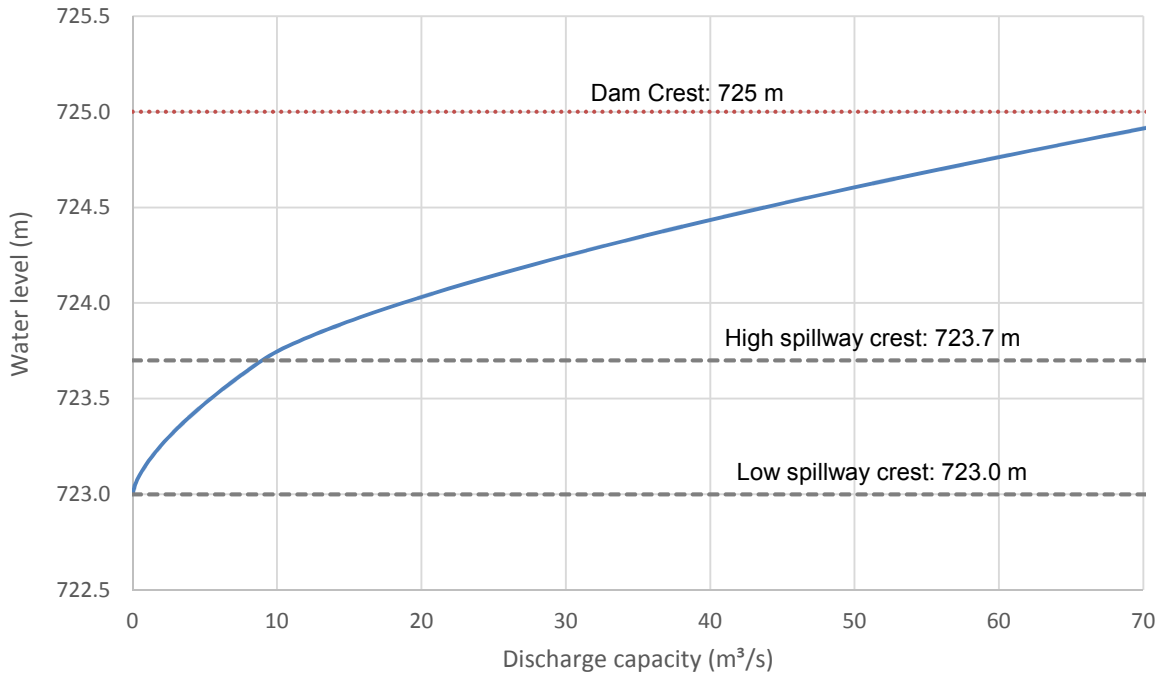
The overflow weir equation was used to determine the capacity of the proposed overflow spillway. A discharge capacity curve for the overflow spillway is presented below.

$$Q = C\sqrt{2g}LH^{3/2}$$

Where,

Q is the flow passing over the weir (in m^3/s)
C is the discharge coefficient, taken as 0.34 which is a conservative value for a long broad crested weir
g is the gravitational constant (9.81 m^2/s)
L is the crest width (in m)
H is the head above the crest (in m)

Figure 5-5: Discharge capacity curve of the overflow spillway of the lower head pond



The capacity of the low crest at the normal pond level of 723.5 m is estimated at 5.4 m³/s, while it increases to 9 m³/s up to the elevation of the higher crest (723.7 m). In the eventuality of the passage of the design flood (estimated at 39 m³/s), the water level in the head pond would reach 724.4 m. Based on this calculated value for the maximum flood level, the crest elevation of the closing dam adjacent to the spillway is set at 725.0 m to provide the minimum 0.5 m freeboard criteria.

Maximum flow velocities over the crest of the spillway are estimated at 2.5 m/s under the design flood scenario. Rip rap with a D_{50} of 300 mm is selected (class 1), which can resist flow velocities up to 3 m/s based on Figure 5-1. The downstream slope of the overflow spillway is set at 10H:1V. This will provide flow velocities of approximately 1 m/s on average, which may be adequate to provide fish passage under most hydraulic conditions through the low crest of the spillway. A small stilling basin will be constructed at the toe of the spillway. The stilling basin will be 15 m long and 0.5 m deep. This will protect the river bed against scour and will allow the formation of a hydraulic jump in a controlled location. The stilling basin will be protected with rip rap with a D_{50} of 300 mm also.

Closing dam

A closing dam will be required on each side of the overflow spillway. Since the headpond is mostly excavated into the ground the dam will be small with a maximum height of 3 m near the bridge. The sheet pile cut off wall will extend into the dam. On the upstream side of the lower head pond, a work terrace will be built at elevation 723.5 m (normal pond operating level) to provide access for maintenance, especially mechanized ice removal if needed. Rip rap (class 1 D_{50} of 300 mm) should be installed up to elevation 724.5 m (maximum flood level) to protect the banks of the head pond against erosion.

As a summary, the following elevations and design parameters are selected for the lower head pond:

- Bottom of head pond: 718.2 m
- Intake invert elevation: 719.2 m
- Spillway crest elevation: 723.0 m (4.5 m width) and 723.7 m (15 m width)
- Normal pond level: 723.5 m
- Minimum pond level: 723.0 m
- Maximum flood level: 724.5 m
- Closing dam crest elevation: 725.0 m
- Rip rap: class 1 – 200-450 mm (D_{50} 300 mm)
- Spillway downstream slope: 10H:1V

5.4.2 Penstock

A preliminary discussion of the selected penstock route was provided in Section 3.2. The final alignment of the lower penstock selected for this study is shown on Drawing 03. The route is dictated by topographical constraints and substantively avoiding privately owned land. The

alignment of the lower penstock traverses significantly more challenging terrain than the existing upper penstock.

The alignment is dictated by the following considerations:

1. Avoid crossing private land at South Pine Drive. The proposed alignment largely avoids this by skirting between the private land and Pine Creek's canyon above the Warm Bay Road Bridge. Crossing a small corner of private land may be unavoidable, but that will need to be determined in future studies.

2. Topographic constraints consisting of small bedrock hills at 2+000 and 2+900. The proposed alignment takes advantage of natural saddles between the hills and the side of Monarch Mountain. Alignment elevations were selected to minimize cut/fill requirements, especially of bedrock.

Over the length of the penstock, terrain and ground conditions vary as follows:

- Between 0+000 and 0+800 the penstock will follow the north side of Warm Bay Road. Soils are anticipated to be predominantly sand and gravel overburden with bedrock near surface.
- From 0+800 to 1+100 the alignment crosses a series of bedrock knobs.
- Terrain conditions from 1+100 to 2+000 are largely unknown, but are anticipated to be blanket of till over bedrock. Soils appear to be adequately drained along this hillside section.
- From 2+000 to 2+500 the alignment is anticipated to cross a challenging area of poorly drained soils. Organic and ice-rich soils (soil that have high ice content either as permafrost or are frozen for most of the year) may be present in this area.
- From 2+500 to 2+850 will be a side-cut into bedrock and talus slope.
- From 2+850 to 4+000 ground conditions are expected to be relatively more mild, consisting of glaciofluvial terraces/benches and alluvial plain materials with no significant bedrock outcrops. Soils appear to be predominantly sand and gravel and are well drained.

Of the total 4 km of the lower penstock, it is assumed a total of 500 m will be running through bedrock with the rest in overburden material. A typical cross section through overburden is presented on Drawing 03 in Appendix A.

The cross-section through overburden will be excavated with side slopes of 1.5H:1V with a minimum horizontal clearance on each side of 0.4 m to facilitate compaction of backfill. It is proposed to install the penstocks over a minimum layer of 0.15 m thickness of granular fill to ensure good drainage at the bottom of the trench. The penstocks will then be backfilled first with select granular fill around and over the penstock. A minimum of 0.7 m of random fill will then be placed above the granular fill to reduce risk of freezing of the penstock in case of extended winter shut-down. The random fill will be graded to cover the whole width of the trench and prevent ponding of water at surface. It is expected that a large portion of the overburden materials excavated from the penstock trench will be used as random fill.

Penstock Selection Considerations

Larger total design flows are required for the lower powerhouse because of the addition of flows from Spruce Creek for the proposed single turbine. A 2 m inside diameter penstock is required based on the considerations described previously in Section 5.3.2 (flow velocities between 1.8 and 2.4 m/s). At this diameter, steel pipe is the only readily available option.

The cost of the lower penstock is the largest cost item for the lower power plant. Therefore a preliminary cost optimization assessment was conducted to evaluate the potential for using two smaller diameter HDPE penstocks in lieu of a single large steel penstock. To meet the flow requirements for the lower power plant, twin 5 ft (1.52 m) I.D. penstocks would be required. The optimization included the costs of both excavation and backfill requirements in both overburden and bedrock sections of the alignment. The assessment concluded that twin HDPE penstocks would be approximately 10% lower material and installation cost with approximately equivalent excavation and backfill costs. However, it is believed that the HDPE option offers substantive constructability benefits as follows:

- Relatively shallower and wider excavations making excavations easier.
- Easier excavation due to typically more weathered and looser surface materials.
- Existing owner experience and comfort with using HDPE penstock.
- Easier handling, welding and installation of smaller diameter, more flexible HDPE pipe.
- Consistent material size with upper penstock may result in overall project savings and improved installation efficiency.

For the HDPE penstock alternative lighter wall weight would be used for the upper portion of the route, getting progressively thicker until the penstock elevation dropped to the point where transition to steel pipe would be required. Based on the elevations/pressures, the following quantities of HDPE penstock are assumed (outside diameters are presented here):

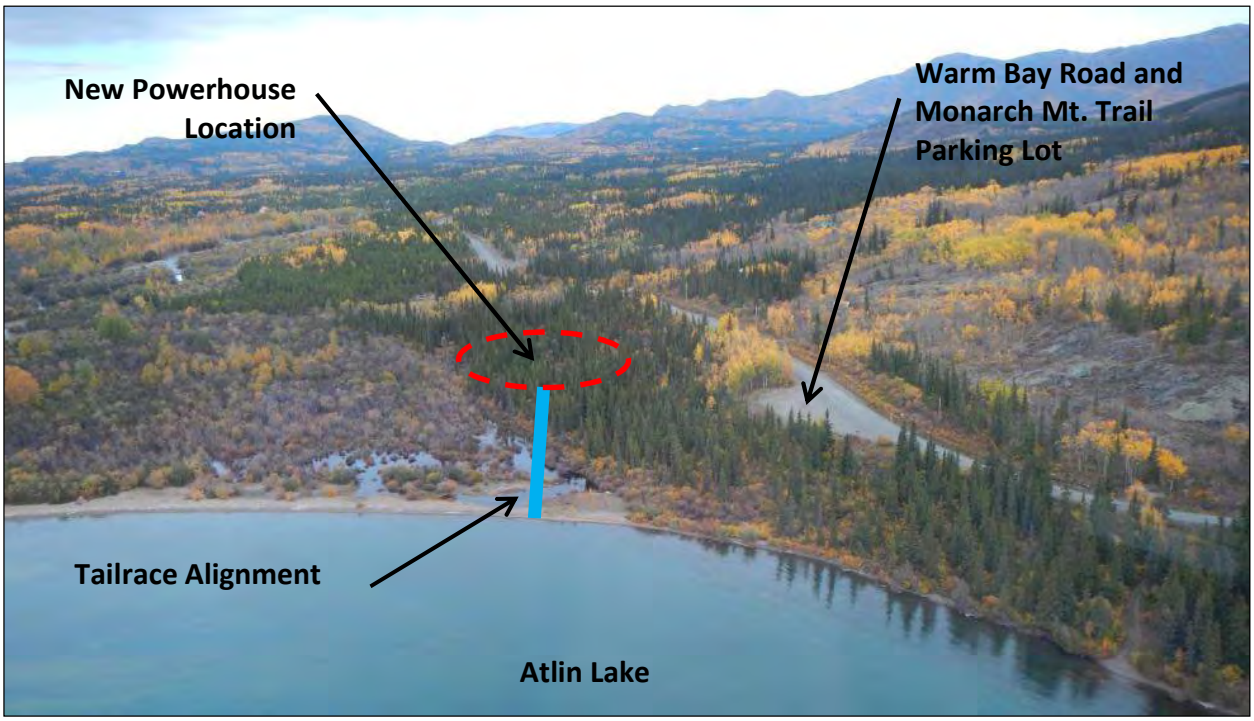
- 2x 3,025 m of 63” DR41
- 2x 375 m of 63” DR32.5 (50 PSI)

For the last 600 m it is assumed the penstock would transition to a 2 m diameter steel pipe. A reverse bifurcation would transition the twin HDPE penstocks to the larger diameter steel penstock.

5.4.3 Lower Powerhouse

The proposed new lower powerhouse will be located on the east side of Pine Creek, approximately 150 m north of Atlin Lake as shown on Drawing 11. The powerhouse would be constructed within the steeply sloped banks below Warm Bay Road in an effort to found the powerhouse in bedrock. The powerhouse will be constructed in the dry, with an overburden plug located within the tailrace to exclude lake water from the foundation excavation during construction. This plug would be removed after the powerhouse has been completed, and the remainder of the tailrace completed in the wet.

Figure 5-6: Layout of Lower Powerhouse



The powerhouse will be located west of Warm Bay Road as seen in the figure above, on the sloped hillside just north of the Monarch Mountain trail parking area. Atlin Lake levels vary through an approximate range from elevation 669.25 m to 666.85 m and the anticipated tailrace elevation would be approximately the same elevation since the tailrace channel would be designed to minimize head losses between the powerhouse and Atlin Lake.

For the preferred head pond and intake being considered, the head pond level would be maintained at approximately El. 723.5 m during normal operation, which would provide an assumed gross available head of approximately +/- 56 m.

5.4.3.1 Foundation Considerations

Subsurface conditions at the proposed powerhouse location are currently unknown. A visual inspection of the site shows significant areas of exposed bedrock immediately to the east of Warm Bay Road dipping down to the west and south underneath the road alignment. To the west of the road there is the Pine Creek alluvial fan which is likely to be composed of a saturated sand and gravel. The slopes west and below Warm Bay Road appear to be comprised at the surface of overburden (till) due to the significant tree cover. Due to the slope and proximity to large amounts of exposed bedrock it is expected that any overburden cover may be limited and has therefore been assumed to be approximately 2 m thick or less. Due to the depth of the structure and the amount of exposed bedrock present in close proximity it has been assumed that structures can be founded on bedrock in the chosen location, though design provisions could be made if there is no bedrock. Given the observed saturated sand and gravel condition of the alluvial fan, considerable groundwater inflow should be expected in any excavations in overburden at or below the lake level.

5.4.3.2 Turbine / Generator Equipment Considerations

Turbine Selection

At this level of study, hydroelectric design flows are typically selected at an exceedance of approximately 25% to 35%, which corresponds to a flow of approximately 6 to 7 m^3/s. On this basis a design flow of 7 m^3/s was selected to provide a maximum plant capacity of 2.8 MW with a gross head of approximately 56 m.

Pelton and Turgo units were also considered for the arrangement at the lower powerhouse location, but due to the relatively low gross head of 56 m for these types of units, an efficient or cost-effective turbine-generator arrangement was not possible. Operating speeds would be much slower and require a large and cost prohibitive generator. Due to this, Francis type units were determined to be the best solution. While two units are a viable option for providing the plant capacity of 2.8 MW and would provide increased reliability of station service power, the costs of providing two sets of turbines and generating equipment were considered to outweigh the potential benefits of a one unit solutions. Given the existing powerhouse upstream and its planned expansion, additional reliability for the community of Atlin was not deemed to have substantial value compared to the incremental cost of additional turbine and generator equipment.

Options with two units for this size of plant would also increase the complexity of electrical considerations and require a larger powerhouse footprint, which would increase the overall cost based on preliminary estimates even though the excavation depths for the smaller units are less than for a single large unit. The single unit's more compact footprint is desirable at this location due to the potential excavation required both into rock and the adjacent slope. While additional studies should be undertaken to confirm or optimize the number of units at the next level of study, a powerhouse with one unit has been selected at this time based on both the supply of equipment and potential construction costs.

The selected unit parameters of the 2.8 MW Horizontal Francis Turbine proposed is summarized below:

- Max headwater level: 724.0 m
- Full Supply Level (FSL): 723.0 m to 723.5 m
- Tailwater Range: 666.85 m to 669.25 m
- Rated head: 55.4 m
- Allowable upsurge: 40%
- Penstock: Dual 1.52 m I.D. diameter HDPE penstock with union to a single 2.0 m diameter steel penstock approximately 600 m upstream of the powerhouse.

Layout Considerations

For this size of Francis turbine, there are several equipment suppliers with vertical or horizontal shaft arrangements that would be suitable. In a comparison between vertical and horizontal arrangements for the chosen Francis turbines with such a diameter, we have reviewed the following considerations:

- A vertical shaft arrangement for Francis turbines would require a lower level under the generator floor for maintenance of the components in the turbine pit such as the distributor assembly, turbine bearings, servomotors, cooling water supply unit, and other facilities. The added lower floor will incur more civil cost which is not likely warranted for such a compact turbine.
- In comparison to a vertical unit, a horizontal shaft arrangement for a Francis turbine features: 1) fewer floors in the powerhouse; 2) decreased overall height of the powerhouse; 3) decreased depth of excavation; 4) decreased civil construction costs; and 5) is easier to monitor, maintain and overhaul the units.
- In general, common practice is to recommend using Francis turbines with a runner size less than 1.75 m diameter in a horizontal arrangement, and using a vertical arrangement for large capacity or large diameter Francis turbines. With a proposed runner diameter of 1.00 m this turbine falls well within the range of an acceptable horizontal unit size.
- On the basis of the considerations listed above, a single horizontal Francis unit has been selected for the proposed lower Atlin Powerhouse. For this type and size of unit, the centerline of the runner has been set approximately 1.7 m above the assumed tailwater level to obtain the correct submergence for the draft tube.

Transient Analysis and Surge Facility

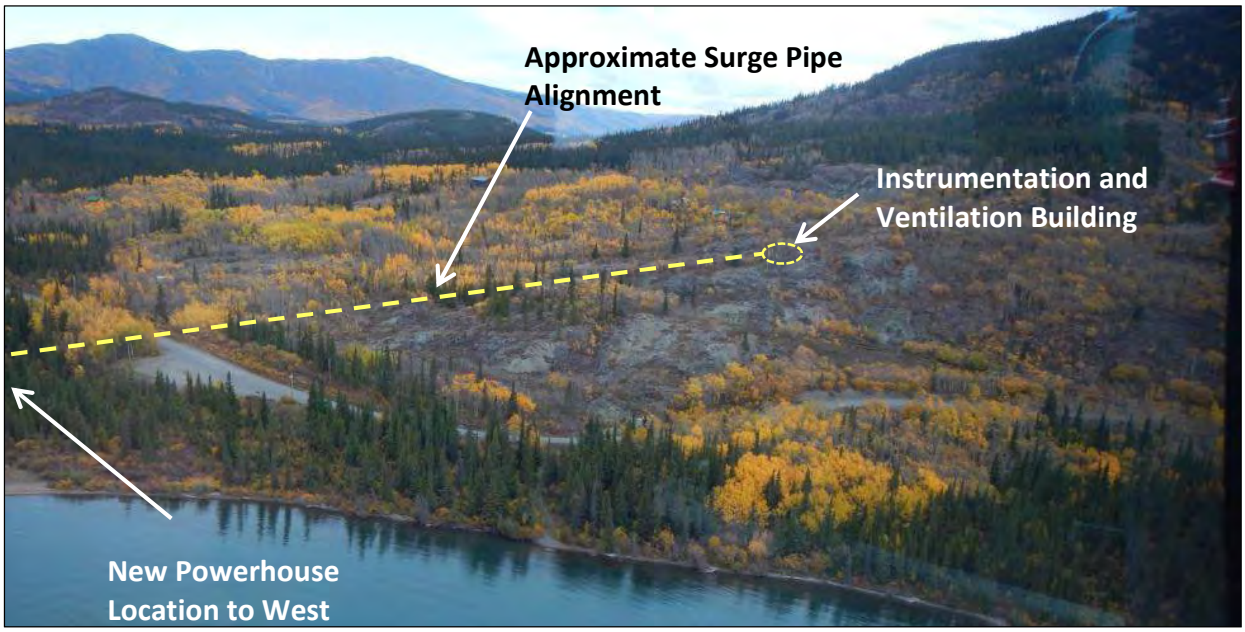
To avoid unnecessary complication with addressing the inclusion of a surge facility it has been assumed the surge connection to the penstock will be provided downstream of the union of the dual HDPE penstocks at a distance of approximately 30 m from the powerhouse. A preliminary transient analysis has considered the following variables: the penstock diameter at the powerhouse, the flow velocity of 2.2 m/s at the rated plant capacity, the preferred head pond and intake location and relatively long length of penstock (4 km). The results of the preliminary transient analysis have indicated that to achieve an acceptable combination of unit governability, gate times, maximum overspeed and maximum penstock pressure during plant operations, there will be a need for a surge facility.

Assuming the construction of a vertical surge tanklocated within approximately 50 m of the powerhouse, it would require a diameter of 6.5 m with an active zone between elevations 713 to 732 m. As finished ground elevation is 670 m at the proposed powerhouse and the adjacent slopes only extend to approximately 680 m, the required surge tank would between 55 and 65 m high, be difficult to construct and be extremely expensive. Alternatively, we have assumed that a surge facility will connect to the steel penstock approximately 30 m upstream of the powerhouse, where it will be possible to extend an approximately 400 m section of steel surge pipe up the bedrock slopes to the east of the powerhouse that quickly rises to the required active zone elevations. Based on the required surface area to meet unit stability criteria, the surge facility could consist of sections of 2.0 m diameter pipe installed at an incline matching the ground profile at this location through the active zone. Ventilation for the shaft and monitoring instrumentation will be provided at a small building at the end of the surge shaft on the eastern slope. The conceptual arrangement of this surge facility is shown in Figure 5-7 and on Drawing 11. The alignment shown was selected to avoid crossing of privately owned land.

Since a surge facility will be located in relative proximity to the powerhouse, the generator's natural inertia will suffice to provide stable operation and good unit response. The maximum overspeed

would be limited to approximately 60% of rated speed. While this is anticipated to be acceptable, a more detailed transient analysis would be required to confirm and optimize these values at the next stage of study.

Figure 5-7: Lower Powerhouse Surge Facility Location



Powerhouse Configuration

Details for the development scheme with a single horizontal Francis unit have been provided in Drawings 11, 12 and 13. A service bay for the powerhouse would be constructed on the east (access) side of the powerhouse at ground level, complete with a control room and overhead crane within an insulated, metal clad steel superstructure. A 30 tons overhead bridge crane with a span of approximately 10 meters will be needed for the selected unit, the heaviest component of which is the generator assembly. The selected crane will be able to perform loading, unloading, insertion and removal of the generator rotor or the assembled generator stator onto or from a truck.

The service bay has been sized such that the generating equipment can be brought in to the powerhouse on flatbed trucks and unloaded using the proposed overhead crane. There is also room to work on the major unit components in the service bay during the initial installation and for any future maintenance work.

Approximately 600 m upstream of the powerhouse the dual HDPE penstocks would transition to a single steel penstock supplying the Francis unit. Turbine flows would enter the concrete powerhouse substructure through a section of steel penstock and then exit through the draft tube to the tailrace and travel 150 m to Atlin Lake. A turbine inlet valve (TIV) would be provided immediately upstream of the turbine as a means of shutting off the flow in an emergency and for use as an isolation device during maintenance activities, in addition to the intake structure slide gate.

Floor elevations have been selected based on the assumed tailwater levels and the setting of the Francis unit. The centerline of the penstock is dictated by the turbine setting, with the lower powerhouse level designed to provide adequate clearances around the turbine inlet valves immediately upstream of the unit. The service bay elevation is set 1 m above the anticipated maximum tailwater level along with the surrounding parking and turnaround area, as shown on Drawing 13. The required elevations would need to be confirmed following subsequent surveys and detailed hydraulic analysis should this project proceed to later stages of study and development.

5.4.3.3 Electrical Equipment Considerations

General Configuration

The basic proposed configuration is a 2.8 MW, single unit plant which is anticipated to require one 3.5 MVA generator at 0.8 power factor (pf).

The remainder of the electrical systems will generally have the following main characteristics:

- Static excitation systems.
- One generator step up transformer (GSU) for the plant, with voltage and power ratings matching the generating unit.
- 15kV class, vacuum generator circuit breakers and arc resistant switchgears.
- Station service system.
- A 69 kV transmission system would be used to transport the energy to the proposed switchyard at the expanded upper Atlin Plant which would then transmit power north to connect with the Yukon's electrical grid or be stepped down for distribution to the community of Atlin.

Medium Voltage System

The generating unit will have arc resistant switchgear that will feature draw out generator vacuum circuit breakers. As well, switchgear sections will house generator side PTs, CTs and surge suppression equipment, tie off for the excitation system and GSU side PTs and CTs and will also include a tie off for the SSLC.

Interconnection between the generating units and the switchgear and between the switchgear and GSU will be by 15kV cable. The generator neutral leads will be connected to the neutral grounding equipment.

AC Station Services

Power for all auxiliary services and AC equipment required at the facility will be provided from the Powerhouse AC station service system. Under normal operation, the station service power will be provided by the station's own generators. The generator step-up transformer can energize its station service transformer from the high voltage network. The Generator circuit breaker will isolate the generator excitation transformers for this case. It has been assumed that a portable backup diesel generator will be available locally or from Whitehorse if required.

Dry-type transformers, switchgear line-ups, main breakers and tie breakers will be sized for the full load of the station.

The AC distribution system will have a single 600V MCC, a single 600V panel, and a single 120/208V panel for the generating unit and its auxiliaries.

Unit and GSU Protection

The Generator and generator step up transformer will be protected by single multifunction digital relays. These relays, which will be powered by a single 125 VDC system, will provide the following minimum protections:

- Generator Reverse Power (32).
- Generator Thermal Protection (49).
- Inadvertent Energization (50/27).
- Breaker Failure Protection (50BF).
- Generator Turn Fault Protection (51SP).
- Generator Stator Ground Fault (59G).
- 100% Generator Stator Ground Fault (64S).
- Generator Field Ground (64F).
- Generator Under-frequency (81).
- Generator Differential (87G).
- Generator V/Hz (96G).
- Transformer Oil Temperature (26T).
- Transformer Winding Temperature (49WT).
- Transformer Overcurrent (50/51).
- Transformer Differential (87T).
- Transformer Restricted Ground Fault (87G).
- Transformer V/Hz (96T).

There will also be other standalone protection for mechanical generator or governor faults, such as overspeed and for GSU, such as oil level, oil temperature, etc.

Controls will be PLC based.

6 TRANSMISSION LINE OPTIONS ASSESSMENT

A transmission line options assessment has been completed as follows to determine the technical requirements and associated costs to deliver power from the proposed Atlin Hydro Expansion project to the Yukon's electrical system. The transmission line options assessment consists of two components:

1. The line from the Atlin hydro facility to Jakes Corner, Yukon; and
2. The connection between the Atlin line and the Yukon electrical system, including new transmission line or upgrades required.

Work conducted as part of this assessment includes:

- the development of a cost estimate for a 69 kV transmission line (section 6.2);
- a system assessment study to determine interconnection/system upgrade needs (section 6.3) and
- development of a cost estimate for substations at either end of the transmission line (details provided in Appendix F).

Some of the options included consideration of 138 kV transmission line components. Costs for development of a 138 kV line were specified by Yukon Energy Corporation for the purposes of this study.

As part of this work a transmission options study was prepared by b7kennedy & Associates Inc. to assess electrical system requirements. This study is provided in Appendix E and provides a high-level assessment of transmission system needs and performance for connecting the Atlin hydro power project to the Yukon electrical system.

6.1 Overview of Transmission Line Connection

The new transmission line from Atlin is proposed to join the southern Yukon electrical system at Jakes Corner at the junction of the Alaska Highway and the Tagish Road. The existing Yukon system at this location is a 34.5 kV system owned primarily by ATCO Electric Yukon. The existing southern Yukon electrical system is illustrated schematically on Figure 6-1. Currently the line suppling power to the Southern Lakes area originates at Yukon Energy's substation S150 located at Whitehorse Rapid Generating Station (WRGS). This line is ATCO Electric Yukon's Southern Lakes distribution line (called line 9L). Substation S150 also provides power to three other ATCO Electric Yukon lines. Yukon Energy operates a 138 kV transmission system with a 138 kV bus at both S150 and the Riverside substation (S171) which is also at the WRGS. S171 is a ring bus to accommodate power generated from all YEC's generating assets (hydro and thermal plants)

Electrical load information for 2013 through late 2015 was provided by ATCO Electric Yukon for the Southern Lakes system. Peak loads are between 8 and 9 MW and occur in December, January and February. Peak loads by community are not known at this time, but ATCO staff have indicated that peak loads in Teslin are on the order of 1 MW. Annual energy consumption for this region has been

39.2 GWh and 38.8 GWh for 2013 and 2014 respectively. Figure 6-2 shows energy consumption in the Southern Lakes area on a monthly basis. Simulated electrical production from the Atlin Hydro Expansion project is shown as a dashed black line on Figure 6-2. See section 4.4 for a discussion of the simulated power production. As can be seen on this figure, the simulated generating profile of the Atlin Hydro Expansion project fits relatively well with the energy demand of the region. Because the generation during winter months is a function of reservoir (Surprise Lake) withdrawals, the operation can be optimized somewhat to match the loads on a seasonal basis.

6.2 Atlin to Jakes Corner Transmission Line: 69 kV and 138 kV Comparison

The base case assumption for the Atlin transmission line is a line at 69 kV. As an alternative, 138 kV has also been considered. The Transmission Options Assessment study by b7kennedy & Associates (Appendix E) confirmed that 69 kV performs adequately for the power being transferred over the line (on the order of 7 MW). At full-load, line losses for the 69 kV transmission line are estimated at 2.2%, or 0.16 MW; losses less than 5% are considered acceptable.

6.2.1 Construction Cost Estimates

Table 6-1 below provides a construction cost estimates for the 69 kV line and 138 kV alternative. The Atlin to Jakes Corner line length is assumed to be nominally 100 km with 50 km in BC and Yukon respectively. Further details on how these cost estimates were prepared are provided in the following sections.

Table 6-1 Atlin to Jakes Corner Transmission Line Options Cost Summary (2016$)

Transmission Line Cost Item	69 kV ($000 CAD)	138 kV ($000 CAD)
Line Construction (inc. OPGW)	21,319	33,444*
Clearing and Access	1,380	4,284
Subtotal Direct Costs	**22,699**	**37,728**
Planning	681	1,132
Property Acquisition & Permitting	1,589	2,641
Survey & Structure Staking	454	755
Engineering	1,816	3,018
Project Management	1,589	2,641
Construction Management	1,135	1,886
Owner's Costs	1,135	1,886
Subtotal Indirect Costs	**8,399**	**13,959**

Overhead & Interest (0.95%)	295	491
Contingency (25%)	7,774	12,922
Total Cost	**39,167**	**65,100**

** Based on YEC provided 138 kV transmission line cost estimate, including optical ground wire (OPGW)*

6.2.1.1 69 kV Transmission Line Construction Cost Estimate

A cost estimate has been prepared for the transmission line component of the Atlin Hydro Expansion Project. This is expected to include the portion of the line between Atlin and Jake's Corner, as well as 69 kV options for other portions of the line towards Whitehorse (discussed further in Section 6.3). A cost estimate at +/- 30% level is presented, which is the level of precision that is typically achieved at a pre-feasibility study level, with no site-specific geotechnical investigations and limited opportunity for detailed project optimization. The cost estimate includes all direct construction costs, as well as indirect, lodging and travel, engineering and permitting studies, construction supervision and Owner's costs. The cost estimate values are presented in Canadian dollars, based on 2016 costs with no escalation for future work. A contingency of 25% was added to all project costs, including Owner's costs.

Further cost estimate details and assumptions for a 69 kV transmission line are presented below.

Line Design Assumptions

Preliminary assumptions were made regarding the technical details of the transmission line design in order to prepare the cost estimate. These assumptions were based on industry standard practices and historical information from a number of 69 kV projects completed by MH for BC Hydro over the past five years. These technical details are not intended to be the basis for future engineering design efforts; they are solely used for cost estimating purposes. The actual aspects of the transmission line design will need to be determined when the engineering for the project begins.

Structures and Framing

The 69 kV transmission line support structures are expected to be single wood poles. Fifty-five foot Class 2 Western Red Cedar poles were assumed as the basis for the estimate. The poles are expected to be direct-embedded into native soil, with standard embedment depths. The framing includes a single timber cross-arm in a triangular configuration. The conductors are expected to be supported by standard porcelain clamp insulators. A standard span length of 100 m between poles has been used for the estimate. For sections of the 69 kV circuit with a distribution underbuild, the pole has been changed to a 65 ft Class 1 Western Red Cedar at 90 m spans. Future work should give consideration for allowing for distribution underbuild at the north end of the transmission line (Jakes Corner to Little Atlin Lake area).

Detailed engineering design has not been performed on the poles, however basic preliminary assessments of the suitability for the poles to support the applied loads and meet vertical clearance requirements has been considered. The structural loading and clearance requirements were taken from CSA Standard C22.3 No.1-10 Overhead Systems.

Conductors

The conductor for the 69 kV circuit is assumed to be 397 kcmil “Ibis” ACSR. There would be three conductors in a triangular configuration on the wood poles. A fibre optic cable underbuild has also been included. The selected cable is a self-supporting optical ground wire (OPGW) attached to the pole below the conductor crossarm.

Terrain Considerations

For the purposes of this cost estimate, average terrain conditions (being typical rolling terrain with well-drained soil with limited areas of bedrock outcrop) were assumed for the length of the circuit. The portion of the line from Atlin to Jake’s corner is expected to generally follow Atlin Road (BC Highway #7) along the relatively low terrain adjacent to Atlin Lake. The route is expected to avoid the more rugged mountainous terrain further to the east of the highway. The highway follows relatively gradual rolling hills, and in general not particularly steep, so major excavation and blasting are not expected.

The soil conditions along the route are anticipated to be primarily well-drained till (unsorted glacially derived sediments) or sand and gravel. There will be underlying bedrock that is exposed at some locations. In the area adjacent to Atlin Road, there is expected to be adequate overburden for direct-embedment of wood poles for the majority of the route, without the need for rock extensive foundations. Detailed geotechnical information was not available at the time of the cost estimate, so these assumptions will need to be confirmed.

A right-of-way for the poles will need to be cleared, generally following the east side of Atlin Road. The right-of-way is assumed to be generally contiguous with the cleared road allowance. The clearing is expected to include light brush and small trees for most of the route, with little to no heavy timber. A 15 metre wide machine cleared right-of-way for the 69 kV circuit has been assumed for the cost estimate which is similar to ATCO's contemporary clearing practice in Yukon. The required total ROW required has not been determined at this time. The Atlin Road in BC has a 200 ft (61 m) total right-of-way of which approximately 24 m total width has been cleared (9.0 m road width plus 7.5 m cleared right of way on either side), as shown on Figure 6-3. According to BC Ministry of Transportation and Highways Technical Circular T-03/14 (2014), transmission lines can be accommodated in the road right-of-way subject to approved design. Similarly in the Yukon the transmission line can be placed in the road ROW (Government of Yukon, Transportation Engineering Branch, Utility Line Guideline, 2005)

It is assumed the poles will be placed 9 m from the road shoulder. This cleared area is assumed to be required for 100% of the circuit route in BC, and 25% of the route in the Yukon because the Yukon portion of the road has significantly wider existing clearing due to recent re-construction of the road in Yukon. The poles are assumed to be directly accessible from the Atlin Road. No separate access road has been included for the circuit.

There are no significant water crossings expected along Atlin Road. There are multiple small creeks (the specific number has not been determined in this stage of study) that will be accommodated by the typical span length of the wood poles. Similarly, no significant avalanche areas were identified along the route.

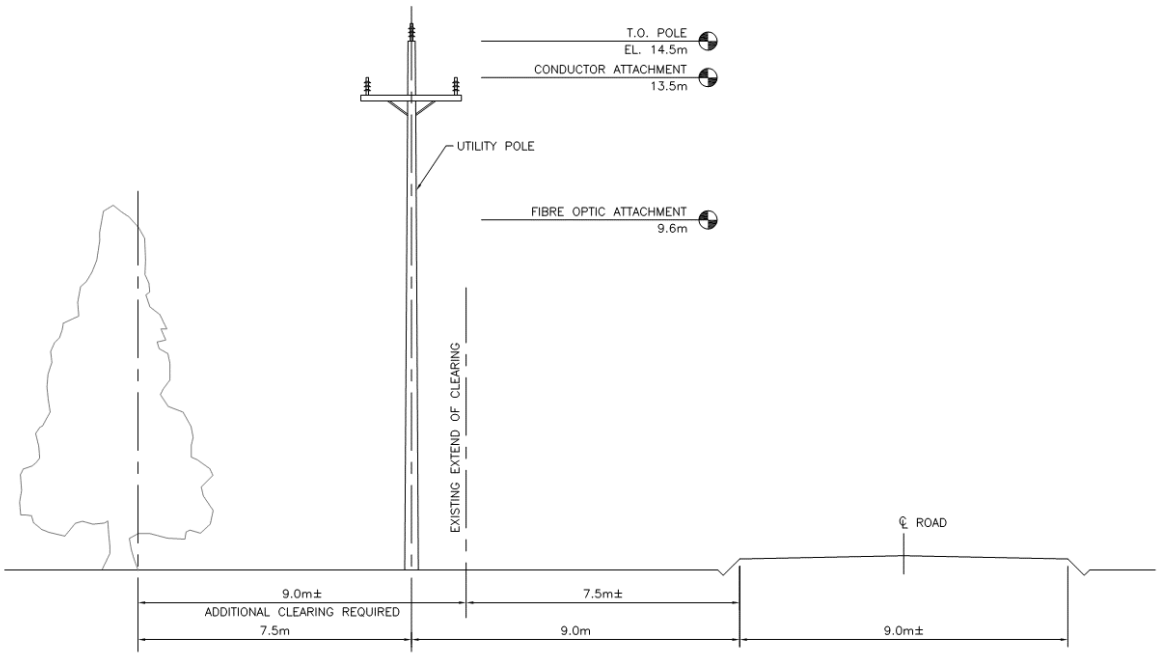

Figure 6-3. Typical 69 kV Pole configuration for BC portion of transmission line.

Indirect Costs

Indirect costs for the project include planning, property acquisition, permitting, survey and structure staking, engineering, project management, construction management, and owners' costs. Where more accurate data is not available these costs are based on historical values for similar transmission line projects in Yukon and British Columbia. Indirect costs are calculated as a percentage of the direct capital costs, and these are presented in Table 6-2 below.

Table 6-2. Indirect Costs as Percentage of Direct Costs

Indirect Cost	Percentage of Direct Costs
Planning	3%
Property Acquisition & Permitting	7%
Survey & Structure Staking	2%
Engineering	8%
Project Management	7%
Construction Management	5%
Owners' Costs	5%

Overhead, Interest and Contingency

The overhead and interest costs are based on historical values for similar transmission line projects in Yukon and British Columbia. They are taken to be 0.95% of the direct and indirect project costs. A 25% contingency has been applied to project components, including the transmission line, to account for unforeseen costs and additional items to be determined in the feasibility study.

6.2.1.2 138 kV Transmission Line Construction Cost Estimate

The cost of developing a 138 kV transmission line was provided by Yukon Energy Corporation (YEC) based on their previous work. In 2014 YEC completed an internal cost estimate for development of a 138 kV transmission line. This line assumes unit direct cost of $327,882 / km including optical ground wire (OPGW) for communication. The same indirect percentages as the 69 kV option were assumed.

The 138 kV line assume the standard wood-H pole design that is used in the Yukon. This requires a cleared right-of-way 30 m wide. In Yukon transmission lines of this size must be separate from the road right-of-way. For the purposes of this assessment it is assumed that the 138 kV transmission line would occupy a separately cleared 30 m right of way separated from the road by a vegetative (tree cover) barrier in both BC and Yukon.

6.2.1.3 Sources of Information

The estimates used data from the following sources:

- Information supplied by the YEC, including recent cost estimated completed for the 138 kV Stewart to Keno transmission line.
- Information contained in the Atlin BC to Yukon Interconnection Costing Study, August 9, 2011, prepared by BBA Engineering.
- Labour productivity values have been based on published data from the National Electrical Contractors Association (NECA) Manual of Labour Units. Factors have been applied to labour hours based on craft skill, worker availability, local conditions, potential winter work, rugged terrain, and complex work.
- RSMeans CostWorks 2015 cost estimating software and database
- Current in-house data and historical project data, available to Morrison Hershfield. This includes materials costs and contractor labour cost rates, typical for British Columbia and the Yukon.

6.2.1.4 Exclusions

- Applicable taxes
- Construction All Risk Insurance, liability insurance, or any other insurance types relevant to a construction project of this type
- Financing costs
- Fees and royalties
- Business development costs
- Removal of hazardous materials
- Public information forums
- Inspections and permits
- Allowance for funds used during construction (AFUDC)
- Overall site security, health and safety
- Ambulances and medical facilities
- Currency fluctuations beyond those specified in this Estimate
- Allowances for scope changes
- Event-driven risk
- Cost Escalations
- Escalation related to Owner's cost.
- Operating and Maintenance costs

6.2.2 Regulatory Considerations

As per Schedule 1, Part 4, Section 1 of the *Yukon Environmental and Socio-Economic Assessment Act* (YESAA) Assessable Activities, Exceptions and Executive Committee Projects Regulations, a 69 kV line of 50 km or less is subject to a Designated Office Evaluation. Under this assessment there is a requirement for an environmental and socio-economic impact assessment as per the Project

Proposal Form (provided by the Yukon Environmental Assessment Board (YESAB)). The form is submitted and subject to a three phase review process: Adequacy, Evaluation, and Recommendation.

Based on the criteria defined in Schedule 3 of the YESAA Regulations, a 138 kV line is anticipated to trigger an Executive Committee Review as the line is not likely to be contiguous to an existing right-of-way for its entire length. As per Schedule 3 of the Assessable Activities, Exceptions and Executive Committee Project Regulations, an Executive Committee Screening is required for the *"Construction or installation of a power line with a voltage of 138 kV or more or of a length of more than 50 km if the power line is not on a right of way developed for a power line, pipeline, railway line or road nor on a right of way contiguous to, for its whole length, a right of way developed for a power line, pipeline, railway line or road."*

Irrespective of whether a 69 kV or 138 kV line is selected, neither option would trigger environmental assessment requirements under the *British Columbia Environmental Assessment Act* (BCEAA), nor the *Canadian Environmental Assessment Act* (CEAA 2012).

Permitting requirements in British Columbia and Yukon are similar between the 69 kV and 138 kV options (additional permits for work within an existing right-of-way will be required for the 69 kV line, whereas the 138 kV will require other permits for development of a new utility right-of-way). With the larger disturbance footprint and separate right-of-way associated with the 138 kV line and Executive Committee level review, it should be expected that the permitting process will be more complicated and take more time than that expected for the 69 kV line.

6.2.3 Comparison Summary

As noted previously a 69 kV transmission line between Jakes Corner and Atlin is adequate for transferring the power from the Atlin Hydro Expansion project to the Yukon electrical system. 138 kV is a voltage that could be used for this line and is thought that this option could provide some benefits.

Advantages and disadvantages of the two options are summarized in Table 3 below.

Table 6-3. Comparison of 69 kV and 138 kV options for Yukon to Atlin transmission line.

Atlin to Jakes Corner Transmission Line Voltage	Advantages	Disadvantages
69 kV	• Lower cost; • Adequate capacity and acceptable line losses; • Can be accommodated in road right-of-way; • Relatively less clearing requirements; • Overall smaller project that has lower impact and simpler to maintain and operate. • Less complicated permitting, assessment and land acquisition requirements	• Requires a 69 kV to 34.5 kV or 138 kV substation in Yukon (either at Jakes Corner or Carcross).
138 kV	• Slightly lower line losses; • Potentially avoids a substation at Jakes Corner or Carcross, potentially saving $3,000,000; however increases substation cost in Atlin. • Significant additional transmission capacity (but is not likely to be required)	• Higher cost; • Requires separate right-of-way; • More complicated permitting & assessment requirements; • Twice as large clearing requirements and project footprint • Likely more complex and difficult to operate and maintain due to higher voltages.

The 69 kV line option is adequate for the proposed project needs and the advantages of the higher voltage option do not appear to outweigh the challenges and costs it possess. Therefore no further consideration of the a 138 kV line from Jakes Corner to Atlin is warranted at this time unless there are significant changes to power demands and supply in the Atlin region.

6.3 Yukon Connection Options Assessment

A set of three options for delivery and transmission of power from the Atlin Hydro Expansion project to the Yukon's electrical system have been considered. For the purposes of this assessment, each of these three options assumes a 69 kV transmission line from Atlin to Jakes Corner is required; therefore costs associated with this line (as presented in Section 1.2 above) are common to all options and not considered further in this assessment. The three primary options are:

1. connect to the existing ATCO's existing southern Yukon system at Jakes Corner;
2. connect to a new 138 kV transmission line in the Carcross valley; or
3. connect to a new transmission line along the Alaska Highway at Jakes Corner.

Each of the three options has two sub-options, described further in Sections 6.3.1to 6.3.3.

To assess these options, a high-level system study was completed by b7kennedy & Associates Inc. This report is provided in Appendix E. Substation costs for these options were prepared by Magna IV Engineering and can be found in Appendix F.

6.3.1 Option 1. Connect to Existing Electrical System

Option 1 looks to supply power to the southern Yukon making maximum utilization of the existing electrical infrastructure. The two sub-options are:

a) Connect to ATCO's line SL622 at Jakes Corner serving the Southern Lakes load as isolated. This assumes there is no interconnection to the existing Yukon electrical system at S150.

b) Connect to ATCO's line SL622 at Jakes Corner serving the Southern Lakes and is interconnected to the Yukon's electrical system via the 34.5kV line 9L to S150 in Whitehorse.

These options include the following new infrastructure (see Figure 6-1):

- A new substation with 69 kV bus at the upper Atlin hydro generating station;
- A 100 km long 69 kV transmission line to Jakes Corner; and
- A 69/34.5 kV substation at Jakes Corner.

The system study concludes that Option 1a) is not recommended because the Atlin Hydro Expansion project is not able to supply the entire Southern Lakes load under peak load conditions. Option 1b) which includes connection to the rest of the Yukon system at S150 is considered feasible and provides acceptable results from the point of view of voltage regulation and losses. Line losses to Jakes Corner at full generation (7.1 MW sent from Atlin) are estimated at 0.157 MW, or 2.2%. If it is assumed there is no load on the Southern Lakes system and all of the Atlin output is absorbed at Whitehorse, then line losses to Whitehorse would be at most 0.403 MW.

From a regulatory perspective, Option 1 is the simplest of the three options assessed, as it does not require any additional transmission infrastructure other than the Atlin to Jakes Corner transmission line itself.

Option 1b) is the simplest and lowest cost option because it does not require additional new transmission infrastructure other than the Atlin to Jakes Corner line and associated substations.

6.3.2 Option 2: Connect to a New 138 kV Transmission Line in Carcross Valley

Option 2 assumes connection to a new (future) 138 kV transmission line developed by Yukon Energy from their substation S171 in Whitehorse to Carcross. The two sub-options are:

a) The 69 kV interconnection to Jakes Corner is extended to Carcross and connected to the 138 kV system via a 138/69 kV substation in Carcross.

b) Extend the 138 kV line from Carcross to Jakes Corner and connect to the 138 kV system via a 138/69 kV substation in Jakes Corner.

These options include the following new infrastructure (Figure 6-4):

- A new substation with 69 kV bus at the upper Atlin hydro generating station;
- A 100 km long 69 kV transmission line to Jakes Corner;
- For Option 2a), a 69/34.5 kV substation at Jakes Corner; for Option 2b), a 69/34.5 kV substation and 69/138 kV substation at Jakes Corner;
- A 50 km long transmission line to Carcross at 69 kV for Option 2a), and 138 kV for Option 2b). The 69 kV assumes a distribution underbuild along the Tagish Road between Carcross and Tagish; and
- A 138 kV tap at an assumed pre-existing substation at Carcross.

Options 2a) and 2b) assume that a 138 kV line has previously been built from Whitehorse (S171) to Carcross.

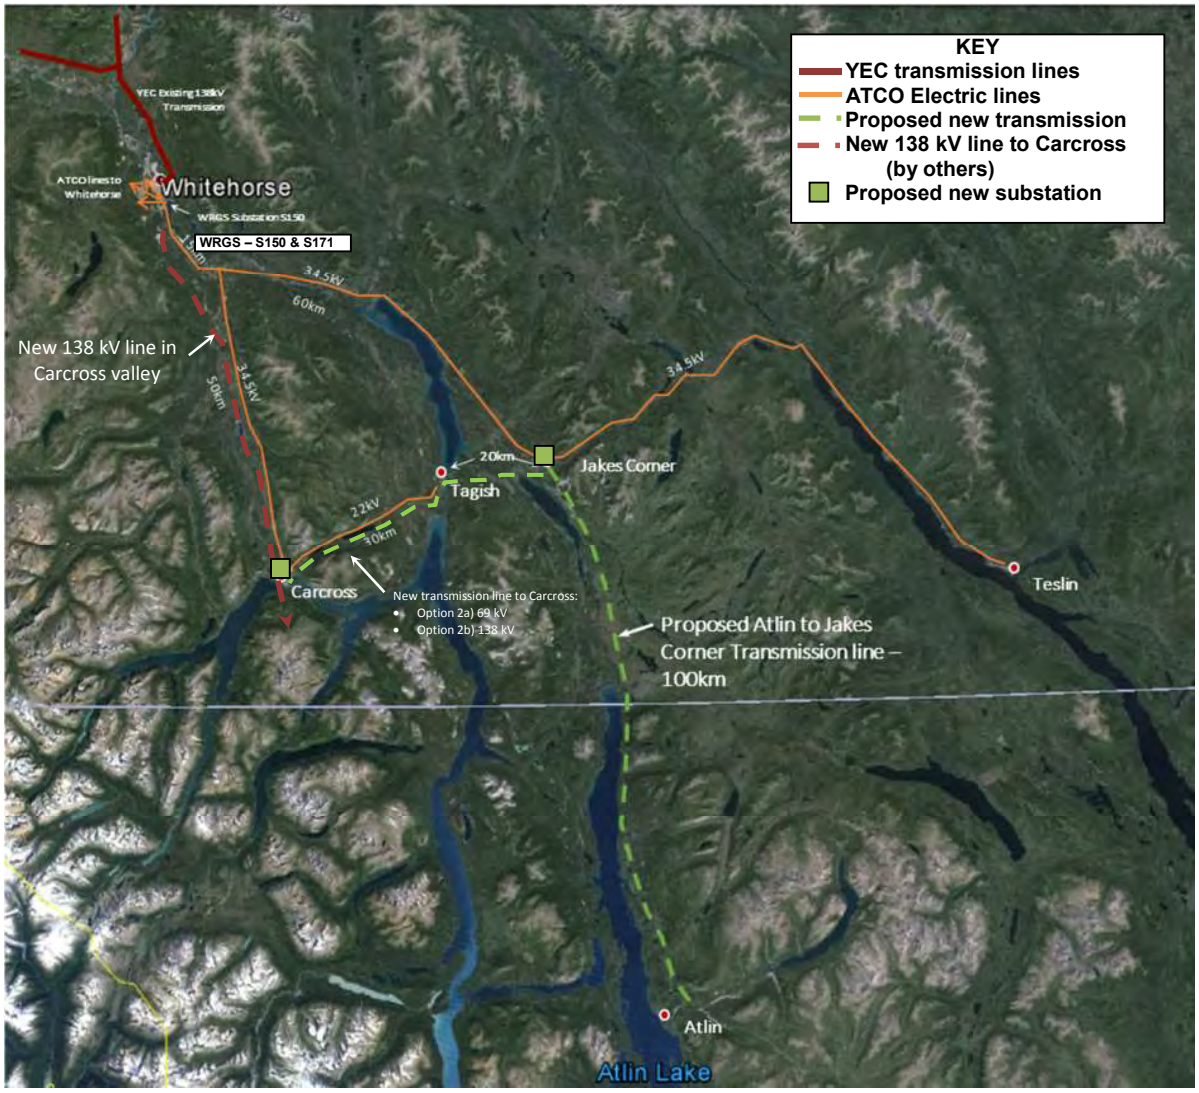
These options provide a connection both at Jakes Corner to ATCO's line SL622 and a connection of the future Carcross valley 138 kV line. It is assumed that the load is split between Jakes Corner and Carcross. Voltage regulation and line losses at full Atlin generation are similar to Option 1b), however with the split loads additional shunt compensation is required. From a performance perspective, Option 2 does not appear to provide any significant advantage, however there could be some system redundancy provided by connecting to the Yukon system at two points.

Assuming the 69 kV line would run within or contiguous to an existing right-of-way for its entire length, Option 2a) would be subject to a Designated Office Evaluation under YESAA. Conversely, it is assumed that a new 138 kV line would be in a separate right-of-way and therefore Option 2b) would be subject to an Executive Committee Screening. With respect to other permitting requirements, both Option 2a) and 2b) would have additional complexity relative to Option 1. Option 2a) would

require permitting and development of an additional 20 km of new 69 kV line between Tagish and Jakes Corner, plus the replacement of 30 km of existing distribution line between Carcross and Tagish. The new line would require a 15 m wide cleared right-of-way and it is assumed the replacement line would occupy the same right-of-way as the existing distribution line. A more involved permitting process is anticipated for Option 2b) when compared with Option 2a) given the larger footprint associated with an additional substation as well as 50 km of new 138 kV transmission line, which includes a 30 m wide cleared right-of-way. This would be separate from the existing distribution infrastructure.

If it is assumed there is no load on the Southern Lakes system and all of the Atlin output is absorbed at Whitehorse, then total line losses to Whitehorse would be at most 0.261 MW and 0.246 MW for Options 2a) and 2b) respectively.

Figure 6-4. Yukon system connection Option 2 - connect to a new 138 kV transmission line in the Carcross valley.



6.3.3 Option 3: Connect to Whitehorse with New Transmission Line along Alaska Highway

Option 3 assumes a new transmission line from Jakes Corner directly to Yukon Energy's Riverside substation (S171) in Whitehorse. This additional line would be in total 75 km long and paralleling the Alaska Highway. The two sub-options are:

a) A new 69 kV transmission line from Jakes Corner to S171. At S171 a 138/69 kV transformer is installed.

b) A new 138 kV transmission line from Jakes Corner to S171. At Jakes Corner a 138/69 kV substation is established.

These options include the following new infrastructure (see Figure 6-5);

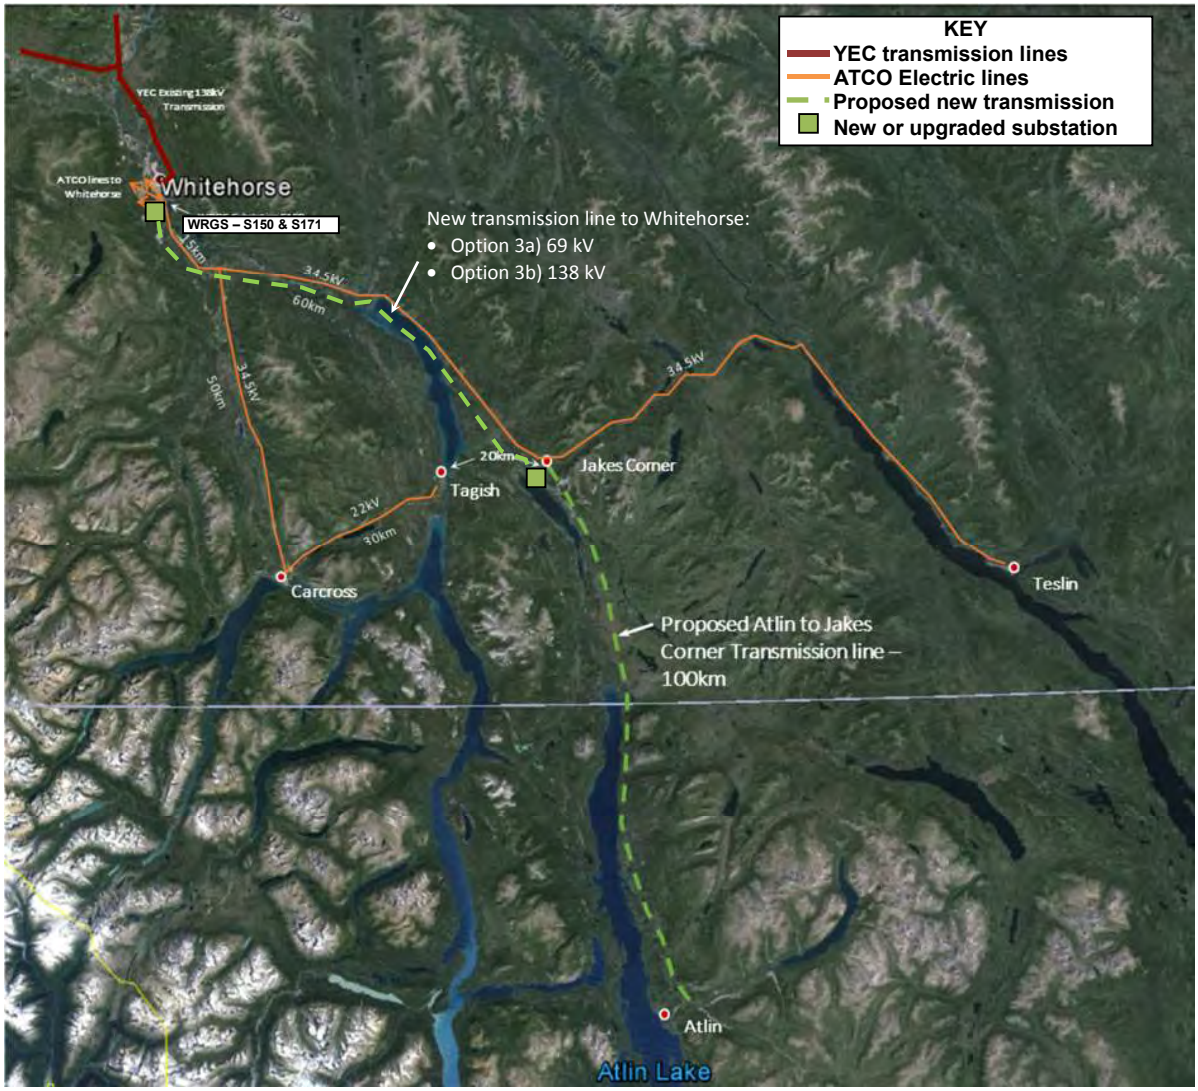
- A new substation with 69 kV bus at the upper Atlin hydro generating station;
- A 100 km long 69 kV transmission line to from Atlin to Jakes Corner;
- For Option 3a), a 69/34.5 kV substation at Jakes Corner; for Option 3b), a 69/34.5 kV substation and 69/138 kV substation at Jakes Corner;
- A 75 km long transmission line to Whitehorse at 69kV for Option 3a) and 138 kV for Option 3b). The 69kV assumes a distribution underbuild along the Alaska Highway between Jakes Corner and Whitehorse; and
- A 138 kV tap at S171 in Whitehorse.

These options provide a connection both at Jakes Corner to ATCO's line SL622 and a connection to S171 in Whitehorse. Shunt compensation is required at Jakes Corner for voltage support. Voltage regulation and line losses at full Atlin generation are similar to Option 1b). From a performance perspective, Option 3 does not appear to provide any significant advantage. Option 3a) assumes replacement of ATCO's aging distribution (34.5 kV) infrastructure along the Alaska Highway between Whitehorse and Jakes Corner. This may provide some infrastructure renewal benefit. Option 3b) does not replace ATCO's existing distribution infrastructure because it is assumed the new 138 kV line would be separate.

Assuming the 69 kV line would run within or contiguous to an existing right-of-way for its entire length, Option 3a) would be subject to a Designated Office Evaluation under YESAA. Conversely, it is assumed that a new 138 kV line would be in a separate right-of-way and therefore Option 3b) would be subject to an Executive Committee Screening. With respect to other permitting requirements, Option 3 would have additional complexity relative to Option 1. Option 3a) would require permitting and replacement of 75 km of existing distribution line between Jakes Corner and Whitehorse. The new line would require a 15 m wide cleared right-of-way and it is assumed the replacement line would occupy the same right-of-way as the existing distribution line. A more involved permitting process is anticipated for Option 3b) when compared with Option 3a) given the larger disturbance footprint associated with an additional substation as well as 75 km of new 138 kV transmission line, which includes a 30 m wide cleared right-of-way. This would be separate from the existing distribution infrastructure.

If it is assumed there is no load on the Southern Lakes system and all of the Atlin output is absorbed at Whitehorse, then total line losses to Whitehorse would be at most 0.275 MW and 0.187 MW for Options 3a) and 3b) respectively.

Figure 6-5. Yukon system connection Option 3 - connect to Whitehorse with new transmission line along Alaska Highway.



6.3.4 Yukon System Connection Options: Cost Estimate Summary

Table 6-4 below provides a summary of the estimated costs for the various options for connecting to the Yukon electrical system. This table details additional costs associated with the connection beyond the Atlin to Jakes Corner transmission line itself. Basis for transmission line cost estimates are provided in Sections 6.2.1.1 and 6.2.1.2 above. Substation costs were developed by Magna IV Engineering and details are provided in Appendix F.

Table 6-4. Yukon electrical system connection options cost summary (2016$).

Connection Cost Item	Option 1a ($000 CAD)	Option 1b ($000 CAD)	Option 2a ($000 CAD)	Option 2b ($000 CAD)	Option 3a [b] ($000 CAD)	Option 3b [b] ($000 CAD)
Additional Line Length	None	None	50 km	50 km	75 km	75 km
Additional Line Voltage	n/a	n/a	69 kV	138 kV	69 kV	138 kV
Direct Cost						
Additional Line Construction	Option not recommended	0 [c]	12,608	17,050	20,733	26,886
Clearing and Access		0	756	2,184	861	3,444
Subtotal Direct Costs		**0**	**13,364**	**19,234**	**21,594**	**30,330**
Indirect Cost						
Planning		0	401	577	648	910
Property Acquisition & Permitting		0	936	1,346	1,512	2,123
Survey & Structure Staking		0	267	385	432	607
Engineering		0	1,069	1,539	1,728	2,426
Project Management		0	936	1,346	1,512	2,123
Construction Management		0	668	962	1,080	1,517
Owner's Costs		0	668	962	1,080	1,517
Subtotal Indirect Costs		**0**	**4,945**	**7,117**	**7,990**	**11,222**
TOTALS						
Additional Transmission Line		0	18,309	26,350	29,584	41,553
Substation		1,446	2,690 [a]	2,501 [a]	2,690	2,501
Overhead & Interest (0.95%)		14	199	250	281	395
Contingency (25%)		362	5,250	7,213	8,068	11,013
Total Yukon Connection Cost	**n/a**	**1,821**	**26,449**	**36,315**	**40,623**	**55,462**

Notes: [a] this options assumes expanding an existing substation in Carcross or Whitehorse

[b] Option 3 assumes same substation costs as Option 2, but Carcross substation is located in Whitehorse.

[c] Option 1 does not require any additional transmission line beyond the primary Atlin to Jakes Corner line.

6.3.4.1 Yukon System Connection Options Conclusions

A summary of the various attributes for the six options are provided in Table 6-5. Based on this work, Option 1b) appears to be the most viable option. Connecting to the existing infrastructure at Jakes Corner is technically viable and should result in acceptable system performance. This option is the lowest cost and simplest to implement. The high-level system study has not identified significant upgrades to the existing grid required for this option beyond those costs presented herein.

Adding additional transmission infrastructure from Jakes Corner to Carcross or Whitehorse does not significantly improve transmission performance or reduce transmission losses from the Atlin Hydro Expansion project. Development of the additional transmission lines may have other benefits to the Yukon's electrical transmission system and the utilities; however they do not appear to be required for the Atlin Hydro project to deliver electricity to the Yukon.

Table 6-5. Yukon system connection options assessment summary.

Yukon System Connection Option	Option 1a) Jakes Corner Southern Lakes, isolated	Option 1b) – Jakes Corner Southern Lakes connected	Option 2a) – Carcross 138 kV 69 kV Jakes Corner to Carcross	Option 2b) – Carcross 138 kV 138 kV Jakes Corner to Carcross	Option 3a) – Whitehorse 69 kV Jakes Corner to Whitehorse	Option 3b) – Whitehorse 138 kV Jakes Corner to Whitehorse
High-level capital cost of connection (total include contingency (25%) & overhead)	n/a	No additional line req'd Substation Only: $1,446,000 Total $1,821,000	Additional line: $18,309,000 Substations: $2,690,000 Total: $26,449,000	Additional line: $26,350,000 Substations: $2,501,000 Total: $36,315,000	Additional line: $29,584,000 Substations[2]: $2,690,000 Total: $40,623,000	Additional line: $41,553,000 Substations[2]: $2,501,000 Total: $55,462,000
Technical feasibility	No Peak loads of Southern Lakes cannot be met	Yes Voltage regulation and losses are within acceptable ranges.	Yes Voltage regulation and losses are within acceptable ranges.	Yes Voltage regulation and losses are within acceptable ranges.	Yes Voltage regulation and losses are within acceptable ranges.	Yes Voltage regulation and losses are within acceptable ranges.
Transmission losses (at full generation of 7 MW sent)[1]	n/a	0.157 to 0.403 MW	0.157 to 0.261 MW	0.156 to 0.246 MW	0.157 to 0.275 MW	0.158 to 0.187 MW
System benefits	n/a	No additional benefits other than generation provided to Southern Lakes at Jakes Corner.	• Atlin hydro generation supplied at both Jakes Corner and Carcross. • Replaces 30 km Carcross to Tagish distribution line with new infrastructure.	• Atlin hydro generation supplied at both Jakes Corner and Carcross. • Extends higher-voltage transmission infrastructure to Jakes Corner.	• Replaces 75 km Whitehorse to Jakes Corner distribution line with new infrastructure[3].	• Extends higher-voltage transmission infrastructure to Jakes Corner[3].
Regulatory & environmental considerations	n/a	• No additional considerations other than Atlin to Jakes Corner transmission line. • YESAB Designated Office Evaluation assumed (69 kV and line ≤ 50 km) for Atlin to Jakes Corner transmission line.	• YESAB Designated Office Evaluation if line is within or contiguous with an existing right-of-way for its entire length. • Option assumes a 138 kV line exists to Carcross. • Requires development of 20 km of new line plus re-construction of 30 km of existing line. • Additional project footprint is assumed to be 15 m x 20 km = 30 ha.	• YESAB Executive Committee Screening, as line is not likely to be contiguous with an existing right-of-way for its entire length. • Option assumes a 138 kV line exists to Carcross • Requires development of 50 km of new line in a separate right-of-way. • Routing could be challenging due to extensive land ownership in Tagish area. • Additional project footprint is assumed to be 30 m x 50 km = 150 ha.	• YESAB Designated Office Evaluation if line is within or contiguous with an existing right-of-way for its entire length • Requires re-construction of 75 km of existing line.	• YESAB Executive Committee Screening, as line is not likely to be contiguous with an existing right-of-way for its entire length. • Requires development of 75 km of new line in a separate right-of-way. • Routing could be challenging due to terrain and land ownership constraints at the north end of Marsh Lake. • Additional project footprint is assumed to be 30 m x 50 km = 225 ha.

Notes [1] Higher line loss value assumes all of Atlin hydro output is absorbed at Whitehorse and all loads at Jakes Corner/Teslin and Carcross are switched off.

[2] For Option 3, substation costs are assumed to be the same as Option 2 but the substation is located in Whitehorse, not Carcross.

[3] ATCO Electric Yukon has indicated that by putting new transmission between Whitehorse and Carcross they could contribute financially to the project's capital cost because they would avoid the upcoming replacement cost of their 34 kV "transmission" infrastructure. Presumably the same would hold true for the Whitehorse to Jakes Corner leg as well. However, this consideration will not be included in the assessment at this time.

7 COST ESTIMATE & CONSTRUCTION SCHEDULE

7.1 Cost Estimate

A cost estimate has been prepared for the Atlin Hydro Expansion Project. A cost estimate at +/- 30% level is presented, which is the level of precision that is typically achieved at a pre-feasibility study level, with no site-specific geotechnical investigations and limited opportunity for detailed project optimization. The cost estimate is considered to be at a class 4 level based on the AACE framework. Quotes were however obtained for some key items of the project such as the turbines providing a slightly higher level of precision than AACE recommends for a class 4 cost estimate. The cost estimate includes all direct construction costs, indirect, lodging and travel, engineering and permitting studies, construction supervision and Owner's costs. A contingency of 25% was added to all project costs, including Owner's costs. Details for the cost basis is presented below while the complete cost estimate is presented in Appendix G.

Unit prices were selected to include both direct and indirect costs (man power, equipment, camp, travel, etc). Unit costs were derived from recent experience by the project team on similar project and ATELP actual costs from 2007 to 2009 for building the existing power plant. It should be noted that the hydropower industry has experienced considerable cost escalation in the last five years. Project experience has shown costs have been escalating faster than inflation and have been on the order of 25% increase since 2009.

Some of the reference projects costs have been provided by KGS based on their recent relevant project experience, including:

New Post Creek (OPG)

- 28 MW plant in north-eastern Ontario with two horizontal Francis turbines
- Preliminary design and tender documents by KGS, currently acting as Owner's Engineer
- Currently negotiating final pricing with design-build contractor (detailed tender cost breakdowns have been provided for KGS review)

Tazi Twé (formerly Elizabeth Falls, SaskPower)

- 50 MW, 4-unit plant in northern Saskatchewan
- Currently proceeding with final design, in Alliance-style partnership with SaskPower and Contractor
- Assisting SaskPower negotiate final project pricing with Contractor (detailed bid price cost breakdowns provided for review)

Mayo B (Yukon Energy Corporation)

- 10 MW, two horizontal Francis units, first power in December 2011
- KGS completed final design and were contact administrators
- Involved in initial negotiations with contractor, administered the open-book construction contract (contractor invoices included details on direct unit prices, quantities, employee hours, indirects, overhead, travel, camp costs, and profit markups)

Wawaitin (OPG)

- 8 MW plant with two Francis units, first power in 2010
- KGS assisted design-build contractor with initial bid, completed final design

Northern Hydro Study (SaskPower)

- KGS conducting pre-feasibility study of 8 potential hydro sites in northern Saskatchewan (near Northwest Territories border) ranging from 5 to 25 MW
- Turbine suppliers solicited for bid pricing
- Contractor with extensive hydroelectric construction experience were retained to review and confirm direct unit prices, indirects, and other markups carried in study cost estimates

Sechelt (Conwest, now Regional Power)

- 16 MW plant in BC with two Pelton units, first power in 1997
- KGS completed final design, contract admin and site supervision

KGS Group has also been involved in several larger hydroelectric construction projects (200 MW +) for Manitoba Hydro, both ongoing and in recent years. They have conducted similar work in northern Canada for repair and construction of water-retaining structures, from conceptual studies to detailed design. From these projects KGS has an extensive and up-to-date cost database, from detailed unit price and equipment costs through to final project costs for various structures and sizes of generating stations. Additional cost information was also obtained from similar local projects from Yukon Government (Highways and Community Services) as well at ATCO Electric Yukon (transmission line costs and Fish Lake Hydro upgrade project).

The following key unit costs were used for the main cost items of the project. Specifics of some of the quantity assumptions are stated in Appendix E. Various components were estimated as lump sum items due to the lack of design information available at this time. For example, the majority of the powerhouse mechanical and electrical balance-of-plant components were estimated as lump sum items based on ratios established on previous construction projects. A total cost allowance of $500,000 was also included for potential environment mitigation works associated with the lower power plant (not including fishways). The specific cost basis for key items is as follows:

Land clearing

Assumed $20,000/ha based on recent construction cost estimate in central Yukon. Actual costs for existing Atlin hydro project could have been lower, but actual unit prices could not be determined at this time.

Access roads (permanent)

$100,000/km based on actual mining resource road costs in Keno, Yukon has been used. Other hydro projects have experienced access road costs as high as $350,000/km.

General Excavation (dry)

$11.25/m^3$ has been used based on 25% cost escalation of actual general excavation costs paid in 2009 as part of the Atlin hydro construction. Other projects have experienced general excavation costs ranging from $20 to $35/$m^3$. The relatively low cost for general excavation assumed in this estimate is probably reasonable due to abundance of earthmoving capability in the Atlin area as a result of the placer mining industry.

General Excavation (rock)

$100/m^3$ has been used based input from ATELP and their actual experience with the previous hydro project. Other projects have experienced rock excavation costs in the order of $125/$m^3$

Rip rap (produce, haul & place)

$112.50/m^3$ has been used based on 25% cost escalation of actual rip rap costs paid in 2007 as part of the Atlin hydro's Surprise Lake control structure. At that time ATELP paid $27/$m^3$ for produce rip rap plus $63/$m^3$ to haul and place rip rap, including geotextile. Other projects have experienced rip rap costs ranging from $120 to $140/$m^3$.

Granular fill (supply and place)

$81.25/m^3$ has been used based on 25% cost escalation of actual supply and placement of drain rock costs paid in 2008 as part of the Atlin hydro construction ($65/$m^3$ in 2008).

Random backfill (supply and place)

$37.50/m^3$ has been used based on 25% cost escalation of actual supply and placement of drain rock costs paid in 2008 as part of the Atlin hydro construction ($65/$m^3$ in 2008).

Sheet Pile Cutoff Wall

$295.10/m^2$ has been used based on 25% cost escalation of actual sheet pile costs paid in 2007 as part of the Atlin hydro's Surprise Lake control structure. At that time ATELP paid $227/$m^3$ for supply and install of the Surprise Lake weir sheet pile wall. Other projects have experienced sheet pile costs up to $840/$m^2$.

1.52 m Ø I.D. HDPE Penstock

Penstock pricing was obtained from two suppliers: Uponor Infra Ltd of Mississauga Ontario and Wolseley Industrial of Langley BC. The latter was the HDPE penstock pipe supplier in 2009. Price for supply of pipe and freight to Atlin from Wolseley is (outside diameters are presented here):

63" DR41	$249.00/ft ($817/m)
63" DR32.5 (50 PSI)	$287.00/ft ($942/m)
63" DR26 (64 PSI)	$332.00/ft ($1089/m)
63" DR21(80 PSI)	$385.00/ft ($1263/m)

Plus installation costs:

- Joint welding = $3670 per day for 4 joints;
- Pipe haul and placement = Assumed $100/15 m using reduced price from Mayo-B;
- Indirect factor 1.25;
- Overhead and profit factor 1.12;

1.52 m Ø I.D. Steel Penstock

A price of $2,350/m for 3/8" coated steel pipe was used. This is based on the Mayo-B Hydro Project penstock prices which were $4.7/kg ($2016 using 5% escalation). This is for coated pipe, interior and exterior. This price is representative of the supply and installation of the pipe including welding and touch-up of the coating. The price does not include any excavation or filing. By way of comparison, in 2011 Mayo-B supply-only pipe was $2.5/kg which is $3.42/kg after escalation. However more current pricing for New Post hydro project is actually $7/kg supply and install, no backfill or excavation, no indirects or overhead and profit, however it is for a larger size pipe than was used in Mayo-B. Indirect factor of 1.25 plus overhead and profit factor of 1.12 have been added to the supply and install cost.

2.0 m Ø Steel Penstock

A price of $3,100/m for 3/8" coated steel pipe was used as per the considerations described for the 1.52 m penstock.

Volumes for penstock excavation and backfill were determined by using a typical cross section times the applicable length. Excavation and volume estimates for the lower head pond, dam and weir were determined using the preliminary design drawings as well as Civil 3D. Other excavation volumes were estimated based on the footprint of the proposed works and the assumed depths. Additional notes regarding the quantities estimated are presented with the detailed cost estimate in Appendix F.

Transmission line and substation costs were estimated for the 2016 report update and are provided in Section 6 of this report. A 2% inflation factor was applied to convert 2015 to 2016 prices.

Additional owner's costs were added to the total project costs on a percentage basis of the direct/indirect costs. The following costs were included, with the percentage value that was used:

- Feasibility study: 1.5%
- Final design & procurement: 5%
- Assessment & licensing (including environmental studies): 3%
- Site assistance & quality assurance: 5%
- Other owner's costs (including legal and financing): 4%

Table 7-1 presents a summary of the construction cost estimate of the Atlin Hydro Expansion Project. The hydroelectric generation project alone, without transmission is estimated at **79.7M$.** A total project cost of **120.7M$** is estimated including transmission required to connect with the Yukon's electrical grid at Jakes Corner.

A financial assessment was completed based on the project capital cost estimate. The total expanded Atlin Hydro project is estimated to produce on average 44.6 GWh/yr, of which between 6.2 and 8.3 GWh/yr is committed to BC Hydro by 2032. Therefore it is assumed the project will deliver 36.3 GWh/yr of energy to the Yukon's electrical grid (net of 2.2% line losses).

7.2 Schedule

Prior to the start of construction, all engineering and regulatory studies will have to be completed. A preliminary schedule is outlined based on the current state of the project and an optimistic development schedule (i.e. financial arrangements are in place). Additional details about engineering, environmental and regulatory studies are provided in section 7. It is assumed that funding will be made available to advance the required studies.

A preliminary construction sequence of the Atlin Hydro Expansion Project has been prepared. It is assumed that works are temporarily stopped during the middle of the winter period (mid-December to end of February). It is expected that construction would take 2 years to complete once all regulatory approvals are in place. It is assumed that work on the upper and lower power plants (and associated penstock) will be conducted simultaneously to achieve that schedule. If construction activities were to be conducted in sequence for each plant, it would likely require a third construction year to complete the project. The schedule that is currently proposed is the most optimal one to achieve the earliest in service date for the project.

Figure 7-1 provides an overview of the conceptual project schedule. A detailed construction schedule is provided in Appendix G.

Phase 1 – Surprise Lake Control Upgrade - Year 1 (March to May)

Work on upgrading the Surprise Lake Control structure should be done at a low-lake level period: March to May. The lake should be drawn down to the lowest level possible before commencing works. This phase could be conducted as early as the year before work on the power plants is initiated should regulatory approvals be in place. Commissioning the expanded operating range on Surprise Lake prior to downstream instream works is desirable because the lake's storage volume can be utilized to manage/minimize flows during downstream works. Work would include:

- Prepare shoreline access (snow / ice road) for excavation of upstream and downstream channel deepening;
- Raise overflow weir;
- Upgrade the fishway;
- Some reservoir clearing of low-area at west end of lake and other locations may be warranted.

Phase 2 –Upper & Lower Power Plants Year 1 (Feb to December)

Year 1 work consists primarily of site preparation and access, excavation and penstock construction. The construction is initiated during the winter with mobilization to site and preparation for the upcoming summer season. The following tasks will take place.

- Mobilization
- All falling and clearing work for intake pond, penstock and powerhouses should be conducted in late winter/spring so that it is completed prior to breading bird season;
- Develop access along the lower penstock and to lower powerhouse;
- Build lower penstock and lower powerhouse access roads;
- Excavation for penstocks and surge facility (overburden and rock);
- Install upper penstock and partially install lower penstock;
- Foundation preparation and excavation for both powerhouse;
- Construction of both powerhouses concrete substructure;
- Install superstructure for upper powerhouse (it should be possible to advance construction of the upper powerhouse faster because of its relatively lower complexity);

Phase 3 – Upper & Lower Power Plants - Year 2 (April to December)

Complete construction of all main works:

- Surprise Lake should be drawn down to lowest level possible prior to spring freshet to allow summer flows in Pine Creek to be attenuated by the lake;
- Construction of the second intake structure at the upper head pond – this should be done in spring when flows in Pine Creek are lowest;
- Excavation of the lower powerhouse tailrace should be done when Atlin Lake is at its lowest level: April and May.
- Excavation and construction of the lower head pond;
- Complete installation of penstock and surge pipe;
- Lower powerhouse superstructure construction;
- Turbines installation;
- Installation of mechanical and electrical balance of plant equipment;
- Construction of transmission line from lower powerhouse to switch yard at upper powerhouse;
- Filling of Surprise Lake up to the new full pond level;
- Commissioning of the upper power plant should be possible by the autumn of year 2 in time for winter generating period. Commissioning of the lower plant should be possible by the end of year two.

It is estimated that the construction of the transmission line to connect with the Yukon grid will take approximately 12 months to complete. It will take place at the same time as the construction of the project: over two summer/fall seasons approximately running from early May to end of October with any clearing done in the proceeding winter/early spring to avoid breeding bird conflicts. Completion of the transmission line should be scheduled to coincide with the commissioning of the upper power plant.

8 SUMMARY AND RECOMMENDATIONS

8.1 Summary

A simplified pre-feasibility study of the Atlin Hydroelectric Expansion Project has been completed. Pine Creek near Atlin, BC has been previously developed in 2009 as a 2.1 MW hydropower project to service the community's electrical needs. The objectives of this current study are:

1. Estimate the scale of the hydropower opportunity readily available for development on Pine Creek. How much power could be generated if the full potential of the site was developed? and
2. Is the expanded development of the site, for sale to the Yukon electrical grid, potentially economically viable?

The study is intended to determine the scale of the opportunity and determine if it is worthwhile to pursue. At this stage the development concepts have not taken into consideration environmental and social mitigations and only limited optimization of the project design has been completed. The design concepts presented in this study are preliminary in nature for the purpose of estimating project costs and are not necessarily representative of the ultimate design or layout of the project.

The study was supported by obtaining new 1-m topographic mapping of Pine Creek from the existing intake to Atlin Lake. A site visit was conducted in September 2014 that included a fly-over of the project site as well as a ground reconnaissance of the location of the proposed works, including a portion of the lower penstock alignment. The study did not include any geotechnical investigations on-site. Foundation condition assumptions for the proposed structures and penstock were determined based on site observations as well as past project experience at the site.

It is proposed to develop a total of 7.8 MW at Pine Creek, consisting of expanding the existing (upper) 2.1 MW powerhouse with an additional two turbines to bring the total installed capacity to 5 MW plus the addition of a second, or lower, powerhouse near Atlin Lake with an installed capacity of 2.8 MW. The upper power plant operates under a gross head of approximately 107 m and the lower plant has a gross head of approximately 56 m.

For the expansion of the upper power plant, a second 4 km long HDPE penstock will be required to convey a maximum flow of 3.55 m^3/s from the existing head pond to the powerhouse. The penstock will require the excavation of a trench, mainly through overburden materials except some limited bedrock excavations near the intake structure. The lower power plant requires 4 km of twin HDPE penstocks to convey a maximum flow of 7 m^3/s. A new excavated head pond just downstream of the existing (upper) powerhouse is required to supply the lower penstocks. Spruce Creek would be diverted into the lower head pond such that flows from Spruce Creek can be used to increase electrical generation at the lower power plant.

Increased storage in Surprise Lake to maximize winter electrical generation will be developed by modifying the existing control structure at the lake outlet. It is proposed to increase the storage range from 1.1 m to 2.5 m by increasing both top and bottom storage by approximately 0.7 m. This operating scheme would not require modification of the project's existing Permit Over Crown Land which allows storage of water up to elevation 913.85. The storage of water allows the project to

generate approximately 70% of its annual average energy production during winter months (November through April). Winter energy is of highest value to the Yukon's electrical grid.

In consideration of the existing hydropower infrastructure the Atlin Hydro Expansion Project has the potential to produce on average 44.6 GWh/yr of energy, of which at 36 to 38 GWh/yr is available for export to the Yukon after the community of Atlin's needs are met. Cost for the hydroelectric development only (without transmission) are estimated at **79.7M$** million. A total project cost of **120.7M$** estimated including a 69kV transmission line to connect with the Yukon's electrical grid at Jakes Corner.

8.2 Recommendations for Future Work

The financial analysis conducted as part of this study concludes that the Atlin Hydro Expansion Project appears to be potentially economically viable and therefore the project should be advanced to the feasibility stage. The feasibility study will need to confirm assumptions made in the current study and optimize technical and economic aspects of the project.

The following tasks should be conducted, in order, to confirm the project concept at the onset of the feasibility study:

1. Continue to operate year-round the flow and lake level monitoring program established in late 2014. The flow gauging program requires routine site visits to download the data and perform maintenance on the stations. Approximately 3 to 4 summer visits and at least 2 winter visits are warranted. Additional flow gauging should also be conducted at high water to refine the rating curves. In late 2015 update power estimates once the additional site-specific flow and water level data becomes available. The hydrology program should be continued until the project is completed.

2. Perform a preliminary geotechnical investigation program to determine foundation conditions at the location of the proposed lower powerhouse. This should initially consist of test pits and seismic surveys to determine soil conditions, groundwater levels and depth to bedrock. Follow-up geotechnical investigations (test pits) should look at foundation conditions at the upper powerhouse expansion, the lower head pond location and the lower penstock alignment. Additionally geotechnical drilling at the lower and upper powerhouse should be conducted to assess deep ground conditions.

3. Assess the economics of the alternative upper power plant arrangement that considers fully utilizing available head on upper Pine Creek. This alternate scheme may result in reduced utilization of the existing powerhouse, but could result in overall greater annual average power production.

4. With the additional data, complete a feasibility study based on the results of the geotechnical investigations, with further optimization of the proposed layouts. Additional attention should be given to the following elements:
    - Optimize operation of Surprise Lake with respect to environmental considerations and seasonal energy production. Optimize installed turbine capacity based on preferred operating schedule for Surprise Lake.

- Further assess the upgrade and outlet (hydraulic capacity) excavation needs for Surprise Lake control structure;
- Further assess the construction requirements for the lower head pond, specifically foundation conditions and impermeability of structures / foundation. Assess hydraulic performance of the lower head pond during winter conditions.
- Refine design of the lower penstock to address varied terrain conditions along the route.
- Optimization of design of the surge facility for the lower powerhouse.

5. Initiate supporting studies such as environmental baseline, land tenure assessment and regulatory matters.

6. Continue discussions regarding commercial arrangements for supply of energy to Yukon Territory's electrical grid.

APPENDIX C:
Site Visit Memorandum

MEMORANDUM

MORRISON HERSHFIELD

TO:	File	ACTION BY:	-
FROM:	Forest Pearson, Project Manager	FOR INFO OF:	ATELP
PROJECT:	Atlin Hydro Expansion Pre	PROJECT No.:	5130792.02
RE:	Site Visit Memo	DATE:	September 26, 2014

M:\PROJ\5130792\09 DESIGN & DEVELOPMENT\SITE VISIT\MEMO-PREFEAS SITE VISIT_FKP-5130792-20140926.DOCX

Site visit to Atlin conducted by F. Pearson, Project Manager Morrison Hershfield, David Morissette, Water Resource Engineering Access Consulting Group; and Shaun Beatty, Structural Engineer KGS Group on September 24-25, 2014.

- Weather on both days clear, cool (0°C up to 10°C) fall weather. No precipitation, but heavy rain over the previous weekend.
- Site visit to visually observe Surprise Lake control structure 7-8pm September 24, 2014.
- Site visit to visually observe intake weir and potential Spruce Creek diversion location 9-10am Sept. 25, 2014.
- Kickoff meeting at ATELP office with Peter Kirby, TJ Esquiro & Stuart Simpson 10:15-12:15
- ½ hr overview flight with Discovery Helicopters (pilot Paula) with S. Simpson, D. Morissette, S. Beatty & F. Pearson. Observed lower power house location, Pine Creek, lower conveyance alignment, potential Spruce Creek diversion location and alternate upper conveyance alignment to lower powerhouse. 1:15-1:45pm.
- Site visit to potential lower power house location on Atlin Lake w/ S. Simpson. Looked at potential penstock drop down rock bluff near Monarch Mt. trail. Quickly observed alignment crossing over Art Centre road.
- Briefly looked at South Pine Drive and highest property (L1252) in this neighborhood. Encountered two local residents (names unknown). Stuart knew them and had discussion of land-owners in neighborhood.
- Visited existing powerhouse w/ S. Simpson
- Conducted 1.5km traverse (see Figure 1) downstream from existing powerhouse along upper portion of potential lower penstock to look at terrain & soil conditions and potential intake locations. Soils generally well drained, course gravel terraces. Large bedrock hill at south end of traverse with saddle on east side that maybe sufficiently low to accommodate penstock alignment. 4-5:30pm.

Staff Gauge Readings:

- Surprise Lake gauge: 0.35m @ 7pm Sept. 24, 2014
- Pine Creek intake weir gauge: 0.53m @ 9:30 am Sept. 15, 2014
- Spruce Creek gauge – not read.

MEMORANDUM

Legal Notice

This feasibility study reports the results of examination of six possible transmission scenarios for the interconnection of new and existing generation at Atlin, BC to Jakes Corner, YK via a 69 kV transmission line between Atlin and Jakes Corner. The results are based on third party information which the author believes is credible and the author's experience in conducting feasibility studies.

Given the nature of the assumptions made for the study the results should not be relied on without further detailed study of the proposed interconnection.

Neither b7kennedy & Associates Inc. nor Morrison Herschfield nor Magna IV accepts any responsibility or liability for use of the information provided in this report outside of the report's stated purpose, that is, a feasibility study of transmission options to connect Atlin generation to the Southern Lakes load.

Executive Summary

Six transmission scenarios were examined for the Atlin interconnection with Yukon Electric. For all options the transmission line from Atlin to Jakes Corner was 69 kV using Ibis, 397 MCM conductor.

- Option 1a – the new interconnection serves the Southern Lakes load as isolated. That is, there is no interconnection to the existing Yukon electric system.
- Option 1b – the new interconnection serves the Southern Lakes load and is interconnected to the Yukon electric system via a 34.5 kV line to Whitehorse S150.
- Option 2a – Yukon develops 138 kV transmission south from Whitehorse existing station S171. The 69 kV interconnection to Jakes Corner is extended to Carcross and interconnected to the 138 kV system via a 138/69 kV transformer.
- Option 2b – the 69 kV transmission line between Jakes Corner and Carcross is replaced by a 138 kV interconnection between Jakes Corner and Carcross.
- Option 3a – a 138/69 kV transformer in installed at S171 and a 69 kV transmission line is constructed to Jakes Corner to interconnect with the new line from Atlin.
- Option 3b – a 138 kV line is constructed from S171 to Jakes Corner and a 138/69 kV transformer is installed at Jakes Corner to interconnect with the new line from Atlin.

With the exception of Option 1a, all other options are feasible and provide acceptable results from the point of view of voltage regulation and losses.

The preliminary conclusion is Option 1b provides the best interconnection for this project.

In addition, a number of issues have been identified for further study.

Additional work using more complete models of the two systems is required to firm up the preliminary conclusions and to develop equipment specifications.

Introduction

Tlingit Homeland Energy Limited Partnership is proposing to develop additional run of the river hydro in the Atlin area of British Columbia. The expanded generation will consist of two 1.45 MW and one 2.8 MW generators. The generators are assumed to be rated at 0.85 pf. In addition, an existing 2.1 MW hydro set serves the community of Atlin.

This study examined the construction of 100 km of 69 kV transmission to interconnect Atlin with Jakes Corner, Yukon. The conductor of choice was Ibis, 397 MCM. Jakes Corner is in the southern part of Yukon. The area is known as the Southern Lakes and consists of four load centers Carcross, Tangish, Jakes Corner and Teslin with a peak load of 8 MW. For the purposes of this study, the load was lumped at Jakes Corner or divided between Jakes Corner and Carcross. The latter was used for Options 2a and 2b, load at Carcross and Jakes Corner. The load power is 0.95 pf. This is based on the winter heating load.

Study Scenarios

Six study scenarios were developed for this study.

- Option 1a – the new 69 kV interconnection serves the Southern Lakes load as isolated. That is, there is no interconnection to the existing Yukon electric system.
- Option 1b – the new 69 kV interconnection serves the Southern Lakes load and is interconnected to the Yukon electric system at the existing 34.5 kV bus in station S150.
- Option 2a – Yukon develops 138 kV transmission south from Whitehorse existing station S171 to Carcross. The 69 kV interconnection to Jakes Corner is extended to Carcross and interconnected to the 138 kV system via a 138/69 kV transformer.
- Option 2b – the 69 kV transmission line between Jakes Corner and Carcross is replaced by a 138 kV interconnection between Jakes Corner and Carcross. A 138/69 kV transformer is installed at Jakes Corner.
- Option 3a – Yukon develops 69 kV transmission south from Whitehorse existing station S171 to interconnect with the 69 kV transmission from Atlin. A 138/69 kV transformer is installed at S171.
- Option 3b – Yukon develops 138 kV transmission south from Whitehorse existing station S171 to interconnect with the 69 kV transmission line from Atlin. A 138/69 kV transformer is installed at Jakes Corner.

For all options studied, the 69 kV development and generation at Atlin, the 100 km 69 kV transmission line from Atlin to Carcross and the 69/34.5 kV transformer at Jakes Corner are common.

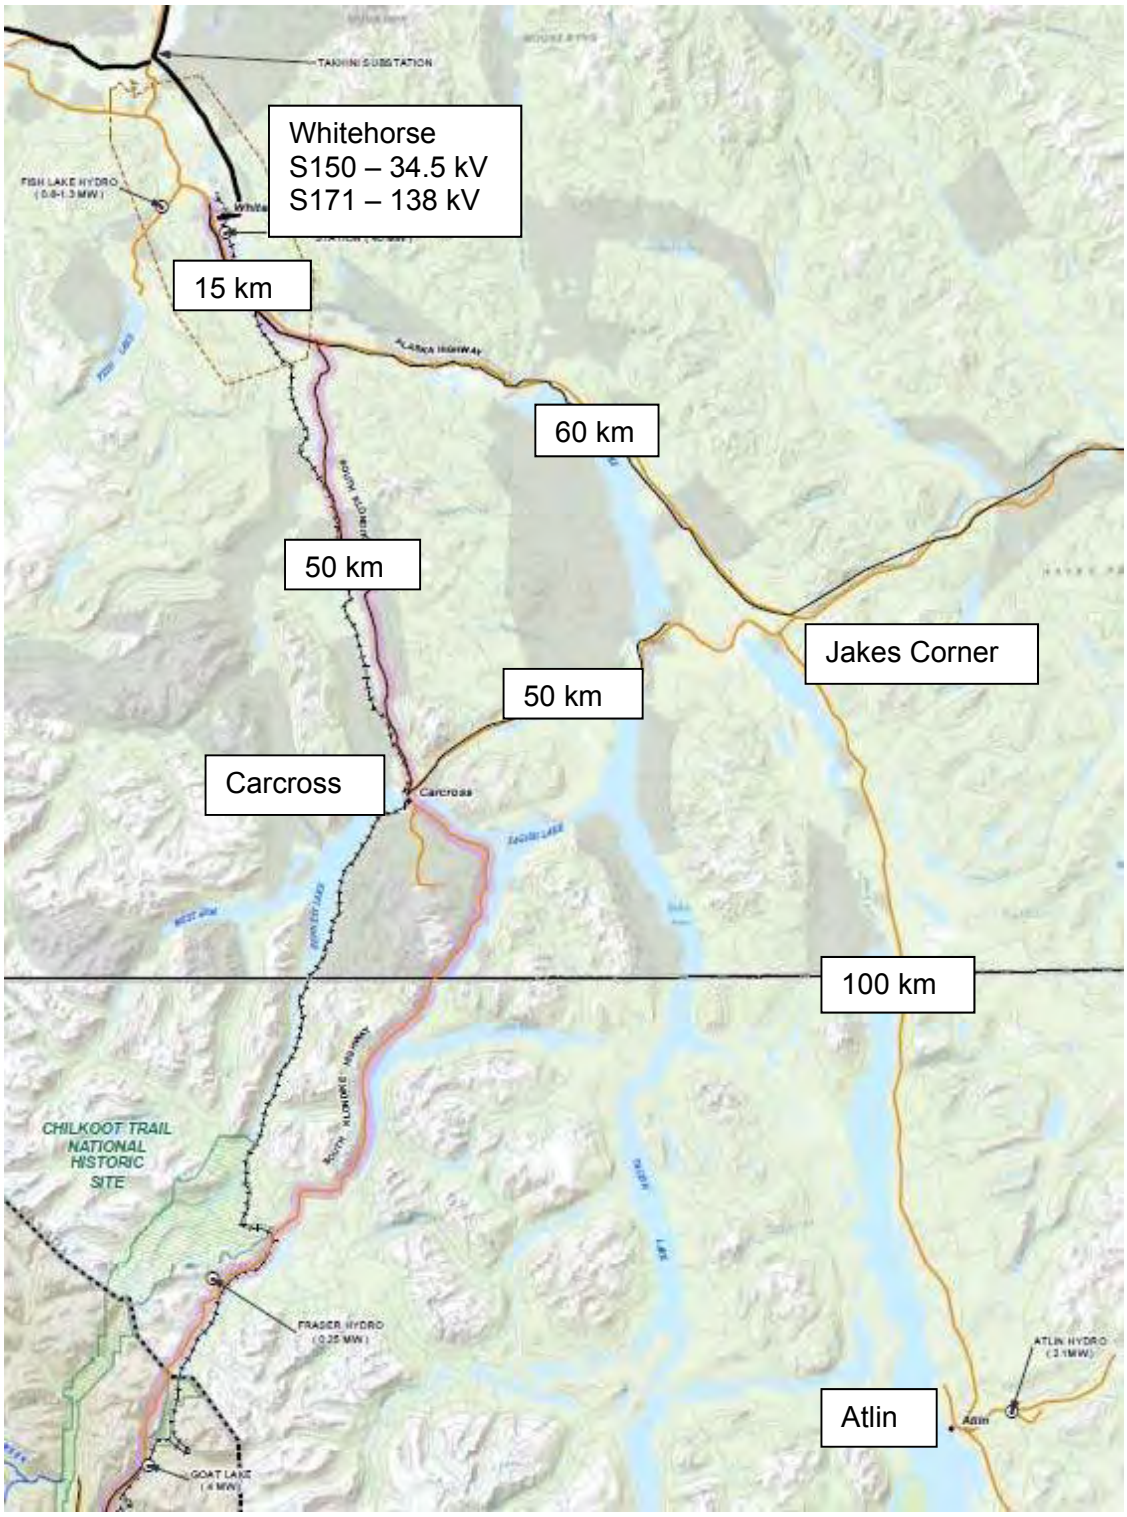
Figure 1 gives an overview of study area.

Figure 1: Map of the Study Area



88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

The existing system feeding the Southern Lakes consists of 34.5 kV transmission from S150 located in Whitehorse. A single circuit line extends south from S150 15 km where it bifurcates to supply Carcross and Jakes Corner. The Carcross section is 50 km and the Jakes Cromer section is 60 km. For this study the 34.5 kV to Jakes Corner from S150 was assumed to be single circuit 75 km in length. There is no interconnection between Carcross and Jakes Corner. The same distance was assumed for the 69 kV and 138 kV options from S171.

Model Development

Referring to Figure 2, a model was developed for Atlin Hydro expansion. The single line shown is Option 2b, the 69 kV interconnection of Jakes Corner to Carcross and the 138 kV interconnection to S171. The pie charts in the single line give an indication of the equipment loading based on line SIL or estimated maximum loading or typical transformer ratings. For example, 138 kV lines have a 50 MW SIL.

At Whitehorse there are two interconnection points; 34.5 kV at S150 and 138 kV at S171. With the exception of Option 1a, S150 or S171 was the swing bus for these studies. For Option 1a, one of the new generators at Atlin was made the swing bus.

Atlin Hydro Development. A new 69 kV bus and infrastructure was developed at Atlin, ATLIN TRM. The three new generators are connected in parallel to the new 69 kV station through their own transformers. Three new generators, two 1.45 MW and one 2.8 MW units are planned. An interconnection between ATLIN TRM and the existing ATLIN 25 kV was developed to allow the excess active power from the existing 2.1 MW hydro generation to the 69 kV bus. In addition, should the existing 2.1 MW be off line for any reason, the new generation can supply the 0.7 MW Atlin load. Finally, the single line shows existing BC Hydro diesel generation at Atlin. This generation was assumed off line for all of the studies.

69 kV Transmission Line. 100 km of transmission line with Ibis, 397 MCM, conductor connects ATLIN TRM to a new station called JAKES COR_69. To complete the interconnection, 69/34.5 kV 9 MVA transformer is installed to supply the Jakes Corner load.

Load Model. The Southern Lakes load is lumped as 8 MW with a power factor of 0.95 pf at Jakes Corner.

Interconnection to Yukon. Finally, the existing 34.5 kV transmission line up to S150 was modeled – see Figure 4. For this study, generation connected to either S150 or S171 was made the swing or slack bus. Figure 2 shows the development of 138 kV transmission from S171 to Carcross and the 69 kV transmission from Carcross to Jakes Corner..

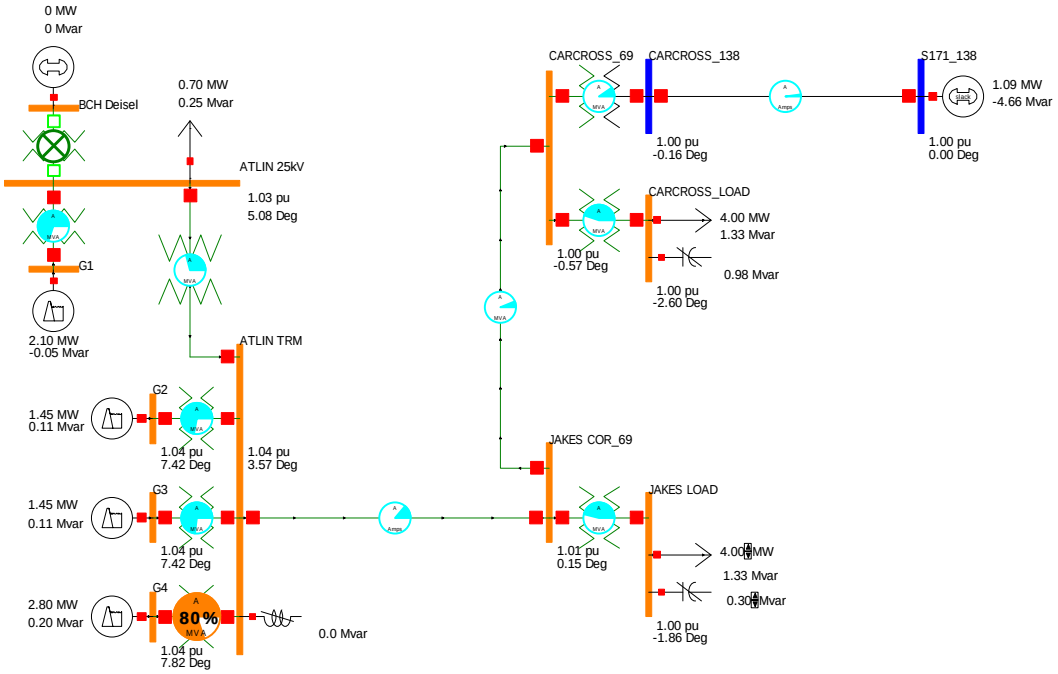
Figure 2: Basic System Studied – 138 kV Connection to S171



Study Parameters

Loading of transmission lines can be divided into three steps. For lines up 80 km in length, the thermal characteristics of the conductor predominate. Between 80 km and 230 km, NERC voltage drop criteria predominate. NERC commonly used criteria is to maintain an absolute voltage drop of no more than 5% between the sending and receiving end terminals during normal operating conditions, commonly called NERC A. Above 230 km, the steady state criterion predominates. These criteria state that the maximum angle across the transmission system between its equivalent Thevenin voltage sources is limited to 45^{o} electrical.

For this study, NERC voltage criteria were used along with keeping line losses to less than 5% of the active power transferred.

The results are presented in a series of tables. Generation at Atlin was increased in increments based on the generator size – 1.45 MW, 2.9 MW, 5 MW and 7.8 MW. The sending and receiving end voltages and active powers were measured along with the transmission line losses. Line losses are calculated as a percentage of sending end active power. In addition, if any shunt compensation was required, this is noted in the tables.

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Option 1a

Table 1, presents the results and the single line is shown in Figure 3. For this option, Jakes Corner load was treated as isolated. That is, there was no interconnection between the Southern Lakes Load and the existing Yukon system at either S150 or S171.

Figure 3: Atlin Transmission Supplying Isolated Southern Lakes Load

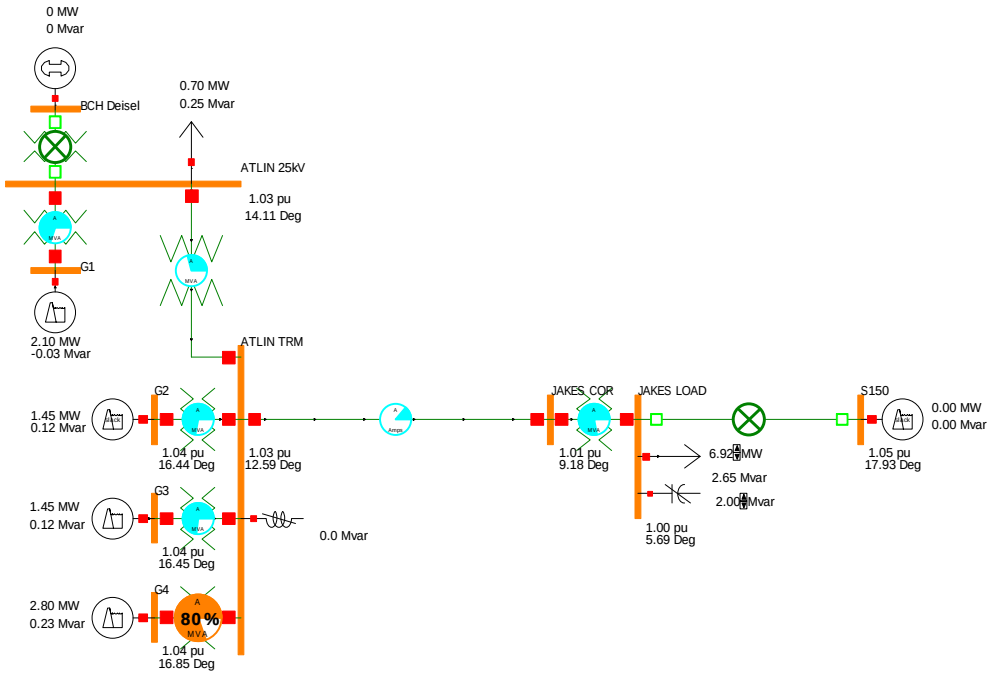


Table 1: Option 1a Results

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.74	0.74	1.03	1.02	1	0.004	0.54	0.00	0.86
2.9	2.20	2.18	1.03	1.02	1	0.018	0.82	0.00	0.91
5.0	4.29	4.23	1.03	1.01	2	0.059	1.38	0.00	1.35
7.8	7.09	6.93	1.03	1.01	2	0.157	2.21	0.00	2.00

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

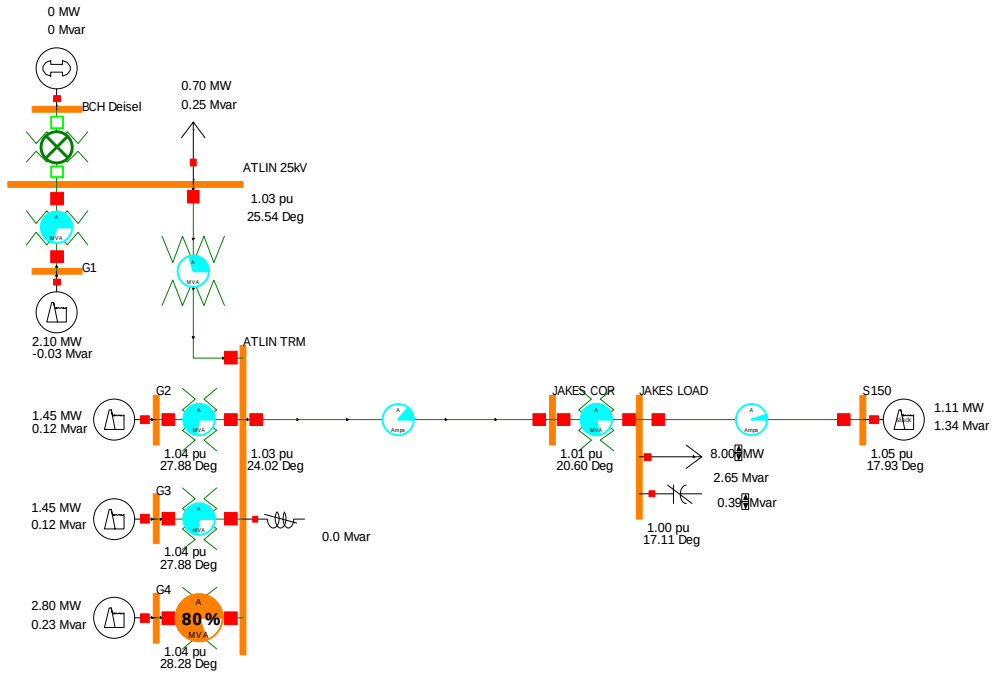
For this option, the load at Jakes Corner was adjusted to match the available generation at Atlin.

The results show that losses are less than 5% at full generation and voltage drop is limited to 2% at full generation. In addition, there is a requirement for shunt compensation at the load because there is no support from Yukon generation. However, Atlin generation is not able to supply the entire 8 MW Southern Lakes load under peak load conditions. This option is not recommended.

Option 1b

Table 2 gives the results and the single line is shown in Figure 4. For this case, Atlin is connected to Yukon at S150.

Figure 4: Atlin Transmission Supplying Integrated Southern Lakes Load



88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Table 2: Option 1b Results

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.75	0.74	1.03	1.02	1	0.004	0.53	0.00	2.33
2.9	2.20	2.18	1.03	1.02	1	0.018	0.82	0.00	1.53
5.0	4.29	4.23	1.03	1.01	2	0.059	1.38	0.00	0.90
7.8	7.09	6.93	1.03	1.01	2	0.157	2.21	0.00	0.39

With the addition of source at Whitehorse, S150, losses are similar to the isolated case. That is losses are limited to 2.2% at full Atlin generation. Voltage regulation is the same is the same with the interconnection to Yukon. In addition, with a reactive source at S150, shunt compensation at the load reduces as the generation from Atlin increases.

The requirement for shunt compensation at the sending end is clarified in the section Other Issues of this report.

Option 2a

For this option, a 50 km 69 kV line is inserted between Jakes Corner and Carcross using Ibis, 397 MCM, conductor. It is expected that the section of line between Atlin and Jakes Corner will be constructed first making this option the most likely. In addition, there is no interconnection between Carcross and Jakes Corner. At Carcross, the 138 kV line from S171 is tapped and a 138/69 kV station is established. Hawk, 477 MCM, conductor has been assumed for 138 kV lines. In addition, the load was split between Jakes Corner and Carcross. The single line is shown in Figure 5 and the results in Table 3.

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Figure 5: Option 2a Single Line

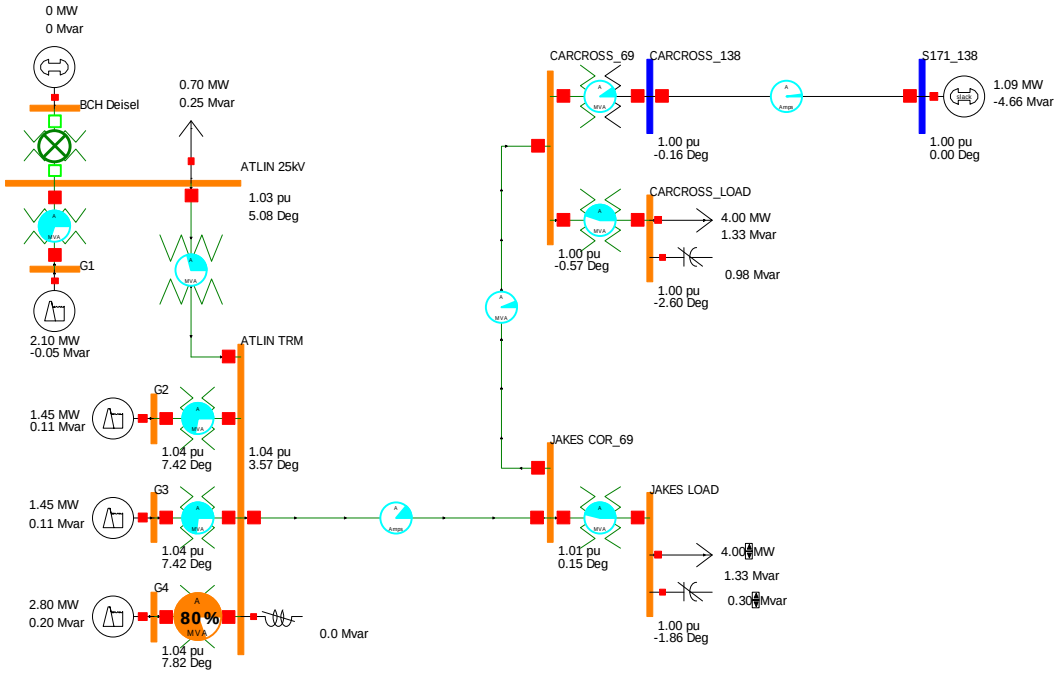


Table 3: Option 2a Results

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.75	0.74	1.02	1.01	1	0.005	0.67	0.00	1.30
2.9	2.20	2.18	1.03	1.01	2	0.019	0.86	0.00	1.08
5.0	4.29	4.23	1.03	1.01	2	0.060	1.40	0.00	1.11
7.8	7.09	6.93	1.04	1.01	3	0.157	2.21	0.00	1.28

The results are similar to Option 1b. Shunt compensation is required at the loads. Voltage regulation is within the 5% and losses maximize at full Atlin generation output of 2.2%.

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Option 2b

A second option had the 69 kV line between Carcross and Jakes Corner replaced by a 138 kV line. Load was modeled as for Option 2a. At Carcross a 138/34.5 kV transformer was added and at Jakes Corner a 138/69 kV transformer was added. A secondary option, not tested, was to build initially the Jakes Corner to Carcross line with 138 kV construction and energize the line at 69 kV. The single line for the 138 kV option between Carcross and Jakes Corner is shown in Figure 6 and the results in Table 4.

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.75	0.74	1.02	1.01	1	0.005	0.67	0.00	2.39
2.9	2.20	2.18	1.03	1.01	2	0.018	0.82	0.00	2.21
5.0	4.29	4.23	1.03	1.01	2	0.050	1.17	0.00	2.19
7.8	7.09	6.93	1.04	1.01	3	0.156	2.20	0.00	2.24

The results are similar to Option 2a. That is voltage regulation and losses are similar. However, with the split loads, additional shunt compensation is required for the laods.

Option 3a

Option 3a sees a 69 kV transmission line from S171 established. At S171, a 138/69 kV transformer is installed. Shunt compensation is installed at Jakes Corner for voltage support. The results are presented in Table 4 and the single line is shown in Figure 6.

Figure 6 Option 3a Single Line

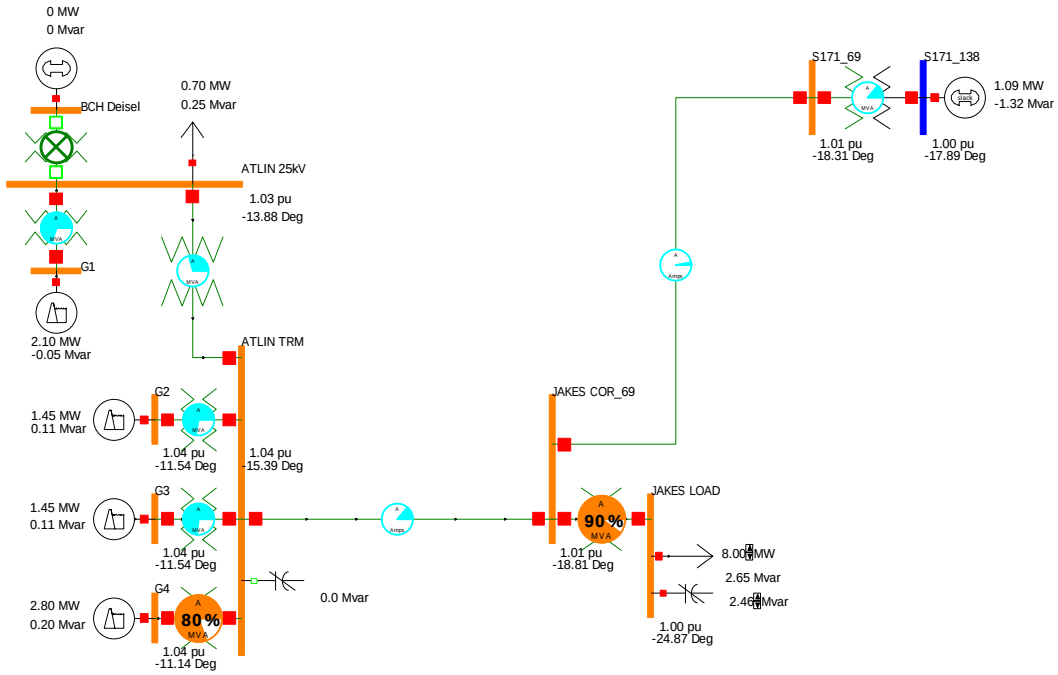

Table 4: Option 3a Results

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.75	0.74	1.02	1.01	1	0.005	0.67	0.00	2.78
2.9	2.20	2.18	1.03	1.01	2	0.019	0.86	0.00	2.55
5.0	4.29	4.23	1.03	1.01	2	0.060	1.40	0.00	2.48
7.8	7.09	6.93	1.04	1.01	3	0.157	2.21	0.00	2.46

For this option voltage drop at maximum transfer from Atlin is maximum at 3% and losses are slightly higher.

Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Option 3b

Option 3b sees a 138 kV line from S171 to Jakes Corner. At Jakes Corner a 138/69 kV transformer is installed. Shunt compensation is installed for the load.

Figure 8: Option 3b Single Line

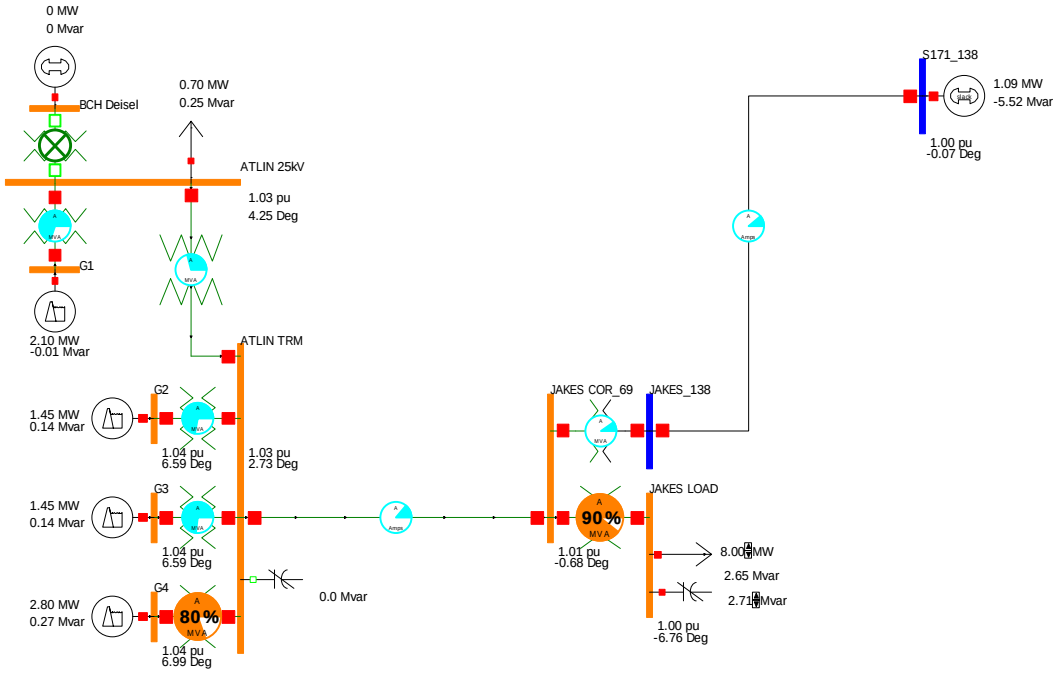

Table 6: Option 3b Results

Atlin Gen	Send Power (MW)	Rec Power (MW)	Vsend (pu)	Vrec (pu)	Vdrop (%)	Loss (MW)	Loss (%)	Comp Send (MVAr)	Comp Rec (MVAr)
1.45	0.75	0.74	1.02	1.01	1	0.005	0.67	0.00	2.68

Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

For this option voltage regulation and losses are similar to Option 3a.

Losses Atlin to Whitehorse

For all of the options studied except 1a, a calculation of the total losses was made for the case where all of Atlin output is absorbed at Whitehorse S150 or S171 as the case may be and the load at Jakes Corner and Carcross was switched off. For all options, Atlin was dispatched at maximum output of 7.8 MW. Table 7 presents the results

Table 7 Losses Atlin to Whitehorse

	Losses (MW)		
Case	Atlin to Jakes Corner	Jakes Corner to Whitehorse	Total
1b	0.108	0.295	0.403
2a	0.154	0.107	0.261
2b	0.154	0.092	0.246
3a	0.154	0.121	0.275
3b	0.157	0.030	0.187

Other Issues

This study used Ibis, 397 MCM, conductor for the 69 kV line. It's recommended that Partridge, 266 MCM, and Hawk, 477 MCM, be evaluated from a financial point of view. Conductor size influences lines costs between 30% to 50%.

Protection of the new 69 kV line can be accomplished using impedance protection. Use of high accuracy current and voltage transformers will allow the Zone 1 reach at each end to be set to 90% of line length. Effectively, this makes the line protection independent of telecommunications, although telecommunications, if available, should be used to enable the line differential protection function of the relay. High-speed autoreclose should be investigated, but may not be applicable to the interconnection.

With full development of Atlin generation, there will be an overfrequency condition when the line to Jakes Corner trip during a transient fault or other condition. The overfrequency or overspeed condition results when the generation exceeds the connected load. Anti-islanding protection will need to be applied for two cases.

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

- Assume all generation is in service and the line trips. The 69/25 kV interconnecting transformer will need to be tripped and the 2.1 MW generator run back to 0.7 MW plus any losses. Hydro generators need to be tripped when their overspeed reaches 125% of rated speed. Assuming an inertia factor, H, of 2, this overspeed will be reached in approximately 0.750 seconds. Assuming a relay plus tripping time of 0.250 seconds, the overfrequency protection needs to initiate tripping within 0.500 seconds. It must be noted that these times are estimates and need further study.
- Assume the 2.1 MW generator is out of service and the remaining generation is in service. For this case to maintain load at Atlin a scheme needs to be devised to determine which generators are tripped and which generator has the runback scheme. A similar tripping scheme as noted above needs to be developed.

Operationally, with Yukon Energy being the larger generation source, the effect of normal load oscillations in Yukon and their effect on Atlin needs to be investigated. This may require additional controls on the Atlin generators, effectively Automatic Generation Control (AGC) to damp out the isolations between the two systems. Additionally, Yukon may need to adjust its AGC controls.

Transformer voltage control at the sending end can be accomplished by off-load transformer taps and the voltage adjusted automatically by the generators. Generators are typically run slightly overexcited. For this study, Atlin generation was operated at 104% voltage. Additional study of the preferred operating conditions is required.

At the receiving end an on-load tapchanger with a suitable range should be investigated.

System synchronization should take place at Atlin, however this needs to be discussed and agreed with Yukon Energy.

Running the Southern Lakes load isolated can be accomplished during times when the Southern Lakes load is below approximately 7 MW. Further study is required for this operating scenario.

Generators with automatic voltage regulation (AVR) have the ability to control their terminal voltage. This is accomplished by increasing or decreasing the rotor voltage. Typically, a generator has the capability to increase its reactive power, overexcited condition, output in the range of 50% of the generator's active power rating. For the underexcited condition, the range is 25%. Energizing the 69 kV transmission line from the Atlin end will require the Atlin generators to operate in their underexcited mode. For the 1.45 MW machines, this is approximately 0.35 MVAr. The charging reactive power of the 69 kV line is 2.0 MVAr. This requirement is greater than the estimated total reactive power capabilities of all four machines at Atlin. To compensate for this a 1.5 MVAr shunt reactor was connected to the 69 kV Atlin bus was added. Additional work needs to be done to determine the reactor size and its controls.

88 Midvalley Cres SE, Calgary, AB, T2X 1N3
Phone (403) 256-1863 (O) (403) 585-3037 (C) E-mail b7kennedy@shaw.ca

Energizing the 69 kV line from the Yukon end and synchronizing at Atlin is the preferred method of connecting Atlin to Yukon. The capabilities of the Yukon generators need to be assessed.

The generation profile needs to be developed at Atlin to determine the energy profile.

The keraunic level for the area needs to be determined to determine the frequency and duration of transient line trips.

Conclusions

This feasibility study examined six scenarios for connecting Atlin generation to the Southern Lakes load in Yukon. All options gave acceptable voltage regulation and loss performance.

Option 1a is not recommended as Atlin generation cannot supply all of the Southern generation under maximum load conditions.

Regardless of the option chosen, the performance of the 69 kV interconnection was similar.

As noted above, Options 1b, 2a and 2b give acceptable performance. Option 1b is the recommended option since it will require the least construction to accomplish the interconnection. A 69/34.5 kV substation is required at Jakes Corner along with shunt reactor of 1.5 MVAr at Atlin.

Other issues identified include:

- Line protection
- Communication
- Anti-islanding and overfrequency protection
- Effect of Yukon load fluctuations on Atlin load.
- Sizing of transformers and the tapchanger requirements.
- Synchronization of the two systems.

Additional study using a full model of Yukon Electric system is required to confirm these results, optimize equipment, develop equipment specifications and identify other technical issues.

1 EXECUTIVE SUMMARY

1.1 Magna has prepared the following Class 5 estimates (-30/+50%) for substations at Atlin Upper Generation Station, Atlin Lower Generating Station and Jake's Corner. Three options have been considered at Jakes Corner, which include an interconnect line to Carcross at 69 kV, a 138 kV interconnect line, and no interconnect to Carcross at all. Estimated installed costs are in Canadian dollars, including GST, PST, Engineering and contractor profits for the Substations are as follows:

Atlin Upper Substation	$ 4,240,000 CAD
Atlin Lower Substation	$ 1,118,000 CAD
Jakes Corner (Option 1b)	$ 1,620,000 CAD
Jakes Corner (Option 2a)	$ 2,800,000 CAD
Jakes Corner (Option 2b)	$ 3,013,000 CAD

1.2 As a comparison, a budget quotation was requested from a US vendor for prepackaged substations. The budget quote received included freight to site, but did not included GST and PST as do the figures above. Prices are in US dollars. Scope of work does not include fencing, site preparations, any required civil works, sub grade grounding etc. Although the initial pricing appears attractive, with currency exchange and the required site works that have not been included, it is inconclusive at this time if this is truly a less expensive option. What the pricing does effectively do, is corroborate the estimating performed in the previous paragraph, and we believe the pricing provided above, considering total installed price falls within the Class 5 estimate range specified.

Atlin Upper Substation	$ 1,919,000 USD
Atlin Lower Substation	$ 908,000 USD
Jakes Corner (Option 1b)	$ 1,987,000 USD
Jakes Corner (Option 2a)	$ 1,531,000 USD
Jakes Corner (Option 2b)	$ 1,545,000 USD

2 DATA SOURCES

2.1 Interconnection and sizing of equipment is based on the report prepared by b7kennedy & associates Inc.

2.2 The adjusted pricing included in the Magna estimate and the US prepackaged vendor quote date is Q1 2016.

2.3 Cost data in the Magna portion of the estimate has been drawn from several sources.

2.3.1 Sources prefixed with a 12 digit identification number have been taken from RSMeans Electrical Cost Data 2014 (January) edition. (Entries are highlighted green in the attached estimates) The "Anywhere USA" material, labour and equipment costs have been adjusted for Whitehorse construction location, using the "City" factors listed in the RSMeans book. This factor is 134.3 for materials and 69.8 for equipment and labour. Values highlighted in green located in columns "Extended Material, Estimated Labour and Equipment" are factored with these two values, as well as an inflation factor 1.25% per year for the year 2014 and 2015.

2.3.2 Data sources prefixed with "MIV" are deemed to be current Q1 2016 costs in Canadian dollars. These values are entered as estimated values using internal Magna information based on similar projects and vendor budget quotations.

2.3.3 Items prefixed with "MH" are unit rates that have been provided by Morrison Hershfield specific to this project as of January 2016.

2.4 Costs in the Dis-Tran provided quotation are provided by Dis-Tran and their origins are unknown, except that a number of sub-vendor names have been provided in the equipment lists, such as ABB, S&C, Tyco, Ohio Brass etc.

3 WHAT'S INCLUDED (IN THE MAGNA ESTIMATES)

3.1 Substations for Atlin Upper and Atlin lower are unaffected by various options considered at Jake's Corner.

3.2 Jake's Corner substation estimates are presented in three configurations, options 1b, 2a and 2b. These configurations are defined in the report provided by b7kennedy and associates.

3.3 Division 1 costs for the installation contractor, such as mobilize, demobilize, site costs, have been included at 7% of the itemized bare costs.

3.4 Installation contractor profit of 15% has been included.

3.5 Engineering has been included at 10% of the factored material, labour, equipment, contractor Division 1 costs and contractor profit.

3.6 PST at 7% has been included on installation cost and engineering.

3.7 GST at 5% has been included on installation cost and engineering.

4 CONSTRUCTION METHODS

4.1 The base estimates have been compiled based on stick built construction at the location, with the exception of:

4.1.1 Modularized substation building for Jakes corner, constructed in an Alberta or BC city.

4.1.2 Protection panels pre-constructed in a panel shop in Alberta or BC city.

4.2 Transformers 2 MVA or larger are to be placed on field constructed slab on grade concrete pads.

4.3 Substation equipment, transmission line dead ends, and other HV equipment is to be supported by fabricated steel structures, attached to screw in steel piles.

4.4 The following support structures are assumed:

4.4.1 34.5 kV disconnecting switches are assumed to be supported on single pole structures. These may be wood or steel.

4.4.2 69 and 138 kV disconnecting switches, circuit switchers, ct sets, etc. are assumed to be supported on two screw pilings with fabricated steel supports spanning the piles and supporting the equipment.

4.4.3 34.5 kV circuit switchers are supported on two screw piles with fabricated steel supports.

4.4.4 Dead end structures for 34.5, 69, and 138 kV are assumed to be supported on 4 screw piles. Dead end structures will also support integrated disconnecting switches where required.

4.4.5 Double dead end structure for 69 kV at Atlin Upper Substation is assumed to be supported by 4 screw piles, although they will likely need to be larger. Piling costs for varying pile sizes were not differentiated in the estimate.

4.5 Generator output cables will be underground, buried 1 meter, in DBII conduit.

4.6 Protection control panels will be located in a self-contained, prefabricated control building at the Jake's Corner substation. Costs for the building and placement have been included.

5 ASSUMPTIONS

5.1 Dual generator output transformers for generators G2 and G3 have been combined into a single generator transformer and 69 kV circuit switcher. Separate transformers and circuit switchers would add considerable cost to the substation and are not deemed necessary.

5.2 Atlin Upper and Atlin Lower substations are assumed to be located on disturbed (placier mining) earth, consisting of modest size rocky earth fill. As such ground wells have been allowed for, due to the likelihood of poor connection of typical 15 foot driven ground rods.

5.3 Jakes corner substation is assumed to be located on undisturbed land, consisting of earth and a lesser amount of rocks, thus negating the requirement of drilled ground wells. A traditional array of driven ground rods is assumed to provide adequate grounding.

5.4 Protection control panels will be located in owner provided space in Atlin Upper Generating Building and Atlin Lower Generating Building.

5.5 125 VDC supplied by station batteries and chargers is assumed to be supplied by the generating stations for the Upper and Lower substations.

5.6 125 VDC batteries and charging equipment shall be supplied by the scope of this estimate for Jake's Corner substation.

5.7 General earthworks will be provided by others. The assumed starting points for substation construction will be level, drained, compacted earth, with access roads provided. No pre-construction clearing or ground preparation costs are carried.

5.8 Costs for ground grid construction, fence construction, washed rock substation backfill, cable trenching and backfill have been included in the estimate.

5.9 Connection from the G1 generator output to the Upper Atlin Substation shall be underground, using insulated cables.

5.10 A lump sum of $85000, bare cost is carried for the connection of the G1 generator output to the Upper Atlin Substation tie transformer. $30,000 bare cost is carried for modifications to the existing G1 protective relay systems for the inclusion of the tie connections. This connection is not well defined at this time and may cost more or less.

6 SCOPE

6.1 Transmission line connection end of scope is the substation dead end. All line construction charges, right of ways, wires, hardware, poles etc are by others.

6.2 No equipment has been allowed for SCADA or other communications. Substations have no visibility to one another or any remote locations. Fibre optic equipment is not included.

6.3 Power metering for electricity sale has not be defined or included. Additional revenue class current transformers, potential transformers and metering equipment will be required at the locations determined by the sale contract.

7 SPECIAL CONSIDERATIONS

7.1 Carcross currently has no 138 kV systems in place.

7.2 Carcross currently has no 138 kV substation in place.

7.3 Equipment supplied for the "Carcross 138 kV substation" as part of estimates 2a and 2b (Jake's Crossing Substation options 2a and 2b) are "loose supplied" "free issue" equipment. The equipment supplied does in no way constitute a complete and working 138 kV substation. Specifically missing from the Carcross location are earthworks, fence, foundations, protection panels, protection equipment, wiring, 125 VDC batteries, 125 VDC chargers, station services, lighting, grounding, etc. The supplied equipment includes the power transformer, circuit switchers, support stands, dead end structures and disconnect switches. As the eventual scope at Carcross is undetermined at this time, attempting to provide necessary infrastructure for a small portion of an overall substation at Carcross would be misleading.

8 ALTERNATE CONSIDERED SOLUTIONS

8.1 The general remote location of the installation may benefit from pre-constructing skid units remotely and transferring them to site for interconnection. Pricing in US dollars, fob site is included in the appendix. Regrettably, the quotation provided did not include general arrangement details, size details, or much other information other than a BOM. As such, it is not possible to determine if this is a cost effective alternative to the stick built solution proposed by Magna. Specific items that are not included in the prepackaged alternative are site preparation, fencing, reactors grounding, connections to generators, connections to remote mounted protection panels, to name a few things. Further investigation will need to be done to determine the cost benefits / disadvantage of this route in upcoming phases of design and estimation.

9 CONCLUSIONS

9.1 The pricing shown in section 1.1 of this report, is believed to be accurate within the Class 5 estimate tolerances, subject to the conditions and assumptions listed.

APPENDIX G:
Cost Estimate

Table G.1 Atlin Hydro Expansion Cost Summary

Atlin Hydro Expansion Prefeasibility Study

Hydroelectric Generation Project Only

Item #	Items	Cost (2016$)	Notes
DIRECT COSTS			
1	Surprise Lake Control Structure Upgrade	$ 291,357	
2	Upper Powerplant Expansion	$ 22,328,547	
3	Lower Powerplant	$ 30,981,824	
	SUB-TOTAL DIRECT COSTS	$ 53,601,728	
ADDITIONAL OWNER COSTS			
	Prefeasibility Study	$ 226,700	Current study actual cost plus hydrology & regulatory scan.
	Feasibility Study	$ 825,725	Assume 1.5% of Direct Costs
	Final Design	$ 2,680,086	Assume 5% of Direct Costs
	Assessment & Licensing	$ 1,608,052	Assume 3% of Direct Costs
	Site Assistance & Quality Assurance	$ 2,680,086	
	Other Owner Costs	$ 2,144,069	Assume 4% of Direct Costs
	SUB-TOTAL COSTS	$ 63,766,447	
	Contingency (25%)	$ 15,941,612	
TOTAL HYDRO GENERATION PROJECT COSTS		**$ 79,708,059**	

Transmission Line

4	Transmission Line to Jakes Corner (inc. substations)	$ 22,699,000	69 kV from MH 2016
5	Jakes Corner Substation	$ 1,446,590	From MagnaIV 2016, including engineering
ADDITIONAL OWNER COSTS (Tranmssion line only)			
	Planning	$ 680,970	3%
	Property Aquisiton & Permitting	$ 1,588,930	7%
	Survey & Structure Staking	$ 453,980	2%
	Engineering	$ 1,815,920	8%
	Project Management	$ 1,588,930	7%
	Construction Management	$ 1,134,950	5%
	Other Owner Costs	$ 1,350,591	5.95%
	SUB-TOTAL COSTS	$ 32,759,861	
	Contingency (25%)	$ 8,189,965	
TOTAL TRANSMISSION LINE COSTS		**$ 40,949,826**	

TOTAL PROJECT COSTS (GENERATION + TRANSMISSION) $ 120,700,000

Table G.2 Surprise Lake Control Structure Upgrade Cost Details

Atlin Hydro Expansion Pre-feasibility Study

Item #	Items	Unit	Quantity	Unit Cost	Cost (2014$)	Notes
1. SITEWORK						
1.1	**Mobilization**	LS	1	$ 50,000	$ 50,000	
1.2	**Clearing**					
	Inlet channel	ha	0.2	$ 20,000	$ 3,800	
	Re-vegetation	LS	1	$ 2,000	$ 2,000	Assuming re-seeding only.
1.3	**Diversion & dewatering**	LS	0	$ 65,000	$ -	Dewatering intake for replacement of gates.
1.4	**Remove & replace fencing, log boo**	LS	1	$ 8,000	$ 8,000	
1.5	**Misc. traffic control, etc.**	LS	1	$ 15,000	$ 15,000	
2. STRUCTURES & EXCAVATION						
2.1	**Inlet channel excavation**					
	Excavation	m^3	2600	$ 18	$ 47,320	Assume ~7m wide x 190m long x aver 2m depth excavation
	Supply & place cobble/riprap	m^3	270	$ 113	$ 30,375	Assume 0.2m thick layer
2.2	**Intake upgrade**				$ -	
	Raise intake platform	LS	1	$ 10,000	$ 10,000	Allowance raising walkway, fencing, etc.
2.3	**Weir upgrade**				$ -	
	Extend sheet pile weir	m^2	45	$ 295	$ 13,220	Assume 1.4m extension by 32m long
	Supply & place rip rap	m^3	364	$ 113	$ 40,929	0.7 m thick Class 1 over 500m2 plus 16m2 Class 2 at bridge abutments
6. ENVIRONMENTAL & MITIGATION ITEMS						
6.1	**Other**	LS	1	$ 15,000	$ 15,000	Environmental measures, during works
6.2	**Upgrade of Fishway**	LS	1	$ 50,000	$ 50,000	Add additional basins & modifications to openings

TOTAL COSTS **$ 285,644.22**

Note all rates are blended with idirects and OH& Profit

Table G.3 Upper Power Plant Expansion Cost Details
Atlin Hydro Expansion Pre-feasibility Study

Item #	Items	Unit	Quantity	Unit Cost	Cost (2015$)	Notes
1. SITEWORK						
1.1	**Mobilization**	LS	0.5	$ 400,000	$ 200,000	Mob for lower power plant project - cost split with upper plant
1.2	**Clearing**					
	Penstock	ha	0.45	$ 18,000.00	$ 8,100	Assumed expanded clearing down the hill to powerhouse expansion - 300m x 15m
	Powerhouse & tailrace	ha	0.375	$ 18,000.00	$ 6,750	Assumed hillside clearing 50m x 75m
	Contractor laydown area	ha	0	$ 18,000.00	$ -	Assumed existing areas will be used and no new laydowns required
1.3	**Access Road**					
	Powerhouse	m	100	$ 50.00	$ 5,000	Additional road around powerhouse
1.4	**Dewatering**					
	Head pond	months	2	$ 20,000.00	$ 40,000	
	Powerhouse	months	0	$ 20,000.00	$ -	Assume no dewatering needed for powerhouse
1.5	**Foundation Preparation**					
	Intake	sq metre	22	$ 32.00	$ 704	2.1x5m for intake box + 6m of wing-walls
	Powerhouse	sq metre	364	$ 32.00	$ 11,648	footprint of 26m x 14m powerhouse
2. STRUCTURES & EXCAVATION						
2.1	**Intake**					
	General excavation	cubic metre	450	$ 11.25	$ 5,063	re-excavation of diversion channel (6m wide, 15m long, 5 m deep)
	Rock excavation	cubic metre	0	$ 100.00	$ -	assume no rock excavation due to previous diversion ex.
	Retaining wall - sheet pile	m2	30	$ 295.10	$ 8,853	sheet pile between intake boxes
	Retaining wall - concrete	cubic metre	25	$ 2,500.00	$ 62,500	Assume 10m of wing wall
	General backfill	cubic metre	450	$ 37.50	$ 16,875	
	Intake structure & trash racks	LS	1	$ 113,750.00	$ 113,750	
	Gates	ea	1	$ 36,250.00	$ 36,250	
2.2	**Penstock**					
	General excavation	cubic metre	37821	$ 11.25	$ 425,484	Assume general excavation from 0+00 to 3+698
	Rock excavation	cubic metre	6600	$ 100.00	$ 660,000	Assume 330 m requires rock excavation - 4x5m
	Supply & Install 1.5 m Φ DR41 HDPE penstock	m	1828	$ 1,239.00	$ 2,264,892	
	Supply & Install 1.5 m Φ DR32.5 HDPE penstock	m	256	$ 1,414.00	$ 361,984	
	Supply & Install 1.5 m Φ DR26 HDPE penstock	m	713	$ 1,619.80	$ 1,154,917	
	Supply & Install 1.5 m Φ DR21 HDPE penstock	m	768	$ 1,863.40	$ 1,431,091	
	Supply & Install 1.5 m Φ steel penstock	m	438	$ 2,300.00	$ 1,007,400	based on current all in pricing from New Post Creek minimum handling thickness
	Granular fill	cubic metre	33523	$ 81.25	$ 2,723,728	
	Random backfill	cubic metre	11109	$ 37.50	$ 416,599	Based on typical cross section providing 0.7m of cover over granular fill.
	Bifurcation	LS	1	$ 40,000.00	$ 40,000	
2.3	**Powerhouse**					
	General excavation	cubic metre	11600	$ 11.25	$ 130,500	clearing for PH and new parking and lay down area to 726 with 2:1 slopes up hill. Neat line for depth of powerhouse
	Reinforced concrete	cubic metre	800	$ 2,500.00	$ 2,000,000	
	Superstructure and architectural finishes	LS	1	$ 410,000.00	$ 410,000	
	Draft tube gates/mechanical	LS	1	$ 100,000.00	$ 100,000	
	Crane supply & install	LS	1	$ 50,000.00	$ 50,000	extension of crane rails from existing building into new
	Miscellaneous embedded and non-embedded items	LS	1	$ 400,000.00	$ 400,000	Assumes existing crane and control room will be used
2.4	**Tailrace**					
	General excavation	cubic metre	1300	$ 11.25	$ 14,625	expand tailrace to 6 m base width, at Elv 723 (1 to 1.5 m depth of flow), expand over plan area shown on drawing to encompass both PH tailraces, less existing 3m wide 1.5:1 tailrace.
	Riprap - supply & place	cubic metre	440	$ 112.50	$ 49,500	assumed new riprap over extents of area 0.4m deep
3. TURBINE - GENERATOR UNIT						
3.1	**Turbine**	ea	2	$ 357,000.00	$ 714,000

Table E.4 Lower Power Plant Cost Details

Atlin Hydro Expansion Pre-feasibility Study

Item #	Items	Unit	Quantity	Unit Cost	Cost (2015$)	Notes
1. SITEWORK						
1.1	**Mobilization**	LS	0.5	$ 400,000	$ 200,000	Mob for lower power plant project - cost split with upper plant
1.2	**Clearing**				$ -	
	Head pond	ha	0.5	$ 20,000	$ 10,800	Triangular area 105m x 90m + 30x45m triangle on N side of creek - scaled off drawing 9
	Spruce Creek Diversion	ha	0.3	$ 20,000	$ 6,000	Assumed 100m long x 30m wide
	Penstock & surge pipe	ha	10.8	$ 20,000	$ 216,650	4.0km x 25m wide + 340m x 25m for surge pipe
	Powerhouse & tailrace	ha	1.1	$ 20,000	$ 21,100	4700 m2 for powerhouse plus 130m long tailrace @ 45m wide clearing
	Contractor laydown area	ha	0	$ 20,000	$ -	Assumed existing areas will be used and no new laydowns required
	Stumpage Fee	LS	1	$ 8,100	$ 8,100	Assumed to be the same as 2009 project
1.3	**Access Road**					
	Penstock	m	4000	$ 100.00	$ 400,000	access/service road paralleling penstock
	Powerhouse	m	175	$ 100.00	$ 17,500	75m to powerhouse + 100m to surge bldg.
1.4	**Dewatering**					
	Head pond	months	3	$ 15,000.00	$ 45,000	
	Powerhouse	months	17	$ 15,000.00	$ 255,000	Dewatering will be required over the length of construction
1.5	**Foundation Preparation**					
	Intake	sq metre	58	$ 32.00	$ 1,856	KGS to provide - assume 5x5m for intake box + 33m of wing-walls
	Powerhouse	sq metre	336	$ 32.00	$ 10,752	KGS to provide - assumed footprint of 28m x 12m powerhouse
2. STRUCTURES & EXCAVATION						
2.1	**Head pond**					
	Pine Creek temporary diversion	cubic metre	2160	$ 11.25	$ 24,300	Assumes 120 m long x 2m deep by 5m base width
	Cobbles for temporary diversion	cubic metre	324	$ 112.50	$ 36,450	Assume 0.3m thick cobbles
	Access over temporary diversion	LS	1	$ 50,000.00	$ 50,000	Assumes culverts/temporary bridge or temporary relocation of existing bridge
	Head pond Excavation	cubic metre	14859	$ 11.25	$ 167,158	pond volume from Civil3D + 2600m3 subcut for 0.7m thick riprap
	Stilling basin	cubic metre	683	$ 11.25	$ 7,678	inc. subcut for riprap - 15m x 35m x 1.3m deep
	Embankment sub-cut	cubic metre	2700	$ 11.25	$ 30,375	Assume 90m long x 30m wide by 1 m subcut.
	Rock fill embankment	cubic metre	4600	$ 112.50	$ 517,500	1900 m3 from Civil 3D plus 1 m subcut volume of 2700
	Sheet pile cutoff wall	sq metre	1288	$ 295.10	$ 380,089	92m long x 14m deep
	Riprap - supply & place	cubic metre	1859	$ 112.50	$ 209,081	0.7m thick on back slope of pond. Dam/weir riprap included in above
	Intake structure	LS	1	$ 113,636.36	$ 113,636	Includes concrete
	Trash racks	LS	1	$ 70,000.00	$ 70,000	Supply & install, double wide
	Gates	ea	2	$ 42,000.00	$ 84,000	for 2 gates
	Fishway	LS	1	$ 95,450.00	$ 95,450	Escalated cost from Surprise Lake fishway
2.2	**Spruce Creek Diversion**				$ -	
	Diversion ditch excavation	cubic metre	2400	$ 11.25	$ 27,000	Assume 4m wide, ave. depth 3m @80 long
	Diversion rock fill weir	cubic metre	190	$ 112.50	$ 21,375	Assume 20m long x 5m wide crest c/w 0.5 m subcut.
	Culvert - supply & install	LS	1	$ 80,500.00	$ 80,500	Assuming 1.5m CSP c/w 2 sets of headwalls.
	Riprap - supply & place	cubic metre	307.2	$ 112.50	$ 34,560	1000m2 x 0.3m thick class 1 riprap
2.3	**Penstock (inc. surge pipe)**					Penstock typ. section should be optimized to reduce volumes.
	General excavation	cubic metre	45679	$ 11.25	$ 513,883	4.4km minus rock segments below
	Rock excavation	cubic metre	3947	$ 100.00	$ 394,740	Assumed rock ex. from 0+800 to 1+075, 2+500 to 2+725 & 310 for surge pipe: total 810m
	Supply & Install 2 m Φ penstock steel	m	1000	$ 3,040.00	$ 3,040,000	
	Supply & Install 2x 1.6m Φ penstock DR41 HDPE	m	3025	$ 2,478.00	$ 7,495,950	
	Supply & Install 2x 1.6m Φ penstock DR26 HDPE	m	375	$ 3,240.00	$ 1,215,000	
	Granular fill	cubic metre	30674	$ 81.25	$ 2,492,279	
	Random backfill	cubic metre	35158	$ 37.50	$ 1,318,440	Based on typical cross section providing 0.7m of cover over granular fill.
	Bifurcation	LS	1	$ 50,000.00	$ 50,000	
	Surge facility (vents and instrumentation)	LS	1	$ 300,000.00	$ 300,000	surge section only, vent structure and instrumentation building
2.4	**Powerhouse**					
	General excavation	cubic metre	19700	$ 11.25	$ 221,600	includes tailrace and road excavation out along penstock route, 3:1 slopes
	Rock excavation	cubic metre	1000	$ 100.00	$ 100,000	assumes rock below 270.25 in PH footprint only
	Reinforced concrete	cubic metre	450	$ 2,500.00	$ 1,125,000	
	Superstructure and architectural finishes	LS	1	$ 465,000.00	$ 465,000	
	Draft tube gates/mechanical	LS	1	$ 100,000.00	$ 100,000	set of stop logs, guides, small hoist
	Crane supply & install	LS	1	$ 350,000.00	$ 350,000	
	Miscellaneous embedded and non-embedded items	LS	1	$ 400,000.00	$ 400,000	
2.5	**Tailrace**					
	General excavation	cubic metre	6000	$ 11.25	$ 67,500	Based on 140 m long tailrace, 5.4 m deep, 8 m wide at base w/ 2.5H:1V slopes
	Riprap - supply & place	cubic metre	1264	$ 112.50	$ 142,200	Class 1 riprap 0.4m thick
3. TURBINE - GENERATOR UNIT						
3.1	**Turbine**	ea	1	$ 1,143,528.10	$ 1,143,528	
3.2	**Generator**	ea	1	$ 1,567,600.00	$ 1,567,600	
3.3	**Turbine Inlet Valve (TIV)**	ea	1	$ 361,753.92	$ 361,754	
3.4	**Auxiliary Systems**	LS	1	$ 482,338.60	$ 482,339	
3.5	**Project Service & Install**	LS	1	$ 1,430,000.00	$ 1,430,000	
4. ELECTRICAL & MECHANICAL BALANCE OF PLANT						
4.1	**Mechanical Balance of Plant**	LS	1	$ 260,000.00	$ 260,000	
4.2	**Electrical Balance of Plant**	LS	1	$ 250,000.00	$ 250,000	
4.3	**Switchyard and Interconnection**	LS	1	$ 929,575.00	$ 929,575	From MagnaIV 2016 (not including engineering) , inflation adjusted to 2015.
5. TRANSMISSION LINE						
5.1	**Clearing**	ha	0	$ 20,000.00	$ -	Clearing assumed to be included in lower penstock ROW
5.2	**Transmission Line**	km	4	$ 209,009.80	$ 836,039	69 kV from MH 2016 estimate, inflation adjusted to 2015.
6. ENVIRONMENTAL & MITIGATION ITEMS						
6.1	**Footbridge over tailrace**	LS	1	$ 30,000.00	$ 30,000	Assumed wooden, locally built by ATELP
6.2	**Other**	LS	1	$ 100,000.00	$ 100,000	Environmental monitoring
6.3	**Tree Planting and Landscaping**	LS	1	$ 50,000.00	$ 50,000	Cosmetic fixes near residential areas and campground to accelerate reclaimation of cleared areas

Appendix 5.9
Wind Site Inventory (CBER, Envint and V3 Energy 2016)

YUKON Wind Site Inventory

Final Report

RFP 2015-060

Prepared for:

YUKON ENERGY

Prepared by:

CBER

with

envint Consulting *and* V3 Energy, LLC

August 9, 2016

EXECUTIVE SUMMARY

For its new planning cycle, the Yukon Energy Corporation (YEC) is investigating renewable energy sources and several parallel assessments have been commissioned. These assessments are to inform YEC of the potential viability of each power generation resource in Yukon, identify suitable sites, estimate capital and operating costs, and determine the resulting per-kWh power generation cost. These results then feed into a resource option plan that evaluates power generation options according to the financial, technical, socio-economic and environmental attributes of each technology.

This report addresses utility-scale wind power, one of the technologies YEC identified as a potential source of electricity generation for the territory. The study has four major objectives:

- **Wind site inventory** to identify potential wind project sites near existing or planned power infrastructure. This task included reviewing existing wind mapping and selecting preferred sites for detailed analysis;
- **Develop potential wind projects at a conceptual level** to include wind resource assessment, site turbine layout, infrastructure footprints, and modelled gross and net power output;
- **Economic modelling** to create site-specific cost estimates for development, construction, power production, and determining the cost of power and energy;
- **Additional information pertaining to wind farm development** that might affect its viability.

The Yukon has significant wind resources although development of those resources is challenging due to the territory's mountainous nature. Most suitable wind farm sites are located on mountaintops, peaks, ridges or crests while YEC's transmission lines naturally route through valleys. The result is a challenging exercise of identifying sites that are not only windy but also able to be *developed*.

A number of criteria influenced the wind site prospecting task. These include:

- **Wind and atmospheric considerations**, such as high mean wind speed and wind power density;
- **Site development considerations**, such as a reasonable distance to a community or YEC office for maintenance purposes or proximity to existing roads.
- **Environmental and human factor considerations**, including potential harmful effects on wildlife and birds, vicinity to parks, use for recreational purposes and other environmental restrictions.

Another criterion was a desire to represent northern, central and southern Yukon. Part of the intent was to screen as wide an area as possible and represent sites of varying characteristics. Because the

Yukon is a high-latitude region with a mostly sub-arctic-to arctic, often maritime-influenced climate, winter-time icing at higher elevations is operationally challenging. For this reason, the most desirable wind-power sites are at lower elevations where icing conditions do not occur. There are, however, few sites in the territory that are both windy and low elevation. Kluane Lake is an exception.

Out of a longlist of 26 sites we selected five locations for an in-depth review and conceptual design. The selections were based on wind speed, distance to transmission lines, road access, and land ownership. Other factors such as potential conflicts with other land uses or anticipated public opposition were also evaluated to determine a shortlist of seven sites. Of the seven, only Kluane Lake is a low-elevation site.

We developed representative wind turbine arrays of 20, 10 and 6 MW capacity for each of the seven selected sites. The site layout and location are on a conceptual level only but sufficient for estimating the power output and the cost of installing wind farms. The layout of each wind farm accounts for the prevailing wind direction(s) and topographic optimization. To locate an access road to each site, we retained an average gradient and turning radius within the limits of requirements to transport a 45 meter blade and a 70 tonne nacelle to the sites.

In the absence of measured wind data, this report relies on computer models that predict wind direction, wind speed, turbulence and power production from wind turbines at a given site. We chose a 2 MW, 80 meter hub height Vestas V90 model as the generic turbine for modeling purposes.

Apart from the generic turbine used for financial modeling, we also separately compared three alternate turbines for each site based on the AWS Truepower Advanced Reports. The resulting monthly data shows that for most sites a turbine designed for higher wind speeds produced less energy per year, but more during the period from October to April when electricity is most need in the Yukon.

At the site with the highest output, Miller's Ridge near Carmacks, a 20 MW farm would produce 57 GWh of energy a year, equivalent to the annual consumption of 5,800 households in the Yukon. For YEC, the annual net energy production may be less important than generation during the colder period of the year. From May to September there is generally a power surplus from existing hydropower generation facilities. Fortunately, all seven sites show a clear pattern of lower monthly mean power production during the summer months compared to winter, despite the higher percentage of energy loss due to icing during winter. On average, three-fourths of wind energy generated would be during the seven months from October to April.

The mean annual power output is 26% to 28% of the nominal wind farm capacity, i.e. a 10 MW wind farm, for example, would generate on average 2.6 to 2.8 MW over the course of the year, more during the winter, less in summer. Wind power is a variable resource and technically cannot guarantee any minimum output at any time of the year. There may be days when wind speeds are below the start-up wind speed; output will drop to zero during these hours.

Capital costs, including hard and soft costs, such as financing and project development costs, range

from $31 million for a 6 MW wind farm to $66 million for a 20 MW project for the average of all seven sites. This equates to mean specific costs of $5.2 million per MW to $3.3 million per MW, respectively. The overall accuracy of these cost estimates is ±30%, commensurate with the project definition of a pre-feasibility or screening level study. Operational costs are approximately $300,000 of fixed cost, and variable cost of around $25 per MWh of net energy produced. These costs are similar for all sites.

The levelized cost of energy at almost all sites and all sizes remains under the current Yukon standard offer price of 21 ¢/kWh but often above the average residential retail price of 12 ¢/kWh, see the table below. Of the seven sites selected, five show above-average performance in terms of the cost of energy produced. These sites are, in the order of performance, Miller's Ridge near Carmacks, Thulsoo Mountain near the Aishihik hydroelectric facility, Kluane Lake, a mountain ridge near Cyprus Mine, close to Faro, and Mt. Sumanik near Whitehorse. The table below provides key economic parameters. There is little difference in energy production cost between these five sites; non-monetary factors may play an important role in selecting the preferred location.

Miller's Ridge near Carmacks and Thulsoo Mountain near the Aishihik hydroelectric facility are the sites with the highest wind resource and a low cost of energy (LCOE). Thulsoo Mountain is near an existing facility, but Miller's Ridge has more expansion potential. Sumanik Mountain is attractive due to its location near Whitehorse. Cyprus Mountain is the furthest from Whitehorse, but appealing due to its brownfield nature next to an abandoned mine. Kluane Lake gets a qualified recommendation because of its low elevation and low energy costs (LCOE), but requires a transmission line to be built first. Tehcho and Sugarloaf are not recommended because the other site options clearly are superior, both in terms of annual energy production and energy cost.

Key Financial Parameter of the Three Wind Farm Sizes at the Seven Sites Evaluated

Site	6 MW		10 MW		20 MW	
	Capital Cost (million $)	Levelized Cost of Energy *	Capital Cost (million $)	Levelized Cost of Energy *	Capital Cost (million $)	Levelized Cost of Energy *
Cyprus Mine	34	17.3¢/kWh	44	13.8¢/kWh	69	11.7¢/kWh
Kluane Lake	26	15.1¢/kWh	36	12.6¢/kWh	62	11.0¢/kWh
Miller's Ridge	39	17.1¢/kWh	49	13.1¢/kWh	73	10.7¢/kWh
Sugarloaf Mountain	28	22.6¢/kWh	38	18.7¢/kWh	62	15.3¢/kWh
Mt. Sumanik	30	17.2¢/kWh	39	14.6¢/kWh	64	12.4¢/kWh
Tehcho (Ferry Hill)	28	21.4¢/kWh	39	16.4¢/kWh	64	15.1¢/kWh
Thulsoo Mountain	36	16.8¢/kWh	46	13.2¢/kWh	72	10.9¢/kWh
Average	**32**	**18.2¢/kWh**	**42**	**14.6¢/kWh**	**67**	**12.5¢/kWh**

** at 3.38% real weighted average cost of capital (WACC)*

Due to fixed costs and economies of scale, larger wind farms have lower energy production costs than smaller ones. The cost of energy at the seven sites averages 13 ¢/kWh for a 20-MW wind farm but increases to 18 ¢/kWh for a 6-MW capacity. Our modelling assumes that all energy produced will be used. Curtailment of the operation during the summer when YEC has a surplus of power

would increase the cost of energy produced during the rest of the year by more than a quarter.

A sensitivity analysis of a 10-MW wind farm at Kluane Lake showed that the cost of energy is most sensitive to forecasted energy production. This underlines the importance of monitoring wind speed, rime icing, and temperature at selected sites. These are key parameters that will determine the output of a generator and thereby the financial performance of the wind farm.

Developing a wind farm in the Yukon will likely require four years, including a wind monitoring campaign during the first year. The schedule may be more relaxed or could be condensed to three years for sites with existing and suitable road access.

If the update to YEC's 20-year plan yields that wind power is a viable source of electricity, then further research should be done on the five sites mentioned above. We recommend a full-scale feasibility study for some or all of those sites, and wind and icing monitoring at several sites in parallel to then select the most suitable one for development.

Notice to Reader

This report was prepared by Cornelius Suchy of Canadian Biomass Energy Research (CBER) Ltd, Martin Tampier of ENVINT Consulting and Douglas Vaught, P.E. of V3 Energy, LLC. The material in it reflects the authors' best judgement in light of the information available to them at the time of preparation.

The sole purpose of this report is to assist Yukon Energy Corporation in its decision of whether to pursue the initiatives discussed herein. The authors and CBER, as the main contractor, accept no responsibility if any party relies on this report for any purpose that Suchy, Tampier and Vaught have not expressly agreed to. Any reliance placed on this report by another party will be at that party's risk and without recourse to Cornelius Suchy or CBER Ltd.

This report involves matters that cannot be precisely determined. Our calculations generally depend on subjective judgements and uncertainties that increase as we forecast further into the future. Much of the information available to us is based on estimates and assumptions provided by third parties. Accordingly, this report does not guarantee a specific result; instead, it is a means of assessing the relative desirability of alternative courses of action, a range of investment requirements, and anticipated income or cash flow, as the case may be.

Cornelius Suchy, Martin Tampier and Douglas Vaught reserve the right (but will be under no obligation) to review all calculations referred to in this report and, if we consider it necessary, to revise them in light of new facts, trends, or changing conditions that become apparent to us after the report is published.

Interested parties are cautioned that decisions of whether to rely on the accuracy and completeness of the information in this report, and whether to invest or provide financing, are theirs alone and neither Cornelius Suchy nor CBER will assume any responsibility for losses resulting from such decisions. Decisions to invest or provide financing will likely require additional information beyond the information in this report.

Opinions expressed in this report are those of the authors and do not necessarily reflect the opinion of the Yukon Energy Corporation.

Inquiries and requests for more information relating to this report should be directed to:

WTG	Wind turbine generator
YEC	Yukon Energy Corporation

1 INTRODUCTION

1.1 Background

The Yukon Energy Corporation (YEC) has a winter peak demand of 82 MW[1] and dependable renewable capacity of 72 MW. Thermal generation is used to provide peak power. If consumer loads continue to grow or if a large industrial customer is added then additional sources of energy may be required.

This report is the result of a two-month study of the wind energy potential in the Yukon Territory. This work will support the planning process that aims at identifying potential resource options to meet the long-term load forecast (2016-2035) of the area served by Yukon Energy Corporation (YEC).

YEC has entered a new planning cycle. A five-year update of YEC's Integrated Resource Plan is scheduled for completion at the end of 2016. To this end, YEC has commissioned a series of assessments on several energy technologies. These assessments are to inform YEC about the potential viability of each power generation resource in the Yukon, identify suitable sites, estimate capital and operating costs, and determine the resulting per-kWh power generation cost.

The assessments then feed into a Resource Option Report that evaluates the various options for power generation according to financial, technical, socio-economic an environmental attributes of the individual technology options.

1.2 Scope and Objective

This report is about power generation from wind turbines. The report is of a technical nature and mainly aimed at YEC staff, but also provides information for other parties interested in wind power with a general understanding of the technology.

This study has four major objectives:

1. **Wind site inventory**: Mesoscale wind mapping (1 x 1 km resolution) to identify potential wind project sites near existing and planned power infrastructure. Select sites for detailed analysis of wind farm capacity (Chapter 2);
2. **Develop potential wind projects at a conceptual level**: Detailed analysis of wind farm capacity, including wind resource assessment (200 x 200 m resolution), site turbine layout, infrastructure footprints (Chapter 3), and gross and modelled net power output (Chapter 4);
3. **Economic modelling**: Create site-specific cost estimates for development, construction, power production, and power costs (Chapter 5);
4. **Additional information pertaining to wind farm development**: Technical and other considerations affecting the viability of wind power development, including potential for rime icing and possible mitigation measures, development risks, and typical development schedules (Chapter 6 to 8).

[1] YEC's generation profile for 2015, Excel spreadsheet provided by Yukon Energy Croporation on March 15th, 2016

1.3 Previous Work

The Yukon has numerous potential sites with excellent wind power potential in addition to the operational Haeckel Hill wind turbine project near Whitehorse. YEC recognizes this and commissioned previous wind resource studies to explore YEC's wind power development options. They are:

- Yukon Energy Corporation, Regional Mesoscale Modelling, Natural Power, February, 2011
- Yukon Energy Corporation, Aishihik Area Mesoscale Modelling, MG Renewables Consulting, July 2012

Other reports and papers reviewed include the Ferry Hill (referred to as Tehcho below) wind feasibility study (two parts) by Natural Power, 2010, *Wind Climate of the Whitehorse Area in Arctic*, by JP Pinard, Sept. 2007, *Wind Power Development in Sub-Arctic Conditions with Severe Rime Icing*, by John Maissan, Mar. 2001, and the *Mt Sumanik Wind Feasibility and Icing Study*, by Natural Power Consultants, Sept. 2010.

These reports were very useful for this project analysis and in several cases our site recommendations overlap. The primary difference is that the present study has a stronger bias toward site access and constructability and less toward optimum wind resource as the primary salient criteria. A strong wind resource is highly desirable, of course, but only if it can be developed at reasonable cost and effort.

2 WIND POWER SITE IDENTIFICATION

2.1 Site Identification Criteria

Due to the Yukon's mountainous topography, most suitable wind farm sites are located on mountaintops, peaks, ridges or crests. YEC's transmission lines naturally route through valleys, typically following highway corridors. The result is a challenging exercise of identifying sites that are not only windy, but can also be *developed*. During the initial screening process, potentially suitable wind power sites were identified within 25 km of existing and planned or proposed Yukon power infrastructure (see Appendix A for a map). YEC determined, and the project team concurs, that potential wind sites located beyond 25 km from existing power infrastructure are too costly to develop and operate, regardless of their wind resource merits.

As can be seen in Figure 1, the Yukon has somewhat less wind potential than the NWT and the eastern part of Alaska. There is more wind power potential (green-yellow areas on the map) in the higher elevation western part of the Yukon than in the lower elevation east. All sites identified are therefore situated in the western half of the Territory. This also reflects the concentration of population and infrastructure in the western and especially southwestern Yukon.

A number of criteria were considered for the wind site prospecting task, including:

Wind and atmospheric considerations

- Desirable wind resource, defined as relatively high mean annual wind speed and wind power density, normal or near normal Weibull distribution, low turbulence and acceptable extreme wind behavior
- Atmospheric rime icing environment (high/low probability)
- Ice throw distance to roads/other public use facilities

Site development considerations

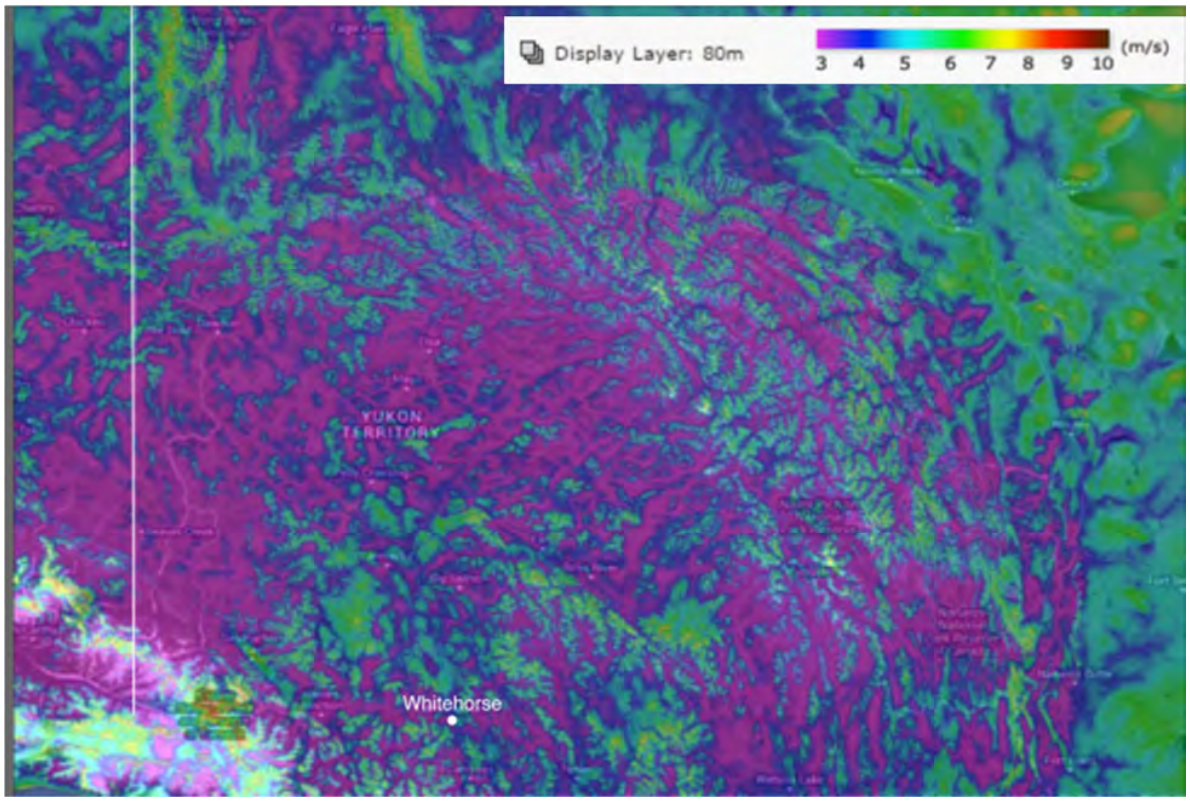
- Reasonable distance to a community, industry, or other electric loads
- Near existing or proposed power transmission infrastructure (<25 km for this project)
- Capacity of existing transmission to accept maximum power output of wind farm
- Suitable geotechnical conditions for foundations and access roads
- Proximity to existing roads; prospective cost to develop access (steepness, river crossings etc.); serviceability
- Airspace restrictions; proximity to airports and/or military airspace use areas
- Land use availability (land ownership, parks, easement restrictions, likely lease rates, nearby cultural sites or natural parks)
- Local geology (based on GeoYukon website)

Environmental and human factor considerations

- Deleterious effect on terrestrial wildlife and avian species (high-level)
- Wetlands, parks and other high-level environmental restrictions
- Noise, and aesthetic considerations; closeness to recreational activities

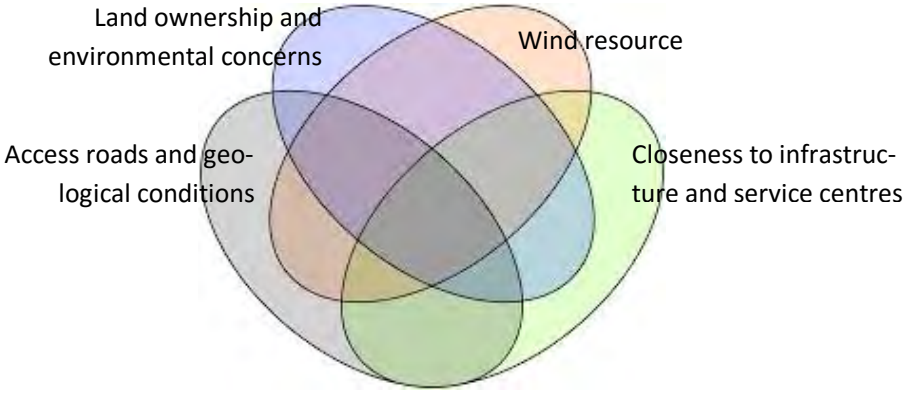
Other criteria were a desire to represent northern, central and southern Yukon and a preference for locations close to cities, larger towns, or existing hydroelectric infrastructure to facilitate wind turbine operations and servicing. Part of the intent was to screen as wide an area as possible and represent sites of varying characteristics.

Figure 1 Yukon Territory AWS Truepower Meso-Scale Wind Resource Map



The authors developed an initial long-list of potential sites that meet all or most of the criteria listed above. The conceptual image of a Venn diagram in Figure 2 below illustrates the process. Each ellipse represents a criterion listed above; the best or most promising solutions lie at the intersection of all criteria.

Figure 2 Conceptual Venn Diagram of Wind Site Criteria and Site Selection



Beginning the site search by reference to the wind resource we selected preliminary options by referencing two data sources, in addition to previously published wind studies noted above:

1. International Renewable Energy Agency (IRENA) 1,000 x 1,000-meter resolution,[2] 100-meter level (representing a typical utility-scale wind turbine hub height), mesoscale wind resource data. Note that IRENA employs Technical University of Denmark (DTU) wind data using their methodology.
2. AWS Truepower Windnavigator 200 x 200-meter resolution, 100-meter and 80-meter level (80 meters also represents a typical utility-scale turbine hub height), microscale wind resource data. AWS data has 25 times higher resolution than IRENA .

Large area AWS Truepower 200 x 200-meter resolution maps of three regional subsets of the territory – northern, central and southern – are presented below. From a broad territory-wide perspective, one can see that high winds are found at higher elevations – mountains, hills, high elevation plateaus – and low winds are found in lower elevation areas, such as valleys.

The Yukon is a high latitude region with a mostly sub-arctic-to arctic, often maritime-influenced climate. The consequence is atmospheric icing at higher elevations that creates wintertime rime ice conditions which are operationally challenging. For this reason, the theoretically most desirable high latitude wind power sites are at lower elevations where rime icing conditions don't occur. But, as one can see in the AWS Truepower Windnavigator wind maps of the Yukon, there are no sites in the territory that are both windy and (relatively) low elevation, with the exception of Kluane Lake, which is a site of interest for this study.

2.2 Initial Site Inventory

Using the Venn diagram model as a conceptual guide, 26 potentially promising sites for wind power development were initially identified and considered before narrowing the list to five sites (later expanded to seven sites with the inclusion of Tehcho and Mt. Sumanik). The 26 sites were evaluated

[2] The resolution refers to the spatial grid resolution of the computational fluid dynamics model. Both IRENA's and AWS's data are based on numerical analysis conducted for a specific land area. The finer the grid the lower the modelling error.

using the criteria mentioned above in a desktop analysis to screen all sites. The results of this exercise are presented in Table 5.

2.2.1 Northern Yukon Sites of Interest

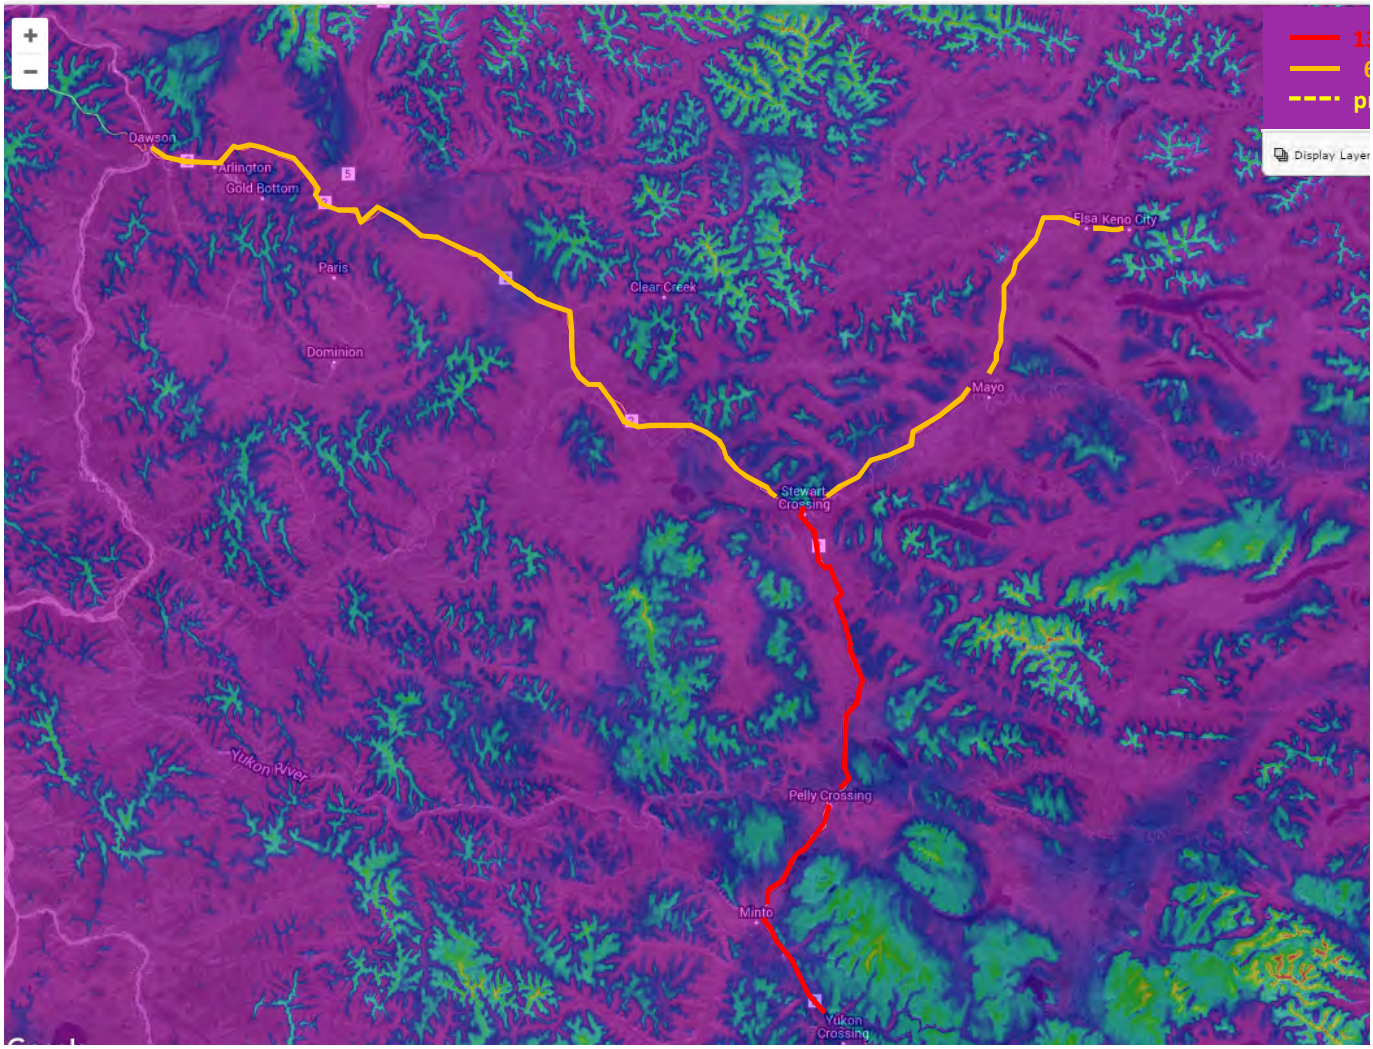
The wind resources in the northern Yukon are fairly sparse compared to the Yukon's central and southern regions. Our analysis did not extend north beyond the developed Dawson-to-Mayo parallel at approximately 64° N latitude. Options are generally limited to particularly high and mostly isolated mountaintops and ridges. The sites listed in Table 1 represent a range of possible wind power development options for this region. Site identification numbers are the same as those used throughout this report on maps and in tables.

The wind resources of the central Yukon that can potentially be developed represent, for the most part, the Carmacks-to-Faro meridian at about 62° N latitude. They are generally quite good but, as noted earlier and true of most of the Yukon, are limited to higher mountain ridges or plateau-like areas.

Table 1 Northern Yukon Wind Sites Considered

#	Site Name	Location	Brief Description
16	Keno City hill	7 km east of Keno City	Hills complex just east of Keno City; access from Keno City
10	Unnamed hill between Wareham and Janet Lakes	11 km northeast of Mayo	Large, plateau-like hill; plenty of space for turbines; near AOI's 9 and 10 identified by Natural Power (2011 report) but easier access
6	Tehcho (Ferry Hill)	Near Stewart Crossing	Hill immediately north of Stewart Crossing; Natural Power study addressed wind power options and icing potential
19	Willow Hills	16 km SSW of Stewart Crossing; 12 km west of Hwy 2	Broad area of hills increasing elevation from east to west; plenty of space for turbines; possible site access from utility easement or due west from Hwy 2

Figure 3 Northern Yukon AWS Truepower Meso-Scale Wind Map



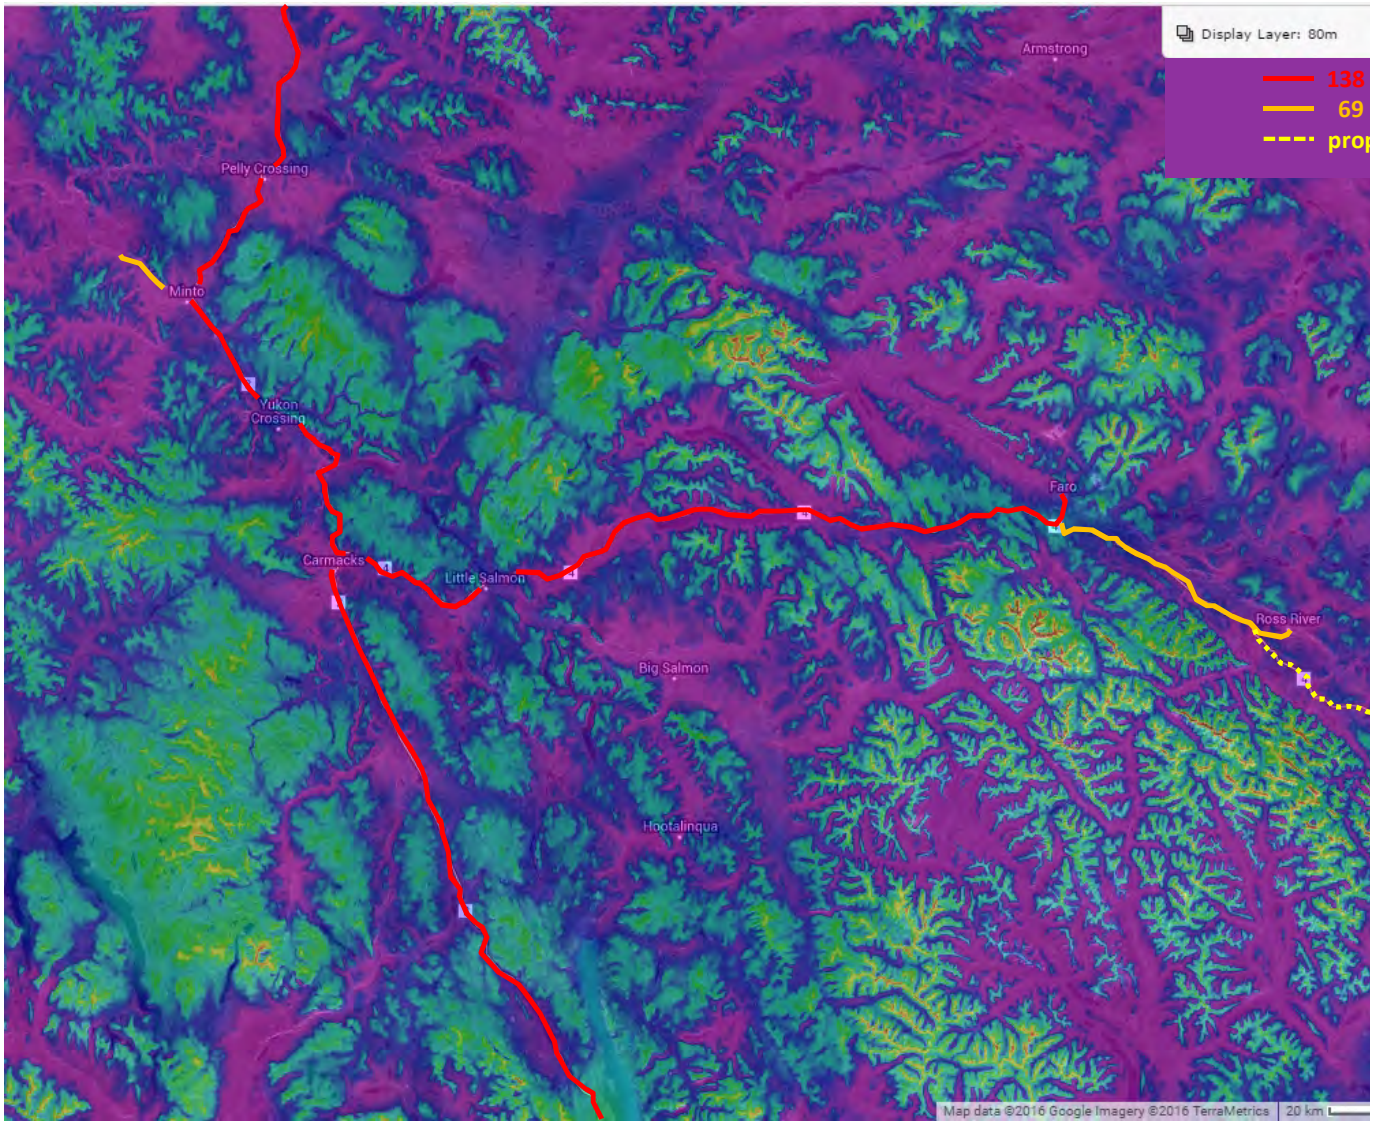
2.2.2 Central Yukon Sites of Interest

The wind resources of the central Yukon, representing for the most part the Carmacks-to-Faro parallel at about 62° N latitude, are generally quite good: They are, however, as noted earlier and true of most of the Yukon, are limited to higher mountain ridges or plateau-like areas. The sites listed in Table 2 represent a range of possible wind power development options for this region.

Table 2 Central Yukon Wind Sites Considered

#	Site Name	Location	Brief Description
3	Miller's Peak/Ridge	15 km west of Carmacks	Large, broad ridge; plenty of space for turbines; identified as AOI 4 by Natural Power (2011 report); near area access via gravel road W of Carmacks; site access from the gravel road
21	Mt. Berdoe	8 km SSE of Carmacks	Large hill near Carmacks with existing road access for a communications tower; site access exists
17	Unnamed hill east of Minto (between Pelly Crossing and Carmacks)	27 km SE of Minto; 18 km from highway	Large hill complex east side of highway near Minto, north of Carmacks
18	Little Salmon hill	39 km east of Carmacks	Very large and broad hill complex north of highway
22	Unnamed hills between Little Salmon and Drury Lakes	85 km E of Carmacks	Two parallel sloping ridges ascending from Little Salmon Lake to NW; plateau-like on top; possible site access from Hwy 4 east side of lake
11	Hill west of Faro, north of highway	27 km west of Faro	North-south trending low ridge just north of highway; access from hwy
12	Hill west of Faro, south of highway	27 km west of Faro	Hill complex south of highway and river access would require river crossing
1	Cyprus Mine hill	20 km N of Faro and 7 km north of the mine	Compact ridgeline immediately north of the mine pit and also a similar hill immediately SE of the mine; possible site access from the mine itself or from mine access roads
26	Hill SE of Ross River	75 km SE of Ross River	Hill group 16 km south of highway; access from the highway

Figure 4 Central Yukon AWS Truepower Meso-Scale Wind Map



2.2.3 Southern Yukon Sites of Interest

The wind power site options identified in the southern Yukon are generally quite good and include the relatively low elevation Kluane Lake. Low elevation has the advantage of low rime icing risk and avoids the considerable operational challenges that icing entails. The southern Yukon includes Whitehorse and hence is the population center of the Territory. That is advantageous from a wind farm operations perspective due to ready proximity to Whitehorse-based utility staff and contractors. The sites listed in Table 3 represent a range of possible wind-power development options for this region.

Table 3 Southern Yukon Wind Sites Considered

#	Site Name	Location	Brief Description
2	Kluane Lake, west shore	8 km SE of Destruction Bay	Midpoint of west shore of Kluane Lake; between Alaska Hwy and the lake
14	East shore of Kluane Lake	12 to 15 km N of Silver City	Two adjacent options: slopes above Grayling Lake, and NE-SW trending ridge just north of Rat Lake. Identified as AOI 4 by MB Renewables (2012 report) and NP (2011 report); gravel road access from Silver City
23	Anticline Mountain and adjacent ridges	75 km NNW of Whitehorse	Two SE-NW trending ridges just east of Little Fox Lakes and Hwy 2; jeep road access on southern ridge from Hwy 2
20	Hard Time Mountain	15 km ENE of Paint Mtn. and 11 km NW of Canyon	Southern end of mountain complex trending N from Hwy 1; site access possible from Hwy 1 west of Canyon
7	Thulsoo Mountain	21 km NNE of Canyon near Aishihik Hydro facility	High, rounded mountain immediately east of Aishihik hydro facility; identified as AOI 1 by MG Renewables (2012 report); site access from Canyon Lake road
15	Flat Mountain ridge	35 km NW of Whitehorse; west of south side of Lake Laberge	Rounded ridge immediately SW of Flat Mountain itself; site access possible from Hwy
4	Mount Sumanik	Immediately west of Whitehorse and existing Haeckel Hill wind turbines	Large, broad hill complex; equipped with Lidar for ongoing wind resource assessment study
9	Grey Mountain	9 km SE of Whitehorse	North-south trending ridgeline; access road to comm. tower on southern end; Whitehorse city recreational parkland
8	Mount Lorne subpeak (Minto Hill)	East of Hwy 2 between Mount Lorne and Carcross, 8 km SE of Mount Lorne	Gentle-top grouping of connected hills just S of more rugged Mount Lorne; no existing access; possible site access from Hwy 2
5	Northeast	7 km SSE of Carcross	Very broad, flat, wide, exposed, above treeline fea-

#	Site Name	Location	Brief Description
	slope of Sugarloaf Mtn.		ture comprising the north slope of Sugarloaf Mtn; plenty of room for turbines; site access via existing gravel road/jeep trail to Montana Mountain from Carcross
25	White Pass	On Canada/ U.S. Border, in B.C.	Open areas of the pass immediately east or west of Hwy 2 on Canada side and AK Hwy 98 on U.S. side; near Klondike Nat'l Historic Park; access from the highway
13	Hayes Peak	10 km S of Johnsons Crossing	Broad shouldered hill just west of northern shore of Teslin Lake

Figure 6 is a map of the 26 sites identified as possibly suitable for wind power production. Sites are colour-coded as red (the preferred seven sites), orange (potential alternate sites) and grey (unlikely to be developed).

Figure 5 Southern Yukon AWS Truepower Meso-Scale Wind Map

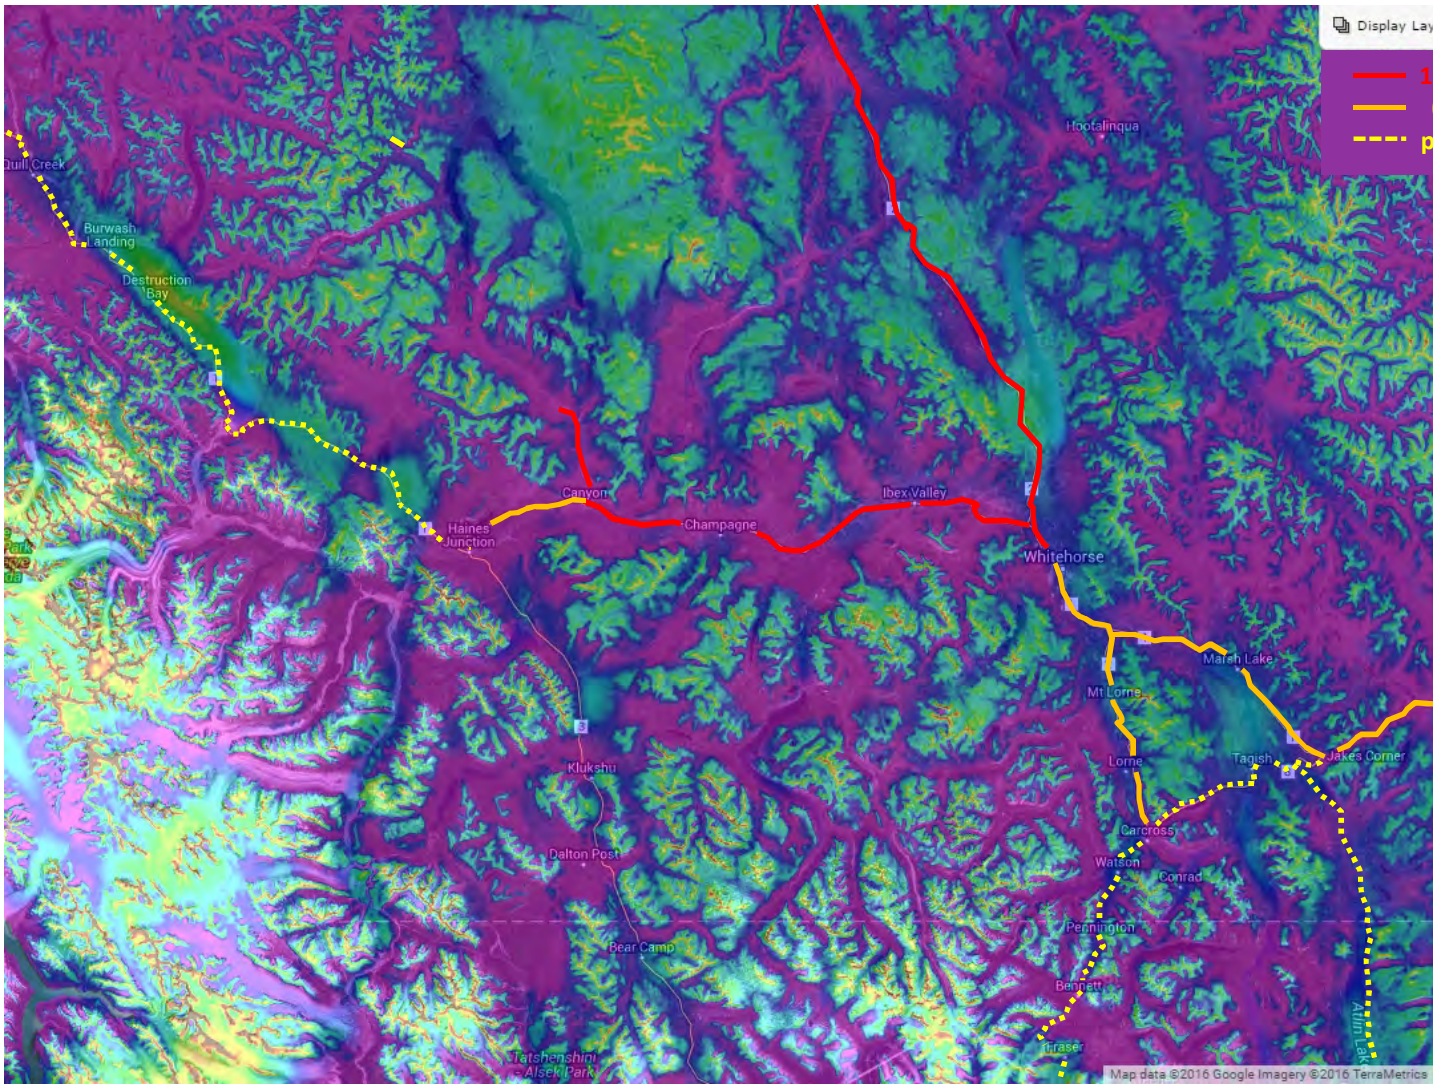


Figure 6 Map of Potential Wind Farm Sites

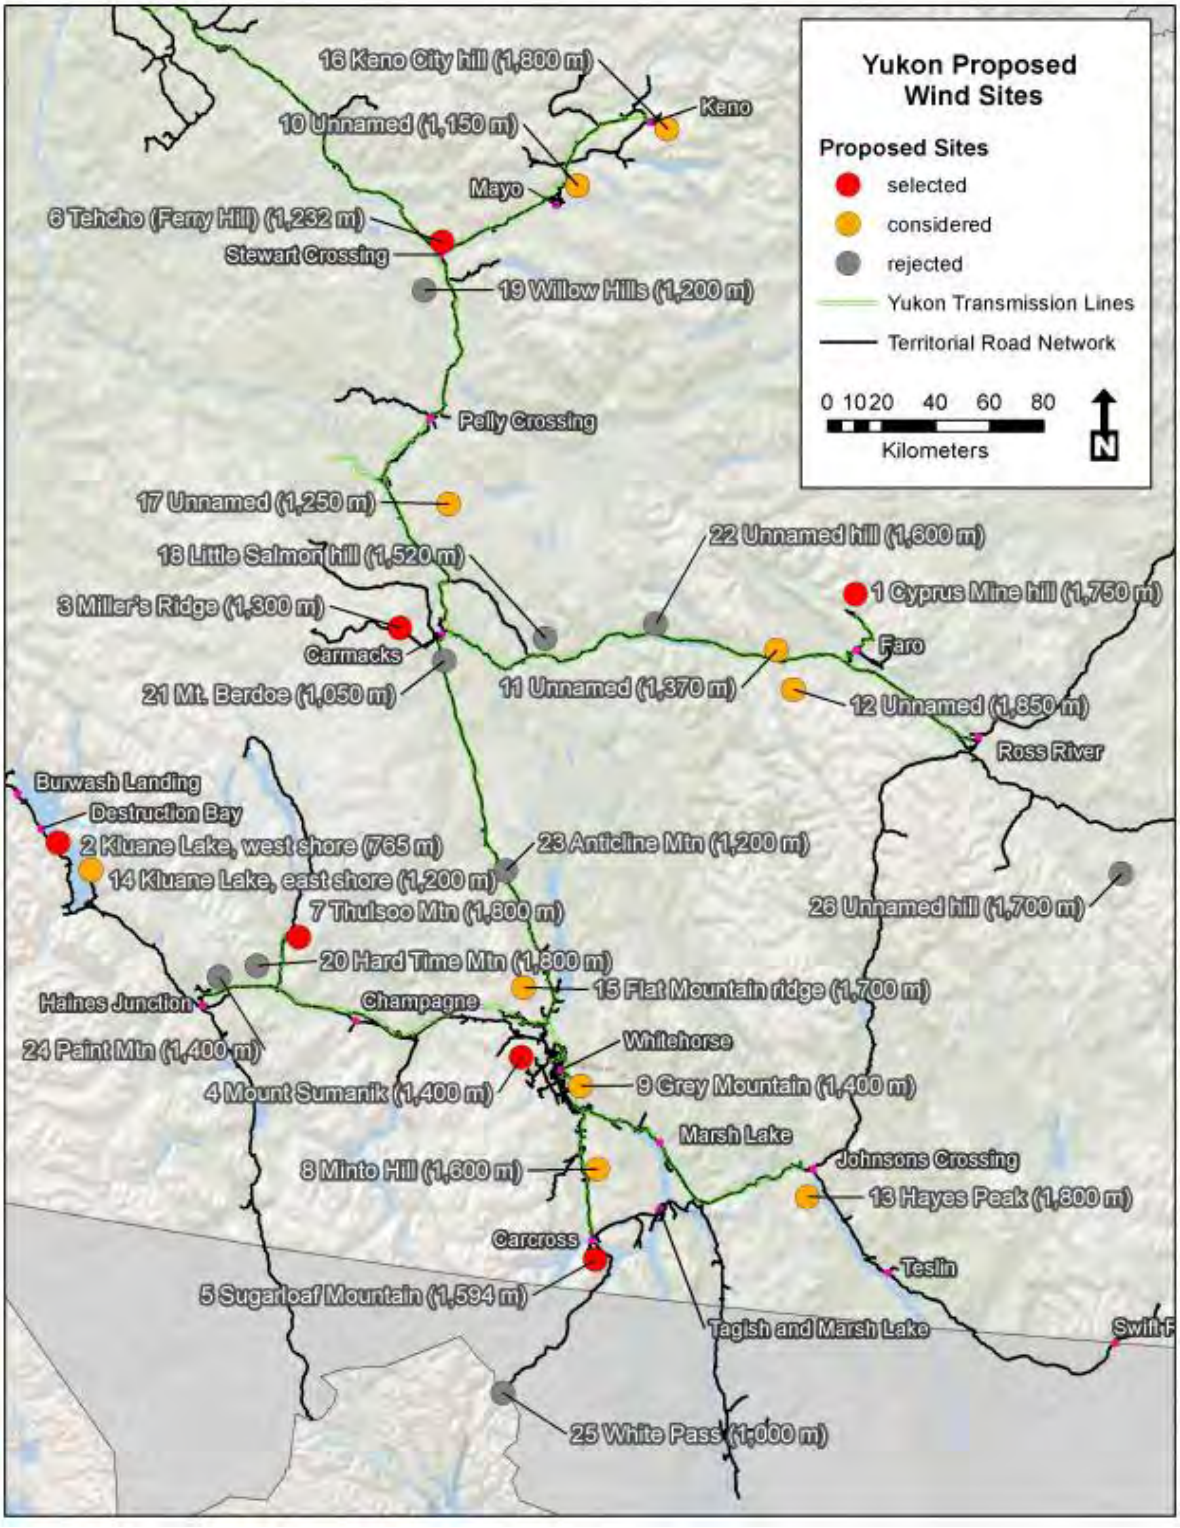

2.3 Yukon Site Visit

Douglas Vaught, P.E. (Ak) of V3 Energy LLC visited the proposed central and southern Yukon sites by helicopter and/or from roads during a site visit in late April 2016 to confirm the selection of the seven preferred sites, obtain photographs of the sites themselves and possible access routes, and garner a general qualitative assessment of site development potential. A number of photos were taken for documentation and to provide additional information. One photo per site was included in Chapter 3; additional photos can be found in Appendix F.

With reference to Figure 6, sites visited from the air in a broad flight loop from Whitehorse to Carmacks, to Faro, to Johnsons Crossing, to Carcross and then back to Whitehorse. Also visited and/or observed by ground travel were the potential sites in the vicinity of and west of Whitehorse.

Table 4 Observations of Yukon Site Visit

#	Site	Observation
4	Mt. Sumanik	Reasonably good access options, somewhat narrow ridge, near Whitehorse, high potential
15	Flat Mountain	Complex ridgeline, hard to access, low potential
23	Anticline Mountain	Complex ridgelines, access appears difficult, low potential
21	Mt. Berdoe	Heavily forested, small site area, very low potential
3	Miller's Ridge	Reasonably good access option with use of Nansen Mine road, huge site area, great exposure, very high potential
17	Unnamed Minto hill	Too far away from the highway, remote site, low potential
22	Unnamed hills between Little Salmon and Drury Lakes	Complex ridgelines, difficult access, remote site, low potential
1	Cyprus Mine hill plus alternate nearby	Easy access, turbine site options limited to ridge edge, alternate site has good site options, confirmed brownfield nature of site, high potential
11, 12	Unnamed hills west of Faro	Access to hill south of highway difficult, not as promising as Cyprus, low potential
13	Hayes Peak	Difficult access, peak too steep to develop, low potential
5	Sugarloaf Mountain	Good access, large, open site, moderate potential
8	Mt. Lorne subpeak/Minto Hill	Difficult access options, remote, low potential
2	Kluane Lake, west shore	Very easy access, new transmission land route would be difficult, very windy day of visit, moderate potential
14	Kluane Lake, east shore	Observed from across lake, transmission connection easier than west shore, moderate potential
24	Paint Mountain	Difficult access, small area, low potential
20	Hard Time Mountain	Difficult and expensive access, too remote, low potential
7	Thulsoo Mountain	Observed from a distance, site ridge appears promising
9	Grey Mountain	Very windy day of visit, complex ridgeline, high value recreational use, low potential

Information gathered from the site visits primarily reinforced the team's thoughts regarding site suitability developed through reference to mapping, Google Earth, photographs available on-line, previous reports, and other sources. Impressions of the site visit are documented in Table 4 above.

2.4 Site Selection

The 26 sites were assessed according to the following criteria:

1. Mean wind velocity (IRENA and AWS data at 80 and 100-meter hub heights)
2. Distance to transmission line (straight line distance)
3. Road access (straight line distance)
4. Land ownership and usage

Other non-quantifiable factors such as potential conflict with other land uses or public opposition expected for certain sites were then evaluated to determine a shortlist of seven sites. This shortlist includes two sites that had previously been examined, Mt. Sumanik and Tehcho (Ferry Hill), that YEC had requested to be included so they could be compared to the sites identified through the comprehensive territorial wind site assessment conducted for this study.

The result of the selection process can be seen in the Table 5 below. Red shaded rows are sites we shortlisted. Second-tier candidates are marked in yellow, while less desirable sites are shaded grey. The emphasis was to give preference to "low-hanging fruit" sites that seemed easiest to develop. Second tier sites are usually also good candidates and could be considered for replacing shortlisted sites that prove too difficult to develop, e.g. after monitoring revealed excessive periods of rime icing.

The location of these sites is illustrated in Figure 6 above. AWS Truepower wind resource maps for the seven selected sites can be found in Appendix B and AWS Truepower Compass-level site reports of all 26 sites can be found in Appendix E.

Table 5 Assessment of Potential Wind Farm Sites

ID	Name	Elevation above sea level	Mean wind velocity AWS data At 80 m hub	Distance to transmission line	Type	Road access River Crossing Required?	Straight line distance to hwy	Hw pav
1	Cyprus Mine Hill	1,750 m	7.0 m/s	7.2 km	138kV Tx Line	Yes	6.9 km	Ur
2	Kluane Lake, west shore	765 m	6.5 m/s	77.9 km	69kV Tx Line	No	1.7 km	P
3	Miller's Peak/Ridge	1,300 m	7.3 m/s	15.5 km	138kV Tx Line	No	2.6 km	Ur
4	Mount Sumanik	1,594 m	6.2 m/s	10.2 km	138kV Tx Line	No	5.2 km	Ur
5	Northeast slope of Sugarloaf Mtn.	1,400 m	5.7 m/s[3]	9.1 km	69kV Tx Line	No	1.7 km	Ur
6	Tehcho (Ferry Hill)	1,232 m	5.8 m/s	3.0 km	69kV Tx Line	No	0.3 km	Ur
7	Thulsoo Mtn	1,800 m	7.8 m/s	5.5 km	138kV Tx Line	No	3.8 km	Ur
8	Mount Lorne subpeak (Minto Hill)	1,600 m	7.7 m/s	4.6 km	69kV Tx Line	Yes	5.1 km	P

3 CONCEPTUAL WIND FARM DEVELOPMENT

We developed representative wind turbine arrays of 20, 10 and 6 MW capacity for each of the seven selected sites. The site layout and location is on a conceptual level only. The level of detail is sufficient for estimating the power output and the cost of installing wind farms of the respective size at these sites. Further and more detailed engineering will be required, though, should YEC decide to move forward any of these proposed installations.

For modelling of the wind farm we employed a wind modelling software called WAsP (Wind Atlas Analysis and Application Program). The WAsP software is a Danish PC-based software for predicting wind climates, wind resources and power production from wind turbines and wind farms and was used to model wind turbine performance. WAsP is the most widely used wind power analysis software in the world. WAsP modelling begins with a digital elevation map (DEM) of the wind farm site and surrounding area and conversion of coordinates to Universal Transverse Mercator (UTM).[4] WAsP modeling results for the seven selected sites can be found in Appendix G.

A wind data reference point (for this project, a purchased AWS Truepower annual data series file for a representative location at the site of interest) is added to the digital elevation map, wind turbine locations identified, and a particular wind turbine (for this project, as noted, a generic 2.0 MW model) selected to perform the calculations. WAsP considers the orographic (terrain) effects on the wind, plus surface roughness and obstacles, and calculates wind velocity increase or decrease at all nodes of the map. The mathematical model has a number of limitations, including the assumption that the overall wind regime of the turbine site is same as the met tower reference site, prevailing weather conditions are stable over time, and surrounding terrain at the wind data reference point and turbine sites is sufficiently gentle and smooth to ensure laminar, attached wind flow. The version of WAsP software used for this study is not capable of modelling turbulent wind flow resulting from sharp terrain features such as mountain ridges, canyons and shear bluffs.

To compare sites, we modelled each site using a generic 90-meter rotor diameter, 2.0 MW capacity, 80-meter hub height wind turbine. Although the modelled turbine is a Vestas V90, it is considered generic for the purpose of this exercise and can be considered representative of other turbines of the same power output class. Note, however, that the generic turbine in this exercise may not be the best choice at every site.

Specific turbine selection is a detailed and significant process of customer and manufacturer consideration and hence appropriate to the detailed design phase of a project. With that in mind, the generic 2.0 MW turbine modelled is a compromise choice. Although it would be suitable for most of the sites, or most turbine locations within a site, for other sites or locations other wind turbine models or manufacturers may be preferable.

[4] UTM is a geographic coordinate system that uses a two-dimensional Cartesian coordinate system to identify locations on the surface of Earth. UTM coordinates reference the meridian of its particular zone (60 longitudinal zones are further subdivided by 20 latitude bands) for the easting coordinate, and distance from the equator for the northing coordinate. Units are meters. Elevations of the DEMs are converted to meters if necessary for import into WAsP software. Digital elevation data was obtained from Natural Resources Canada (http://geogratis.gc.ca/site/eng/extraction) as TIFF format files.

For the representative wind turbine layouts presented in this section, an approximate turbine separation of five rotor diameters, or 450 meters, was consistently used. This is the conservative end of the three-to-five rotor diameter separation range generally recommended in the wind power industry for turbines oriented perpendicular to the prevailing wind. For turbine placement parallel to the prevailing wind, which only applies to the Kluane Lake site, a separation distance of approximately 1,000 meters, or 11 rotor diameters was chosen. This separation distance is also consistent with industry practice.

For actual design of a wind farm, an optimization analysis of turbine separation distance would be accomplished. The optimization of turbine separation and placement recognizes the non-coincident relationship between turbine distance and wake loss. Increased inter-turbine distance decreases wake loss but increases project development costs. This is because of the need for longer access roads, larger land area purchases or lease, longer electrical transmission lines, etc. The opposite, naturally, is also true. There is no one correct answer, other than to reference industry practice and guidelines of approximately five percent aggregate wind farm wake loss as a suitable compromise with respect to site development costs.

The following sections summarize the results of the WAsP model and observations from Google Earth and site visits. Details on annual gross energy production, wake losses and monthly generation profiles for each site can be found in Appendix H.

3.1 Cyprus Mine Hill

The hill complex immediately north of Cyprus Mine near Faro is an excellent wind farm site option due to the 'brownfield'[5] nature of the mine. Additional industrial-type development at a brownfield site, such as a wind farm, generally elicits less public opposition than greenfield development.

3.1.1 Site Description

Being close to a former large mine, significant advantages of Cyprus Mine Hill are the vicinity of a 138 kV transmission and partially developed high quality road access to the site. The ridge has a desirable orientation perpendicular to prevailing wind directions. Figure 7 shows a Google Earth image of the site area, and Figure 8 is a photo taken during the site visit, with the site area shown in the foreground (orange line).

A possible alternative or adjunct to Cyprus Mine Hill as a wind power site are hills of similar elevation immediately east of the connecting road between the northern and southern mine pits. AWS Truepower and WAsP modelling both predict a strong wind resource on the more accessible western slopes and ridges of these hills. Should a wind power project be contemplated for Cyprus Mine area, we recommend that data collection with met towers or LIDARs [6] of both hill groups: the proposed and the alternate.

[5] Term to describe land previously used for industrial purposes and potentially contaminated with hazardous waste or pollution.

[6] LIDAR: Light Detection And Ranging is a method of measuring wind speeds by projecting a laser into the air and detecting the backscatter from random particles in the atmosphere.

Figure 7 Cyprus Mine Prospective Wind Power Site, Google Earth Image

Figure 8 Cyprus Mine Prospective Wind Power Site, Photo (East view)

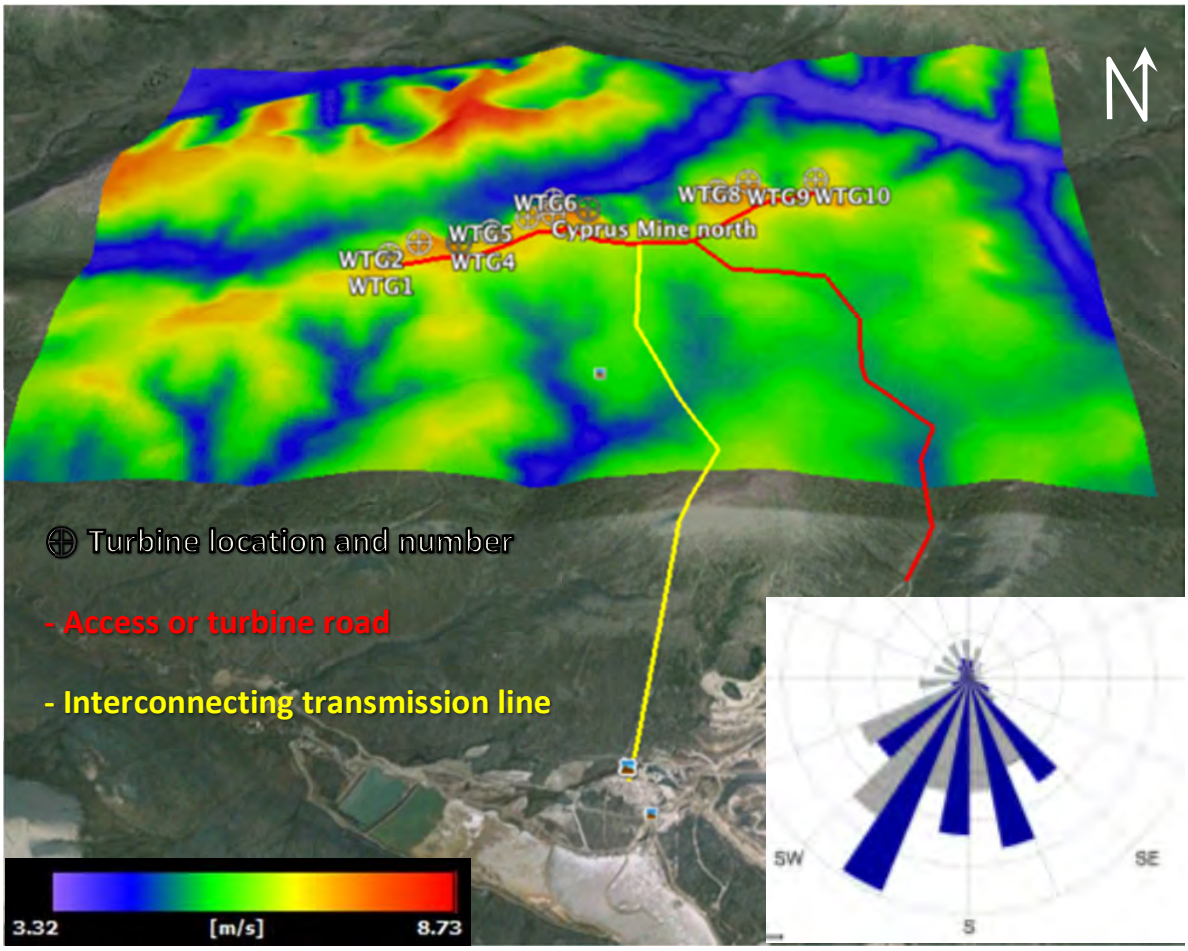
3.1.2 Site Layout

The ridgeline where turbines would be located is quite long and perpendicular to the prevailing wind direction as noted in Figure 9. This is advantageous in that the ridge can support installation of many wind turbine and wake loss would be minimal.

A 20 MW wind farm (ten two-MW wind turbines) would be arrayed at higher elevation points along the ridge as shown in Figure 10 below. Turbines in this figure are identified as "WTG", the AWS Truepower data reference point for the WAsP model is noted by "Cyprus Mine north", recommended turbine access roads are indicated by red lines, and the existing communication tower electrical connection that would be upgraded to support wind turbines is indicated by the yellow line.

Additional turbines to the west of Turbine 1 (WTG1) are possible as are installing turbines on an adjoining parallel ridge to the north. Access to that ridge would be possible via a broad "pass" between the two (visible left center of Figure 8). Beyond this site area, the alternate site option east of the two mine pits could support at least another 20 MW of wind power capacity, if not more.

Figure 10: 20 MW Wind Farm Layout for Cyprus Mine Hill Site, WAsP Wind Speed Overlay



3.2 Kluane Lake (West Shore)

As a prospective wind power site, the west shore of Kluane Lake presents intriguing possibilities. It is the only relatively-low-elevation location in the Yukon with projected high wind speeds. The mountains west and east of the lake concentrate and funnel wind along the long axis of the lake.

Although the highest wind speeds at Kluane are straight down the middle of the lake, as one would expect, the west shore has only a minimally lower wind resource.

3.2.1 Site Description

At 720 meters above sea level, Kluane Lake is much lower elevation than the six other sites profiled in this report. As such, the problematic winter rime icing environments that would be an operational challenge at the higher elevation sites would not exist at Kluane Lake, or at least would be significantly reduced in frequency and severity.

A disadvantage of Kluane Lake is that currently there is no electrical transmission line nearby, although a planned new line would run very closely to the site. Today, YEC's transmission terminates at the Aishihik Generating Station and all communities and load centers to the west operate as isolated grids. The map in Appendix A shows the proposed transmission to possibly as far west as Destruction Bay. If constructed, a Kluane Lake project would be quite viable. The west shore of Kluane Lake as a site recommendation is presented in this report based on a presumption that the proposed transmission is constructed independently of a wind project; in other words, a Kluane Lake wind project would not absorb the cost of transmission to Haines Junction.

A possible site alternative to the west shore of Kluane Lake are sloping hills near Grayling and Rat Lakes, nearly directly across the lake from the west shore site and about 12 to 15 km from Silver City. An advantage of the east shore is a shorter transmission connection to Haines Junction, should an extension of the transmission line to the west shore Kluane Lake communities of Destruction Bay and Burwash Landing not be possible. Disadvantages are higher elevation sites and more complex access and construction requirements.

Figure 11 indicates the proposed Kluane Lake west shore site on a Google Earth image, and Figure 13 shows a photo of the lake shore near the site, which was taken during a site visit in late April 2016.

Figure 11 Kluane Lake Prospective Wind Power Site, Google Earth Image

3.2.2 Site Layout

A ten-turbine, 20 MW wind farm (assuming 2 MW wind turbines) could be arrayed in two rows of five turbines between the Alaska Highway and the Kluane Lake shoreline as shown in Figure 14. The site area is entirely forested and pad areas and access roads would require clearing. The AWS Truepower data reference point for the WAsP model is adjacent to WTG6, recommended access roads (one road for two turbines) are indicated by red lines, the recommended new wind farm electrical sub-transmission connection to existing transmission is indicated by the yellow line (under "WTG3"), and the planned transmission line is indicated as a light blue line.

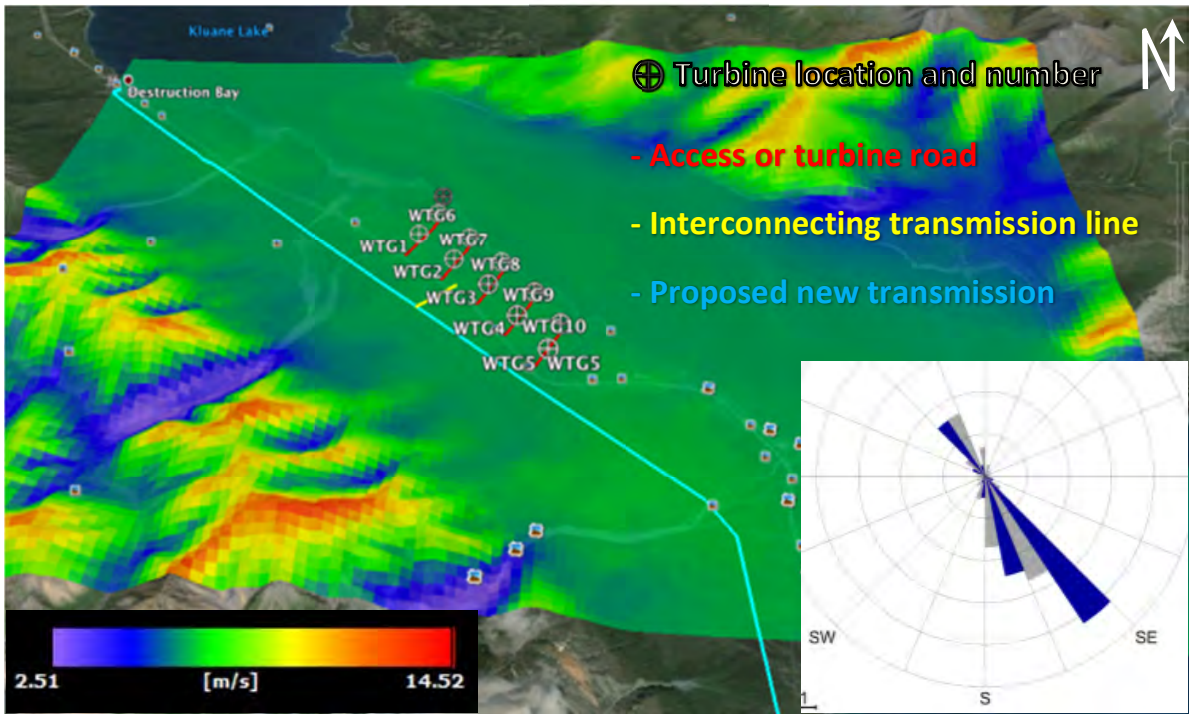
To account for the highly directional nature of the Kluane Lake wind resource (refer to Figure 12) along the axis of the lake and the site constraint that requires turbine alignment along the same axis, inter-turbine distances are higher for the parallel-to-wind turbines than the perpendicular-to-wind turbines, requiring a larger overall site footprint than one might expect for a ten turbine array.

The west shore of Kluane Lake has room for at least twice, if not three times, the number of turbines shown in Figure 14. The proposed access arrangement of one road to serve two turbines could be repeated northwest all the way to Destruction Bay and southeast along the shoreline. The maximum site capacity is estimated to be in the range of 40 to 60 MW rated output.

Figure 13 Kluane Lake Site, Photo of West Shore Site

Note: turbine sites would be in the forested area to the left

Figure 14: 20 MW Wind Farm Layout for Kluane Lake (West Side), WAsP Wind Speed Overlay



3.3 Miller's Ridge

Miller's Ridge near Carmacks has superb potential for wind power production and perhaps is the most preferred site for a large wind farm of 20 MW or more capacity. The ridge is expansive, very wide, fairly flat, well exposed in all directions, and suitably oriented to the prevailing winds.

3.3.1 Site Description

A significant advantage of Miller's Ridge as a wind power site is the existing Nansen Mine Road, which runs immediately under the south side of the ridge. Although further road access to the ridge itself would be required, Nansen Mine Road transforms what otherwise would have been a suitable but rather isolated site into one with considerable development potential.

An electrical transmission connection to Carmacks would be expensive, though, as would an access road to the ridge, so a larger capacity wind farm on Miller's Ridge would be preferable to a smaller one. Figure 15 shows a Google Earth image indicating the site area, and Figure 16 shows a photo taken during site visits, illustrating the openness and flatness of this location.

Figure 15 Miller's Ridge Prospective Wind Power Site, Google Earth Image

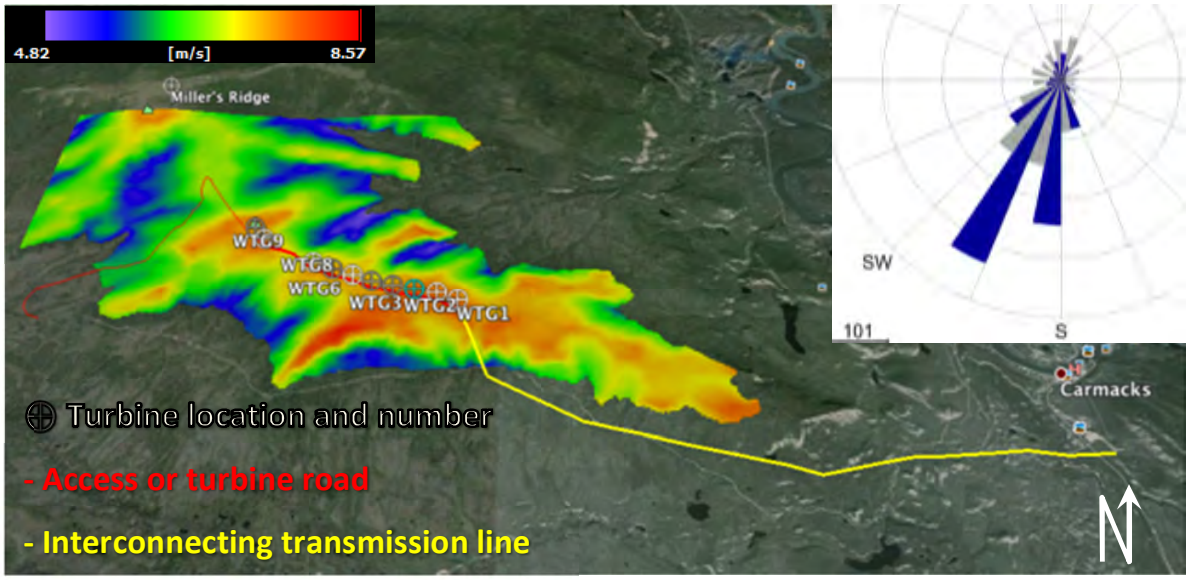
Figure 16 Miller's Ridge Site, Photo of NW View

3.3.2 Site Layout

The mostly east-west orientation of Miller's Ridge is perpendicular to the strongly south-southwest prevailing wind (see Figure 17), which is ideal for a wind farm layout and results in low wake loss.

A 20 MW wind farm (10 turbines each 2 MW) would be arrayed at higher elevation points along the ridge as shown in Figure 18 below. Turbines in this figure are identified as "WTG", the AWS Truepower data reference point for the WAsP model is noted by "Miller's Ridge", recommended access roads (to Nansen Mine Road) are indicated by red lines, and the recommended new wind farm electrical sub-transmission connection to existing transmission is indicated by the yellow line.

Figure 18: 20 MW Wind Farm Layout for Miller's Ridge Site, WAsP Wind Speed Overlay



3.4 Sugarloaf Mountain

Sugarloaf Mountain near Carcross, due to its lower wind resource, was perhaps the most difficult prospective wind turbine site recommendation in this report, but site access is very good and it would be easiest site in the southern Yukon to develop for wind power.

3.4.1 Site Description

Site access to Sugarloaf – not the high knob itself but the lower portion of the alpine slope below it to the northeast – is already possible via the Montana Mountain jeep road, and a transmission extension from Carcross to reach the site would be relatively short. But wind speeds at the site appear to be fairly low in comparison to the other profiled sites. Modelled data is not perfect, however, and may underestimate the actual wind resource. With that in mind, obtaining site data from a met tower or Lidar is recommended.

Note that a possible alternative to Sugarloaf Mountain is Mt. Lorne Subpeak just northeast of Carcross. Although higher and windier, the site is more remote than Sugarloaf with no improved road, or even trail, access. Further, due to topography and terrain features, road access options would be somewhat circuitous. The trade-off of development costs versus higher energy production potential for Sugarloaf and Mt. Lorne Subpeak is beyond the scope of this project. Figure 19 shows a Google Earth image identifying the site area, and Figure 20 is a photo taken during the site visits, also showing the existing access road.

Figure 19 Sugarloaf Mtn. Prospective Wind Power Site, Google Earth Image

Figure 20 Sugarloaf Mountain Site, Photo of NW View Showing Access Road

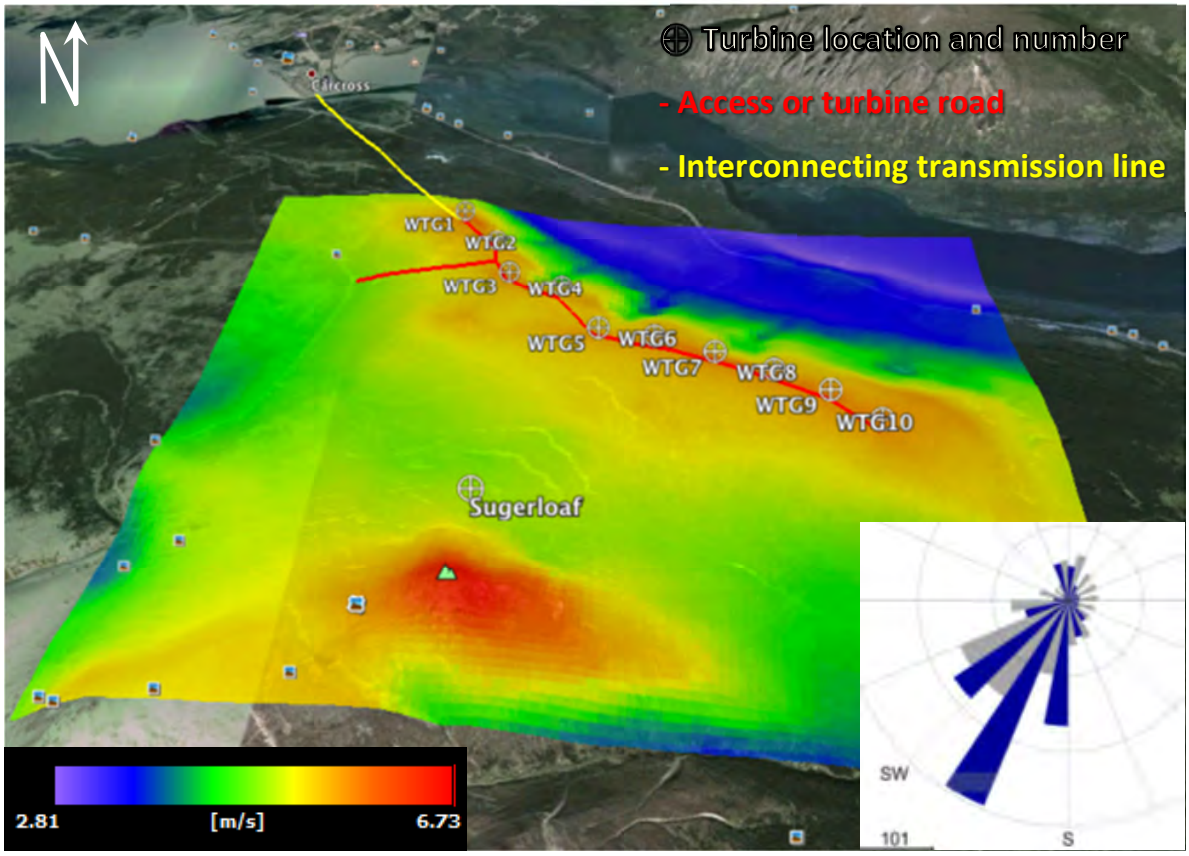
3.4.2 Site Layout

A 20-MW wind farm (ten turbines each 2 MW) would be arrayed at higher elevation points along the ridge as shown in Figure 23. The AWS Truepower data reference point for the WAsP model is noted by "Sugarloaf." The orientation of the prospective wind turbine site area is perpendicular to the southwest prevailing wind (see Figure 21) and hence would result in minimal wake loss.

Also note in Figure 23 below that the wind resource of Sugarloaf suitable for wind power development is limited to the low bench that marks the transition between lower elevation forest and higher elevation tundra. The summit of Sugarloaf itself indicates a very good wind resource but this knob is too small and steep for installation of wind turbines. WAsP modelling indicates that winds between the knob and the bench are low, although interestingly, very well defined wind-blown snow sastrugi was observed during the late April site visit overflight.

Additional wind turbines at Sugarloaf beyond the ten turbine layout of Figure 22 would be possible by closer inter-turbine spacing or use of larger turbines. The modelled array wake loss was very low and a tighter turbine spacing would be acceptable.

Figure 23: 20 MW Wind Farm Layout for Sugarloaf Mountain, WAsP Wind Speed Overlay



3.5 Mount Sumanik

Mount Sumanik was originally excluded from the project analysis by YEC and then added later for comparison to the five sites identified during the site assessment.

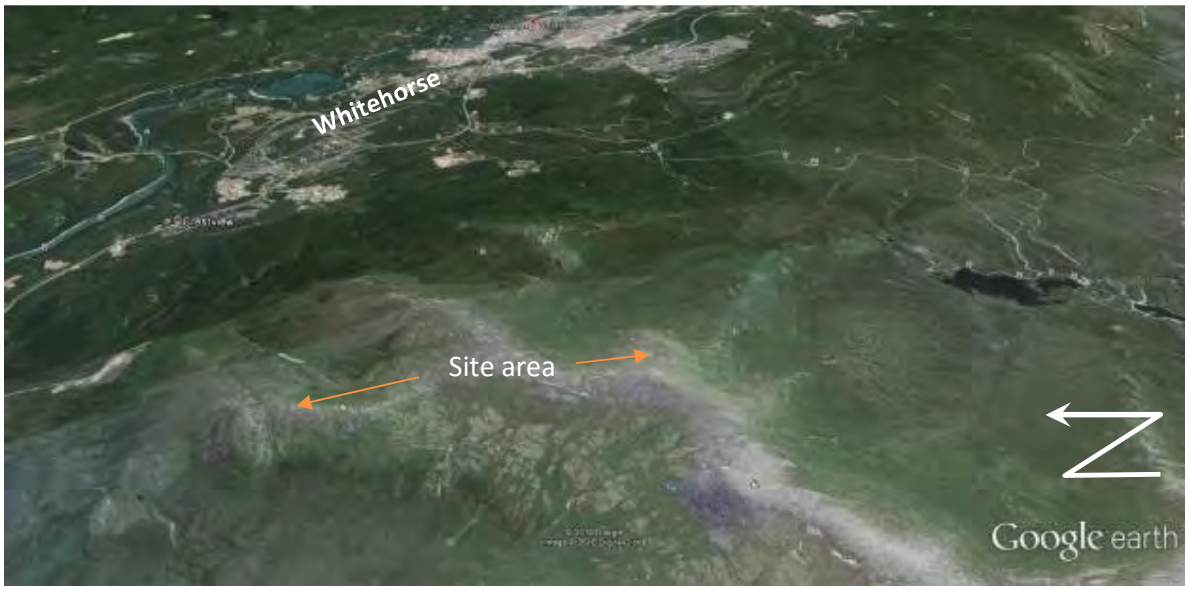
3.5.1 Site Description

Mount Sumanik is a natural wind turbine site option due to its immediate proximity to Whitehorse, the presence of two older wind turbines (reportedly, only one is presently operational) on nearby Haeckel Hill, and exhibits a very good wind resource. YEC's interest in Mount Sumanik as a wind

turbine project site is extensive and long-standing. At present, the site wind resource is being measured with a Lidar unit located on the summit of the mountain (more accurately described as the high point of a long ridgeline).

Development access to Mount Sumanik might be somewhat challenging though as an extension of the Haeckel Hill access road may not be the ideal access route to the Sumanik ridge itself. It appears that better access may be via a quarry/borrow pit northeast of the mountain. **Error! Reference source not found.** shows a Google Earth image indicating the site location, and Figure 25 is a photo taken during the site visits, also showing the Lidar monitoring device (middle of photo).

Figure 24 Mount Sumanik Prospective Wind Power Site, Google Earth Image

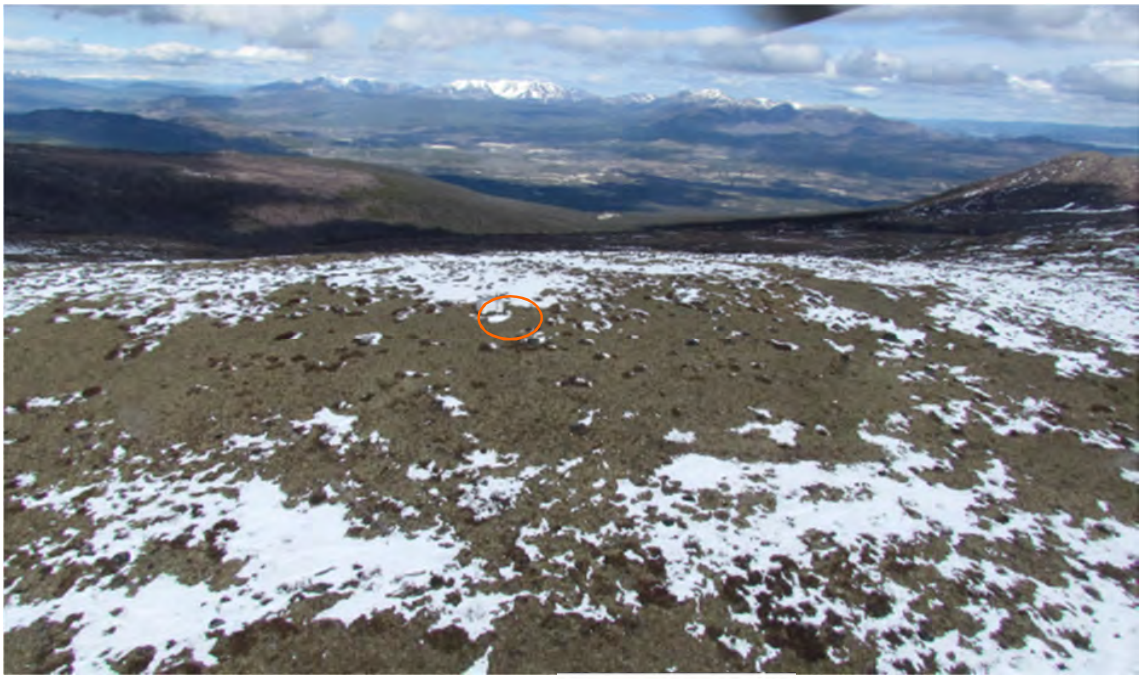


3.5.2 Site Layout

The Mount Sumanik wind resource predicted by AWS Truepower predicts mostly southerly winds with some variability from east-to-west, as seen below in Figure 26. Power production winds, however, appear to be strongly south-southeasterly, which complicates wind turbine layout at the site as the ridge orientation is north-south.

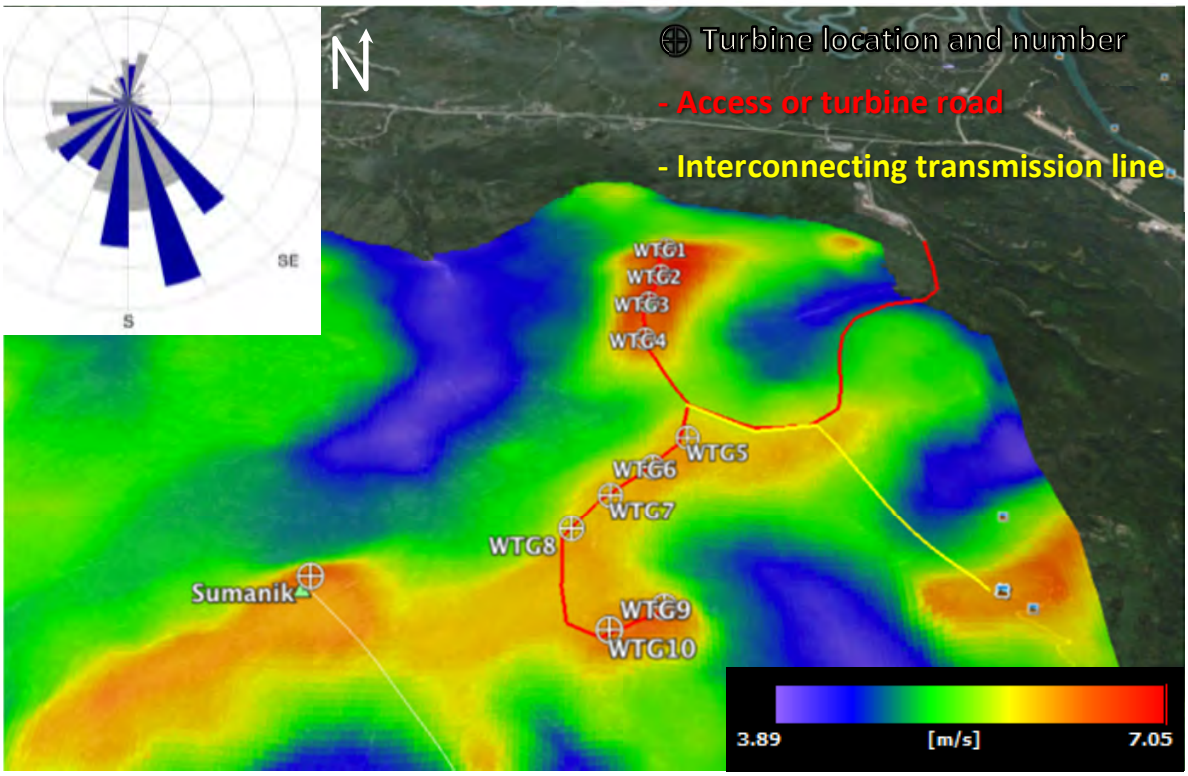
Interestingly, it appears from modelling that a 10 x 2-MW wind farm would be best arrayed along the ridgelines north of the actual summit area as shown in Figure 25, not along the higher elevations of the summit itself. Turbines in this figure are identified as "WTG", the AWS Truepower data reference point for the WAsP model is noted by "Sumanik." Although road access via the north-side borrow pit is recommended, electrical sub-transmission connection to existing transmission at the Haeckel Hill wind turbine site would likely be most efficient and is indicated by the yellow line in Figure 25.

Figure 25 Mount Sumanik Site, Photo Looking East



Note: LIDAR wind monitoring equipment can be seen in the middle of the photo

Figure 26 20 MW Wind Farm Layout for Mount Sumanik, WAsP Wind Speed Overlay



As demonstrated in Figure 27, the proposed turbine site area consists of two separate ridges north of the summit itself. Additional turbines could be installed along the ridge line extending towards the peak, although wind speeds are somewhat lower from south of WTG8 to near the Mt. Sumanik summit where WAsP modelling indicates they would be higher. Sumanik could accommodate a larger wind farm with use of additional or larger capacity wind turbines.

3.6 Tehcho (Ferry Hill)

Tehcho, previously referred to as Ferry Hill, was originally excluded by YEC from the project analysis and then later added for comparison to the 5 originally recommended sites.

3.6.1 Site Description

Tehcho would be relatively straightforward to develop due to an existing road to the summit of the hill and an existing transmission line from Stewart Crossing to the summit to power a communications tower. Although the transmission line would require an upgrade, the existing easement is a significant development advantage. Figure 27 shows the site area on a Google Earth image.

Tehcho has received considerable attention as a possible wind turbine site with installation of two met towers and a 2011 two-part study by Natural Power that assessed the met tower data, icing potential and prospective wind turbine layout. Project history of the met tower study is not entirely clear, but the Natural Power report indicates that data was collected from October 2001 until June 2005. In their study, Natural Power did not analyze the overall measured wind resource *per se*; rather, they concentrated on data loss due to icing, assessment of effects of rime icing on energy production at the site, and a financial analysis of a prospective wind project.

Figure 27 Tehcho Prospective Wind Power Site, Google Earth Image

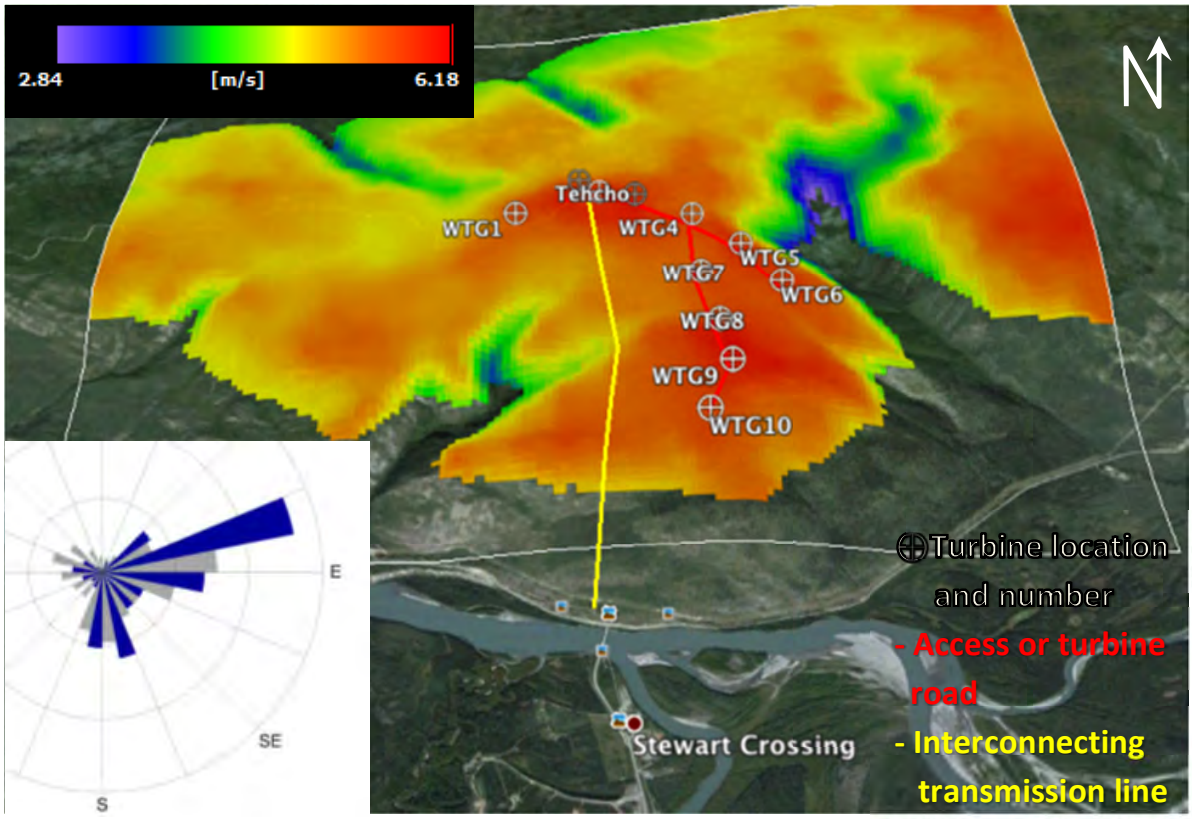
3.6.2 Site Layout

The Tehcho wind rose, as predicted by AWS Truepower, indicates mostly easterly, with some southerly, winds (see Figure 28). For the more frequent easterly winds, this is advantageous as the ridgeline orientation is generally north-south.

A ten-turbine, 20-MW wind farm would be arrayed along the southern shoulder of Tehcho as shown in Figure 28 below. This is slightly different than Natural Power's 2011 site layout, which concentrated wind turbines along the southwest shoulder of the hill. Note that the AWS Truepower data reference point for the WAsP model is indicated by "Tehcho". This is the same site as the larger met tower in the 2001 to 2005 wind study.

Additional wind turbine capacity at Tehcho could be installed on the southwest shoulder of the hill as laid out by Natural Power in 2011.

Figure 28: 20 MW Wind Farm Layout for Tehcho, WAsP Wind Speed Overlay



Note: the connection may have to go to Stewart Crossing south substation, on the south side of the Stewart River (not the north side as shown) as there is probably enough space at the existing substation. This would slightly increase the capital costs for his project.

3.7 Thulsoo Mountain

Thulsoo Mountain near the Aishihik hydroelectric facility (north of Canyon, between Haines Junction and Whitehorse) has superb potential for wind power production and, along with Miller's

Ridge, can be considered the preferred sites for wind power in the Yukon, although Thulsoo has less absolute wind power capacity potential than Miller's Ridge.

3.7.1 Site Description

Although there is no existing access road to the summit of Thulsoo, a new access road would be relatively short. Similarly, transmission to tie to the Aishihik substation would be short distance as well. Figure 29 is a Google Earth image identifying the site, and Figure 30 is a photo taken during the site visit trip in April 2016. Unfortunately, flight scheduling did not enable us to have an over-flight during the site visit and poor weather prevented a close visual examination of the mountain from the Aishihik canyon access road.

Figure 29 Thulsoo Mtn. Prospective Wind Power Site, Google Earth Image

Figure 30 Thulsoo Mtn. Site, Photo taken from Alaska Hwy (view north)

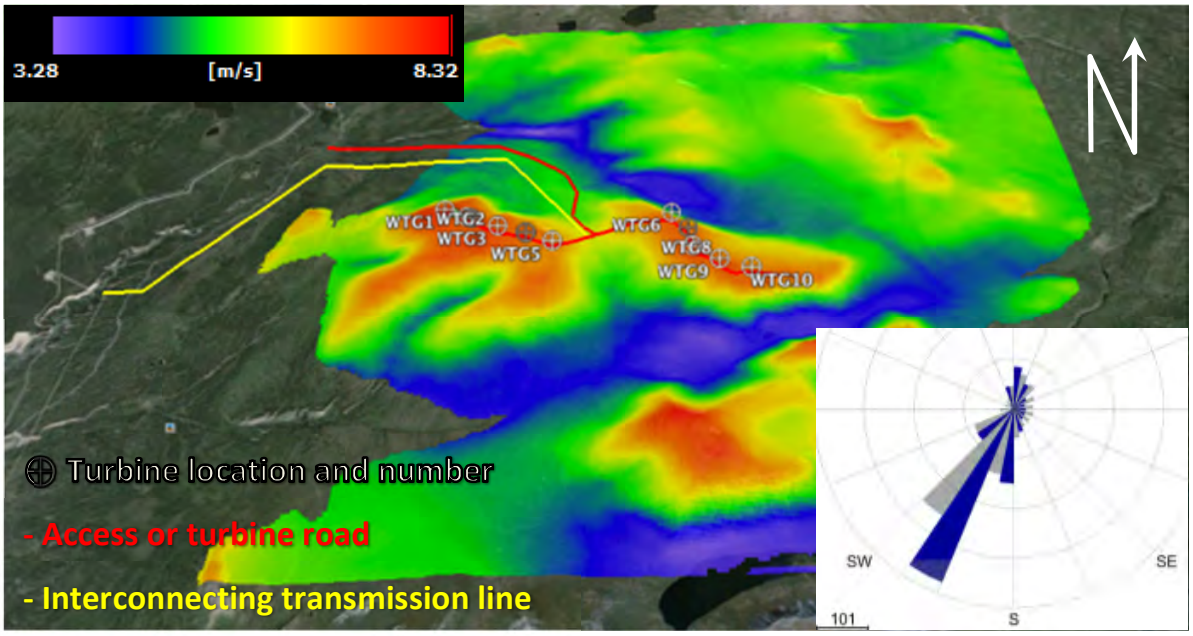
3.7.2 Site Layout

Thulsoo Mountain has an excellent wind resource with strongly prevailing south-southwesterly winds that complement the generally east-west orientation of the mountain (see Figure 31), but the site area that can be developed is somewhat constrained.

For a 10 x 2.0-MW wind farm, half the turbines would be located at an adjacent ridge of Thulsoo Mountain as shown in Figure 31. Turbines in this figure are identified as "WTG", the AWS Truepower data reference point for the WAsP model is adjacent to WTG5.

The site might allow one additional 2.0 MW turbine to the northeast of turbine WTG10 to be installed at the end of the turbine road. The maximum capacity of the site would then be 22 MW (11 x 2 MW). No other additional turbines could be deployed without negatively affecting the performance of the 20-MW array.

Figure 31: 20 MW Wind Farm Layout for Thulsoo Mountain, WAsP Wind Speed Overlay



3.8 Land Use

Wind farms require significant amount of land. For a 20 MW wind farm at each of these seven sites between 70 and 190 hectare of land are required, three to nine hectare per MW of installed capacity. Only about one third of the land is used by the turbines themselves, the rest is for the access road and a connection to YEC's transmission line, including the required easement offset. On average, both, the access road to the site and the interconnecting transmission line are six to seven kilometer long.

Land will be used for the turbines itself, a road connecting the turbine, an access road, unless existing and a power line connecting the turbines to YEC's grid. Along power lines and access roads we

assumed an easement of 60 meters. The latter includes the width of the road, typically around seven meters.

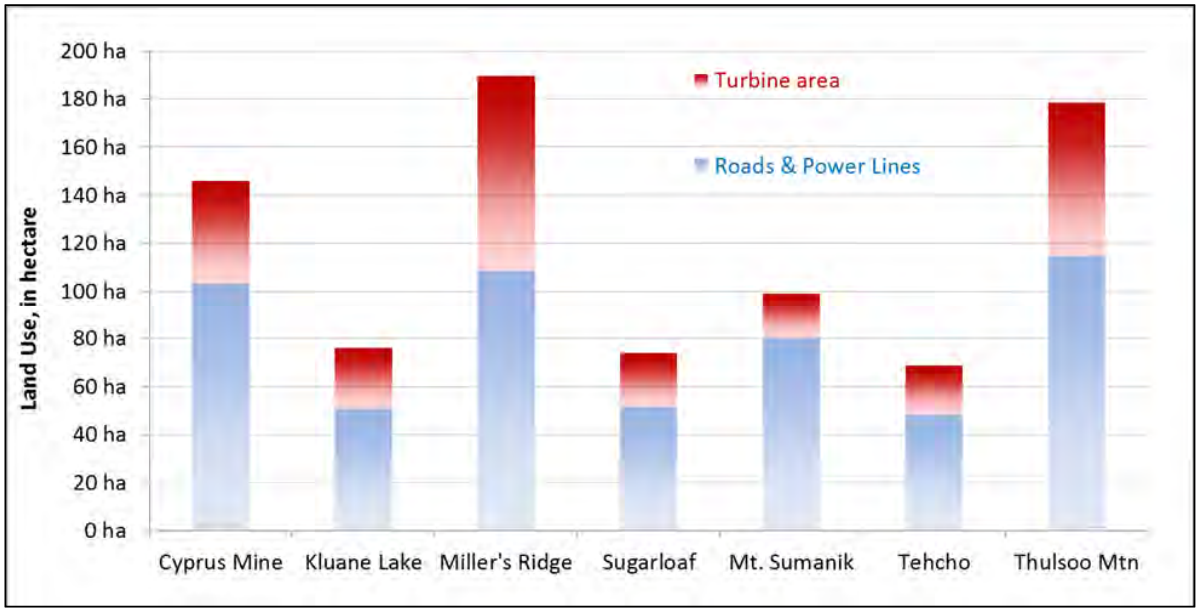
We used a buffer of 45 meters around the turbine. This is the rotor radius for a 2.0-MW turbine. From a bird's eye view the tower can swivel 360°. The downward projection of this area, a circle 90 m in diameter, needs to be purchased from a legal point of view.

The 45-meter buffer would go along the entire array of turbines. The total land to be purchased would be the length of the road connecting the array of turbines (the 'turbine road') plus 45 m x 45 m on either end of the road. An underground collector line between the turbines will run along the turbine road. The 90-meter easement will also be used by turbine transformer and the area for the switch yard. Finally, this easement allows the rotors and turbine to be laid down during construction. Usually the three blades are assembled on the ground and then lifted up onto the erected tower.

As an example: An array of 10 turbines, each placed five rotor diameters apart, are arranged in a line, e.g. along the ridge of a mountain. This array may be 5 km long. There has to be a 45 m buffer on either side of this array. The total width of the buffer is 90 meters. If the array is 5 km long the total area would be 5 km x 90 m = 45 ha.

Trees can create turbulence. Most of the wind-farm sites are on ridgelines above the tree line, though. No cost for land clearing has been assumed for the turbines or the turbine road. Kluane Lake is an exception to this.

Figure 32: Land Use of a 20 MW Wind Farm at the Seven Selected Sites



4 WIND FARM ENERGY PRODUCTION

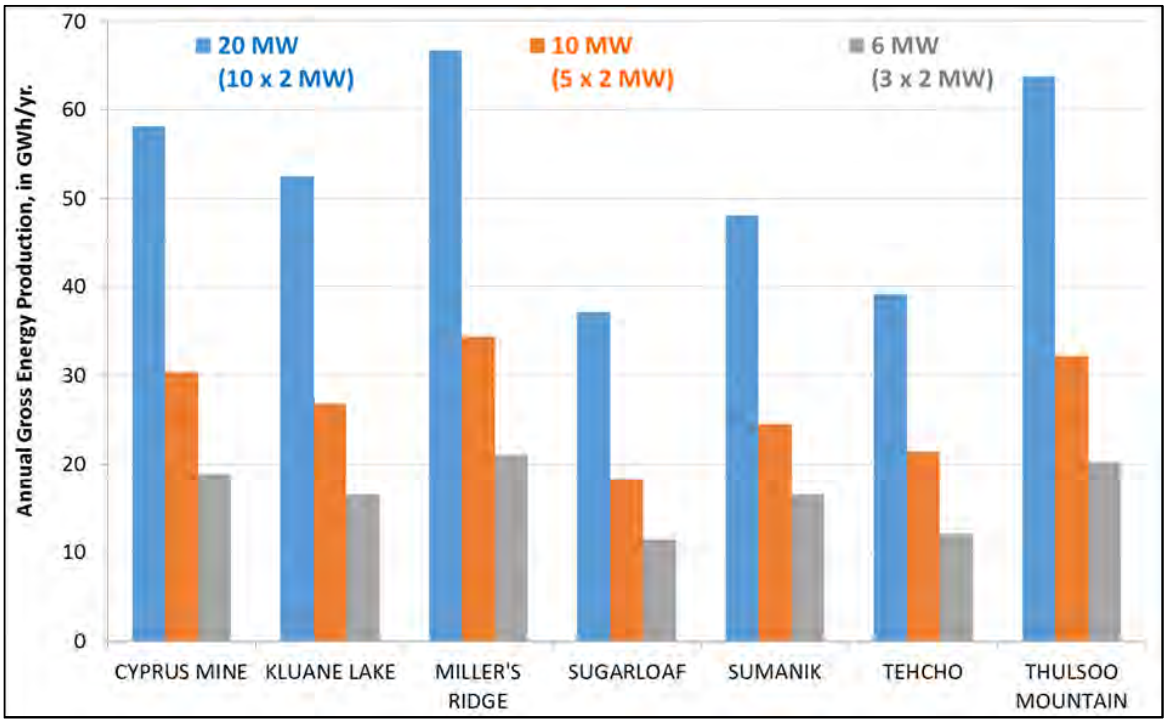
This chapter presents projected energy output of wind farms at the seven selected sites. Modelled energy production is a key input to the financial model in Chapter 5. Details on energy production , losses, and monthly generation profiles for each of the seven sites are given in Appendix H.

4.1 Annual Gross Energy Production

For modelling the energy production of the various sizes of wind farms at the seven sites we employed the wind modelling software called WAsP mentioned in the previous chapter. Based on topography, wind resource and site layout WAsP determines the Annual Energy Production (AEP).

A 20 MW wind farm produces 52 GWh per year on average at the seven sites, equivalent to the annual consumption of 5,300 households in the Yukon.[7] A 6 MW farm will only generate 17 GWh annually. Comparing the three sizes of wind farms, a clear pattern can be recognized: the fewer wind turbines there are on site, the lower the wake losses and the higher the capacity factor. While the annual energy production is obviously higher for larger wind farms, the average capacity factor is lower (generally about 2-4% lower for 10 MW and about 4-7% lower for a 20 MW farm, compared to 6 MW). A wind farm with five turbines produces slightly more than half the energy that the wind farm with ten turbines – see Figure 33 below.

Figure 33 **Summary Results of WAsP Wind Farm Modelling:** Annual gross energy generation of various wind farm sizes, 2 MW generic turbine



[7] Over the past years, Yukon residential customers consumed an average of 9,801 KWh per year. Source: Yukon Bureau of Statistics, "Yukon Energy Facts 2013", see www.eco.gov.yk.ca/pdf/energy_2013.pdf, accessed on June 7th, 2016

4.2 Energy Losses

The actual energy fed into the grid is lower than the numbers stated above. A wind farm will face the following losses:

- Wake loss due to turbulences and the shadowing effect turbines have on each other;
- Curtailment during extreme temperatures and icing to protect the blades
- Parasitic energy, such as electricity for melting ice on the blades,
- Conversion losses when transforming turbine voltage to grid transmission voltage
- Sub-optimal performance, e.g. due to soiled blades
- Downtime necessary for maintenance;

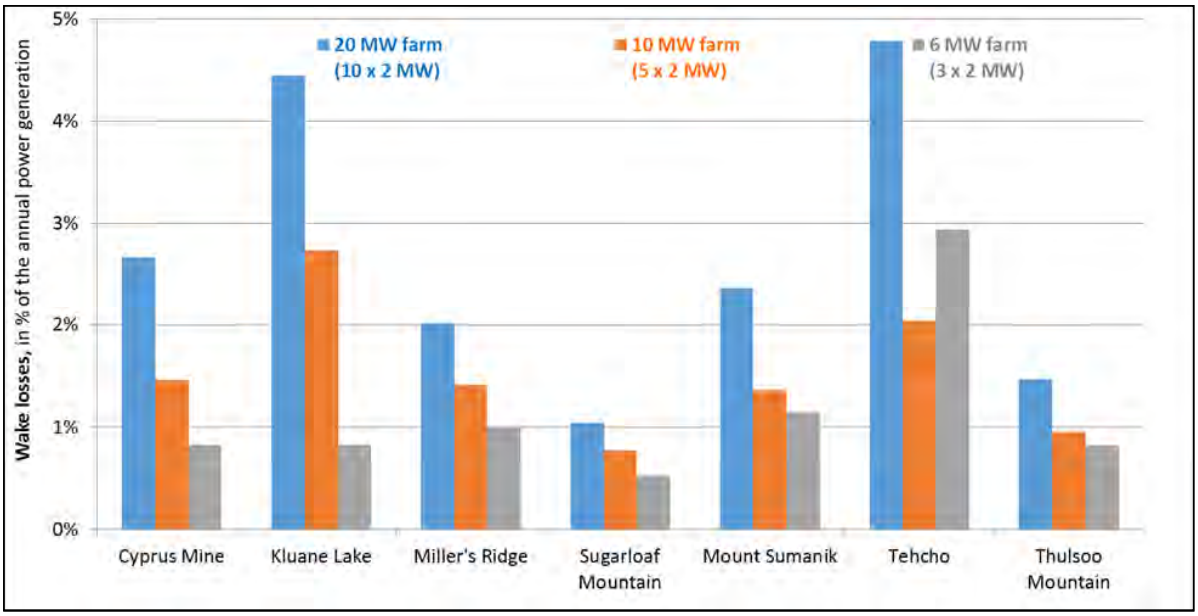
The following chapters quantify these losses.

4.2.1 Wake Losses

Turbine array wake loss is due to the shadowing effect that upwind turbines have on those down-wind. This effect is highest very near a turbine and dissipates with distance until the wind-free stream velocity resumes. As one might expect, wake loss is relatively high in large arrays, especially those with multiple rows of wind turbines, and high at sites with complicated or highly variable prevailing winds.

Wake losses for the seven selected site range from 0.5% to close to 5%, depending on the site and the size of the wind farm. This is well within an industry standard range of three to five percent. Of the seven sites studied in this report, wake losses are predicted as highest at Kluane Lake and Tehcho and lower at the other sites. As discussed in Section 3, this is due to the unavoidable parallel-to-the-prevailing wind orientation of turbines at Kluane Lake and the constrained site size at Tehcho.

Figure 34 Wake Losses of the Three Wind Farm Sizes at each of the Seven Sites



Wake loss can be reduced by moving turbines further apart, both parallel and perpendicular to prevailing winds, but there is a cost tradeoff. A larger site footprint is more expensive to develop, hence the industry rule of thumb of three to five percent wake loss as economically optimal.

4.2.2 Extreme Temperature Curtailment

For many wind turbine models, power output automatically curtails (by sensor input, via the turbine control system) at temperatures below -30°C and the turbine shuts down at -40°C. This protective feature reflects metal fatigue and lubricant limitations in severe cold. Whereas temperatures below -40°C are rare, even in the Yukon, the AWS hourly time series data for each site suggests a number of hours below -30°C each year. For Tehcho, near Stewart Crossing, and the coldest site, AWS hourly time series data predicts 241 hours a year with air temperatures below -30°C. At Kluane Lake by comparison -30°C are predicted for only five hours per year. Using these numbers of hours, we determined the curtailment losses due to extreme temperatures, see Table 6 below.

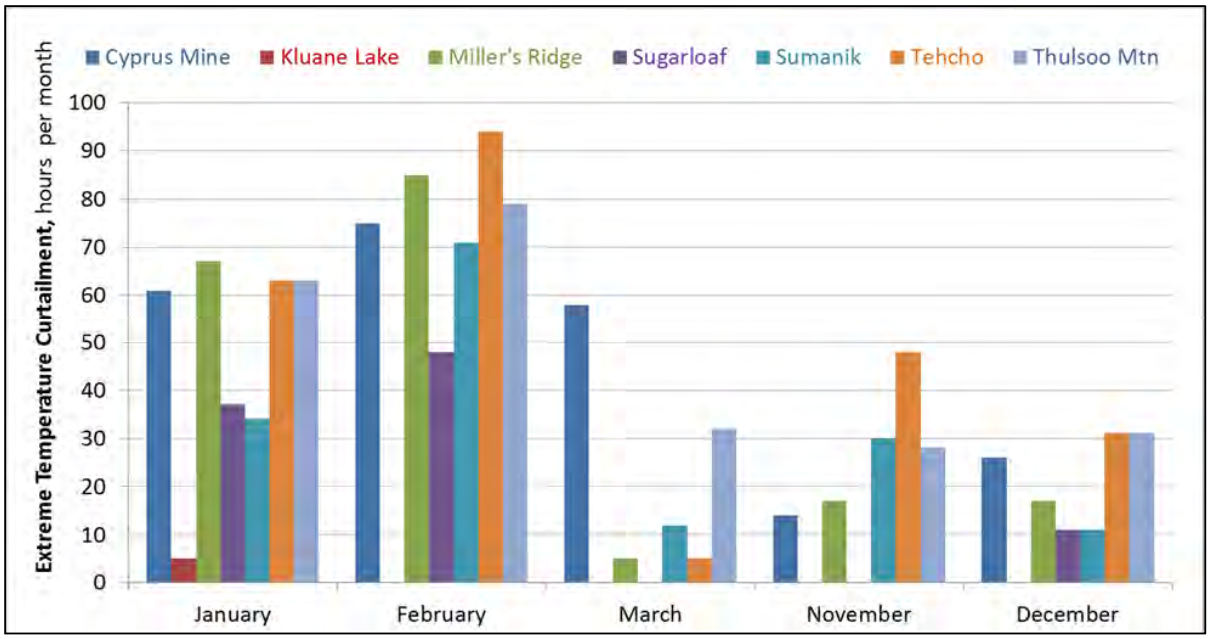
Table 6 Losses Due to Low Temperature Turbine Curtailment

Site	Hours below -30°C	Curtailment losses of a 20 MW wind farm	
Cyprus Mine	234 hours / year	2.7%	-1,552 MWh/yr.
Kluane Lake	5 hours / year	0.1%	-30 MWh/yr.
Miller's Ridge	191 hours / year	2.2%	-1,455 MWh/yr.
Sugarloaf Mountain	96 hours / year	1.1%	-407 MWh/yr.
Sumanik	158 hours / year	1.8%	-868 MWh/yr.
Tehcho	241 hours / year	2.8%	-1,077 MWh/yr.
Thulsoo Mountain	233 hours / year	2.7%	-1,695 MWh/yr.
Average	**165 hours / year**	**1.9%**	**-1,012 MWh/yr.**

Although some manufacturers allow their turbines to operate below -30°C, especially direct drive turbines, we have conservatively assumed that the turbine will stop operating to protect the turbines against extreme cold-weather risk. It is likely that the entire wind farm will stop operating during these hours.

Because these losses occur during winter, they can reduce output during the coldest months by up to 14% in an extreme case (Tehcho in February), although typical cold-temperature curtailment would be much lower. Curtailment due to extremely cold temperatures is presented in Figure 35.

Figure 35 Hours of Curtailment due to Temperatures below -30°C



4.2.3 De-icing Energy and De-icing Downtime

Another factor reducing turbine output is icing. Contrary to cold temperatures, icing may only affect one or some of the turbines at a given time so that the plant can maintain a portion of its power-generation ability. Icing losses have been estimated as 7.8% of total production in the Natural Power's 2010 Tehcho study,[8] and above 25% of production in the study on Mt Sumanik (also referenced in Section 2.1).

For all sites except Kluane Lake, which is not expected to display icing, we assume that 20% icing loss could occur without mitigation. De-icing equipment is expected to largely reduce the downtime from icing but will consume energy. In total, we estimate that the annual loss can be reduced to 5% of annual gross output with de-icing equipment. Half of this – 2.5% – will be downtime due to rime icing, the other half will be energy required for de-icing. Again, this energy loss will be mainly during the winter and could account for ten or more percent of a winter month's energy production.

4.2.4 Transformer Losses

There will be two types of step-up transformers at each wind farm: one from the turbine voltage, around 1,000 V, depending on the model, to 12.47 kV. Each turbine will be equipped with a transformer to achieve the turbine connection bus voltage. A final transformer will be at the end of the collector lines in the switch yard. This transformer will step-up the voltage from 12.47 kV to either 69 kV or 138 kV, depending on the voltage of the transmission line it will connect to.

Both transformers are estimated as 98% efficient. Combined losses are therefore approximately 4% of turbine power output. Line losses are included in this estimate.

[8] Natural Power, *Ferry Hill Wind Feasibility Study, Stages 1 and 2*, 2010

4.2.5 Sub-optimal Performance

A number of factors, such as soiled rotor blades, can lead to sub-optimal performance of a turbine. We have assumed 1% losses due to sub-optimal functioning.

4.2.6 Maintenance Downtime

Each turbine will require preventive maintenance and will also experience some unscheduled downtime. The former may be accomplished in the summer when YEC has a surplus of hydropower and wind turbines can be taken off line with little consequence. We estimate that 2% of the potential annual energy output will be lost due to maintenance; half of this will be unscheduled over the course of the year, the other half during the summer as a regular revision.

4.2.7 Total Losses and Net Output

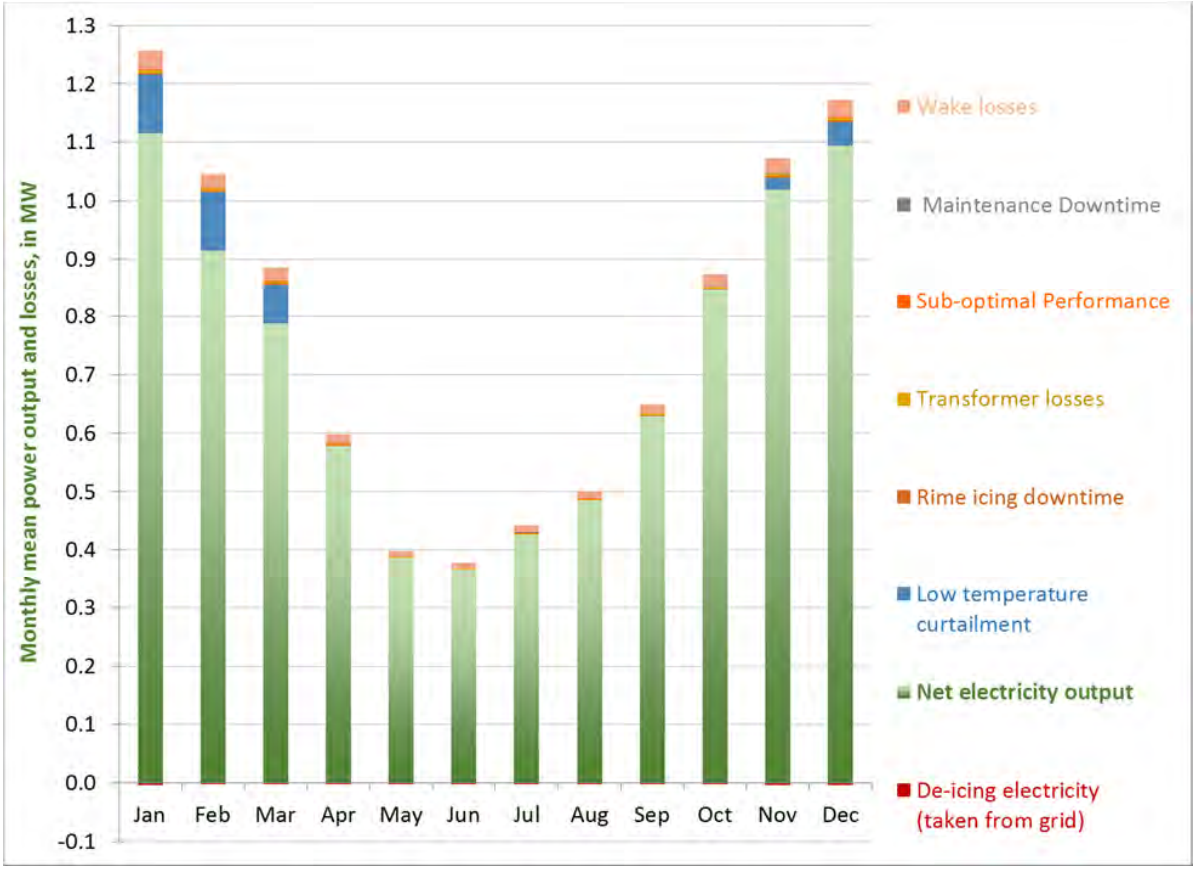
WAsP wind farm analysis software, which was used to create turbine layouts presented in Section 3, calculates wake losses due to shadowing between turbines, are specific to each capacity option per site, and are summarized in the following subsections. All other losses, however, are summarized in Table 7. Wake losses aside, we estimate approximately 9% annual energy loss for Kluane Lake and 14% for the other sites.

Table 7 Wind Farm Energy Production Loss Summary

		Kluane Lake	All other sites
1	Wake losses	0.83% - 4.45%	0.5% - 4.8%
2	Rime-icing downtime	1.0%	2.5%
3	De-icing energy (taken from the grid)	1.0%	2.5%
4	Low-temperature curtailment	0.7%	1.1% - 2.7%
5	Transformer losses	4.0%	4.0%
6	Sub-optimal performance	1.0%	1.0%
7	Maintenance	2.0%	2.0%
	Annual net production	**86% - 89%**	**81% - 86%**
	(% of gross output)		

Other restrictions may apply, such as curtailment of the wind turbines due to overcapacity of energy production during the summer. These limitations are outside the scope of this study and are not considered in Table 7 and other analyses of this report.

Figure 36: Monthly Mean Net Power Output for a GE-100-1.7 MW Turbine at Cyprus Mine

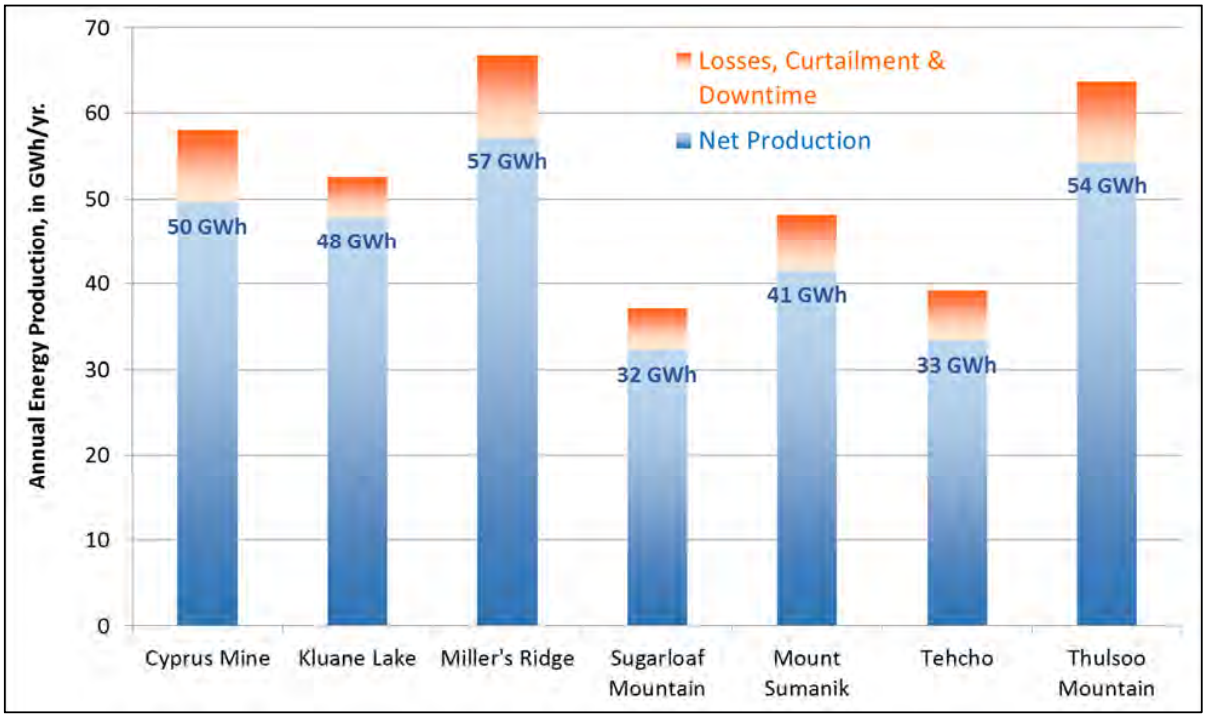


4.3 Annual Net Energy Production

The following graph compares the seven sites in terms of their annual net energy production (Figure 37) by site. Thulsoo and Miller's Ridge appear to be the highest yield sites, followed by Cyprus Mine. Sugarloaf Mountain, Sumanik Mountain and Tehcho are expected to produce significantly less energy. Kluane Lake, the only low elevation site, shows a sligthly lower annual gross output than the top performing sites. This comparison is based on a generic 2.0 MW turbine and does not take into account that different turbine choices might result in an improved performance. The overall ranking of the seven sites is unlikely to change.

A wind farm at Kluane Lake will still perform well due to lower de-icing losses and less curtailment due to extreme weather, such as temperatures below -30°C when most turbines are stalled to avoid failures. The financial analysis in the next chapter also takes lower site development costs for this site into account.

Figure 37 Summary Results of 20 MW Wind Farm Modelling: Annual net energy generation and losses;

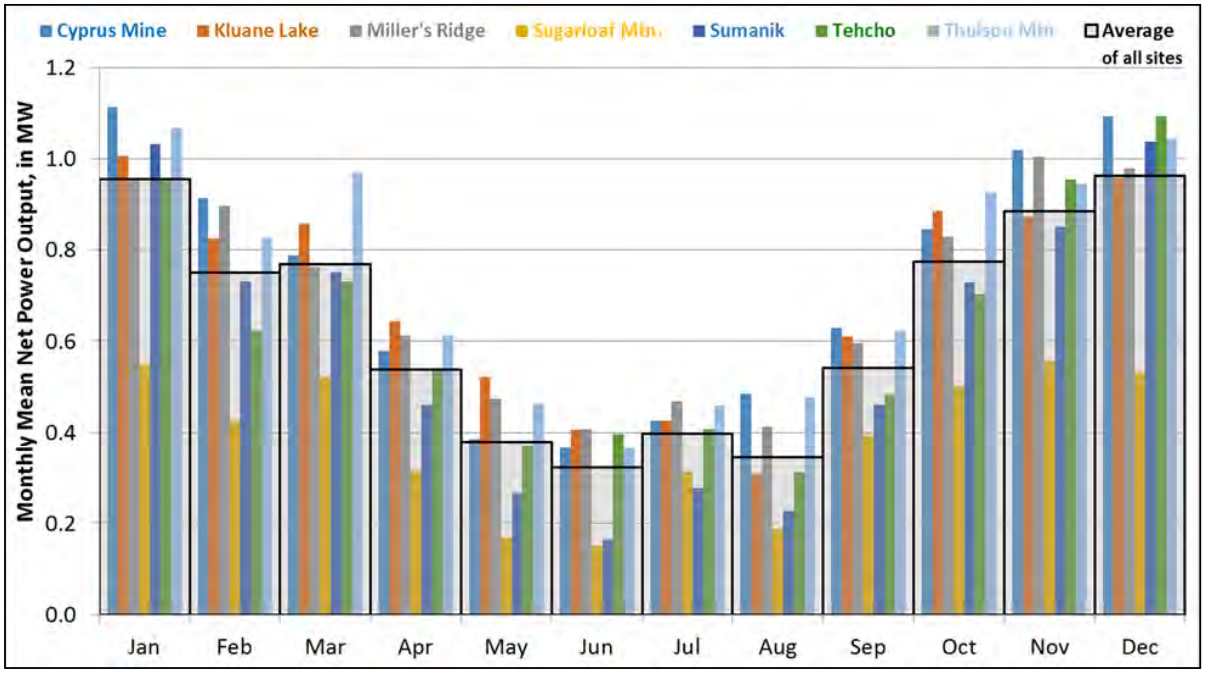


4.4 Monthly Generation Profile

All sites show a clear pattern of lower monthly mean power production in summer than in winter. This is despite the higher percentage of curtailment and parasitic electricity in winter. On average, two-thirds of the energy that the turbines feed into the grid are generated during the seven months from October to April. Mean power output in June and August is one third of the output in January. Wind power therefore fits well into YEC's demand profile.

There is no wind farm site that clearly outperforms all other sites for every month of the year – see Figure 38 below. The numbers below are based on the turbine model with the highest winter output. Wake losses are not included.

Figure 38 Monthly Power Output Profile of a Single 1.7 MW to 2.35 MW Turbine at the Seven Sites (excluding wake losses)



The mean annual power output is 26% to 28% of the nominal wind farm capacity, i.e. a 10 MW wind farm, for example, would generate on average 2.6 to 2.8 MW over the course of the year, more during the winter, less in summer.

For the purpose of creating data of monthly net electricity output of the three sizes of wind farms combined the annual gross energy production forecasted by the WAsP model with the monthly distribution of energy production of the AWS report. We then subtracted all other losses described in the main report to obtain monthly net electricity production data. The results given below are for a generic turbine (Vestas V-90) only. While the sum of the monthly electricity generation is accurate, the monthly data is an approximation only.

Table 8 Losses and Net Annual Energy Production of the Three Wind Farm Sizes
(after wake losses, after all other losses)

4.5 Reliable Winter Capacity

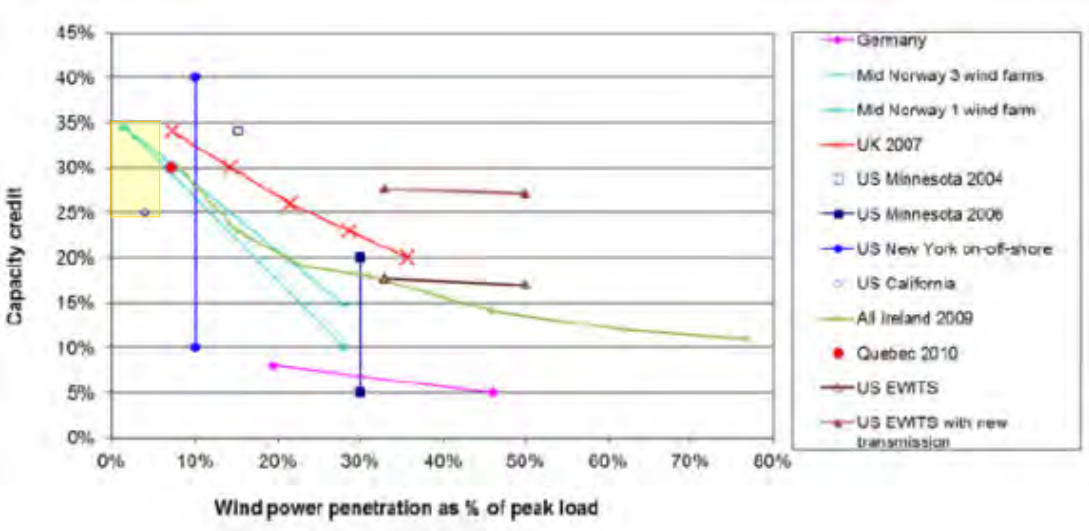
The Excel sheet for the financial analysis provided by YEC asks us to estimate "reliable winter capacity." We understand this to mean firm capacity for power generation, i.e. a minimum guaranteed output. Wind power is a variable resource and technically cannot guarantee any minimum output at any time of the year. There may be days when wind speeds are below the start-up wind speed, so output will drop to zero during these hours.

On the other hand, for planning purposes, wind power is recognized as having an ability to displace other power generation sources. For example, in Germany, the Effective Load Carrying Capability (ELCC) of wind power is valued at about 10% of its rated capacity for planning purposes.[9]

The capacity credit depends on various factors including grid penetration levels. The capacity credit decreases as the share of wind power on the grid grows. A 6-MW wind farm in the Yukon would have a 3% penetration of YEC's generation in 2015. For a 20-MW wind farm, the penetration level would increase to approximately 11% of the total generation in 2015 (416 GWh). A single wind farm in the Yukon can be considered low-penetration and would be located in the far left side of the graph below. [10] Worldwide, the ELCC for low penetration wind energy has been determined to be between 25% and 35% of total rated wind power capacity on the grid, see the yellow highlighted area in Figure 39 below.

At maximum output a 20-MW wind farm would deliver about one-quarter of the peak winter capacity demand and one-half of summer demand. There is a high correlation with the seasonally-changing load of YEC's grid: A wind farm will supply more energy in winter when more energy is needed.

Figure 39 Capacity Credit of Wind Power in Various Parts of the World[11]

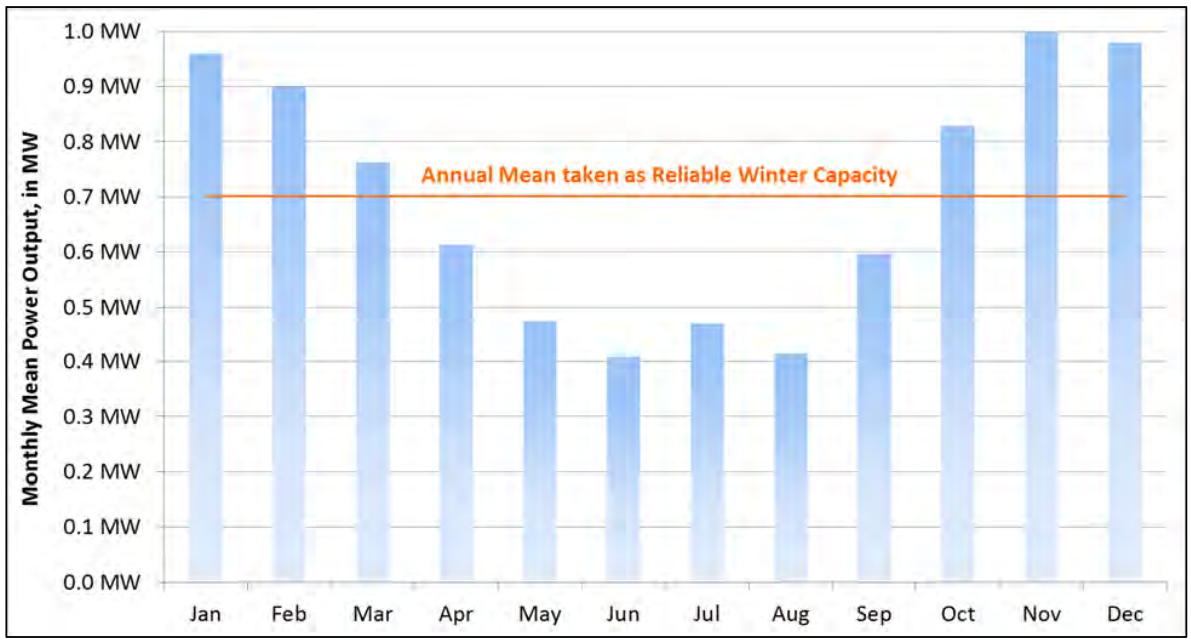


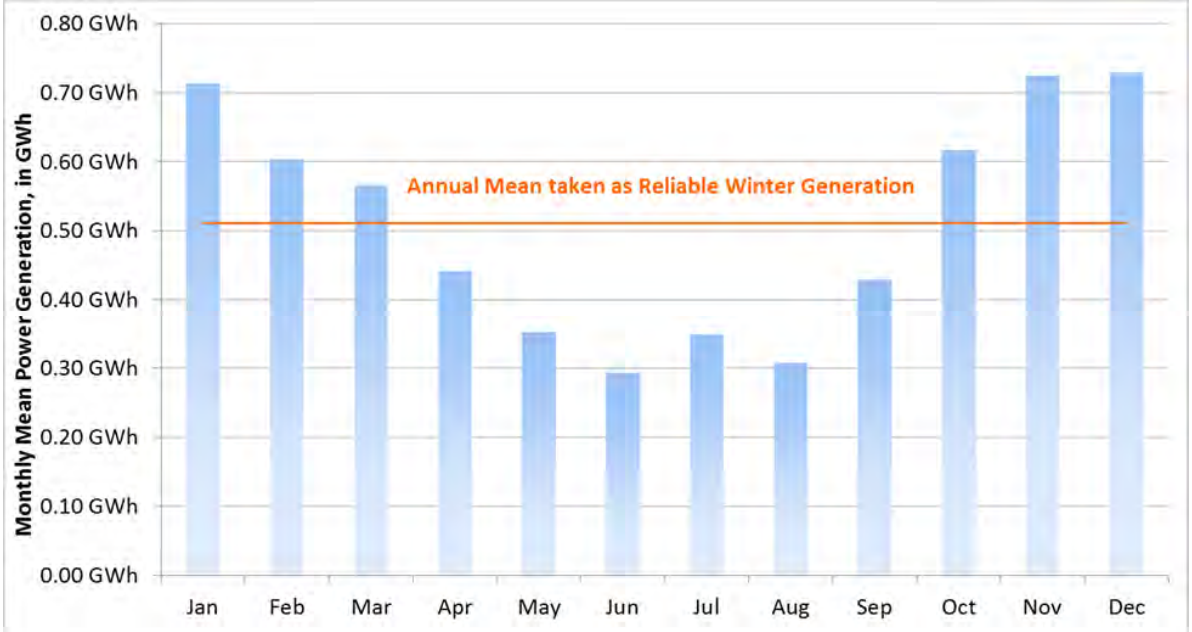
[9] See http://www.wind-energy-the-facts.org/capacity-credit-values-of-wind-power.html
[10] Penetration is defined as the fraction of energy produced by wind compared with the total generation
[11] Source: http://energyskeptic.com/2015/wind-capacity-value-elcc/

To account for varying capacity factors at the different sites examined, we estimate the reliable winter capacity is equal to the mean annual power output. This estimate is conservative, because the winter output from a wind farm in the Yukon is higher than the mean output see Figure 40 below.

This approach is an estimate and should be confirmed based on the Yukon energy mix, taking into account system flexibility, load profiles, and specific wind farm parameters. Additional wind farms would lower the capacity credit per farm; they could also increase the ability of wind to provide base load power (firm capacity) when they are geographically distant. This separation of sites increases the probability that wind will still blow at one site when it does not at the other. The combined wind farms will provide a minimum output because the start-up wind speed is virtually always reached at one of the wind farms.

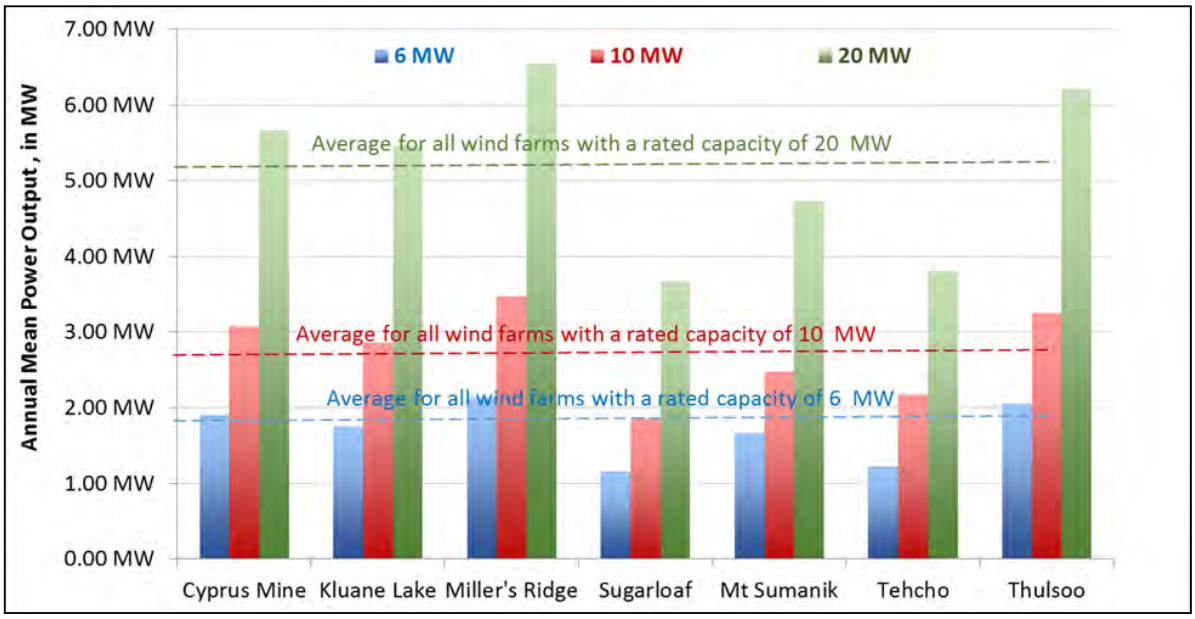
Figure 40 Seasonal Power Output and Reliable Winter Capacity of a 2.35 MW Enercon Turbine at Miller's Ridge





Applying this approach to all wind farm sizes and sites, the firm winter capacity ranges from 1.7 MW for a wind farm rated 6 MW (28% capacity factor) to 5.2 MW for a 20-MW wind farm (26% capacity factor) – see below.

Figure 41 Annual Mean Power Output taken as Reliable Winter Capacity



4.6 Turbine Choice

AWS Truepower Advanced Wind Site Assessment Reports were obtained for each of the seven selected sites. The advanced reports are designed to present an in-depth prediction of the wind resource of a site to include annual and month-specific mean wind speed, power density, Weibull dis-

tribution of wind speed, 50-year maximum gust, diurnal variation of speed and power density, and frequency and energy wind roses. The wind data in the AWS advanced reports is modelled at 80 meters above ground level, which is the hub height of the generic 2.0 MW wind turbine discussed in above and is a typical hub height of wind turbines in the approximately 2 MW class range. AWS Truepower Advanced Reports for each site can be found in Appendix I.

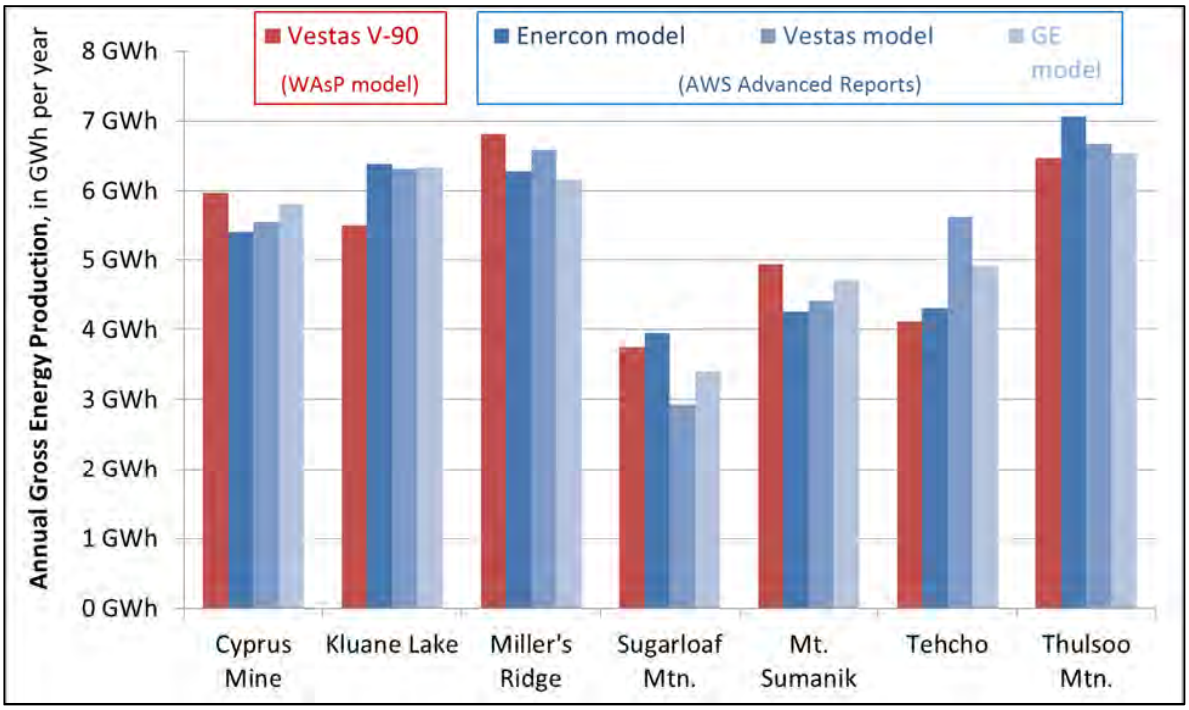
Besides a highly detailed description of the wind resource, AWS Truepower advanced reports contain annual energy production estimates for three different wind turbines selected by the user, at user-specified hub height. The project team focused on three wind turbine manufacturers: Enercon of Germany, Vestas of Denmark, and General Electric (GE) of the United States. All three are large, well-established companies with long track records of highly successful projects. For each of the seven profiled sites, an IEC wind classification was presumed based on the mean annual 80-meter height wind speed. With that, and by reference to the Enercon, Vestas, and GE websites, suitable 2 MW class wind turbine models were chosen and are listed in Table 9.

Table 9 Wind Turbines Profiled in AWS Truepower Advanced Reports

Site	Latitude	Longitude	Assumed IEC class	Enercon model	Vestas model	GE model
Cyprus Mine	62.422	-133.417	II-B	E92	V100-2.0	GE 1.7-100
Kluane Lake	61.214	-138.665	III-B	E92	V100-2.0	GE 1.7-100
Miller's Ridge	62.109	-136.568	II-B	E82 E2/2.3	V90-1.8	GE 1.85-87
Sugarloaf Mtn.	60.118	-134.642	III-B	E92	V110-2.0	GE 1.7-103
Mt. Sumanik	60.744	-135.284	III-B	E92	V100-2.0	GE 1.7-100
Tehcho	63.413	-136.677	III-B	E92	V110-2.0	GE 1.7-103
Thulsoo Mtn.	61.034	-136.932	II-B	E82 E2/2.3	V90-1.8	GE 1.85-87

With this selection AWS Truepower prepared Advanced Wind Site Assessment Reports for each of the seven sites (Appendix I). We then compared the annual gross energy output of each turbine provided in the Advanced Reports with the results of the WAsP model (Appendix G), see Figure 42 below.

Figure 42 Annual gross energy generation of various turbines using two models



For all sites, except Kluane Lake and Tehcho, the annual energy production predicted by AWS is in close agreement with the results of the WAsP model. In three out of the seven sites the Vestas V-90 turbine outperforms the best turbine of the Advanced Reports.

Table 10 Best Performing Turbine Models for each of the Seven Sites

Site	Best Turbine Model	Rated Capacity
Cyprus Mine	Vestas V-90	2.0 MW
Kluane Lake	Enercon E92	2.35 MW
Miller's Ridge	Vestas V-90	2.0 MW
Sugarloaf Mtn.	Enercon E92	2.35 MW
Mt. Sumanik	Vestas V-90	2.0 MW
Tehcho	Vestas V110-2.0	2.0 MW
Thulsoo Mtn.	Enercon E82 E2/2.3	2.35 MW

These results have to be taken with a grain of salt: A main difference in the two models is that the Advanced Reports determine the annual energy production of a turbine at only one particular location within the site. This site may not be the optimal location. WAsP, on the other hand, calculates wind speed and subsequently annual energy production at every location with the site. This allows placing turbines at the best spots. As a consequence WAsP tends to yield higher annual energy production than AWS. WAsP, on the other hand, takes the effect of the terrain's topography and turbu-

lences created by neighbouring turbines into account. In general the agreement between the two models is within 10% of each other providing sufficient confidence in the outcome.

The comparison also does not take into account the difference in low-temperature curtailment. Gearless turbines, like all Enercon models, can be operated below -30°C. For some sites, such as Tehcho this might increase output by up to 3.7% and outweigh the advantage of an optimized foil design.

Finally, the data above are annual energy productions. Seasonal energy production, e.g. from October to mid-May when electricity is most needed and when wind speeds tend to be higher favours turbines optimized for high wind speeds. Appendix H provides further detail.

In detail the following can be said about the turbine choice at each site:

- **Cyprus Mine**: The advanced report turbines and the WAsP V90 (20 MW average) are in close agreement, there is little difference between the four turbine types.
- **Kluane Lake**: Clearly, the turbines profiled in the advanced reports are more suitable for the Kluane wind regime than the Vestas V90.
- **Miller's Ridge**: Like Cyprus, the advanced report turbines and the generic turbine used for WAsP are in close agreement. The models worked well together.
- **Sugarloaf**: This site was complicated to analyze, with significant differences between the WAsP and AWS models. The close agreement of the results between the two is coincidental and masks these differences. Results for this site should therefore be regarded preliminary and would require on-site monitoring to confirm the resource.
- **Mount Sumanik**: The advanced report turbines and the WAsP V90 (20 MW average) are in close agreement. The models worked well together. That said, there are significant differences between the WAsP and AWS models.
- **Tehcho**: The turbines profiled in the advanced reports are more suitable for the Tehcho wind regime than the Vestas V90. Note though that the annual energy production of the Vestas V110 is quite a bit higher than the other two. Consultation with Vestas would be required to ensure that it is indeed a suitable choice for the site.
- **Thulsoo Mountain**: The advanced report and the WAsP V90 are in close agreement except with the Enercon E82. The other two choices are very similar. Consultation with Enercon would be required to ensure that it is indeed a suitable choice for the site.

Note that wind turbine manufacturer and model choice is a complex task and should a large wind project be developed in the Yukon, YEC is encouraged to consider not only other manufacturers besides Enercon, Vestas, and GE, but also the full suite of available models from each. It is possible, of course, that more optimal turbine choices are possible than those profiled in the AWS Truepower advanced reports.

5 FINANCIAL ANALYSIS

We conducted financial analyses for the seven sites described in the previous two chapters. The analyses are based on three main inputs:

1. Gross and net energy production of the wind farms
2. Capital cost estimates
3. Operational cost estimates

A predetermined Excel file supplied by YEC was used to determine various financial parameters. The file calculates these parameters in the same way for all energy technologies, allowing cross comparisons. The cost data feeding into the financial model were determined based on a variety of sources as outlined below, including direct quotes, expert estimates, previous studies, and experience with similar projects in remote areas.

For the financial analysis, we used the same turbines for all sites to allow for better comparability. In reality, turbine choices (brands and capacities) may vary between sites and should only be selected once one year of wind monitoring results are available.

5.1 Capital and Development Cost Estimates

We estimated capital costs for each of the seven sites and each of the three capacity sizes, 6 MW, 10 MW and 20 MW. The cost presented includes hard and soft costs, such as financing and project development costs. All costs are calculated at the point of interconnection to YEC's transmission line and in constant 2015 dollars.

Where applicable, we factored costs according to parameters determined during the layout of the wind farm as described in Chapter 3 above. Details are provided as Appendix C in the form of three Excel-files, one for each wind farm size.

The overall accuracy of these cost estimates is ± 30%, commensurate with the project definition of a pre-feasibility or screening level study (AACE Class 4). This accuracy can only be applied to the total capital cost, not individual line items.

For each site, we grouped capital costs into nine categories:

1. Logistics
2. Civil Works
3. Electrical Works
4. Labour Costs not already included in other cost items
5. Financing Costs
6. Land Costs
7. Project Development Costs
8. Equipment Costs
9. Contingencies

5.1.1 Logistics

This item summarizes all costs related to transporting the equipment to the site, including the following:

Transportation cost: $500,000 for transporting one complete turbine from the manufacturer by sea to either the Port of Skagway, Alaska,[12] or from the port of Vancouver, Oregon by train through Nelson, BC and on by truck. From the port it will take three trips per turbine by truck to transport mast, nacelle, tower, and other wind-farm-related parts, such as transformers. A 20-MW wind farm would require three trips to the site. Each trip is assumed to cost $100 per km, including empty returns. Transportation costs for a 20-MW wind farm range from $5.3 million for Kluane Lake to $6.5 million for Cyprus Mine, the farthest site from the port.

90-tonne crane for lay down etc.: A crane for taking equipment off the trucks and laying it down will be needed. A hydraulic crane of this capacity is available in Whitehorse. A lump sum of $30,000 is assumed for mobilization and de-mobilization plus $2,500 per day in the field. On average, four days are required to erect a turbine. High wind conditions may require an additional two days per turbine, for a total of six days. The total cost of the 90-tonne crane is $180,000 for a 20-MW wind farm.

550-tonne crane: A larger 550-tonne crane is required to erect the mast and lift the assembled rotors and nacelle in its location. Again, six days are assumed to erect a turbine, including idling time due to high or gusting wind conditions. This crane will have to be brought in from Edmonton at a cost of $200,000. Daily rental costs are assumed to be $15,000, whether in operation or idle. The total cost of the 550-tonne crane is $1,100,000 for a 20-MW wind farm.

Erection cost: Operating the crane and all other labour involved in the erection and installation of the complete wind turbine is budgeted at $450,000 per turbine. This is based on previous experience in remote BC and AB locations.

5.1.2 Civil Works

Construction costs include several items relating to access, site preparation, foundations, and transport of construction material such as gravel. These costs also vary based on site location, the length of the access road, and distance to Whitehorse. Additional factors can be the type of prevalent rock and the gradient to reach the site.

In general, gradients should not exceed 10% with a maximum of 14% to transport turbines by truck. Road width is five meters, the maximum road loading 70 tonnes. The minimum turning radius is 25 meters. This may require adjusting the access roads sketched out for this assessment, which may then become longer than anticipated at the prefeasibility level. It may also be necessary to use blasting to create access.

Road ways and road sides can be accurately planned using high-resolution LIDAR-derived digital elevation maps.

[12] Transport via White Pass and Highway #2 is unrestricted up to 77 tonnes (Dan Nickason, Highways & Public Works, April 2016)

Table 11 Costs of Civil Works

#	Item	Specific Cost	Comments
1.	Geo-technical report, Digital terrain model, Road way design	$75,000 total	Assume an engineer from AB or BC, some of the cost is mobilization; LIDAR map taken from flight over site
2.	Access road	250,000 $/km	From existing road to turbine road; may vary significantly according to geotechnical conditions
3.	Turbine road	250,000 $/km	Assuming gravel pit within 20 km distance
4.	Cement supply for foundation	300 m^3 per base, $575 per m^3	Mobile concrete plant
5.	Cost of rebar including delivery	35,000 kg per base, $1.5 per lb	Delivered to site
6.	Foundation installation cost	$60,000 per base, including labour	Depends on type of foundation (geo-tech conditions)

The construction of a wind farm is expected to take at least three years in the Yukon, due to the short construction season of only five months. We assume that the road would be built in one year and then the turbines would be purchased and set up in the following year. Turbine parts would be transported by truck, with two blades and two nacelles per truck.

Note that a special permit is necessary for transporting loads heavier than 77 tonnes.[13] The construction crane may weigh considerably more than this, but components such as the boom or counter weights are usually transported separately. Without these the transport weight of the crane would be 54 tonnes.

We anticipate about 90 days of construction activity to pour ten foundations for wind turbines. This concrete needs to cure for about 30 days, which means that turbine erection can start halfway into the concrete-pouring task while the last foundations are still being completed. Turbine foundations may be either anchors or concrete foundations (assumed here, and conservatively costlier than anchors). We have based our estimate on a quote for labour and material from a local construction company, resulting in costs between $475,000 to $1,029,000 per turbine, depending on the size of the wind farm.

For the access and turbine-connecting roads, we assume a cost of $250,000 per km. A local service provider quoted a budget price above $1 million per km though. This quote is, however, not in line with previous Yukon experience and is based on trucking gravel from Whitehorse. On the other hand, the need for blasting or adjusting gradients and poor geotechnical conditions may increase road construction costs at specific sites.

5.1.3 Electrical Infrastructure

The following items were considered for the cost of the electrical infrastructure:

[13] The stator/rotor of an Enercon turbine may weigh more than 80 tonnes.

Table 12 Electrical Infrastructure Costs

#	Item	Specific Costs	Comment
1.	Low voltage step-up transformers	$60,000 per piece	Per turbine 1 kV/12.47 kV step-up transformer
2.	Collection system	$200,000 per km	Underground cable
3.	Substation	$2,500,000 total	12.47 kV/138 kV step up transformer & switching yard
4.	Interconnection to existing transmission line	$500,000 per km + 17% engineering and interest	Including labour; see Table 13 for details
5.	Line-tap & protection system	$1,500,000 total	From high voltage transmission to utility tx (gang switch with fused cut-outs)

To interconnect the turbines before they are connected to the transmission line transformer (collection lines), we assumed costs of $200,000 per km, including the cost of burying cables and/or a concrete channel.

The estimate for transmission line construction (about $500,000 per km plus 17% owner's cost) is informed by the Stewart Keno project cost estimate, see Table 13 below.

Table 13 Per-Kilometre Line Construction Costs

Cost Item	Yukon, Stewart Keno Project Estimate
Material, labour & line	$366,882
Contingency & Escalation	$67,632
Project management	$51,312
Other	$12,684
Sub-total	**$498,510**
Owner's cost (17%)	$84,747
TOTAL	**$583,257**

In addition to transmission line construction, a protective switch (line-tap & protection system from high voltage to utility transmission) needs to be installed at the interconnection with existing long-distance transmission. We ascribed this cost to transmission cost and budgeted $1.5 million. Transformers ($600,000 per wind farm) were considered part of the wind farm capital cost and are thus are not included in the transmission costs.

Total interconnection cost range from $3.5 million for Tehcho to $9.4 million for Miller's Ridge. Land costs are not included and are given in Table 14 below.

5.1.4 Labour Costs

Much of the labour cost has been included in the estimated above, e.g. for road and transmission construction. Additional labour costs for personnel involved in turbine erection and other tasks above and beyond what is already accounted for are estimated at 10-person-years per site and 1 person-year per turbine. We assumed labour costs of $200,000 per person-year including over-

head, but excluding per diem. The latter adds $150 per day per person for 250 days of construction over a two-year period. Again it is assumed that most of these personnel will come from outside the Territory or will be too far from their homes and therefore require accommodation.

5.1.5 Financing Costs

Legal costs to arrange financing are estimated at $800,000, independent of the size of the project. Additionally, we budgeted bank financing costs or lender charges at 1.5% of capital cost, i.e. around $1 million for a 20 MW farm. These are charges leveraged by credit institutions to cover for the administrative costs of arranging for a loan.

5.1.6 Land Costs

We have estimated land costs based on the surface area required for both the wind farm and road and transmission access, for each of the seven sites as laid down in Chapter 3.8 above. For land without existing ownership as per the GeoYukon site, we assume the land will be purchased at a rate of $500 per acre.[14] At this rate, costs range between $60,000 and $230,000, less than 1% of the total cost.

For turbines, roads and/or transmission lines on First Nation land we assume land will be leased. Annual leasing rates for First Nation land are assumed as 10% of purchasing costs, and are not included here but under operational costs in Chapter 5.2.

Total land area to be acquired, including access roads and easement for power lines, range between 76 ha (Kluane Lake) and 189 ha (Miller's Ridge) for a 20 MW farm, see Table 14 below. Land for Kluane Lake and Sugarloaf Mountain will have to be leased. A developer may want to rent enough land to set up the turbines for the initial three years of the project and then purchase only the land required by the turbines.

Table 14 Land Costs for a 20 MW wind farm

Site	Total road length	Total power line length	Land area	Land price	Land Cost
Cyprus Mine	13.4 km	16.2 km	146 ha	$2,000 /acre	$703,956
Kluane Lake	2.0 km	6.2 km	76 ha	$2,500 /acre	Lease only
Miller's Ridge	8.3 km	21.8 km	189 ha	$2,000 /acre	$913,294
Sugarloaf Mountain	6.8 km	10.6 km	74 ha	$2,500 /acre	Lease only
Sumanik	7.5 km	10.7 km	99 ha	$2,500 /acre	$596,511
Tehcho	7.4 km	10.8 km	69 ha	$2,000 /acre	$332,088
Thulsoo Mountain	8.5 km	19.2 km	178 ha	$2,000 /acre	$860,283

[14] YEC paid up to $2,000 per acre for the development of the Mayo B plant area in 2010. According to the YUKON AGRICULTURE STATE OF THE INDUSTRY REPORT 2010–2011–2012, titled agricultural lands within 30 minutes from Whitehorse have been valued at over $3,000 per acre while land located 30 to 60 minutes from Whitehorse has been valued at around $2,500 per acre.

5.1.7 Development Costs

We budgeted eight items for the development of a wind energy project. Development costs presented include all aspect of project development. Table 15 itemizes individual items.

Development costs are estimated at $1.9 million. This also includes wind monitoring,[15] bird/bat studies, stakeholder relations and internal personnel costs.

Development costs are a fixed cost and are the same for a 6 MW wind farm as for a 20 MW wind farm.

Table 15 Development Costs (2015 $)

#	Item	Cost	Comments
1.	Wind measurement campaign	$200,000	LIDAR equipment lease or Met-tower purchase, installation & operation
2.	Environmental assessment (incl. FN consultation)	$300,000	Bird/bat studies
3.	Stakeholder relations	$100,000	Open houses, etc.
4.	Engineering	$300,000	For logistics, construction layout, interconnection studies, turbine supply
5.	Legal fees (various)	$500,000	Leases/land agreements, FN joint agreement, construction contracts, project equity
6.	Legal fees for turbine supply agreement	$250,000	Sales contract
7.	Legal fees for stakeholder relations	$50,000	Appeals, tribunals
8.	Development personnel and travel	$200,000	Owner's cost / YEC staff
	TOTAL	**$1,900,000**	

5.1.8 Equipment Costs

Wind turbine costs for the Vestas V-90 2.0 MW turbine, including de-icing kits, are estimated as $1.2 million per MW, delivered-duty-paid (DDP). A comparable Enercon turbine would be $1.3 million per MW but would likely have less curtailment and lower maintenance costs. Higher up-front capital costs would be traded for lower operational costs. This option, however, has not been modelled but should be researched during the next phase of the project.

5.1.9 Contingencies

10% contingency is included in the capital cost estimate. This includes the risk of currency fluctuations.

[15] To develop a wind site in the Yukon, both wind monitoring and icing monitoring are necessary. The report on Ferry Hill (Tehcho) estimates costs of about $200,000 for the wind monitoring mast with icing detector, as well as annual costs of about $25,000 for a generator and cell phone connection.

5.1.10 Total Capital and Development Costs

Figure 43 compares the capital costs of each of the seven wind farm sites selected for this assessment. Land and development costs are small items compared to equipment costs, transmission (electrical), and labour required for wind farm construction. Road costs are included in civil works, together with the turbine foundations, but are not among the most significant cost items.

Most of the larger cost items are fairly well established based on past experience with wind farms. As such, it appears that currency exchange risk is the most important factor that could affect wind farm construction costs, since it may affect equipment costs and also much of the labour cost anticipated. Site-specific differences, such as more expensive road construction, would not by themselves have a major impact on overall capital costs. Capital costs for the seven sites range from $3.0 million to $3.6 million per MW of rated capacity and are within a 20% margin of each other.

As Figure 44 shows, less than one-third of the total capital expense is for the turbine equipment itself. Most of the money will be spent in the Yukon. Kluane Lake would be the cheapest to develop as it would be right next to a planned transmission line.

Figure 43 Capital and Development Costs of the Seven 20 MW Wind Farm Sites

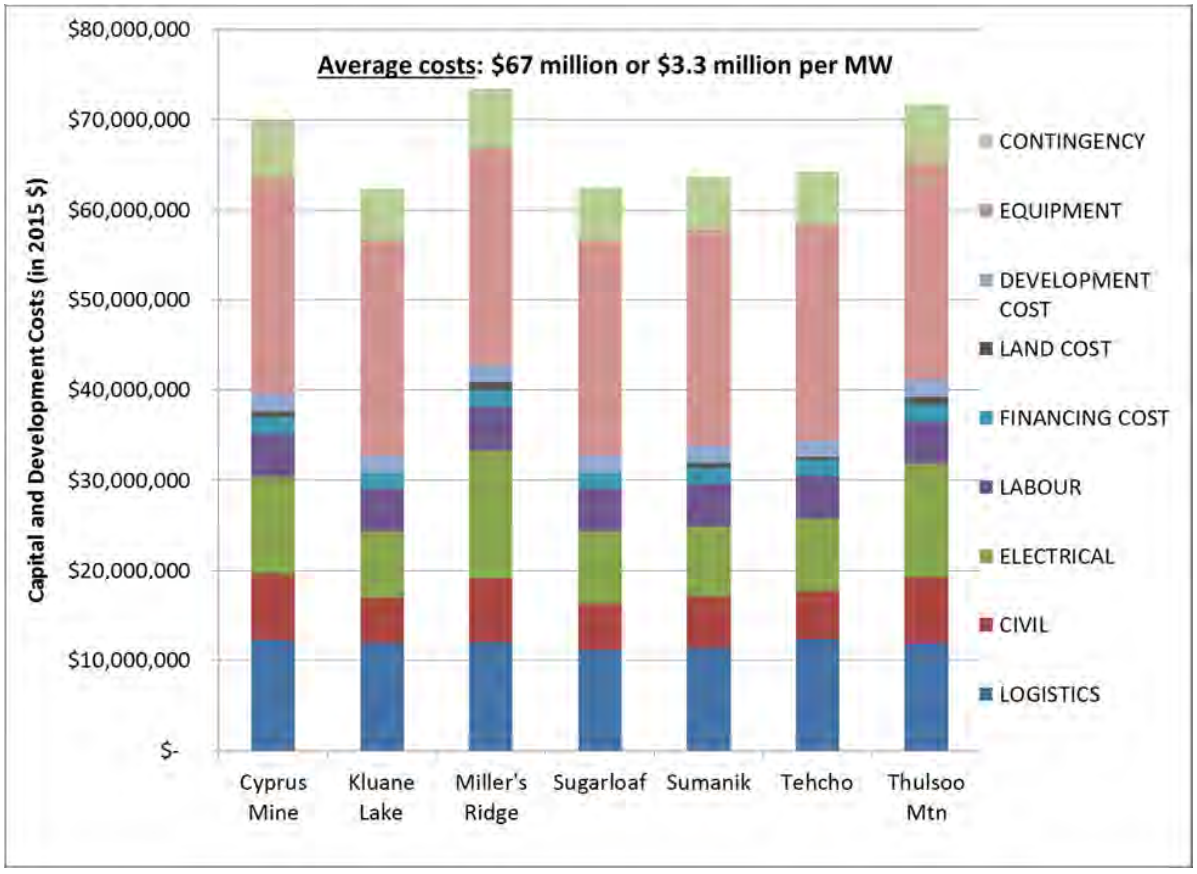


Figure 44 Capital and Development Costs of a 20 MW Wind Farm at Miller's Ridge

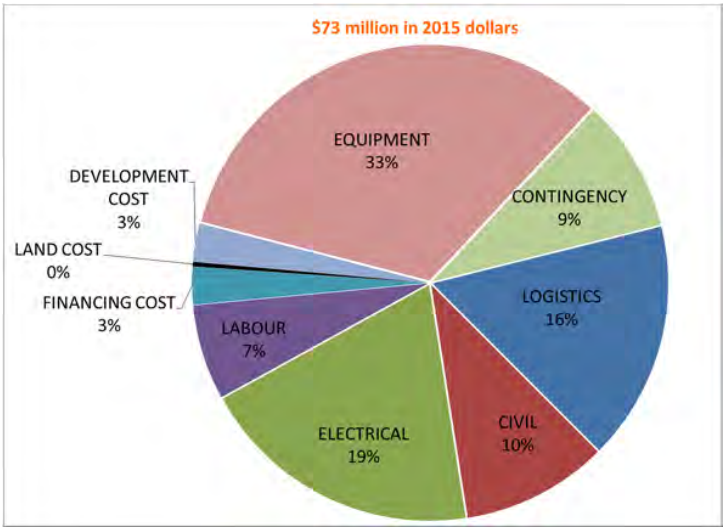

Figure 45 compares the capital cost items for three different wind farm sizes for Miller's Ridge. Since development costs and much of the electrical costs (transmission line) are fixed, their proportion of the capital costs increases as the farm size decreases. Equipment costs are an average of 33% for the 20-MW wind farms, 25% for a 10-MW size and only 20% for the 6-MW wind farms. For this site, the specific capital costs increase from $3.6 million per MW for a 20-MW wind farm to $4.8 million for a 10-MW farm and $6.5 million for a 6-MW wind farm.

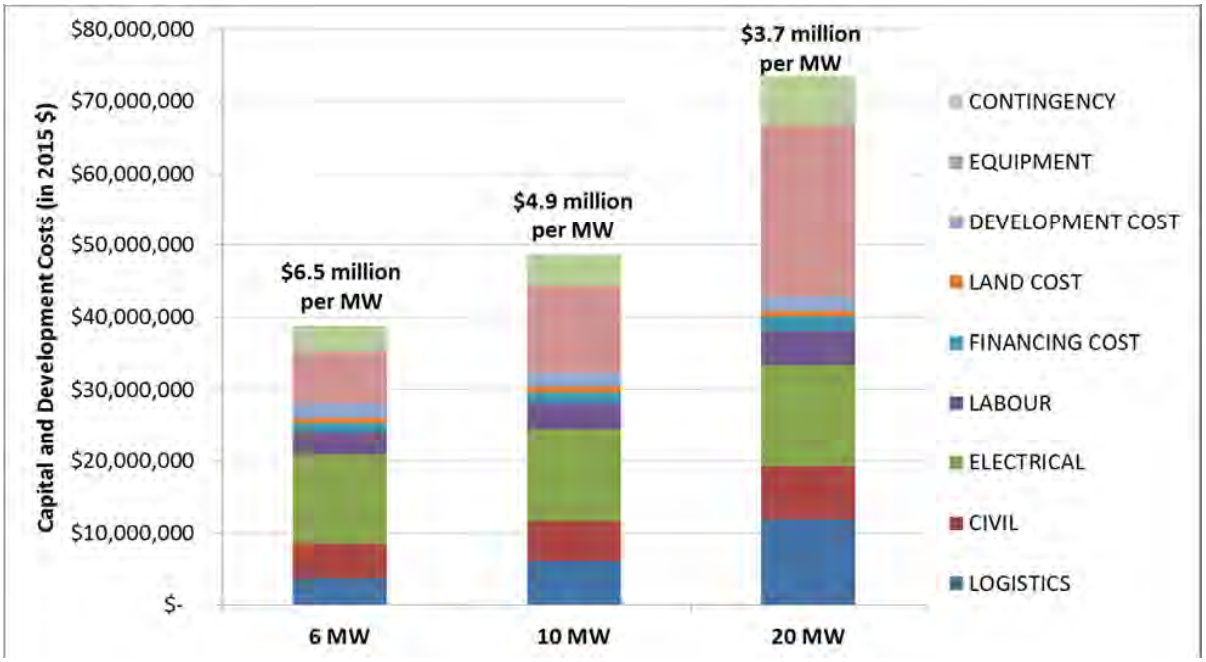
Figure 45 Capital and Development Costs of Three Sizes of Wind Farms at Miller's Ridge



5.2 Operational Costs Estimate

5.2.1 Fixed Operational Costs

YEC would have to employ two technicians to be working out of an office near any of the planned wind farms for small maintenance and troubleshooting and other operational purposes. Most sites are within about 200 km from Whitehorse, and the Tehcho farm would likely be serviced out of the existing Mayo office. We therefore assume $60,000 annual office rental costs only for the Cyprus Hill and Kluane sites. The salaries of these technicians have been considered at a cost of $100,000 per year, per person. Other fixed costs include:

- For turbines on aboriginal land, we assume the land will be leased at a cost of 10% of the theoretical purchasing price of $2,500 per acre. [14]
- Insurance costs are estimated at 0.15% of capital costs.
- There is a cost per turbine for its own electricity consumption (mainly for de-icing, some for lighting) but we accounted for this by reducing net output due to icing losses.

We further assume that no property taxes will have to be paid as none of the sites examined lie within municipal administrative borders.

Table 16 Fixed Operational Costs (2015$)

#	Item	Specific Cost	Annual Costs
1.	Operators	Two staff per wind farm	$200,000
2.	Office	$5,000 per month, (only for sites too far from existing YEC offices)	$60,000
3.	Insurance	$0.15 per $100 of CAPEX	$90,000 to $107,000 for 20-MW farm
4.	Land lease	10% of $2,500 per acre = $603/ha [14]	$46,000 (Kluane) to $45,000 (Sugar-loaf) for 20-MW farm

5.2.2 Variable Operational Costs

Wind turbine manufacturers offer service contracts that are calculated based on turbine output. For the Vestas V-90, annual service contracting costs of $15/MWh are assumed. This cost only applies to the first five years, increasing to $25/MWh until year 10, then to $30 after that.[16] This cost would include gearbox replacements every seven years (the Vestas turbine is not gearless; gearless turbines are discussed in Section 4.6).

In addition, royalties will have to be paid for turbines on aboriginal land. We assume that 5% of wind farm revenue would be paid to aboriginal landowners. Revenue is based on net energy output and valued at $120 per MWh, similar to retail electricity prices). We also applied a 5% contingency to variable costs.

[16] Enercon has lower rates that only increase once, after 10 years. This has not been modelled.

Table 17 Operational Costs for a 20 MW Wind Farm (annual, Year 1 -5)

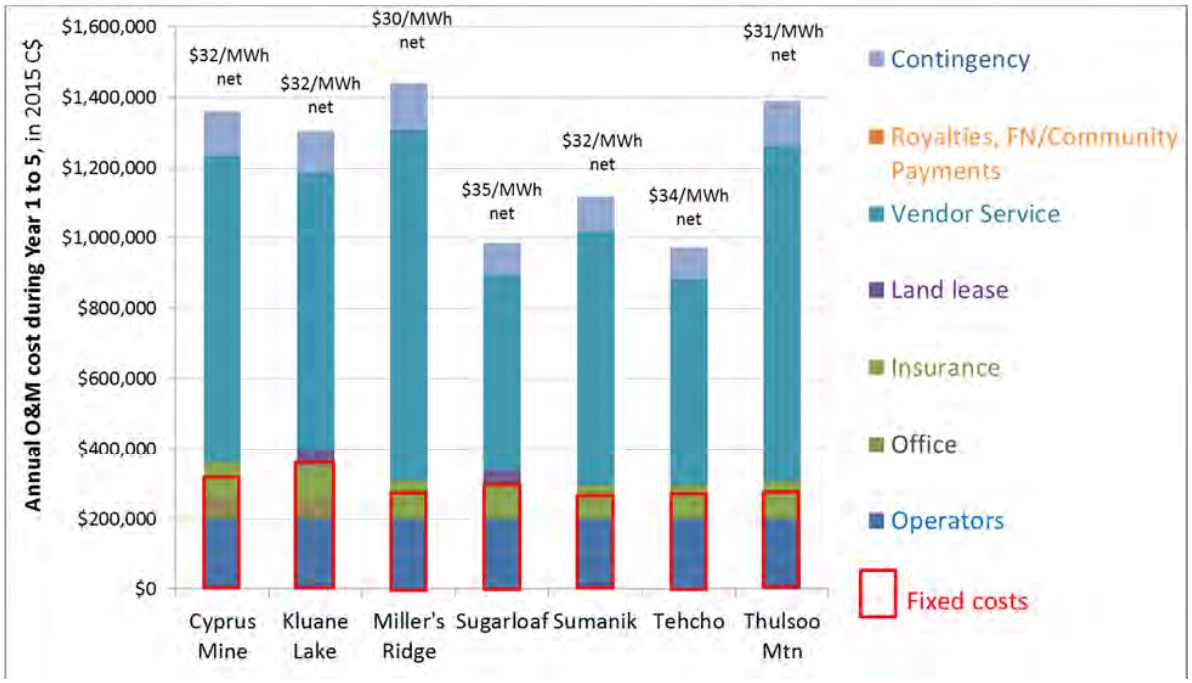
Site	Fixed Costs				Variable Costs		
	Office costs	Operators	Land lease	Insurance	Contin-gency	Royalties	Vendor Service*
Cyprus Mine	$60,000	$200,000		$104,018	$123,661	$0	$871,725
Kluane Lake	$60,000	$200,000	$45,858	$93,560	$118,777	$0	$788,355
Miller's Ridge	n/a	$200,000		$110,238	$131,093	$0	$1,000,695
Sugarloaf	n/a	$200,000	$44,573	$93,649	$89,487	$0	$556,650
Sumanik	n/a	$200,000		$95,476	$101,743	$0	$721,950
Tehcho	n/a	$200,000		$96,460	$88,374	$0	$587,280
Thulsoo Mtn	n/a	$200,000		$107,556	$126,361	$0	$956,055

Note: Sites in *italics* are on aboriginal land; assumes land lease; * Service contracts are based on turbine gross output

The largest share of the O&M costs are the vendor service contract: For a 20 MW turbine 55% of the operational costs are spent on getting the turbines regularly serviced and parts replaced by trained technicians. Because service contracts are based on energy generated, YEC may consider shutting the turbines down during the summer period when no power is required.

Figure 46 illustrates the magnitude of the individual O&M costs.

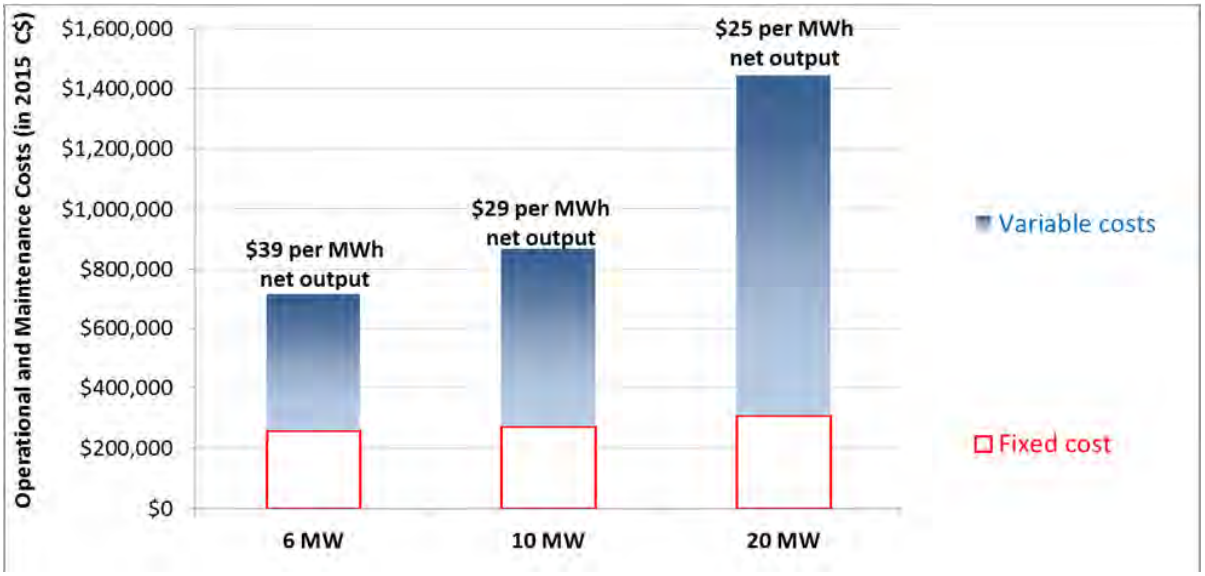
Figure 46 Operation and Maintenance Costs of a 20 MW Wind Farms at the Seven Sites



Operational costs were very similar for each site: fixed costs $265,000 for a 20 MW wind farm to $317,000 per year for a 6 MW wind farm and variable costs of about $24/MWh for all sizes of wind farms. Sugarloaf and Tehcho have low capacity factors (based on net production after losses due to icing, maintenance, etc.), which explain their lower financial performance.

Because the bulk of O&M costs are variable, there is only a small reduction of O&M cost from building larger-size wind farms. Figure 47 illustrates this.

Figure 47 Operation and Maintenance Costs of Three Wind Farms Sizes at Miller's Ridge



5.3 Financial Modelling

Table 18 summarizes the economic modelling results for each site. More detailed results can be found in Appendix D. The values below are based on a real weighted average cost of capital (WACC) of 3.38%. Two more cases (4.61 and 8.82%) can be found in the appendix. The lifetime of each of the wind farms is assumed to be 25 years.

At 3.38% WACC, the levelized cost of energy (at full utilisation, i.e. no curtailment) at almost all sites and all sizes remains under the current Yukon standard offer price of 21¢/kWh [17] but above the residential rate of 12¢/kWh [18] , see the Table 18 and Figure 48 below. For some sites the self-generation costs, the levelized cost of energy, is as low as 12.5¢/kWh. This is not as good as some more southern wind farms, which may produce at between 8 and 10¢/kWh, but highlights the good wind regime at some Yukon sites.

Of the seven sites selected, five show above-average performance in terms of the cost of energy produced. These sites are, in the order of performance, Kluane Lake, Miller's Ridge near Carmacks,

[17] Yukon Energy Mines and Resources: „ENERGY STRATEGY FOR YUKON - Independent Power Production Policy" May 20, 2014, page 7
[18] YEC's Residential Rate Schedule 1160 (Hydro, Non-Government) in May 2016: 12.14 ¢ per kWh for the first 1,000 kWh.

Thulsoo Mountain near the Aishihik hydroelectric facility, a mountain ridge near Cyprus Mine, close to Faro, and Mt. Sumanik near Whitehorse. On the other hand, we notice that both Sugarloaf Mountain and Tehcho have lower performance than the remaining sites, with Kluane Lake and Miller's Ridge showing the best financial performance. There is some, but not a lot of difference in energy production cost between these five sites; non-monetary factors may play an important role in selecting the preferred location.

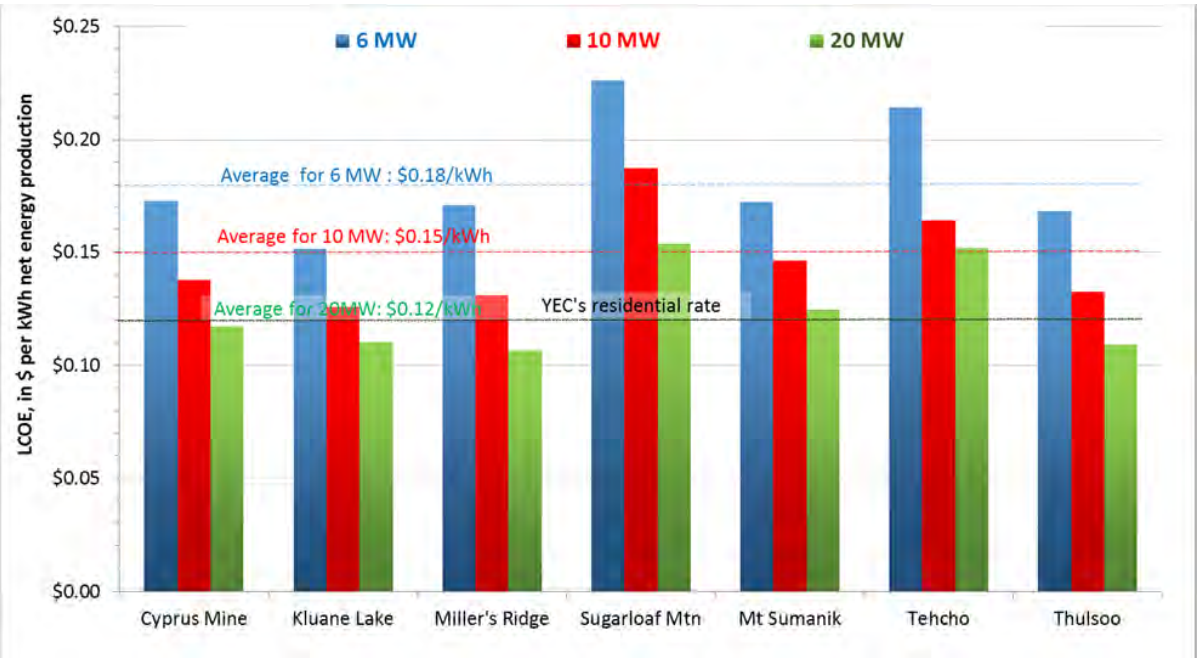
Table 18 Financial Modelling Results

Site	6 MW		10 MW		20 MW	
	Capital Cost (million $)	Levelized Cost of Energy *	Capital Cost (million $)	Levelized Cost of Energy *	Capital Cost (million $)	Levelized Cost of Energy *
Cyprus Mine	34	17.3¢/kWh	44	13.8¢/kWh	69	11.7¢/kWh
Kluane Lake	26	15.1¢/kWh	36	12.6¢/kWh	62	11.0¢/kWh
Miller's Ridge	39	17.1¢/kWh	49	13.1¢/kWh	73	10.7¢/kWh
Sugarloaf Mountain	28	22.6¢/kWh	38	18.7¢/kWh	62	15.3¢/kWh
Mt. Sumanik	30	17.2¢/kWh	39	14.6¢/kWh	64	12.4¢/kWh
Tehcho (Ferry Hill)	28	21.4¢/kWh	39	16.4¢/kWh	64	15.1¢/kWh
Thulsoo Mountain	36	16.8¢/kWh	46	13.2¢/kWh	72	10.9¢/kWh
Average	**32**	**18.2¢/kWh**	**42**	**14.6¢/kWh**	**67**	**12.5¢/kWh**

** at 3.38% real weighted average cost of capital (WACC), 25 years life expectancy, no curtailment*

Financially, the site at Kluane Lake performs best of all seven sites, despite its mediocre wind resources. This can be explained by the very short transmission connection required once the new line is built. Also, less rime icing and less frequent low temperature curtailment helps to increase the net energy generation. Though there are plans, currently there is no transmission line at this site.

Figure 48: Levelized Cost of Energy (LCOE) by Site and Wind Farm Size at 3.38% Real WACC



Due to fixed costs and economies of scale, larger wind farms have lower energy production costs than smaller ones. The cost of energy at the seven sites averages 13 ¢/kWh for a 20-MW wind farm, but increases to 18 ¢/kWh for a 6-MW capacity, see the table below. Our modelling assumes that all energy produced will be used. Curtailment of the operation during the summer when YEC has a surplus of power would increase the cost of energy produced during the rest of the year by more than a third.

5.4 Sensitivity Analyses

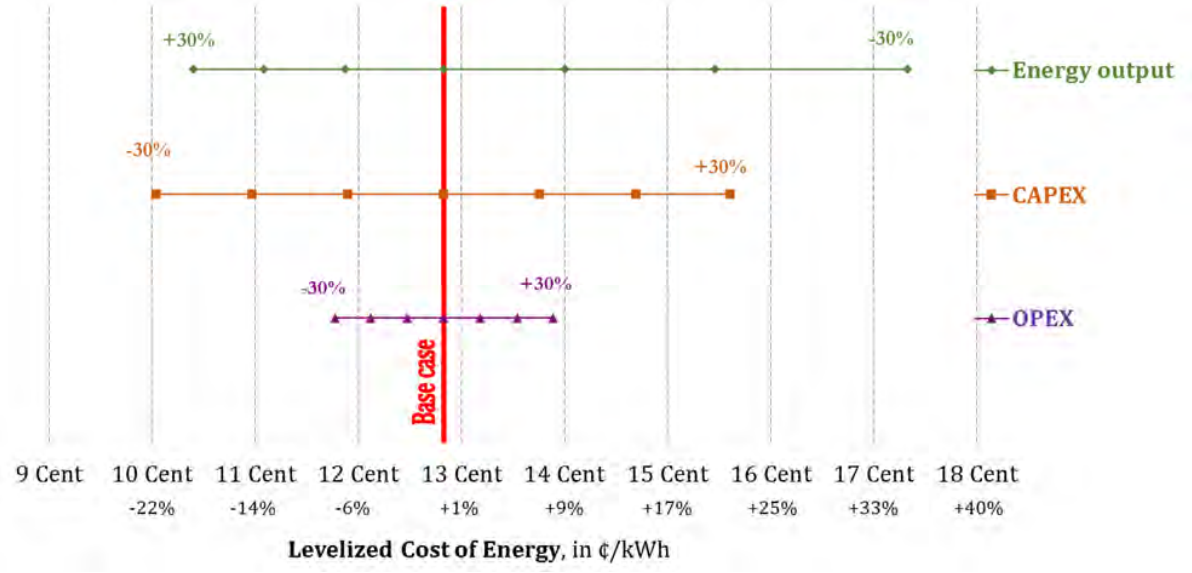
The data above are based on the given assumptions and naturally contain errors. We estimate the margin of error as ±30% for each of the three main inputs: energy production, capital costs and operational costs.

We conducted a sensitivity analysis on key variables affecting the financial results. This involved recalculating the cost of energy (LCOE) for different values of the energy production, capital costs and operational costs. Varying these input parameters, one at a time, by as much as +30% to -30% of the original value, we noted the change in the financial evaluation. The impact of the parameters on the cost of energy is illustrated in the graph below for a 10-MW wind farm at Kluane Lake. The results of the sensitivity analysis for the 20 MW wind farm at Miller's Ridge were comparable. Other sites are likely to show a similar sensitivity.

The results indicate that the project is most sensitive to the forecasted energy production. Assuming a 30% lower net energy production than forecasted would result in energy costs (LCOE) of 16.8 cents per kWh rather than the 12.5 cents determined in the base case. 30% higher operational costs, on the other hand would only increase the cost of energy to 13.5 cents per kWh. A 30% error

in capital costs would yield a 22% error in energy costs. All numbers use weighted average cost of capital (WCAA) of 3.38%.

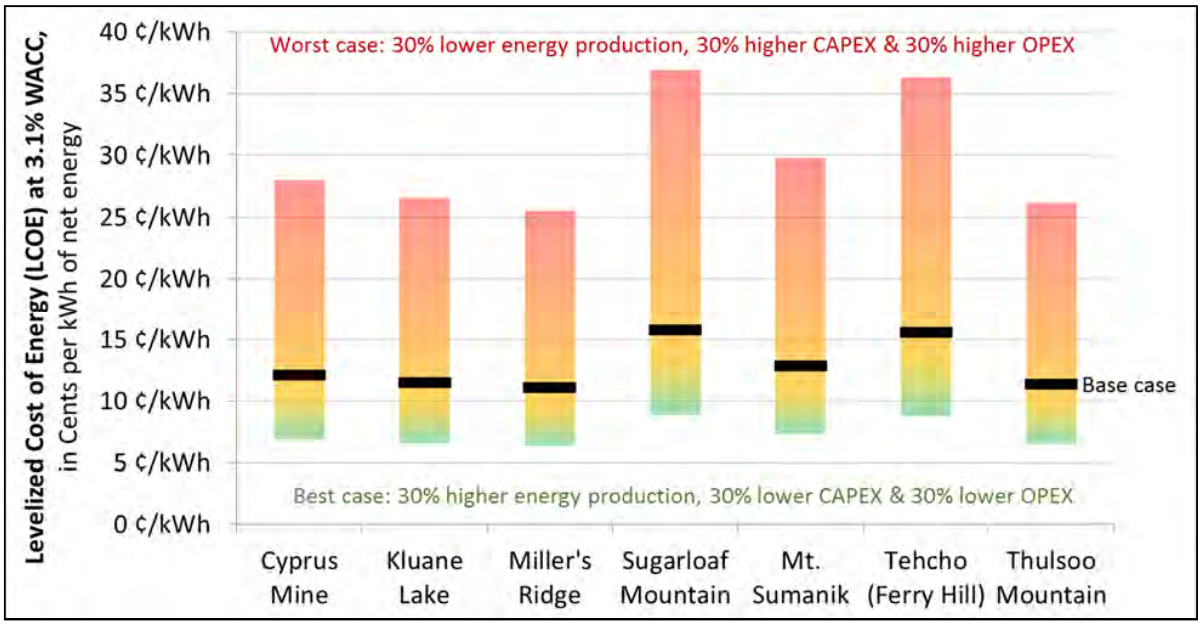
Figure 49 Sensitivity of the Cost of Energy (LCOE) of a 10 MW Wind Farm Size at Kluane Lake at 3.38% Real WACC



This underlines the importance of monitoring wind speed, rime icing, and temperature at selected sites. These are key parameters that will determine the output of a generator and thereby the financial performance of the wind farm.

Because the margin of error is 30% for each of the three main input parameters, a worst-case scenario would be 30% lower annual energy generation and 30% higher capital and 30% higher operational costs then determined in the base case. Conversely, a best-case scenario would be 30% higher energy production and 30% lower capital and operational costs. The resulting margin of error of the cost of energy is + 75%/-43% and is illustrated in Figure 50 below. Further project definition is needed to reduce the error margin.

Figure 50 Margin of Error of the Cost of Energy (LCOE) of the 20 MW Wind Farms



6 ADDITIONAL INFORMATION

6.1 Ice Mitigation Review

Rime icing of concern for wind power forms when small, wind-driven, super-cooled water droplets in clouds rapidly freeze on contact with a surface at sub-freezing temperatures. This often occurs during winter on high elevation mountains and ridges exposed to humid, maritime climate-influenced winds. At sub-arctic latitudes such as in the Yukon, rime icing conditions occur at lower elevations and are of longer seasonal duration than at temperate latitudes.

Figure 51 Rime Icing on Guy Wire of Collapsed Met Tower in Alaska

The frozen droplets contain a mixture of ice and trapped air, are rough surfaced and crystalline in structure, and are opaque to semi-transparent (see Figure 51). Rime ice can be heavy and quite tenacious in its grip on the contact surface and to itself, which can lead to a tremendous accumulation of weight. Rime ice accumulation on the wings, propellers and/or engine nacelles of aircraft has resulted in many aviation fatalities and explains why commercial aircraft are often carefully de-iced (and coated with an anti-icing solution) prior to take-off during the winter when atmospheric icing conditions are anticipated.

Wind turbine rotor blades are rotating airfoils, and can accumulate rime ice on the leading edges during icing conditions. In contrast to an aircraft which flies through an icing risk zone relatively quickly, a wind turbine is fixed in place and for energy production reasons, especially in higher-latitude, mountainous terrain, must be located at sites with considerable environmental rime icing risk. Rime icing adversely affects wind turbine performance in three ways:

- Ice accumulation on the leading edges of the rotor blades reduce aerodynamic efficiency and spoil lift,
- Asymmetric accumulation of ice on the rotor blades leads to vibration and subsequent shutdown,
- Ice accumulation on control sensors results in erroneous control functions, such as maintaining the turbine in shut-down mode even with sufficient wind for energy production.

A number of wind-power studies and journal articles address Yukon icing potential for wind power operations. These papers proved very helpful to the project team for consideration of icing risks and anticipated energy production cost in the Yukon. They include:

- Maissan, John, *Wind Power Development in Sub-Arctic Conditions with Severe Rime Icing*, Circumpolar Climate Change Summit and Exposition, March 2001
- Pinard, Jean-Paul, *Wind Climate in the Whitehorse Area*, Arctic, September 2007
- Pinard, Jean-Paul, *Wind Climate in Yukon Mountainous Terrain*, PhD thesis, University of Alberta, 2008.
- Green, Mark, *Ferry Hill Wind Feasibility Study*: Stage 1, Tasks 1, 2 & 3, Natural Power, September 2010
- *Mt. Sumanik Wind Assessment and Feasibility Study*, AECOM, March 2011
- Maissan, John, *Wind Development in Yukon*, presentation to Yukon Energy wind workshop, March 2013

A number of more recent reports and studies reference a paper presented by Bengt Tammelin and Henry Seifert, *Large Wind Turbines go into Cold Climate Regions,* presented at European Wind Energy Conference 2001 in Copenhagen. This paper notes that at particularly severe rime icing sites, annual energy production losses may range from 20 to 50 percent without de-icing and/or anti-icing features, especially if the turbine is not operated during winter when icing conditions are expected (Figure 52). Note that de-icing refers to active or passive removal of ice from rotor blades while anti-icing refers to prevention or mitigation of ice accumulation.

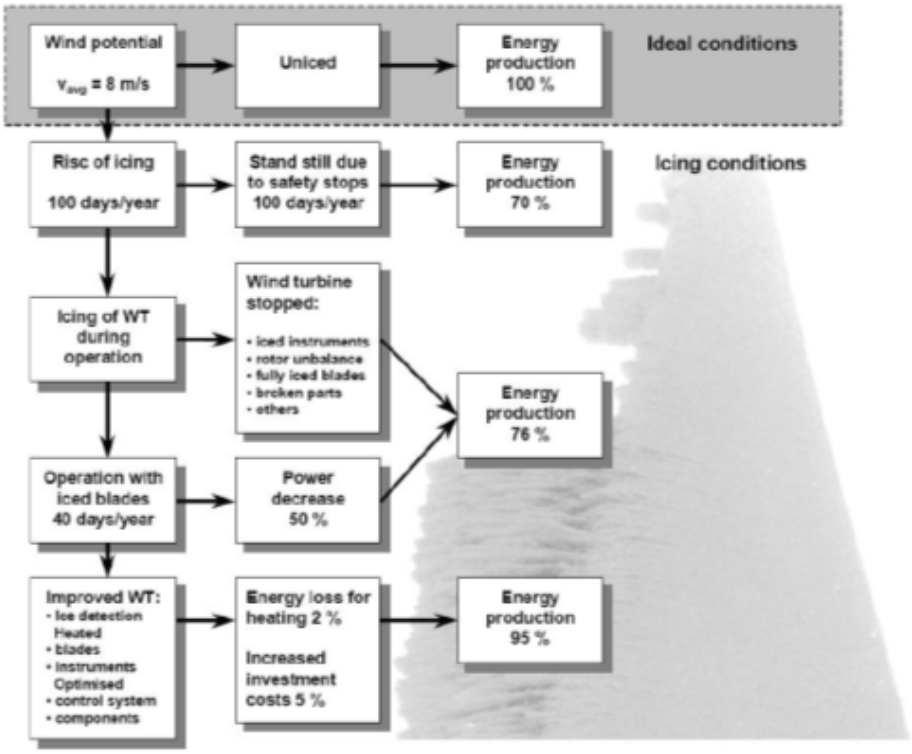
With continued reference to Figure 52, energy production loss decreases somewhat, but nevertheless remains substantial, if wind turbines operate during winter but are shut down during bad icing conditions (instrumentation ice-up, rotor imbalance, power output/wind speed mismatch, etc.). Last, energy loss due to icing can be maintained at acceptable levels with de-icing and anti-icing mitigation measures. These measures come at a cost though in terms of capital expense, energy usage for de-ice heating, and operator involvement to operate ice mitigation systems.

With reference to John Maissan's 2013 Yukon Energy wind workshop presentation and based on YEC's own experience with the two Haeckel Hill wind turbines near Whitehorse, all high elevation sites in the Yukon are at risk of substantial winter energy production loss due to rime icing conditions without mitigation measures. This is the inherent nature of high latitude, mountainous environments exposed to maritime climate-influenced storms.

Rime icing mitigation can be separated into two distinct measures: anti-icing and de-icing. Anti-icing includes heated turbine control instrumentation (this is absolutely critical), software to detect mild icing conditions (power output vs. wind speed mismatch) and retaining the operational status of the turbine as long as there is no rotor imbalance, as well as the use of black hydrophobic blades to allow for passive de-icing. Passive de-icing aside, active de-icing includes direct measures to rid the rotor blades of ice. Primary methods to achieve this are leading edge resistive heaters and internal blade air heating. Both methods have proven effective with wind turbines in North America and Europe, but these methods are not automatic; they require operator involvement and control.

Naturally, there are benefits and costs for any ice-mitigation measure and inclusion of features where not necessary, or where icing is infrequent, would be wasteful. Conversely, exclusion of ice mitigation measures where necessary could be very costly with potentially significant energy production loss due to icing conditions.

Figure 52 Illustration from Tammelin and Seifert, 2001



Naturally, there are benefits and costs for any ice-mitigation measure and inclusion of features where not necessary, or where icing is infrequent, would be wasteful. Conversely, exclusion of ice mitigation measures where necessary could be very costly with potentially significant energy production loss due to icing conditions.

Of the seven potential projects sites profiled in this report, only Kluane Lake is relatively low elevation and likely largely free of significant rime icing potential. Kluane Lake aside, significant rime ice mitigation investment will be necessary for successful wind turbine operations during the all-important winter season when YEC's hydropower resources are less productive. For the remaining six higher-elevation, mountainous sites, anti-icing and de-icing (passive and active) are recommended[19] unless site-specific met tower or Lidar data and modelling prove they would not be necessary, or are not cost effective.

Atmospheric rime icing and wind turbine icing mitigation are complex topics and a truly comprehensive analysis for Yukon wind energy production is beyond the scope of this project. Besides the papers and reports already mentioned in this section, the reader is urged to consult the following additional sources for papers, presentations, and background information. Beyond that, prospective wind turbine site wind data that includes direct or inferred ice detection is highly recommended.

Also recommended is participation in Winterwind International Wind Energy Conference, sponsored by the Swedish Windpower Association and held annually – typically in February – in Swe-

[19] Note that Enercon sells all its turbines in Canada with de-icing kits.

den, and the recently-organized Optimizing Wind Farms in Cold Climate conference, most recently held in Helsinki, Finland in December 2015.

6.2 Birds and Parks

For any wind farm, a detailed bird and bat impact study needs to be completed. For this assessment, we have merely reviewed a few key sites of interest to highlight potential conflicts with wildlife and parks.

Three major migration routes through the Yukon are identified on birdnature.com:

1. The *Pacific Flyway (*gulls, ducks and other water birds*)* leads from the delta of the Yukon River in Alaska through the southern area of the Yukon (Dawson and Whitehorse) into BC and then the US and Mexico.
2. The *Central Flyway* uses two parallel routes from Alaska through the Yukon and BC/Alberta into the central US.
3. The *Mississippi Flyway* (ducks, geese, shorebirds, blackbirds, sparrows, warbler and thrushes,) stretches all the way from Alaska to the Mississippi Delta, passing by the northern end of the Rocky Mountains and crossing the Prairies.

Many of the birds will fly through the Tintina Trench,[20] which crosses the Yukon diagonally from the southeast to the northwest and lies further north than most of the proposed wind sites. The Trench crosses the Campbell Region in the south-central Yukon, close to the Ross River sites and also along Tehcho and Willow Hill. The area is known as one of the best migration observation sites in the Yukon.[21] No major concerns may exist as the birds usually migrate through the middle of the trench and not along the higher elevations to the side where potential sites were identified.

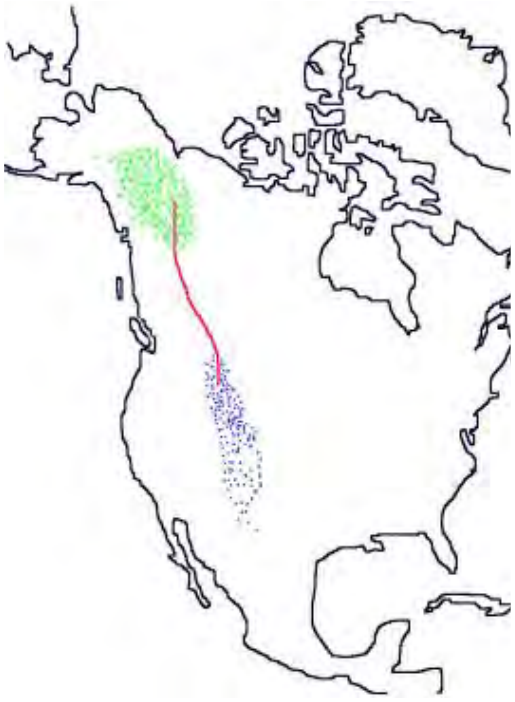
[20] http://sightsandsites.ca/central/site/tintina-trench
[21] A BIrder's Checklist of the Faro and Ross River Region. Yukon Environment, 2003

Further south lies the Shakwak trench, which is also a bird migration pathway. The Shakwak Trench is between eight and 12 km wide and stretches from the southern end of Kluane Lake towards Haines Junction. The Paint and Hard Time Mountain sites are close to this pathway, and the Kluane Lake sites are situated towards its end.

A birdwatching area is situated in the vicinity of the Minto Hill and Sugarloaf Mountain sites, at Tagish Bridge Recreation Site.[22] In the same general area, the Swan Haven Interpretive Centre, about 45 km south of Whitehorse, is located on the shores of M'Clintock Bay on Marsh Lake, YT. This area is one of the first areas of open water every spring and, combined with a delta formed by the M'Clintock River, creates a rich foraging area attracting swans, geese, ducks, gulls, and shorebirds in the spring. At the northern end of Marsh Lake lies the Lewes River Marsh, which is likewise important bird habitat. The turbine sites do, however, appear to be far enough from these sensitive areas.

The Anticline Mountain site lies in the same area as the Aishihik Lake Campground, which is a habitat for waterfowl. Again, the site is somewhat removed from the lake so as to avoid impacts on birds.

Figure 53 Eagle Migration Zones



Source: http://eaglewatch.ca/wp/wp-content/uploads/2013/04/migration-sites-ab_1.jpg

The Yukon is also an important area for eagles. Figure 38 shows the general migratory path for eagles and their territory, which stretches from the Yukon into Alaska. Deaths of Golden Eagles and other eagle species due to collisions with wind turbines and cables have been the reason for controversy around wind park development in the US in recent years.[23] As for peregrine falcons, it appears that their habitat around Stewart Crossing lies between the wind sites identified in this area (Wareham/Site 16, Willow Hills) and does not overlap (Figure 54).

6.3 Comparison to Recent Site-Specific Consultant Reports

Two reports, one on the Tehcho site (full report) and one on the Mt Sumanik site (wind monitoring results for June 2016 only), were either recently prepared or are currently being completed for YEC. As can be expected from the use of different models, there are some differences between the yield estimated between these reports and this one. These cannot be fully explained without more

[24] Source: http://www.cpawsyukon.org/images/map-oilgas-peregrines.jpg

detailed comparisons as to the specific assumptions made and mode inputs used but Table 19 provides a brief appreciation of these differences and offers some high-level conclusions.

Table 19 Comparison of AWS Results to Site-Specific Report Results

Site	This Report	Consulting Reports	Comments
Mount Sumanik	The actual summit of Mt. Sumanik (location of the ZephIR Lidar unit) seemed an unlikely location for wind turbines considering that the best approach route for a road is that quarry on the north side. Plus, winds modeled higher on the ridges north of Mt. Sumanik than on the summit itself, hence also why the AWS data point was not on the actual summit.	In June, the ZephIR wind monitoring report[1] recorded a mean wind speed of 5.88 m/s (at 76 m) and AWS predicts 3.98 m/s (at 80 m).	The ZephIR report covers only the month of June, wind data is not corrected for long-term variability and uses a different location (about 2.2 km from the one used in this report). Data are therefore not directly comparable. Once monitoring data for a complete year is available, AWS model outputs could be compared to the outputs obtained by the model used by ZephIR.
Tehcho	AWS data was used, not monitoring data, to remain consistent with how the other sites were assessed. AWS estimated a wind speed of 5.8m at 80 meters. Annual net output is 33 GWh per year for a 20 MW wind farm. The same GE 1.7-100 turbine was used for modeling.	Average wind speed at 60m is 5.7m, which is in line with about 5.8m at 80m height based on AWS. Annual energy production is higher in the *Natural Power* (NP) report[2] (54 GWh per year for a 25 MW wind farm- considerably higher than what would be expected from the results of this report) than this report but it is not clear why that is so without having access to the underlying data and assumptions.	Data recovery from the met tower – note that this was highlighted as well in the earlier reports that we were sent – was highly problematic with long periods of missing data and lots of icing problems. This data was corrected to create a complete data set, but that is an imperfect process. Generally, the site does not appear to be a good side whether AWS of NP outputs are used.

7 PRELIMINARY PROJECT SCHEDULE

Developing a wind farm in the Yukon will likely take three to four years. This includes the following phases:

Year 1: Wind monitoring campaign – a necessary basis for an investment decision. While the campaign will be for two years, one year of data collection should suffice to make a go/no-go decision on whether to proceed.

Year 2: Project development phase: permitting, financial engineering and stakeholder involvement. Except for the geotechnical assessment, all of these tasks are off-site. Based on the results of the assessment during the first half of this phase, a decision to go ahead will have to be taken. Tasks such as detailed engineering and negotiations will only take place after this decision has been taken. Wind monitoring continues during the second year.

Year 3: Site preparation: access to and preparation of the site.

Year 4: Erection of turbines, grid intertie and commissioning. The schedule for this phase is rather tight and may have to be stretched over two years. An early start with pouring concrete for the foundations in April will require covering the area with plastic and heating the interior. If the work started in May there might be scheduling problems with turbine erection by October (a minimum of one month curing should be allowed, pushing the erection of the towers towards the end of the construction season).

The schedule laid down in Figure 55 is for a 20-MW wind farm with no existing access road. The earliest in-service date would be October 2020, provided the wind measurement campaign starts no later than June 2017.

For sites with existing access roads or for smaller wind farms, the schedule may be more relaxed. The wind farms in Kodiak and Kasigluk, Alaska took four years to develop,[25] although subsequent farms may have been realized in shorter timeframes.

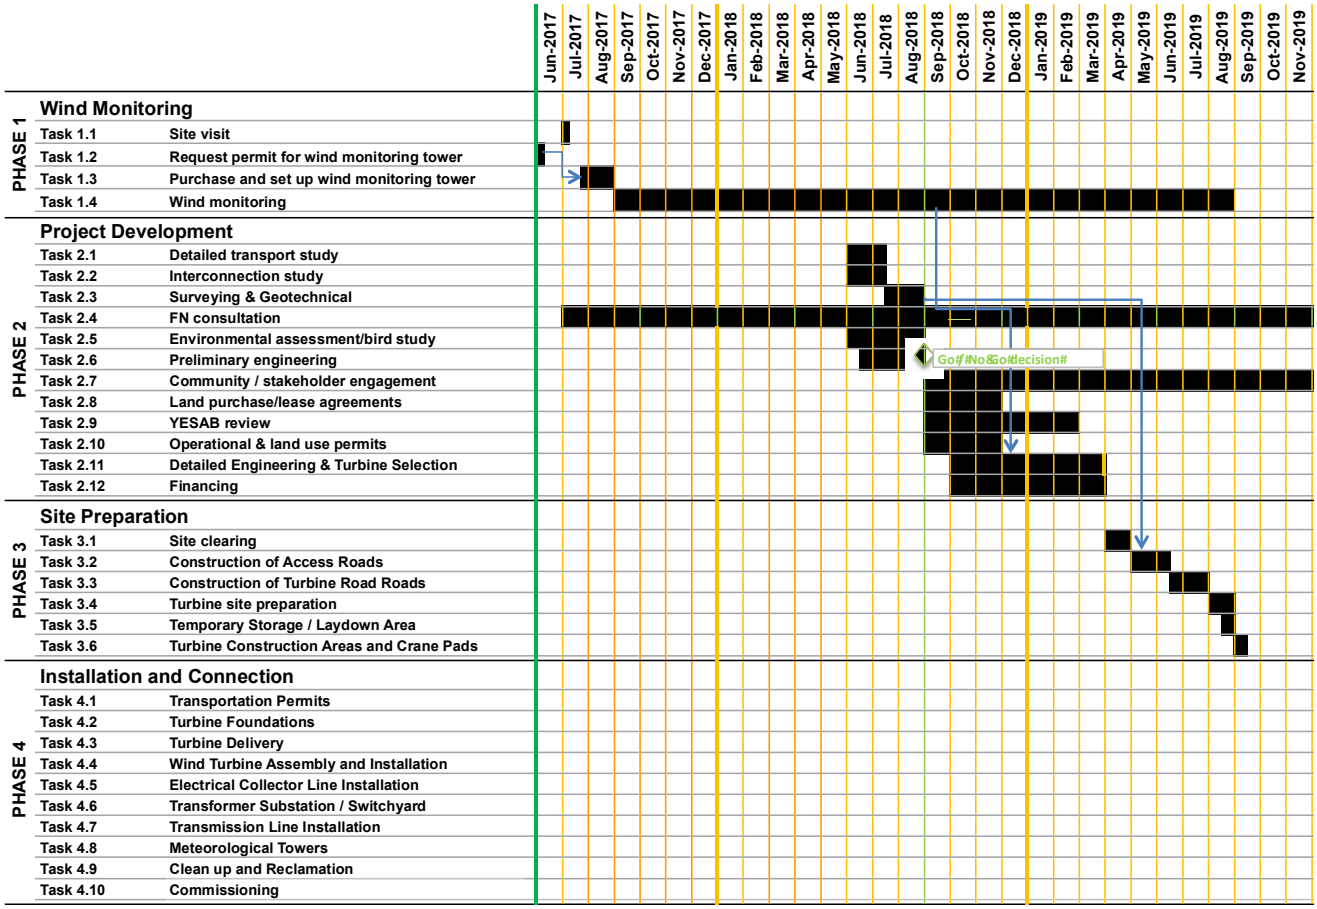
Erecting wind turbines is constrained by weather and wind conditions (wind speeds must be below 10 m/s), i.e. the process for a 20-MW wind farm may take three months due to waiting periods until conditions allow each turbine to be erected. There are also periods when heavy loads may not be allowed on the road (shoulder seasons). Generally, we assume:

- One year of wind monitoring must precede any development;
- Sites with existing good road access could be constructed within a single construction season;
- Sites where extensive road construction is necessary would be built over two construction seasons.

Risks identified in the next chapter may extend the schedule. Notably, it may take up to two years to obtain the necessary permits, which would add to the time required to complete the project.

[25] COMMUNITY WIND TOOLKIT: A Guide to Developing Wind Energy Projects in Alaska Renewable Energy Alaska Project (REAP) March 2011

Figure 55 Preliminary Project Schedule



8 RISK ASSESSMENT

8.1 Introduction

This chapter provides a high-level[26] risk assessment of wind-farm construction. Table 20 summarizes the risks and mitigation measures. Given that YEC would be developing the first commercial-scale wind farm in the Yukon, risks relating to construction expertise and permitting need to be more carefully considered.

8.2 Key Risks

Permitting: Whereas YEC is likely able to obtain all necessary permits for a wind farm, there may be unexpected delays with obtaining permits due to the inexperience of permit authorities with this type of project. Also, projects involving multiple levels of permit authorities (municipal/First Nation, territorial, federal) may incur additional delays as one permit may depend on another, or additional studies and requirements may be imposed. In Alaska, permitting for typical wind projects can take anywhere from two to four years once the site is selected. Permitting should therefore be initiated fairly early in the process (once siting is confirmed and land purchasing is reasonably underway) to reduce this risk. A project development consultant may be of assistance in securing permits and providing project experience from other wind farms in Canada to authorities to facilitate the process, and ensure best practices are applied to project design, construction, and operation.

Stakeholders' opposition: It is best practice to involve stakeholders early in the project development process. This will help identify issues early on and will help design the project so its impacts on stakeholder interests are lessened. Also, land ownership issues can be addressed early to conclude agreements on compensation or land leasing so the project can move forward smoothly. Given that most of the recommended seven sites are on Commissioner's land and the interest by Yukon aboriginal groups in wind power project development, we do not anticipate major resistance against wind projects, and have not classified this as a 'high risk' area. Still, interest groups need to be identified early and included in discussions around project design, also addressing any economic interests stakeholders may legitimately have in the project.

Schedule risk: Due to the short construction season in the Yukon (likely even shorter at the selected locations due to their elevation), there is considerable risk associated with construction activities. We have built extra days into the schedule (Chapter 7) to account for weather-related delays. Nevertheless, several components may cause delays, including turbine and crane transport, availability of key personnel and permitting delays. These risks can be mitigated by contracting out project construction to an experienced EPC company. Usually, turbine vendors will function as EPC contractors for turbine delivery and erection. They will then confirm a realistic schedule, identify the best transport routes and methods, and also look after turbine erection. They may also cooperate with local companies for site preparation, access road and line construction, and the electric and foundational works required. Otherwise, YEC may look after site preparation and civil works based on the specifications provided by the turbine vendor.

[26] For a more in-depth treatment of wind-farm-related project risks, consult http://writepass.com/journal/2012/11/risk-assessment-of-a-wind-farm/

Icing risk: This will essentially be dealt with through de-icing devices integrated into the turbines. However, during the wind monitoring phase, icing should also be monitored to quantify this risk. As mentioned above, the report on the Mt Sumanik wind farm identified a potentially severe icing risk, which may lead to severe power output losses during winter, even with de-icing measures. If icing is too severe and would reduce power output by more than 10% (with de-icing measures), the site may have to be abandoned as unsuitable for wind power production.

Curtailment: This risk is more likely to occur during the summer than during winter, given the Yukon's electricity consumption profile. However, curtailment during the summer will negatively affect the economic performance of the wind farm. This aspect was not the subject of the current study but needs to be assessed when deciding on wind farm siting and size.

8.3 Lesser Risks

Financial: As a utility, YEC is well positioned to develop and finance a wind farm. As such, no major risks are related to financing. We identified currency exchange risk as one potential financial risk. This risk can be monetized by a forward currency purchasing contract. A 30% increase in turbine costs and some labour costs would only result in about an 11% increase in the project budget though.

Transport: Transportation can become a major issue when the existing infrastructure is insufficient. The heavy 550 t crane required to set up large-scale turbines as proposed in this study weighs about 90 tonnes (it can be disassembled; the counterweight alone weighs 36 tonnes). Any weight above 77 tonnes will require a special permit from Yukon Highways and Public Works. It is uncertain that such a permit can be granted for all sites, however. Length is another restriction: trucks transporting turbine blades can be 60 m long or more, making navigation around needle turns difficult or impossible. Also, the access road to be built needs to be smooth and have a gradient no steeper than about 10-14%. Wherever a transport study shows that it is not possible to bring the required equipment to the site, infrastructure must either be specially built, equipment transported in sections and reassembled at the site, or smaller turbines could be selected to reduce transport bottlenecks.

Wildlife and vandalism: Two problems may arise with respect to wildlife. During the environmental assessment, sensitive areas may be identified near the site, which could require changing transmission or access road routes to avoid harming protected species. Wild animals can also be a hazard for workers on site and may have to be deterred from accessing the site either by fencing the area or using other deterrents. Vandalism may also be a risk in some areas. A developer should speak to locals to identify both wildlife and vandalism risks and take countermeasures if need be.

Delivery: Related to schedule risk, deliveries of equipment and turbine sections may be delayed due to vendor-caused delays, weather events or other unforeseen problems with transport, such as accidents or truck breakdowns. Usually, this risk is contractually passed on to the vendor within a turbine purchasing contract that essentially makes the vendor an EPC contractor for timely delivery and turbine erection.

Some other issues have not been included in the tables such as ice throw (turbine sites are remote), budget risks (will be reduced at the detailed engineering stage and are addressed by contingen-

cies), inflation or interest rate changes (thought to be low at this time in Canada), bankability (YEC as the project developer expected to provide value of a PPA), engineering risks/design failures (typically mitigated by assessing company capabilities through an RFP process), and accidents (covered by insurance; adequate on-site worker training presumed).

Table 20 Risk Factors and Mitigation

Risk	Importance	Probability	Impact	Mitigation
Currency exchange increases cost of turbines and some services	Low	High	Low	Obtain binding quotes; rely on Canadian labour and material inputs as much as possible
Icing events reduce turbine output	High	High	**High**	Icing monitoring and de-icing measures
Schedule/weather risk during construction	High	Medium	**High**	Provide conservative timeframes for construction; split up construction over two years; contract out project to an EPC firm to pass on risk to contractor
Operational risk	High	Low	Low	Obtain servicing contracts and warranties; buy new turbines with a cold-weather track record; keep crucial spare parts near site; stall turbines at temperatures below -30 °C
Wind resource variability and turbine choice	Medium	Low	Low	Obtain more than 12 months of monitoring data, select turbine late in project development process based on monitoring results
Local operation/know-how	High	Low	Low	Train two technicians to perform routine turbine maintenance
Curtailment/financial losses	High	High	**High**	Assess capacity of grid to absorb wind farm output and size farm accordingly
Community protest against wind farm	High	Medium	Medium	Engage community and stakeholders early in the process; offer co-benefits to landowners; select sites to avoid scenic, tourist, heritage or recreational locations; confirm low wildlife impacts through environmental assessment
Crane and nacelle transport may exceed permissible weight and length thresholds	High	Medium	Medium	Work with authorities early in the process to determine best routes; provide adequate road access to site; split up components where possible; select smaller turbines if necessary

Risk	Importance	Probability	Impact	Mitigation
Permits take longer than expected	High	High	**High**	Work with authorities early in the process; provide examples from other jurisdictions for authorities; follow best practices in terms of siting, signalization, access road and transmission routing; contract a development consultant to deal with permitting
Wildlife & vandalism risk	Medium	Medium	Medium	Assess potential of appearance of protected and/or hazardous wildlife (e.g., wolves, bears) at planned site and take mitigation measures if needed to ensure worker safety or take precautionary measures to protect wildlife during construction; set up guards if there is a perceived risk of vandalism
Delivery risk	High	Medium	Medium	When purchasing turbines and scheduling machinery, include damage clauses in contracts in case of delays caused by the vendor

9 CONCLUSIONS AND RECOMMENDATIONS

This study identified 26 potential sites for wind farms. Of these, 17 were considered further and seven selected for a detailed analysis. The selection process was tailored to the prerequisites of the project. These prerequisites may change over time. The shortlist should not be taken as final and YEC may want to look further into some of the sites that were not selected.

Of the seven sites selected, five show an above-average performance in terms of the cost of energy produced. These sites are, in the order of performance, Kluane Lake, Miller's Ridge near Carmacks, and a mountain ridge near Cyprus Mine, close to Faro. There is not a lot of difference in energy production cost between these five sites; non-monetary factors may play an important role in selecting the preferred location.

Miller's Ridge near Carmacks and Thulsoo Mountain near the Aishihik hydroelectric facility are the sites with the highest wind resource and a low cost of energy (LCOE). Thulsoo Mountain is near an existing facility, but Miller's Ridge has more expansion potential. Sumanik Mountain is attractive due to its location near Whitehorse. Cyprus Mountain is the furthest from Whitehorse, but appealing due its brownfield nature next to an abandoned mine. Kluane Lake gets a qualified recommendation because of its low elevation and low energy costs (LCOE), but requires a transmission line first. Tehcho and Sugarloaf are not recommended because the other site options clearly are superior, both in terms of annual energy production and energy cost.

The levelized cost of energy (LCOE, assuming no curtailment) at almost all sites and all sizes remains under the standard offer price of 21 ¢/kWh but many are still above the average residential retail price of 12 ¢/kWh. Financially, the sites at Sugarloaf and at Kluane Lake perform best in terms of capital costs. In terms of LCOE, the Miller's Ridge site (20 MW) performs best but is closely followed by the Thulsoo and Kluane Lake sites, despite the mediocre wind regime of the latter. This can be explained by the very short transmission connection required once the new line is built. Also, less rime icing and less frequent low temperature curtailment helps to increase the net energy generation at Kluane Lake. Though there are plans, currently there is no transmission line at this site.

Our modelling assumes that all energy produced will be used. Curtailment of the operation during the summer when YEC has a surplus of power would increase the cost of energy produced during the rest of the year by more than a third. This needs to be considered when assessing the sites. If the update to YEC's 20-year plan yields that wind power is a viable source of electricity, then further research should be done on the five sites mentioned above. We recommend a full-scale feasibility study for one or all of the five top sites. This includes, but is not limited to:

1. Wind velocity, temperature and rime ice monitoring;
2. Determining the maximum size of the wind farm;
3. Modelling of monthly power generation based on monitored data;
4. Modelling and selection of various wind turbine models and sizes;
5. Review of the geotechnical conditions on site and procuring LIDAR elevation maps;
6. Conceptual design of roads and their routing;
7. Capital costing based on quotes;
8. Review of service contracts and costs;
9. Transportation study.

APPENDIX H – ENERGY PERFORMANCE OF THE SELECTED SITES

1 CYPRUS MINE HILL

Wind turbines at Cyprus Mine would perform well. A 2.0 MW turbine would produce between 5.2 and 6.5 GWh of energy annually, depending on the size of the wind farm and the particular location of the turbine within the site. This is 14% to 17% less than the same turbine at Miller's Ridge, the top wind resource site.

1.1 Annual Energy Production

WAsP modeling of the three wind farm capacity options – 20 MW, 10 MW and 6 MW – indicates an approximate 33% wind turbine net capacity factor based on the net annual energy production (AEP) given in Table 22 below.[1] A 33% capacity factor is very good but perhaps could be slightly improved upon with a wind turbine model more attuned to this site, in place of the generic 2 MW model for the modeling exercise. Chapter 1.2 below describes the impact of various turbine models.

Figure 1 and Table 22 below state the key production parameters. Given are the potential energy output, the gross energy production and the net energy production. The gross energy production is representative of the wind energy resource were there no wake losses due to terrain roughness and neighbouring turbines. Subtracting these wake losses yields the gross energy production. Conversion or efficiency losses, curtailment, downtime and parasitic energy consumption further reduce the annual output. The remaining net energy production is what will be fed into YEC's grid.

[1] Capacity factor of a wind turbine is defined as the mean annual power output divided by rated power or the total annual power output divided by the capacity and by 8760, the number of hours in a year.

Table 22 Cyprus Mine Hill Wind Farm Annual Energy Production, 2 MW generic turbine

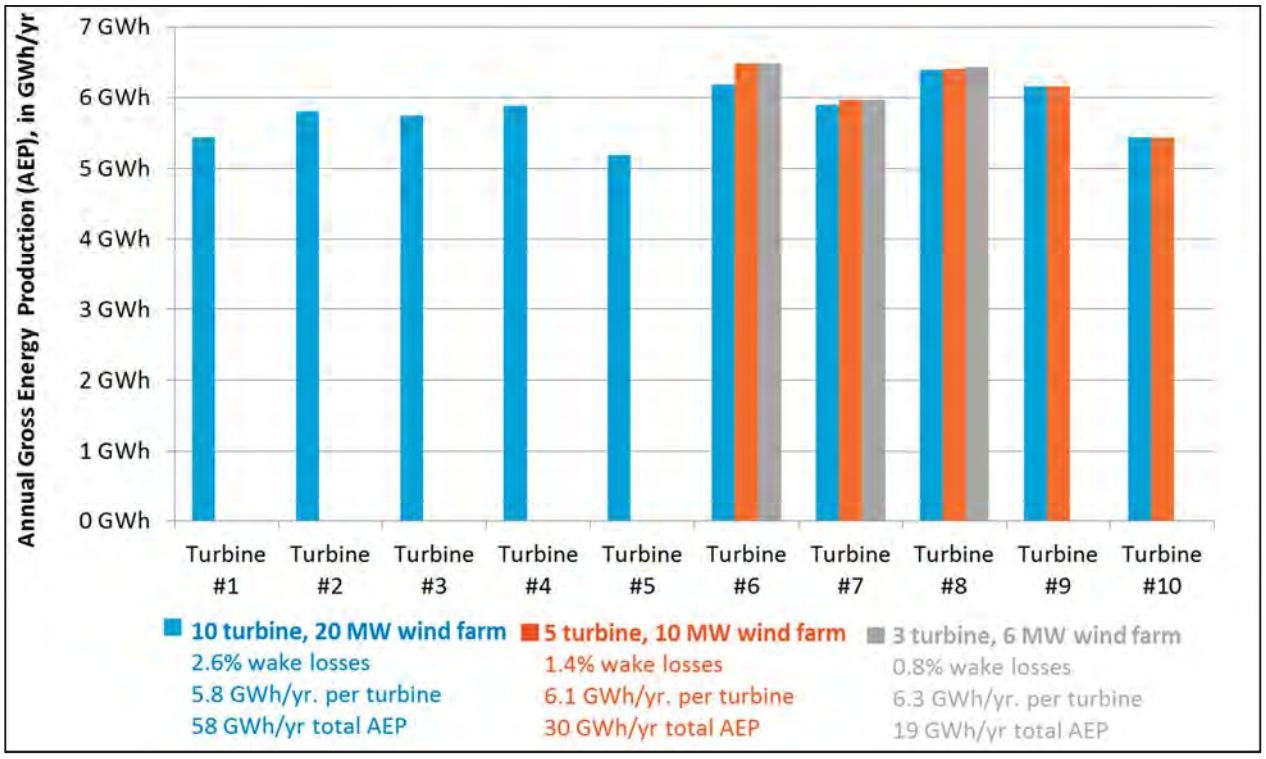
Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	59.7	5.97	5.40	6.57
	Wake loss	2.7%	-	-	-
	AEP after Wake Loss	58.1	5.81	5.20	6.39
	Additional Losses and Downtime	14.7%			
	Net AEP	**49.6**			
10 MW	Gross AEP	30.9	6.18	5.50	6.57
	Wake loss	1.5%	-	-	-
	AEP after Wake Loss	30.5	6.09	5.44	6.48
	Additional Losses and Downtime	14.7%			
	Net AEP	**26.0**			
6 MW	Gross AEP	19.0	6.35	6.01	6.57
	Wake loss	0.8%	-	-	-
	AEP after Wake Loss	18.9	6.29	5.97	6.48
	Additional Losses and Downtime	14.7%			
	Net AEP	**16.1**			

Losses and downtime are calculated as a percentage and are therefore proportionally smaller for a small wind farm than for large wind farm. The difference in relative losses between the three sizes of wind farms modeled is solely due to wake losses. These tend to increase with the size of a wind farm because the individual turbines start to 'shade' each other or create a wake, turbulences or reduced wind speed that effects a downwind or adjacent turbine.

Figure 1 indicates the annual gross energy output of the site turbines. The ten turbine 20 MW capacity turbine layout was developed first and selected turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Retained turbines were chosen to reduce the site footprint *and* retain the higher performing locations. This approach applies to all seven selected sites.

For the five-turbine (10 MW) option at Cyprus Mine, Turbines 6 through 10 were retained (refer to Figure 10 in Chapter 3.1 of the body of the report). For the three-turbine (6 MW) wind farm location, Turbines 6, 7 and 8 were retained as the model demonstrates high energy production for turbines at these locations and the turbines are near each other, minimizing infrastructure costs.

Figure 1 Annual Net (wake loss only) Energy Generation, Cyprus Mine Hill



For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance. Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

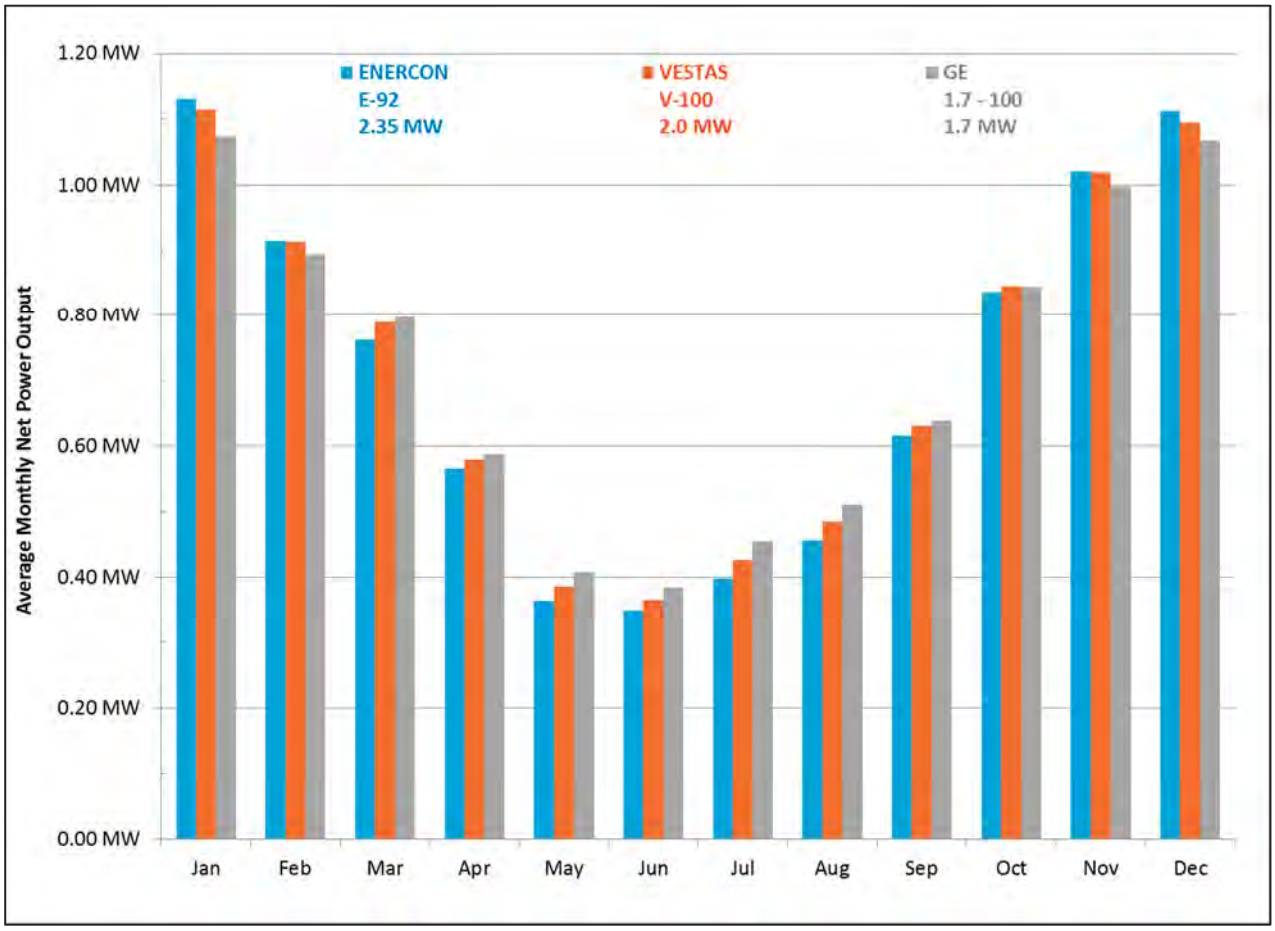
1.2 Turbine Choice

The numbers presented above are based on a generic 2.0 MW turbine. This may not be the best choice for this site. To gauge the impact of different types and sizes of turbines we compared three alternate types of turbines. Modeling of an Enercon E-92, a Vestas V-100 and a GE-1.7-100 turbine showed that a smaller General Electric 1.7 MW turbine yields a slightly higher (1%) output than the larger capacity 2.3 MW Enercon E-92. In the higher wind speed period from October to April, however, the Vestas V-100 performs slightly better than the other two turbines, see Figure 2 below.

1.3 Monthly Generation Profile

As for all sites selected, a wind farm at Cyprus Mine generates more energy in winter than summer, as one would expect. Modeling indicates that 69% to 71% of annual energy production will occur October to April (see Figure 2).

Figure 2 Monthly Generation Profile of a three types of wind turbines at Cyprus Mine Hill

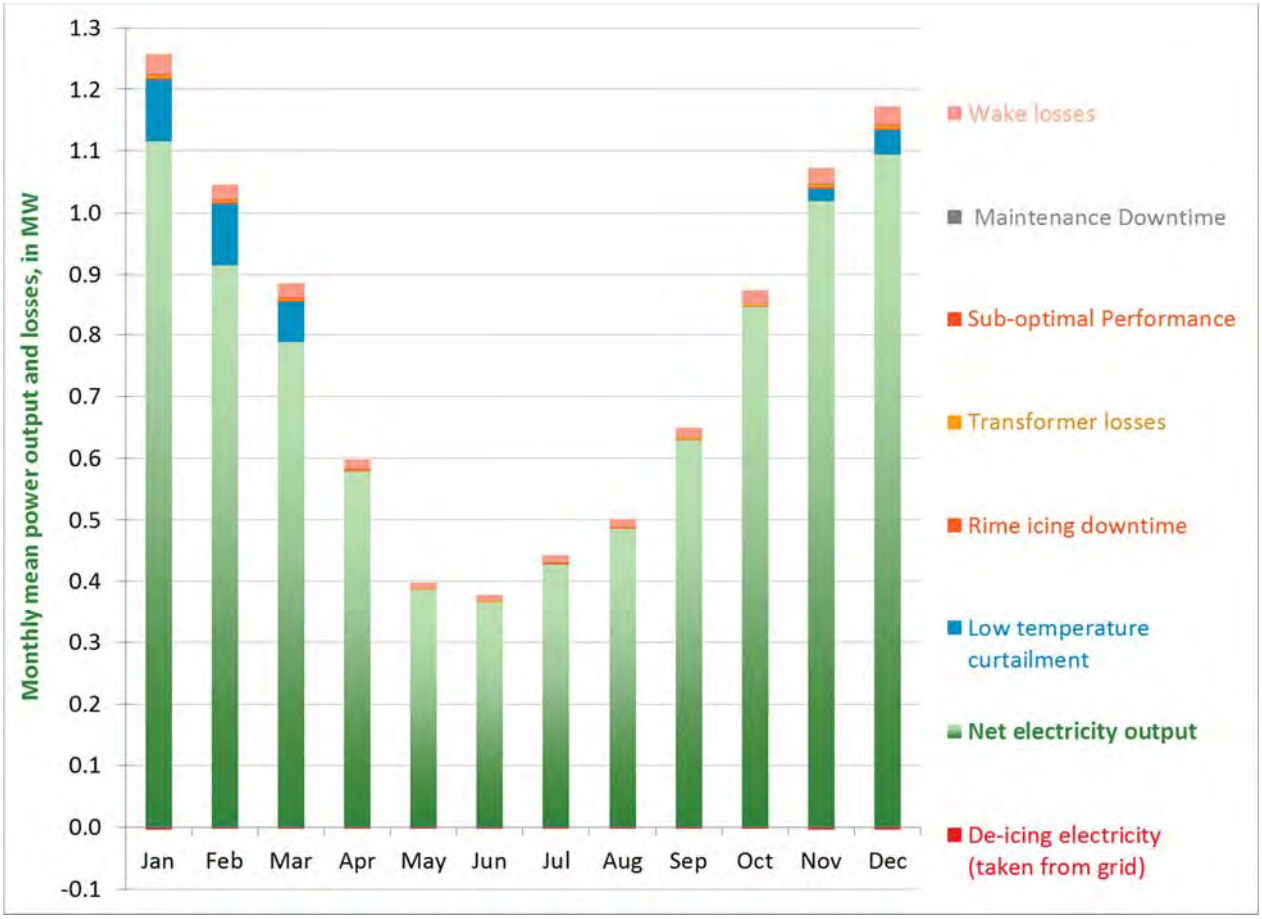


The numbers presented above are the net energy production delivered to the grid of a single turbine. Wake losses from terrain features or nearby turbines are not taken into account. The mean power outputs to the grid presented above are relevant in terms of turbine selection and monthly generation profile rather than as absolute numbers. AWS software does not take the impact of terrain features and nearby turbines into account the way WAsP modeling does.

Just as power output, monthly losses, curtailment, and downtime described in Chapter 4.2 of the body of the report vary over the course of the year. Figure 2 below displays monthly losses in relation to the monthly mean power that will be fed into the grid assuming a Vestas V-100 turbine at Cyprus Mine. Energy production is higher during the winter months and so are losses. De-icing energy is shown as negative because it will actually draw power from the grid. Over the course of the year 14.7% of the annual energy that could be generated at Cyprus Mine will be lost due to downtime, curtailment, losses or energy consumption for de-icing.

This scheme is similar for all seven sites, though there are differing losses depending on the air temperature over the course of the year and the elevation of the site.

Figure 3: Monthly Mean Net Power Output for a GE-100-1.7 MW Turbine at Cyprus Mine



For the purpose of creating data of monthly net electricity output we combined the annual gross energy production forecasted by the WAsP model with the monthly distribution of energy production of the AWS report. We then subtracted all other losses described in the main report to obtain monthly net electricity production data.

Table 23 Cyprus Mine Hill: Losses and Net Annual Energy Production of the Three Wind Farm Sizes

Annual Energy Production of a 20 MW WINDFARM

2 KLUANE LAKE (WEST SHORE)

2.1 Annual Gross Energy Production

Despite its low elevation Kluane Lake features a reasonable wind resource and good energy production compared to the other six, high-elevation sites. A generic 2.0 MW turbine would generate between 5.1 and 5.6 GWh a year, mainly depending on the size of the wind farm and resulting wake loses.

Wind farm (WAsP) modeling of the three wind farm capacity options – 20 MW, 10 MW and 6 MW – indicates an approximate 30% wind turbine net capacity factor based on the gross annual energy production in Table 24 below.

Kluane Lake is unique of the seven sites profiled in this report in that icing loss and/or icing-related operational challenges is expected to be relatively low. Apart from wake losses only 9.1% of the gross energy production are lost due factors such as icing, operations and maintenance, and electrical efficiency.

Table 24 Kluane Lake Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	55.0	5.50	5.40	5.59
	Wake loss	4.5%	-	-	-
	AEP after Wake Loss	52.6	5.26	5.10	5.37
	Additional Losses and Downtime	9.1%			
	Net AEP	**47.8**			
10 MW	Gross AEP	27.6	5.52	5.40	5.59
	Wake loss	2.7%	-	-	-
	AEP after Wake Loss	26.8	5.37	5.33	5.41
	Additional Losses and Downtime	9.1%			
	Net AEP	**24.4**			
6 MW	Gross AEP	16.7	5.56	5.53	5.59
	Wake loss	1.4%	-	-	-
	AEP after Wake Loss	16.4	5.48	5.40	5.53
	Additional Losses and Downtime	9.1%			
	Net AEP	**14.9**			

As for all other sites the ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and* retain the higher performing locations.

Due to the prevailing wind parallel to the shoreline there are higher wake losses than for other 20 MW wind farm sites considered in this report. This could be mitigated by either locating the turbines further apart or reducing the size of the wind farm. A 6 MW wind farm has only 1.35% wake losses, a 20 MW farm almost three times as much.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance. Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

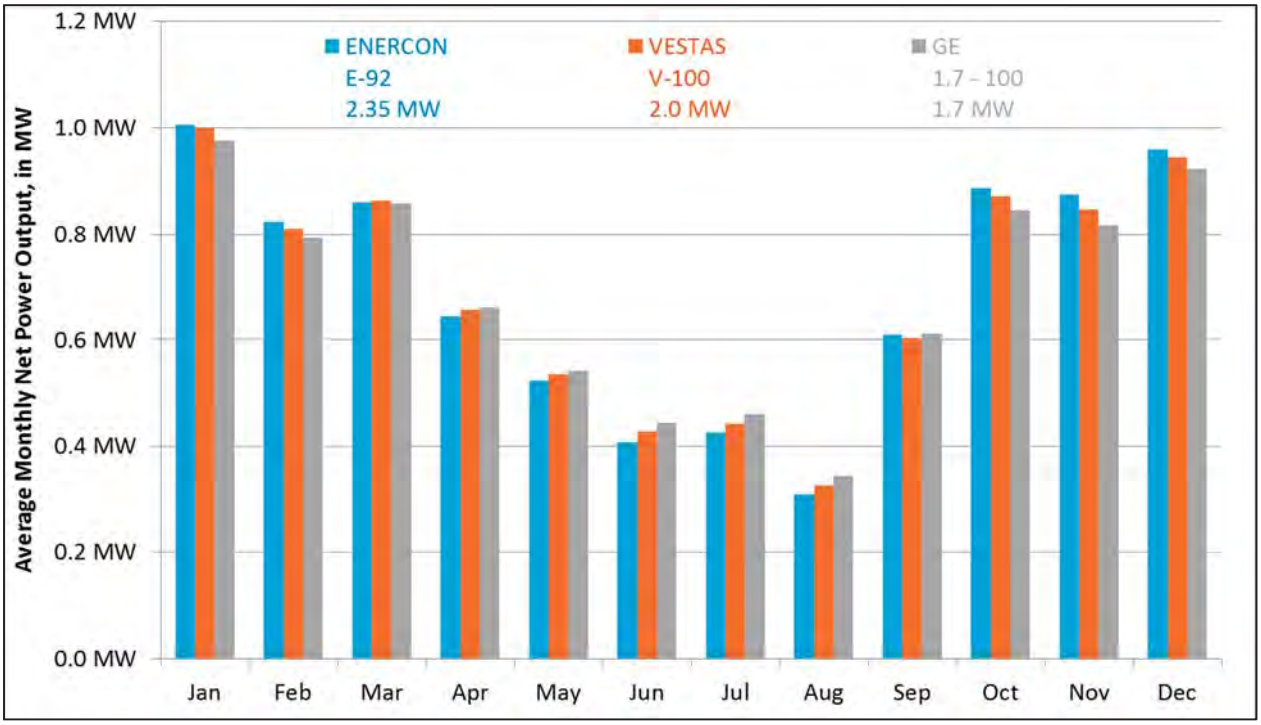
2.2 Monthly Generation Profile

Peak production for a turbine at Kluane Lake is December and January. As at all the selected sites, a wind farm at Kluane Lake would generate more energy in winter than summer. According to AWS modeling, 71% to 73% of the energy will be produced from October to April, see Figure 4 below.

2.3 Turbine Choice

Kluane Lake should have fewer rime ice problems than the other sites. Temperatures at Kluane Lake also tend to be higher and hence present less of a cold weather operational concern than the other sites. Geared drive turbines could be considered for Kluane Lake. Modeling of alternative turbines shows, however, that the gearless 2.35 MW Enercon E-92 model has 1% to 3% better performance in the period from October to April than the other two, smaller, but geared turbines. Considering that the site is next to the Alaska Highway and that there are no steep access roads, a larger turbine may also be considered from a logistics point of view.

Figure 4 Monthly Generation Profile of a three types of wind turbines at Kluane Lake



Data on the monthly losses and net production is provided below.

3 MILLER'S RIDGE

Miller's Ridge has the best wind resource of all sites reviewed.

3.1 Annual Energy Production

With its excellent wind conditions, Miller's Ridge has the highest gross energy production of all sites. A 2.0 MW turbine would be able to generate 6.3 to 7.2 GWh of energy, depending on the size of the wind farm and the particular location of the individual turbine, see Table 26 below.

WAsP modeling of the three wind farm capacity options – 20, 10 and 6 MW – indicates an approximate 39% wind turbine net capacity factor based on the gross annual energy production given in Table 26 below. A 39% capacity factor is extraordinarily good. If a larger capacity turbine more suitable for higher energy winds is chosen, overall net capacity factor will decrease slightly.

Table 26 Miller's Ridge Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	68.1	6.81	6.45	7.19
	Wake loss	2.0%	-	-	-
	AEP after Wake Loss	66.7	6.67	6.28	7.06
	Additional Losses and Downtime	14.2%			
	Net AEP	**57.2**			
10 MW	Gross AEP	34.9	6.98	6.63	7.19
	Wake Loss	1.4%	-	-	-
	AEP after Wake Loss	34.4	6.88	6.60	7.07
	Additional Losses and Downtime	14.2%			
	Net AEP	**29.5**			
6 MW	Gross AEP	21.3	7.10	7.03	7.19
	Wake Loss	1.0%	-	-	-
	AEP after Wake Loss	21.1	7.03	6.93	7.17
	Additional Losses and Downtime	14.2%			
	Net AEP	**18.1**			

The ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and* retain the higher performing locations.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance. Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

Miller's Ridge is long and oriented perpendicular to the prevailing wind direction, south-south-west. Additional four turbines could be installed southeast of turbine #1 (WTG1) without creating significant additional wake losses (refer to Figure 18 in Chapter 3.3 of the body of the report). This would bring the maximum capacity up to 28 MW.

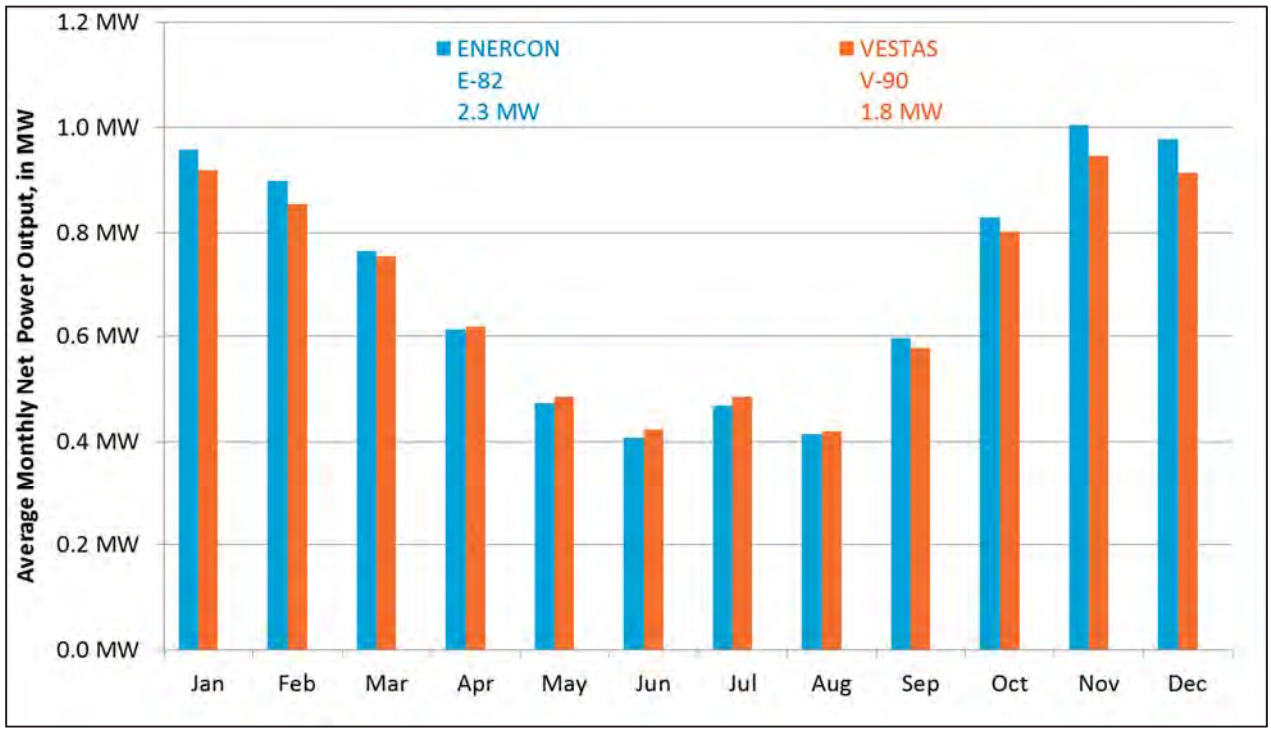
3.2 Monthly Generation Profile

As for all sites selected a wind farm at Miller's Ridge produces more energy in winter than in summer. According to AWS modeling 71% to 72% of the energy will be produced from October to April, see Figure 5 below.

3.3 Turbine Choice

From a wind speed and wind direction point of view Miller's Ridge is likely one of the best sites in Yukon. AWS' advanced reports model the highest yield for the Enercon E-92 turbine. A larger IEA Class II turbine, such as the E-82 with 2.3 MW rated capacity can be expected to perform better at Miller's Ridge than the smaller 1.8 MW Class III Vestas V-90 model. The E-82 series performs better during the high wind speed winter months and worse during the summer with generally lower wind speed, see Figure 5 below. A decision regarding turbine choice, however, would require site-specific wind monitoring data.

Figure 5 Monthly Production Profile for three types of turbines at Miller's Ridge Site



Data on the monthly losses and net production is provided below.

Table 27 Miller's Ridge: Losses and Net Annual Energy Production of the Three Wind Farm Sizes

4 SUGARLOAF MOUNTAIN

Of all sites selected, Sugarloaf Mountain is the site with the lowest wind resource

WAsP modeling of the three wind farm capacity options – 20, 10 and 6 MW – indicates an approximate 21% wind turbine net capacity factor based on the Gross Annual Energy Production given in Table 28 below. A 21% capacity factor is low and could be improved upon with a wind turbine model more attuned to this site in place of the generic 2 MW model for the modeling exercise. A decision for the latter, however, would require site-specific wind monitoring data to verify a likely IEC Class III wind regime, i.e. a low wind speed class.

4.1 Annual Energy Production

As expected from the wind resource, modeling of three wind farm sizes at Sugarloaf Mountain yields lower energy production than the remaining six sites selected. The annual mean gross energy production of a single 2.0 MW turbine is only 3.7 to 3.8 GWh. This is 39% to 51% less than the mean output of the same turbine at Miller's Ridge.

These numbers are the gross energy production and only reflect wake, or wind turbine array efficiency, loss though. Other loss factors such as icing, operations and maintenance, and electrical losses are determined in Chapter 4.2 in the body of the report.

Table 28 Sugarloaf Mountain Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	37.5	3.75	3.47	3.98
	Wake Loss	1.0%	-	-	-
	AEP after Wake Loss	37.1	3.71	3.43	3.96
	Additional Losses and Downtime	13.1%			
	Net AEP	**32.2**			
10 MW	Gross AEP	18.5	3.70	3.47	3.98
	Wake Loss	0.8%	-	-	-
	AEP after Wake Loss	18.4	3.67	3.44	3.96
	Additional Losses and Downtime	13.1%			
	Net AEP	**15.9**			
6 MW	Gross AEP	11.4	3.81	3.63	3.98
	Wake Loss	0.5%	-	-	-
	AEP after Wake Loss	11.4	3.79	3.61	3.96
	Additional Losses and Downtime	13.1%			
	Net AEP	**9.9**			

The ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and*

retain the higher performing locations. For Sugarloaf, a reduction of the site footprint was paramount and the lower capacity turbine layouts successively removed the southern-most turbines.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance. Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

4.2 Monthly Generation Profile

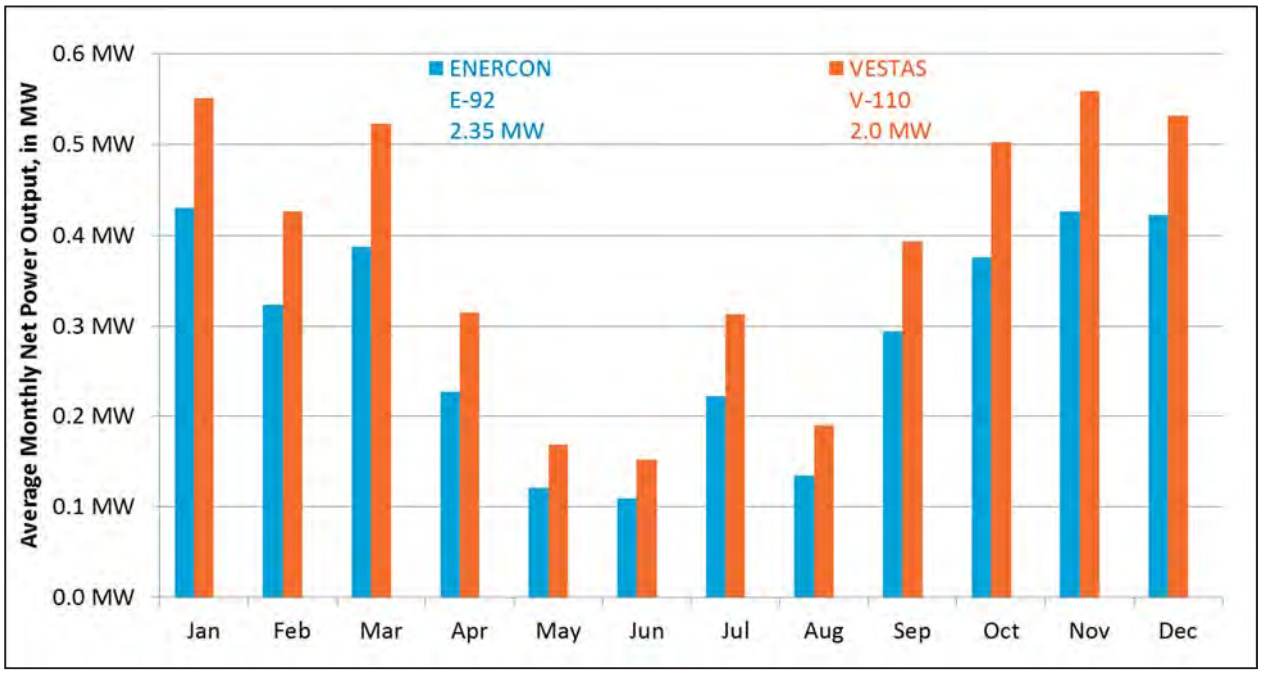
Sugarloaf Mountain is a site with medium to low wind speeds. There is a more pronounced difference between winter and summer than for other sites; especially during the summer months the output and capacity factor is low, see Figure 6 below.

Despite the generally favorable monthly production profile the site is low performing: During the winter months the sites produces only 55% of a wind turbine during the same period at the best performing site, Miller's Ridge.

4.3 Turbine Choice

Being a low-wind speed site, a IEA Class III turbine, such as the Vestas V-110 is a better choice than a Class II Enercon E-92 model. AWS models that the 2.35 MW Enercon E-92 produces 25% less energy annually than the less powerful (2.0 MW) Vestas V-110.

Figure 6 Monthly Production Profile for three Turbine Types at Sugarloaf Mountain



Data on the monthly losses and net production is provided below.

5 MOUNT SUMANIK

Compared to the other sites reviewed Mount Sumanik has an average wind resource. Consequently, the energy production is below the average of the seven sites.

5.1 Annual Gross Energy Production

Modeling of three wind farm sizes at Mount Sumanik yields lower energy production than the remaining six sites selected. The annual mean gross energy production of a single 2.0 MW turbine is 4.8 to 5.5 GWh. This is 21% to 29% less than the output of the same turbine at Miller's Ridge.

WAsP modeling of the three wind farm capacity options – 20, 10 and 6 MW – indicates an approximate 27% wind turbine net capacity factor based on the Gross Annual Energy Production in Table 30 below. A 27% capacity factor is good but perhaps could be improved upon with a wind turbine model more attuned to this site, in place of the generic 2 MW model for the modeling exercise. A decision for the latter, however, would require a review of the site data collected to date and more detailed terrain wind flow modeling to confirm the suitability of the northern and lower elevation ridges of Mount Sumanik for turbines.

Table 30 Mount Sumanik Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	49.3	4.93	4.32	5.76
	Wake Loss	2.4%	-	-	-
	AEP after Wake Loss	48.1	4.81	4.18	5.66
	Additional Losses and Downtime	13.8%			
	Net AEP	**41.5**			
10 MW	Gross AEP	24.9	4.97	4.51	5.65
	Wake Loss	1.4%	-	-	-
	AEP after Wake Loss	24.5	4.90	4.42	5.56
	Additional Losses and Downtime	13.8%			
	Net AEP	**21.1**			
6 MW	Gross AEP	16.6	5.55	5.24	5.76
	Wake Loss	1.2%	-	-	-
	AEP after Wake Loss	16.5	5.48	5.22	5.67
	Additional Losses and Downtime	13.8%			
	Net AEP	**14.2**			

The ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and* retain the higher performing locations.

Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance.

5.2 Monthly Generation Profile

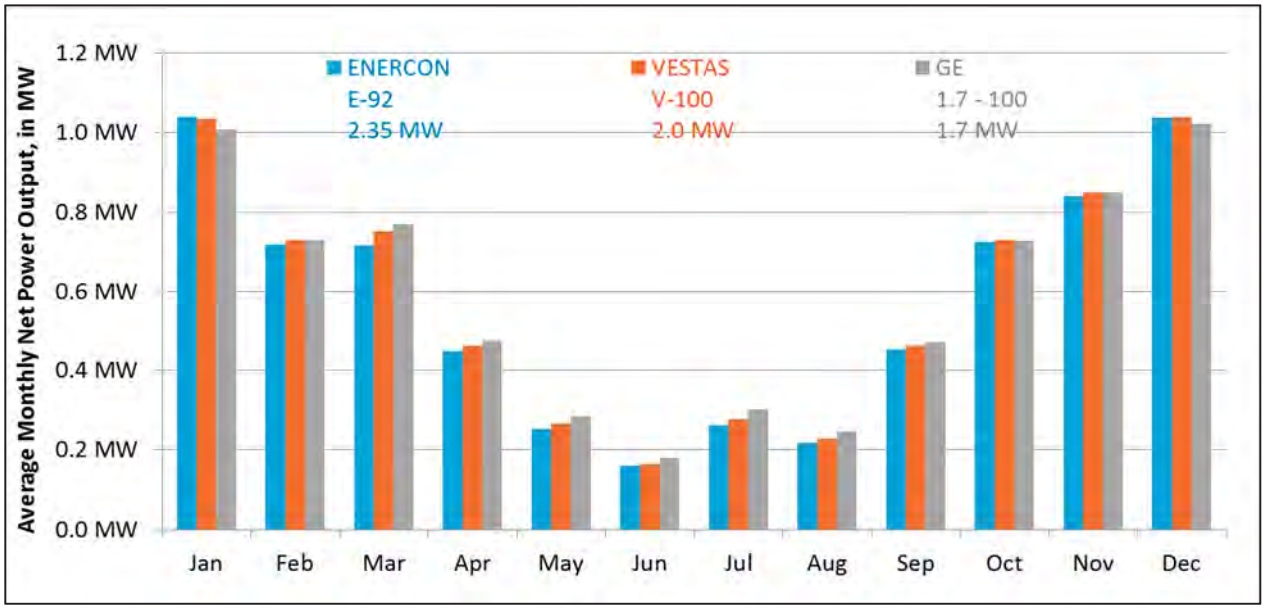
Mount Sumanik has a good power output in January and December, but rather low wind resources during the summer period. Moreover, wind direction changes by 90° from winter to summer, increasing wake losses in summer as the turbines start shading each other.

According to AWS modeling 79% to 81% of the energy will be produced from October to April, see Figure 7 below.

5.3 Turbine Choice

Comparing three options of turbine choices, AWS modeling yields that over the course of the year the GE-1.7-100 model with a rated capacity of only 1.7 MW yields slightly higher annual output than the 2.0 MW Vestas V-100 or the 2.3 MW Enercon E-92 turbine. In the period from October to April the Vestas V-100 turbine slightly outperforms the other two models.

Figure 7 Monthly Production Profile for three Turbine Types at Mount Sumanik Site



Data on the monthly losses and net production is provided below.

6 TEHCHO (FERRY HILL)

6.1 Annual Gross Energy Production

Tehcho is a site with an average wind resource compared to the remaining six sites. Modeling of three wind farm sizes at Mount Sumanik yields lower energy production than the remaining six sites selected. The annual mean gross energy production of a single 2.0 MW turbine is 3.4 to 4.4 GWh, depending on the size of the wind farm and the location of the individual turbine. This is 41% to 46% less than the output of the same turbine at Miller's Ridge.

These numbers are the gross energy production and only reflect wake, or wind turbine array efficiency, loss though. On a net energy basis a wind farm at Tehcho has a 39% to 43% lower output than the same size wind farm with the same turbine at Miller's Ridge.

WAsP modeling of the three wind farm capacity options – 20, 10 and 6 MW – indicates an approximate 22% wind turbine net capacity factor based on the Gross Annual Energy Production in Table 32 below. A 22% capacity factor is low and could be improved upon with a wind turbine model more attuned to this site in place of the generic 2 MW model for the modeling exercise. A decision for the latter, however, would require additional site data, or re-review of the older met tower data, to verify a likely IEC Class III wind regime.

Table 32 Tehcho Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	41.1	4.11	3.63	4.47
	Wake Loss	4.8%	-	-	-
	AEP after Wake Loss	39.2	3.92	3.35	4.36
	Additional Losses and Downtime	14.8%			
	Net AEP	**33.4**			
10 MW	Gross AEP	21.9	4.38	4.20	4.47
	Wake Loss	2.0%	-	-	-
	AEP after Wake Loss	21.5	4.29	4.07	4.41
	Additional Losses and Downtime	14.8%			
	Net AEP	**18.3**			
6 MW	Gross AEP	12.4	4.15	3.87	4.38
	Wake Loss	2.9%	-	-	-
	AEP after Wake Loss	12.1	4.03	3.80	4.21
	Additional Losses and Downtime	14.8%			
	Net AEP	**10.3**			

The ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and* retain the higher performing locations.

Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance.

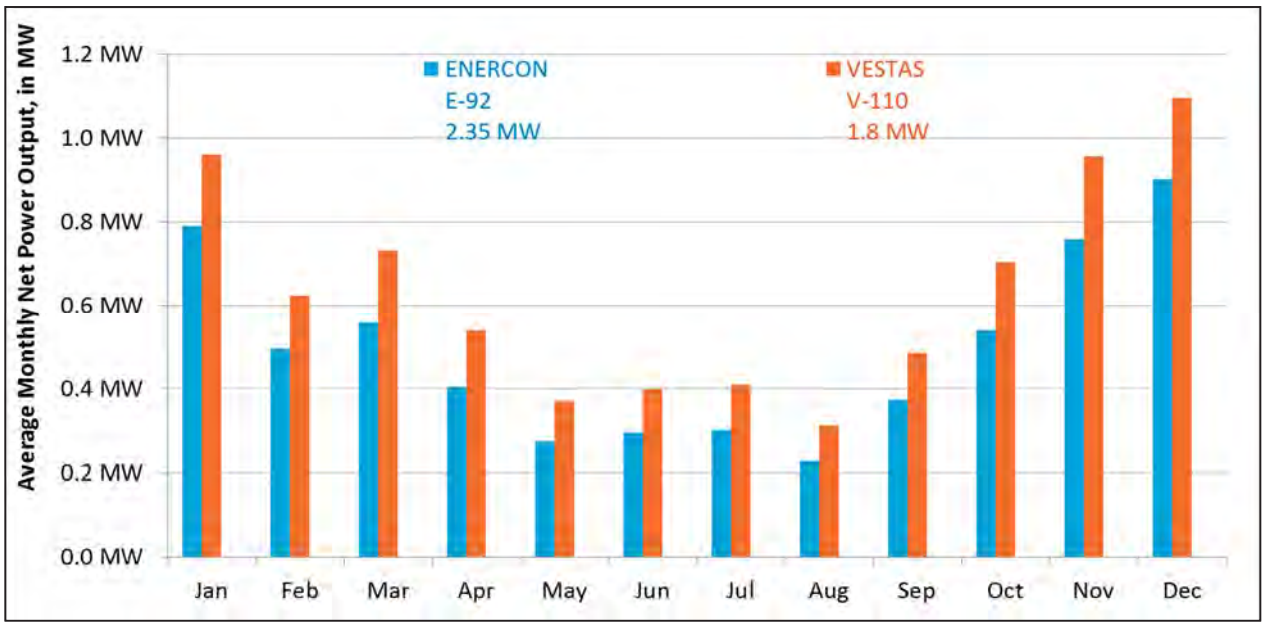
6.2 Monthly Generation Profile

As for all sites selected a wind farm at Tehcho produces more energy in winter than in summer. According to AWS modeling 75% to 76% of the energy will be produced from October to April, see Figure 8 below.

6.3 Turbine Choice

AWS modeling shows that for Tehcho (Ferry Hill) the 1.8 MW Vestas V-110 turbine yields 28% higher annual output than the 2.35 MW Enercon E-92 model. During the period from October to April the Vestas turbine still outperforms the Enercon turbine by 25%.

Figure 8 Monthly Production Profile for three Types of Turbines at Tehcho Site



Data on the monthly losses and net production is provided below.

7 THULSOO MOUNTAIN

Thulsoo Mountain has excellent wind resources, the second best wind resource of the seven sites selected. The mean annual wind speed is almost as high as for Miller's Ridge and consistently SSW, perpendicular to the turbine array of (see Figure 35 in Chapter 3.7 of the body of the report)

7.1 Annual Gross Energy Production

Modeling of a 6 MW, a 10 MW and a 20 MW wind farm yields almost the same energy as Miller's Ridge, the site with the highest mean wind velocity. The annual mean gross energy production of a single 2.0 MW turbine is 5.8 to 7.1 GWh, depending on the size of the wind farm and the location of the individual turbine. This is only 5% to 8% less than the output of the same turbine at Miller's Ridge.

WAsP wind farm modeling indicates an approximate 36% wind turbine net capacity factor based on the Gross Annual Energy Production in Table 34 below. This applies to all three wind farm sizes. A 36% capacity factor is extraordinarily good.

Table 34 Thulsoo Mountain Wind Farm Annual Energy Production, 2 MW generic turbine

Wind Farm Capacity	Parameter	Total all turbines (GWh)	Average turbine (GWh)	Lowest turbine (GWh)	Best turbine (GWh)
20 MW	Gross Annual Energy Production (AEP)	64.7	6.47	5.88	7.15
	Wake Loss	1.5%	-	-	-
	AEP after Wake Loss	63.7	6.37	5.84	7.05
	Additional Losses and Downtime	14.7%			
	Net AEP	**54.4**			
10 MW	Gross AEP	32.5	6.50	5.88	7.15
	Wake Loss	1.0%	-	-	-
	AEP after Wake Loss	32.2	6.44	5.87	7.06
	Additional Losses and Downtime	14.7%			
	Net AEP	**27.5**			
6 MW	Gross AEP	20.4	6.80	6.59	7.15
	Wake Loss	0.8%	-	-	-
	AEP after Wake Loss	20.2	6.75	6.52	7.06
	Additional Losses and Downtime	14.7%			
	Net AEP	**17.3**			

As for the previous six sites the ten turbine, 20 MW capacity, turbine layout was developed first and turbines were removed for the 10 MW (five turbine) and 6 MW (three turbine) capacity wind farm options. Wind turbines selected for removal for the lower capacity options were chosen to reduce the site footprint *and* retain the higher performing locations.

For a detailed wind farm design of a lower capacity option, one may wish to reconsider turbine locations with just the intended number in mind as possibly this may yield higher performance. Detailed WAsP wind farm reports for the three capacity alternatives can be found in Appendix G.

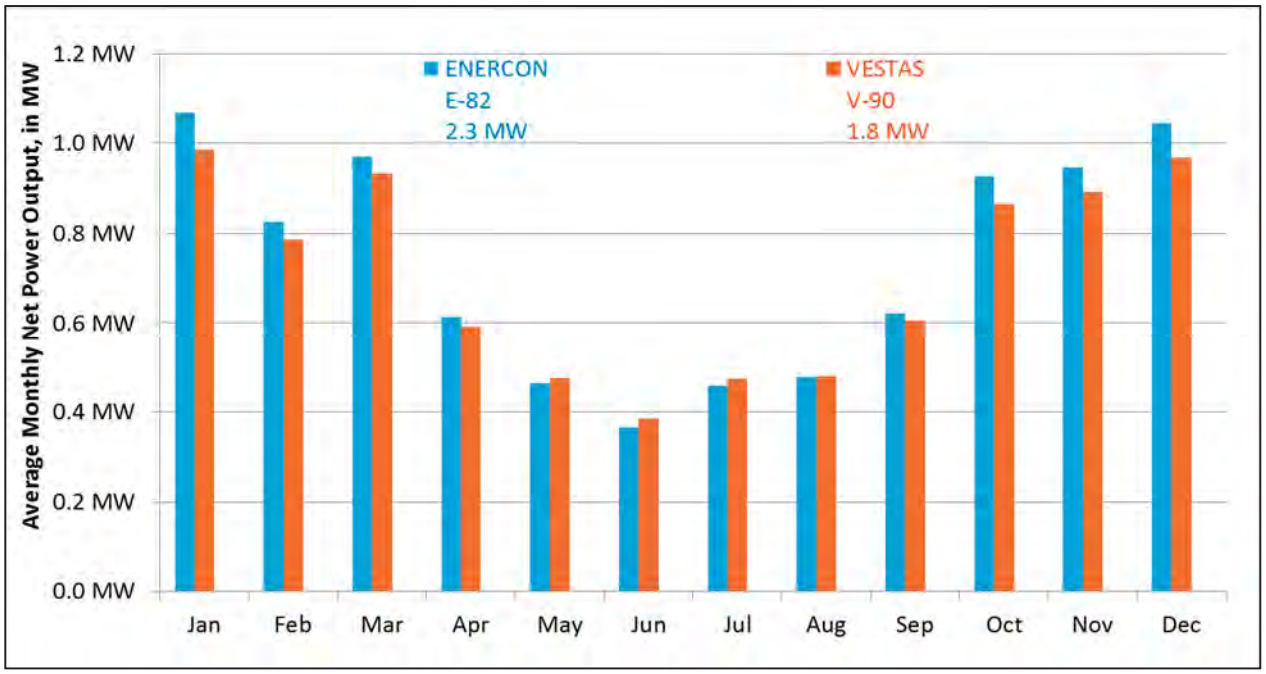
7.2 Monthly Generation Profile

As for all selected sites, a wind farm at Thulsoo Mountain produces more energy in winter than in summer. According to AWS modeling 72% to 74% of the energy will be produced from October to April, see Figure 9 below.

7.3 Turbine Choice

According to AWS modeling a larger (2.35 MW) Enercon E-92 turbine yields 6% to 8% higher annual energy production than the medium-sized 2.0 MW Vestas V-90 and the smaller size 1.7 MW GE 1.7-100 model. Thulsoo is a high wind speed site and a larger IEA Class II turbine, such as the E-92 can be expected to perform 4% better than the Class III GE-model.

Figure 9 Monthly Production Profile for Thulsoo Mountain Site



Data on the monthly losses and net production is provided below.

RE: Geothermal Review and Site Inventory
Final – Rev 0

Dear Mr. Lavigne:

Please find enclosed a PDF version of our revised draft report for the Yukon Energy Corporation Geothermal Review and Site Inventory. The primary objective of this study was to develop potential geothermal projects at a conceptual level. This study included identifying potential sites and providing economic analysis for these sites to determine whether a geothermal project was feasible in the Yukon. This revision addresses the comments received from Yukon Energy Corporation on the Draft B report.

After reviewing past reports and performing a volumetric assessment; the Vista Mountain and McArthur Springs locations were determined to have the largest production capacity for sites located near Yukon Energy Corporation's existing or planned infastructure. As the exact amount of production capacity is unknown, we have considered alternatives for both sites. The best and worst case senario in terms of production from the geothermal wells were considered for our analysis. For each alternative, we have developed monthly generation profiles and cost estimates including the construction and long term costs for developing these geothermal projects.

Please review the report and provide any comments you may have. We thank you for the opportunity to work on this project.

Sincerely,

Joel Lambert, P.Eng.
Senior Mechanical Engineer

EXECUTIVE SUMMARY

Yukon Energy Corporation retained the engineering services of KGS Group to develop conceptual designs for geothermal projects in the Yukon. KGS Group retained Mannvit hf from Iceland to perform the final review of the site selections, assessment of geothermal well field needs, plant sizing, and determination of the appropriate technology and process to be used for the selected sites. KGS Group also retained InterGroup Consultants to perform the economic evaluation of the concepts developed. The study includes identifying potential sites and providing cost estimates and energy generation profiles for these sites to determine whether a geothermal project is feasible.

KGS Group and Mannvit hf reviewed the memoranda and reports provided by YEC and established a ranking of the sites from most favourable to least. The terms of reference for the project were to consider only sites that were located within 25 km from existing or future planned infrastructure.

Of the sites within the geographic location criteria, the Vista Mountain site was the most attractive because it is located on crown lands, close to the load centre of Whitehorse, has a relatively high inferred temperature, and it is very close to the North Klondike Highway and the Takhini substation.

The most promising site reviewed was McArthur Springs. Although it does not lie within the corridor 25 km on either side of existing or planned infrastructure, it has the highest inferred temperature. Unfortunately, the length of the access road and transmission lines required to develop this site increase the expected project costs considerably.

Since no exploration wells have been drilled at any of the sites reviewed, including the Vista Mountain and McArthur Springs sites, there is considerable uncertainty regarding the actual reservoir temperature, chemistry and production index (PI) of the geothermal wells. This report presents optimistic and pessimistic cases for the PI at each site and the resulting plant capacities were determined using the geothermal fluid temperature that was inferred using geothermometer calculations.

The expected plant capacities from the Vista Mountain site range from 0.9 MW net output to 2.3 MW net output. The expected plant capacities from the McArthur Springs site range from 2.1 MW net output to 5.5 MW net output. The actual plant capacity that can be developed will be dependant on the actual geothermal fluid temperature and the PI values encountered once the wells are drilled. The plant capacities being limited by the estimated capacity of the geothermal resource.

The Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for the Vista Mountain site are shown in the Table below.

Geothermal Cases	Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC)					
	3.38% Real WACC		4.61% Real WACC		8.82% Real WACC	
	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)
	$/kW.h	$/MW	$/kW.h	$/MW	$/kW.h	$/MW
A	B	C	D	E	F	G
Vista Mountain Case 1: 0.9 MW	$0.368	$2,330,074	$0.412	$2,658,409	$0.577	$3,901,681
Vista Mountain Case 2: 2.3 MW	$0.194	$1,094,589	$0.214	$1,248,829	$0.290	$1,832,876

The Vista Mountain Case 1 with 0.9 MW net development scale shows about two times higher LCOE and LCOC under each WACC scenario compared to the higher scale capacity and energy Case 2 [with 2.3 MW]. This highlights that any small scale version of the project is likely not financially attractive.

The Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC) for the McArthur Springs site are shown in the Table below.

Geothermal Cases	Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC)					
	3.38% Real WACC		4.61% Real WACC		8.82% Real WACC	
	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)
	$/kW.h	$/MW	$/kW.h	$/MW	$/kW.h	$/MW
A	B	C	D	E	F	G
McArthur Springs Case 3: 2.1 MW	$0.469	$3,220,803	$0.527	$3,674,652	$0.746	$5,393,197
McArthur Springs Case 4: 5.5 MW	$0.225	$1,388,937	$0.250	$1,584,655	$0.343	$2,325,759

The McArthur Springs Case 3 with 2.1 MW net development scale shows more than two times higher LCOE and LCOC under each of the WACC scenarios compared to the higher scale Case 4 capacity and energy. This highlights that any small scale version of the project is likely not financially attractive.

1.0 INTRODUCTION

Yukon Energy Corporation (YEC), established in 1987, is a publicly owned electrical utility which provides reliable electricity to close to 15,000 consumers. The hydro facilities at Whitehorse, Mayo, and Aishihik Lake provide 92 megawatts of power to the surrounding communities. With 39 megawatts produced by diesel generators (currently used for back up) and 0.65 megawatts by a small wind turbine on Haeckel Hill near Whitehorse, Yukon Energy has the capacity to generate close to 132 megawatts. In support of Yukon's long term load forecast, YEC seeks to refine the knowledge and determine the feasiblity of potential geothermal generation projects in the Territory.

Yukon Energy Corporation retained the engineering services of KGS Group and indirectly, KGS Group's subconsultants, Mannvit hf of Iceland and InterGroup Consultants, to review existing reports and data, identify preferred sites, and develop conceptual designs for geothermal projects in the Yukon. The study includes cost estimates and energy generation profiles for these sites as well as the expected levelized costs of energy and capacity. The results of this study will be used to support Yukon Energy Corporation's planning process to look at potential resource options to meet the long term load forecast for 2016-2035.

1.1 TERMS OF REFERENCE

The scope of work for this study included the following:

- Attend a project kickoff meeting with YEC by conference call.
- Project Management.
- Review the 26 memoranda and reports previously completed by YEC on the available geothermal resources available in the Yukon.
- Identify all potential geothermal sites within 25 km of existing and/or planned infrastructure as illustrated by Figure 1 from the RFP.
- Employing the above information, select the best three (3) sites. Evaluate the site-specific requirements (procurement of land, # of wells, and type of equipment and cost of transmission/distribution) and develop conceptual level geothermal projects for various generation capacities, namely 5 MW, 10 MW and 20 MW.

- Develop monthly generation profiles for the three sites based on the projected capacities.
- Develop AACE Class V cost estimates (-50% to +100%) for the three sites based on the projected capacities.
- Identify preliminary risks and potential "Show Stoppers" for the three sites. However, it is noted that the evaluation of the three geothermal projects against the environmental and socio-economic attributes will be completed as a separate project.
- Identify and evaluate potential O&M costs for operation of the three sites based on the various generation capacities.
- Generate high-level project schedules (including provisions for further exploratory work, data collection, effects assessment, permitting and the like) from the early planning/exploration phase through to the project commissioning phase.
- Evaluate the earliest possible in-service date and potential project life for each of the three sites.
- Prepare a report detailing the study process and findings.

The items identified below were excluded from the scope of work:

- Collection of any additional environmental, geotechnical, or physical data; and
- Evaluation of the three geothermal projects against any environmental and socio-economic project attributes.

1.2 MODIFICATION TO THE ORIGINAL TERMS OF REFERENCE

Given the budget set aside by Yukon Energy Corporation to complete the study, the KGS Group proposal indicated that there would be greater value to Yukon Energy Corporation in developing fewer concept designs and providing a more in-depth review of fewer design options, than could be done if the 9 scenarios requested in the RFP were pursued. It was decided at the kick-off meeting that the existing data would be reviewed and the sites ranked from most to least attractive. From these intial rankings, a determination was made as to the number of total sites to be evaluated, and for the range in generating capacity for each site.

As described in Section 2, two sites were selected for concept design development and two different capacity levels were considered at each site; thus resulting in a total of four concept designs and cost evaluations.

2.0 REVIEW OF EXISTING INFORMATION AND RANKING OF SITES

KGS Group collected and reviewed pertinent documentation, reports, drawings, surveys and other data, assessed the available information, and identified the additional information required to effectively complete the study. The reports received from Yukon Energy Corporation are listed in Appendix A – Bibliography**.**

Information from CanGEA/Energy Branch was also used in this assessment. The information had not yet been published but Yukon Energy Corporation provided “early access” to assist with this work.

2.1 COMMENT ON AVAILABLE INFORMATION

In general, the reports provided by YEC were compiled over a number of years of study (typically between 2009 and 2012), and for the most part by the same engineering consultant. Some of the reports, such as more broadly based, sub-regional to regional aerial photography interpretation reports and/or other geophysical studies, for example, are of general interest in defining possible geothermal source signatures over larger areas, but did not factor directly into assessments and calculations necessary for completion of the current study. As such, these more regionally based reports were not reviewed in detail, other than to provide some context if/as necessary in relation to site terrain or general geological conditions of the region of interest.

Key data sources necessary for developing the current study included:

- Basic details associated with the overall geological setting and geological structure(s) of the potential geothermal resource;
- Measured surface spring temperature data;
- Measured water quality data to infer the possible relationship of the flow system(s) to deeper seated plutonic heat sources;
- Calculation of geothermal source temperatures via geothermometer calculations (typically SiO2 geothermometer techniques);
- Isotope signatures of source waters to infer residence times and possible deep-seated geothermal sources;

- Measured or estimated geothermal gradients (if any were available); and
- Typical ground temperatures for the region, and climate normal data, used to assess heat exchange processes necessary with the power generation schemes assessed in the study.

Each of the potential geothermal resources, ranked into the project shortlist during the course of this study, included some basic understanding of the geological framework and hydrogeological setting within which the possible geothermal resourse is hosted. This is of importance as there must be a conduit through which groundwaters can circulate to depth, become heated, and return back toward surface, to provide a signature for a possible geothermal resource target. The geochemistry of these heated spring waters will vary, depending on the geology, residence times, and flow path length/depths to which these groundwaters circulate. These signatures, in absence of direct measurements of a possible geothermal resource, are important in deducing the potential for a viable geothermal system.

Those resources in the vicinity of Whitehorse (e.g. Vista Mountain, Takhini, Stinky Lake and Versluce) are hosted within fault zones and ancillary fault zones of the “Whitehorse Trough”. The Whitehorse Trough is associated with an intermontane setting, comprised of an intensely folded, faulted and metamorphosed geology, and is juxtaposed along the Nahlin Fault zone, and south of the Tintina Fault, which is a significant, territory-wide structural feature.

Other short-listed geothermal features, namely Jarvis River, Partridge Creek, and the McArthur spring, are associated with a valley setting comprised of thick sediment cover, though bounded by assumed deep and sub-vertical fault zones; a zone of intense fracturing, faulting, and shearing along the Tintina Trench; and within the Selwyn Fold Belt, respectively. The Tintina Trench is associated with a massive Territory-wide fault zone, extending continuously for hundreds of kilometers, and the Selwyn Fold Belt formed during a phase of basin folding and during large scale mobilization of regional fault structures.

It is important to note that the evaluation of all of these potential geothermal resource sites as necessary for the current study are being completed using inferred data. None of these geothermal resources have been measured directly, and it is possible that direct measurement of these geological and geothermal features at depth could result in a different conclusion.

Site rankings and interpretations of possible geothermal resources are discussed in the following report sections.

2.2 SITE LOCATION CRITERIA

The terms of reference for this study stipulated that sites located within a 25 kilometre range of existing and planned future Yukon Energy Corporation infrastructure (i.e. transmission & distribution lines, substations, switchyards, etc.) would be considered for evaluation. This is due to the relatively high additonal costs of support infrastructure such as construction of access roads and interconnections via new transmission lines. This was the first screening criteria applied to all target geothermal resources, and several of the sites discussed in the reports and memos were eliminated from consideration based only on this proximity criteria. Figure 1 is a map of the geographical area in question, which includes the locations of the potential geothermal sites. Table 1 lists the longitude and latitude of the sites that meet the location criteria, as well as the "straight-line" distance to the existing or planned infrastructure and estimates of the transmission line and access road lengths that would be necessary to develop the site.

TABLE 1
SITES LOCATED WITHIN 25 KM OF EXISTING OR PLANNED INFRASTRUCTURE

NAME OF SPRING	LATITUDE	LONGITUDE	STRAIGHT LINE DISTANCE TO TRANSMISSION LINE	ESTIMATED ACCESS ROAD LENGTH	ESTIMATED TRANSMISSION LINE LENGTH
	[deg - min]	[deg - min]	[km]	[km]	[km]
Takhini	60 52	135 22	1	1	1
Versluce	60 46	135 09	1	1	1
Mayo well	63 36	135 53	1	1	1
Stinky Lake	60 45	135 08	1	1	1
Vista Mountain	60 55	135 11	4	2	5
Jarvis Creek	60 54	137 57	5	5	5
Partridge Creek	63 41	137 18	15	20	20
Atlin	59 24	133 35	20	1	22
Morin North	59 59	134 13	22	33	33
Morin Middle	59 58	134 13	22	33	33
Jones Lake	59 53	134 00	22	22	22
Morin South	59 58	134 13	25	30	30

Of these sites, the Takhini, Versluce, Vista Mountain and Stinky Lake sites are attractive from a geographical location point of view because of their proximity to Whitehorse and the major load centre in the Territory.

There were a few sites that, while not within the area of interest, were reviewed. These sites are listed in Table 2.

TABLE 2
SITES LOCATED CLOSE TO LOCATION CRITERIA

NAME OF SPRING	LATITUDE	LONGITUDE	STRAIGHT LINE DISTANCE TO TRANSMISSION LINE	ESTIMATED ACCESS ROAD LENGTH	ESTIMATED TRANSMISSION LINE LENGTH
	[deg - min]	[deg - min]	[km]	[km]	[km]
McArthur	63 04	135 42	37	43	43
McPherson	61 52	129 37	41	50	50
Volcano Mountain	62 54	137 20	33	35	35

2.3 SITE RANKINGS

Once the location screening criteria was applied, the available information for the remaining sites was reviewed. This amount of information available for each site varied. Some sites had almost no information at all (e.g. Volcano Mountain and the Sites near Atlin), while reports contained water temperature, groundwater chemistry, spring flow rates and isotope analyses for some of the other sites.

The following sites were eliminated from consideration from this study based on the lack of available information.

- Volcano Mountain.
- Atlin.
- Jones Lake.
- Morin (South, Middle and North).
- Mayo Well.

Further investigation/exploration may indicate geothermal resources worth developing at these sites, but there is not sufficient information available at this time to make this determination. The remaining sites, each including enough base information for a cursory resource evaluation, were ranked as follows (Refer to Appendix B – Site Ranking Summary for further details):

- Vista Mountain Warm Spring.
- Takhini.
- Stinky Lake Warm Springs.
- Versluce.
- Jarvis Creek (Jarvis River) Warm Spring.
- Partridge Creek.
- McArthur Spring.

Interestingly, based on the available data, the McArthur Spring, although not in accordance with the proximity to existing/future infrastructure criteria, appears overall to be the site with the greatest inferred potential for a “low temperature” geothermal source. It was ranked at 7 due to its distance from the nearest transmission line (Carmacks-Stewart line), and associated complexities in constructing road access and power transmission interconnections in a rugged terrain setting.

Vista Mountain ranks high due to its close proximity to infrastructure and the main load center of Whitehorse, location on Crown lands, and relatively high inferred resource temperature (110°C, or “low temperature” geothermal) in comparison to other possible Whitehorse region sites which have an inferred temperature of <100°C (Klump and Dennett, December 2012). The Takhini geothermal resource is also in a good geographical location, however it is situated on private land and it is currently being operated as a recreational “Hot Spring” business, which is a major destination in the Whitehorse area. The inferred temperature of the Takhini geothermal resource is just below the “low temperature” geothermal resource threshold cutoff, at an inferred resource temperature of approximately 96°C (Klump and Dennett, December 2012).

It should be noted that, of the remaining sites in the Whitehorse region (i.e. Stinky Lake, Versluce, and Jarvis River), there is not one site that is siginificantly better than the others, and

the associated inferred maximum resource temperature of these sites is approximately 100°C. Partridge Creek, while in accordance with the transmission right-of-way screening criteria, is further from the main Territory load center of Whitehorse, located approximately 115 km southeast of Dawson City. The inferred resource temperature of Partridge Creek is somewhat low, with geothermometer readings as low as 95°C, though depending on the geothermometer calculation used, reported estimates on reseource temperature vary between approximately 100°C and 120°C (Klump and Dennett, April 2012). Access/transmission construction to Partridge Creek is overall within rugged terrain, thus increasing site development logistical complexities, and overall associated costs as compared to possible geothermal resources located closer to Whitehorse. The difference in the current site rankings is within the expected margin of error, and given more information from further investigations or explorations, the site ranking order may vary.

All the reviewed sites for this report are low/medium temperature resources. Low/medium temperature resources have temperature less than 150°C. The fluid is usually pumped from the wells as a liquid. The heat from the fluid is used for generating electrical power in a binary power cycle as described in Section 3.2.1. For comparison, the temperature in high temperature resources are typically over 200°C. The fluid from the wells is usually in two phases, liquid and steam, but in some cases dry steam. The steam can be used directly in turbines. The efficiency and feasibility of such power plant is usually better than for a power plant using low/medium temperature resource in a binary power cycle.

2.4 PREFERRED SITES AND POTENTIAL PLANT CAPACITIES

Given that there was not a marked difference between the attractiveness of the Whitehorse region potential geothermal resource sites (other than for inferred resource temperature), the KGS Group team and Yukon Energy Corporation decided to develop concept designs for only one of these sites. Due to the limited baseline data available, there is little to no difference in the concept design that would apply to any of these sites. However, it was decided that a site with the highest inferred geothermal resource temperature, and relatively straightforward construction considerations (i.e. Vista Mountain), would form the best base case for assessment in the Whitehorse region. The Vista Mountain concept design is in general representative of the concept that could be developed for the remainder of these Whitehorse region sites.

The Vista Mountain Warm Spring site was selected because it:

- Ranked better that the other Whitehorse region sites, based on inferred geothermal resource temperature.
- Is geographically located near Whitehorse and near the Takhini substation.
- Is located near the North Klondike Highway.
- Has a relatively gentle surrounding terrain with good access; and
- Is located on public (Crown) land.

Regarding the resource capabilities, the main assumption for the preferred sites is that each geothermal resource capacity declines annually by 2%, as a "natural" decline. As a face value, the lifetime of each project is just over 30 years, if no new make-up wells are drilled. For the range of the selected Productivity Indices (PI) and temperatures, as well as assuming the power generating processes presented in the following report sections, each well power output was estimated to be 0.6 to 3.5 MW_e. The annual well decline would be approximately 0.02 to 0.1, depending on the PI and temperature.

The annual production decline of 2% is taken from the world literature and it applies to high temperature geothermal projects with successful reinjection. For the Yukon projects which are assumed to be operated at much lower temperature, the 2% annual decline is a reasonable estimation.

For this type of reservoir, reinjection will boost the reservoir pressure by providing an extra mass flow. Ideally the reinjection strategy is to locate the injection and production wells close together to provide pressure support, but far enough apart to prevent premature thermal breakthrough. Without any reservoir simulations in hand, the minimum distance between a production and a reinjection well is considered to be about 1,000 m. The world average between production and reinjection wells for this type of reservoir is about 1,300 m.

The two cases at Vista Mountain are primarily based on two assumptions for PI. Case 1 has a PI of 1 kg/s/bar, producing 1.2 MW gross and 0.9 MW net. Case 2 has PI of 5 kg/s/bar, producing 3.1 MW gross and 2.3 MW net. The number of wells and completion depth of the wells are the same for both the cases and the expected geothermal resource temperature is

estimated at 120°C. The only difference between the cases is the PI value which results in different mass flow from the production wells. Wells with less mass flow like in Case 1 do not need as powerful well pumps as Case 2 and other parasitic load for such a plant (e.g. power to run well pumps and condenser fans, etc.) is also less. The two PI values are estimates of likely ranges estimated for the McArthur reservoir as well.

The McArthur Warm Spring site was also selected for assessment. Although it is situated outside the geographical proximity to transmission tie-in screened within this study, and while the terrain/access conditions appear difficult, it was the only site where the available raw data showed a geothermal resource that was of significantly higher temperature than all other potential geothermal resource sites studied to date. In fact, based on the raw water quality data provided, a recalcuation of the silica geothermometer for this resource indicates it may be inferred to be as high as approximately 155°C – 160°C. While not included in the current assessment, it is important to note that the site is located on land that has significance to the local First Nations community.

The two cases at McArthur are, as in the Vista Mountain case, primarily based on two assumptions for PI. Case 3 has PI of 1 kg/s/bar, producing 2.8 MW gross and 2.1 MW net. Case 4 has PI of 5 kg/s/bar, producing 7.0 MW gross and 5.5 MW net. The number of wells and depth of the wells are the same for both the cases, and the expected temperature value is estimated at 160°C. The only difference betweem the cases is the PI value which results in different mass flow from the production wells. Wells with less mass flow like in Case 3 do not need as powerful well pumps as Case 4 and other parasitic load for such a plant is also less.

Drilling of make-up wells is usually a part of the normal operation of a geothermal power plant in order to replenish the reduced capacity of the production wells. How frequently make-up wells are drilled depends on the decline rate as well as number of wells. The cost of drilling one make-up well can, however, be a large part of the total cost for power projects with few wells making the make-up drilling less feasible. In the case of the Vista Mountain and McArthur Springs sites, it is expected that the drawdown in the wells will be governed by the general drawdown in the resource. As the temperature decline and degradation of equipment are also independent of the wells, we conclude that make-up wells will not remedy the output degradation.

Due to lack of geophysical data, the actual size of the geothermal resource could not be delineated. Therefore, a conventional volumetric capacity estimate was not possible. The approach here was to use the length of the mapped faults to determine how many wells could be drilled in each area. The assumption is that the faults are the main providers of the necessary permeability to sustain the proposed geothermal production. The second assumption is that 1000 m spacing is required between the wells. These assumptions lead to the conclusion that both the areas (Vista Mountain and McArthur Springs) could each sustain two production wells and one injection well. The limited number of wells that could be sustained at each site limit the plant capacities that could be developed at these sites to the values included in this report.

Dissolved solids and/or gases may require water treatment mitigations, such as relatively high plant operation pressure and/or necessary chemical treatment. The nature of geothermal plants is such that these problems are normally inherited and unavoidable, but mitigatable. The mitigation methods depend on the nature of the geothermal fluid (like chemical composition, temperature and pressure). Since little is known about the nature of the geothermal fluid in these resources which are being dealt with here, the extent of the mitigation process is unknown. Possible problems and mitigations for geothermal fluids are listed in Table 3.

TABLE 3

WATER TREATMENT MITIGATIONS

PROBLEM	MITIGATION
High CO_2 gas content of the fluid leads to high CO_2 emission into the atmosphere.	Keep the CO_2 dissoved in water by relatvely high wel head pressures and reinject it back into the reservoir.
Low pH (acid geothermal fluid) which can be corrosive for wells and pipelines.	Injecting a solution with high pH value into the well to neutralize its acidity.
Mineral scaling due to silica (SiO_2) and/or calcite ($CaCO_3$).	Inhibitors injected into the well, high operation pressures, repeated cleaning.

2.5 FURTHER EXPLORATION

The geological information available for the Vista Mountain site is general and further work is needed to assess the geothermal potential of the area. The assessment should be divided into two phases.

The first phase should focus on the surface geology, structural arrangements and geochemistry in the Vista Mountain area. The target of the work is to estimate the resource temperature and to delineate the geothermal area. With this information, the power capacity can be estimated. The estimated power capacity value will be used as a go/no-go decision for further work.

If the decision is to continue the investigation, the assessment will move to phase two. The work in this phase mainly focuses on geophysical surveys. There are several geophysical surveys which can be utilized. Normally two to three individual surveys are recommended. Typical surveys are resistivity surveys (for this area, Transient Electro-Magnetic (TEM) surveys are ideal and Magnetotelluric (MT) surveys are less so due to the low probability of adding information on the resistivity structure of the area), gravity surveys and magnetic surveys. Surface surveys, like soil temperature and soil gas mapping are also ideal, as well as thermal gradient drilling. The soil/gas temperature mapping measures the temperature and the gas flow in the soil down to 1 meter depth. Soil temperature/gas mapping will find anomalously hot areas, which are normally tied to permeable structures. These permeable structures could be then targeted at greater depths. Prior to drilling thermal gradient wells, the regional gradient must be known so anomalous areas can be delineated. In other words, the proposed thermal gradient survey will focus on finding anomalously hot areas. In low temperature areas, the thermal gradient wells only need be 30-60 meters deep, if the permeability is low. The number of wells will vary greatly, but 10-15 wells are not an unrealistic number of thermal gradient wells.

If after the completion of the assessment, deep drilling is still considered too risky, one option is to drill “slim” exploration wells (i.e. test boreholes with diameters less than 150 mm, or 6 inches) which are deep enough to penetrate into the top of the geothermal resource. Slim wells offer cost effective solution compared to a full diameter research well. The resource temperature can be measured in slim wells and short production/injection testing can be carried out as well. Nevertheless, slim well drilling is risky, particularly with deep wells, and it is highly unlikely they can be used as either production wells or reinjection wells.

3.0 VISTA MOUNTAIN

3.1 SITE DESCRIPTION

Vista Mountain is located approximately 4 km North of Takhini Substation and approximately 1 km West of the North Klondike Highway, as shown on Figure 2. Access to the site is good. Most of the distance between the North Klondike Highway and the spring is generally flat, with a rise in elevation on approach to the spring site itself. It is estimated that the optimum transmission line route will follow the access road from the plant to the North Klondike Highway. The line would then follow the existing right of way to the Takhini substation.

3.1.1 Regional Geology and Site Observations

Site visits were not included in the scope of this project, therefore the Vista Mountain site, and any geological observations are based on the available reports (e.g. Klump and Dennett, December, 2012), and satellite/aerial images of the surrounding landscape. Review of aerial photography indicates a relatively flat (+/- 2 m elevation variation) rock outcrop south of the spring site suitable for construction of the powerhouse and condenser. There is strong evidence of glacial scouring, with most exposed outcrops with a smooth and rounded morphology. The rock is generally of low relief, with fluted outcrops trending in a northwest-southeast orientation, separated by narrow shallow depression areas. Limited overburden stripping and minimal bedrock excavation is estimated to be necessary to prepare the preferred construction site, south of the spring. Based on the extents of visible bedrock, it is estimated that all major structures can be founded on concrete slabs cast directly on the prepared bedrock surface, with smaller components such as pipe supports or doweled directly to the rock surface. Rock types in the area include massive to thickly bedded limestones, and sandstones, shales, and conglomerates. Specifically, outcrops of limestones and shales are observed at the spring site itself. As reported by Klump and Dennett (December, 2012), typical slopes are gentle (e.g. 15% to 26%), to moderate in other site areas (i.e. 27% to 49%) away from the relatively flat location that would be targeted for construction of any facility, and as described above.

As described by Klump and Dennett (December, 2012), two regional fault trends are typical in the study area, subsidiary zones associated with the more regional Whitehorse Trough. These

faults trend in a northwesterly direction, and in a north-northeast, to northerly direction. The spring site itself is located at the intersection of two prominent faults. Dominant jointing directions measured at the site are generally in a north-south direction, dipping to the west, with secondary discontinuity orientations northwest-southeast (dipping southwest) and/or oriented northeast-southwest with a sub-vertical dip. The project area includes zones of glaciolacustrine deposits, overlying the bedrock.

The project site as well lies within the zone of discontinuous permafrost in Canada, where frozen ground is scattered throughout these kinds of glaciolacustrine fine sediments. In general permafrost is most common within poorly drained and low-lying bog areas where layers of peat and vegetation insulate the ground and prevent permaforst thaw. At this time, permafrost design issues are not included within the conceptual assessments. However, based on the extents of visible bedrock at the site it is not estimated that permafrost issues would be significant for development at this site.

3.1.2 Availability of Construction Material

Construction materials would need to be sourced to provide for aggregates for access road construction as well as concrete production. From a review of satellite photography, established aggregate sources are located within 15 km of the site which could likely provide all aggregate needs for the project. If the available local aggregate sources are not sufficient or accessible, other established aggregate sources in the Whitehorse area would provide the required construction materials.

3.2 PLANT ARRANGEMENT

3.2.1 Organic Rankine Cycle (ORC) Power Plant

The Vista Mountain site was estimated to produce geothermal liquid at 120°C. The design concepts for the site are comprised of ORC geothermal plants for both cases where the geothermal fluid is kept as single phase liquid. An ORC plant uses the high temperature steam and/or water from the production wells to heat a binary fluid, which most often is a hydrocarbon, with a low boiling point in a heat exchanger. The heat absorbed from the geothermal source

causes the hydrocarbon fluid to evaporate, producing the high-pressure vapor that is then expanded through a turbine. The turbine drives a generator to produce electrical power. The low pressure turbine exhaust vapor is then condensed to be recirculated through the system repeatedly. The lower boiling point and higher molecular weight of the hydrocarbon fluid allows the use of smaller equipment than a conventional steam cycle operating at low temperatures. After the geothermal fluid has heated the hydrocarbon fluid in the heat exchanger, it is reinjected into the reservoir through a reinjection well. Figures 3 and 4 demonstrate schematically how an organic rankine cycle (ORC) functions for different PI values.

For both Case 1 and Case 2, it is proposed that the arrangement consist of two production wells and one injection well. All wells were assumed to be 2700 metres deep and they would be located approximately 1000 m apart. The wells will have ø13 ⅜" anchor casings down to approximately 400 m depth and a ø9 ⅝" production liner from 300 m down to approximately 1000 m. The production part of the wells will be drilled with a ø8 ½" drill bit and a ø7" slotted liner will be run in the production part down to the bottom of the well or 2700 m depth. Installed in the wells will be ø8" line-shaft pumps. A small building covering the well head and associated equipment would be equipped with either a roof hatch or a completely removable roof to allow for easy installation and maintenance of the pumps. Buried insulated pipe would connect the wells to the plant. Although the exact location of the plant relative the wells cannot be determined without further field investigations, the preferred option is to locate the plant close to the reinjection well, even within the well field.

Figure 5 and Figure 6 show the proposed plant layout. The turbine, generator and control rooms will be housed in a powerhouse due to the local climate. The heat exchangers and condensing equipment are located outdoors adjacent to the powerhouse.

3.2.2 Transmission Line

The transmission line for the Case 1 and 2 is 34.5kV which will follow the Vista Mountain access road until it dead ends to Highway #2. It will then follow Highway #2 and interconnect with the transmission line at the Takhini Substation. The proposed transmission line path does not interfere with any Ta'an Kwach'an First Nation settlement land.

With little site specific geological or terrain information evaluated, the exact construction location within the Vista Mountain region may vary along with the required transmission line alignment. For cost estimating purposes, the transmission line length is estimated to be 5 km from the geothermal plant to the Takhini Substation.

There has been no consideration to the overall grid capacity at the tie-in locations, and any constraints or limitations of the existing or future grid extensions have not be evaluated. Costs for upgrades that may be required have not been carried in the estimates in this report.

3.3 POWER AND ENERGY POTENTIAL

3.3.1 Estimates of Potential Energy

The efficiency of an ORC geothermal power plant is inversely proportional to the ambient temperature. In other words; the efficiency of the plant decreases as the the ambient temperature increases. Also, as the ambient temperature increases, more power is needed to condense the working fluid. This results in a lower plant capacity during the summer. In the winter months, the efficiency increases and less power is required to condense and a higher plant capacity is achieved. The following tables show the gross and net plant capacity ranges for both cases.

CASE #1

	T_{amb} [°C]	P_{gross} [MW]	P_{net} [MW]
	15	1,1	0,7
Design case:	**8**	**1,2**	**0,9**
	0	1,4	1,1

CASE #2

	T_{amb} [°C]	P_{gross} [MW]	P_{net} [MW]
	15	2,7	1,9
Design case:	**8**	**3,1**	**2,3**
	0	3,6	2,8

As mentioned earlier, a constant decrease of 2% per year has been assumed. The actual performance of the wells would depend on the local conditions. Monitoring of the well production rates and drawdown values would be required during the operation of the station.

3.3.2 Case 1 - Monthly Generation Profile

The energy production was estimated using monthly climate normals recorded from 1981 to 2010 at the Whitehorse A station which were provided by weather records of Government of Canada.

The assumptions used for this estimation of the average annual energy production are:

- The plant net capacity was linearly interpolated between 1.1 MW – 0.9 MW for monthly climate normals between 0°C - 8°C.
- The plant net capacity was linearly interpolated between 0.9 MW – 0.7 MW for normals between 8°C and 15°C.
- The plant net capacity is 1.1MW for any monthly climate normal under 0°C.
- Plant availability of approximately 95%.

The monthly generation profile for Case 1 is shown in Figure 7.

The maximum energy production would occur in between the months of December and March. The following table summarizes the monthly generation profile resulting with an initial yearly total of 8.15 GWh. As discussed, the capacity and yearly energy production of the plant decreases over time; therefore, after 30 years, it is expected that the annual energy production will be decreased to 4.54 GWh.

TABLE 4
CASE 1 SUMMARY OF INITIAL AVERAGE MONTHLY ENERGY

	MONTHLY AVERAGE ENERGY (MWh)
January	777
February	702
March	777
April	735
May	648
June	532
July	509
August	543
September	629
October	769
November	752
December	777
Yearly Total (MWh)	**8150**

3.3.3 Case 2 - Monthly Generation Profile

For Case 2, the plant net capacity was linearly interpolated between 2.8MW – 2.3MW for monthly climate normals between 0°C - 8°C and 2.3MW – 1.9MW for normals between 8°C and 15°C.

The assumptions used for this estimation of the average annual energy production are:

- The plant net capacity was linearly interpolated between 2.8 MW – 2.3 MW for monthly climate normals between 0°C - 8°C
- The plant net capacity was linearly interpolated between 2.3 MW – 1.9 MW for normals between 8°C and 15°C
- The plant net capacity is 2.8MW for any monthly climate normal under 0°C.
- Plant availability of approximately 95%, to account for inspection/repair time.

The monthly generation profile for Case 2 is shown on Figure 8.

The maximum average energy production would occur in between the December and March months. Table 4 summarizes the monthly generation profile resulting with a yearly total of 20.95 GWh. The capacity and yearly energy production of the plant decreases over time; therefore, after 30 years, it is expected that the annual energy production will be decreased to 11.66 GWh.

September	1,607
October	1,957
November	1,915
December	1,979
Yearly Total (MWh)	**20,950**

3.4 COST ESTIMATES

Costing for both cases was completed for comparison. The total 0.9 MW net plant, Case 1, is estimated at approximately $37,800,000, as summarized in Table 5. The total 2.3 MW net project cost, Case 2, is estimated at approximately $45,200,000, as summarized in Table 5. Detailed estimates of the project direct costs have been provided in Appendix C – Detailed Cost Estimates. This appendix also include a brief discussion of the basis for the cost estimate.

TABLE 6
VISTA MOUNTAIN SUMMARIZED COSTS

ITEM			CASE 1 0.9 MW COST (2015 $)	CASE 2 2.3 MW COST (2015 $)
Contractor Direct Costs			**$15,130,000**	**$18,160,000**
Site Work			$100,000	$120,000
Structures & Excavation			$930,000	$1,190,000
Power Plant			$2,900,000	$5,400,000
Wells & Water Supply System			$9,070,000	$9,320,000
Transmission Line & Interconnection			$990,000	$990,000
Access			$640,000	$640,000
Environmental & Mitigation Items			$500,000	$500,000
General Contractor Indirect Costs	*35%*	of Directs	**$5,300,000**	**$6,360,000**
Travel and Accommodation Costs	*6%*	of Directs	**$910,000**	**$1,090,000**
Subtotal			**$21,340,000**	**$25,610,000**
Contingency	*30%*	*of Subtotal*	**$6,400,000**	**$7,680,000**
Total Construction Cost			**$27,740,000**	**$33,290,000**
Contractor Markups			**$5,600,000**	**$6,720,000**
Profit	12%	of Const.	$3,329,000	$3,995,000
Head Office Overhead	7.0%	of Const.	$1,942,000	$2,330,000
Bonding & Insurance	1.2%	of Const.	$333,000	$399,000
Total Contractor Price			**$33,340,000**	**$40,010,000**
Owner Costs			**$4,440,000**	**$5,180,000**
Environmental Licencing/Consulting	3.0%	of Directs	$454,000	$545,000
Prefeasibility Study	0.5%	of Directs	$76,000	$91,000
Feasibility Study	1.5%	of Directs	$227,000	$272,000
Final Design	9.0%	of Directs	$1,362,000	$1,634,000
Site Assistance & Quality Assurance	6.0%	of Directs	$908,000	$1,090,000
Owner's Administration	2.0%	of Contract	$667,000	$800,000
Pre-Drilling Go/No Go Exploration			$750,000	$750,000
Total Project Cost			**$37,800,000**	**$45,200,000**

The total project costs shown are expected to be inclusive of all project costs. Given the limited amount of design work performed to date, a contingency of 30% has been included. Also, the allowances for contractor indirect costs, travel and accommodation, profit, overhead, etc. are based on KGS Group's recent experience on hydroelectric development projects in various remote locations in Canada (including the Mayo B Hydroelectric project).

3.5 CONSTRUCTION SCHEDULE & LIFE OF THE PROJECT

The preliminary construction schedule is shown on Figure 9. A pre-design phase including the test well drilling and confirmation of plant capacity has been considered in the context of the total project schedule. If the pre-design phase where to start immediately, site works and transmission line construction would start 1ST quarter 2018. The earliest possible in service date would be 1ST quarter 2019.

The potential life span for both Case 1 and 2 are estimated at 30 years.

3.6 OPERATION AND MAINTENANCE COSTS

At this early stage of design, it is difficult to estimate the operation and maintenance costs, but generally, an ORC geothermal plant of the sizes in question here can be operated by one person working approximately half-time. On top of this, scheduled and unscheduled maintenance needs to occur. The O&M cost includes all expenses that are related to the operation and maintenance of the power plant like overhead costs, supervision of equipment (turbine, generator, heat exchangers, buildings, pipes, wellhead etc.), maintenance (both work and material) and monitoring. Besides the labor cost, the other costs include some consumable goods (lubricants, spare parts, etc.), taxes and other expenses such as waste disposal.

To estimate yearly average maintenance costs, published data for ORC geothermal plants was used. Costs per kW of capacity from the report “Assessment of Current Costs of Geothermal Power Generation in New Zealand (2007 Basis)”, by Sinclair Knight Merz, 2009, was used as a basis. The published data was for 20 MW plants, therefore, the values obtained were scaled up to account for the anticipated increase cost per kW for the significantly smaller Vista Mountain cases. The O&M costs were estimated at:

- Case 1 (0.9 MW net plant): $350,000 per year.
- Case 2 (2.3 MW net plant): $800,000 per year.

3.7 LEVELIZED COSTS

The Levelized Cost of Energy ("LCOE") and Levelized Cost of Capacity ("LCOC") are a useful means of comparing energy options based on financial attributes, providing the levelized cost of a unit of energy or capacity of a resource option at the point of interconnection with the Yukon power grid. The LCOE and LCOC estimates adopted for this assessment assume a full utilization of the energy and capacity of the reviewed option.

The following financial assumptions are used for LCOE and LCOC analysis ($2015) of the Vista Mountain geothermal resource option:

- The capital costs, including transmission/interconnection costs identified during the review and provided in this report;
    - Vista Mountain case 1 at $37.0 million.
    - Vista Mountain case 2 at $44.4 million.
- Annual fixed operating and maintenance costs identified during the review and provided in this report;
    - Vista Mountain case 1 at $0.350 million/year.
    - Vista Mountain case 2 at $0.800 million/year.
- Annual energy output [KWHr] and capacity [MW] outputs are based on evaluation of each option provided in this report, including the assumed 2% yearly degradation over the life;
- Expected life of all options is assumed to be 30 years and the in-service date is assumed to be the start of 2019.
- Inflation rate of 2%.
- Weighted average cost of capital (WACC) as specified by YEC.
- Rate of 5.45% (nominal) and 3.38% (real), assuming 2% inflation.
- The options are also reviewed using higher WACC (assumed to be used in the assessments of independent power producers [IPP] options):
    - Rate of 6.7% (nominal) and 4.61% (real).
    - Rate of 11% (nominal) and 8.82% (real).

Table 7 below provides a summary of the LCOE and LCOC for each scale of Vista Mountain development cases under each of the WACC scenarios.

TABLE 7
LCOE AND LCOC FOR VISTA MOUNTAIN CASES

Geothermal Cases	Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC)					
	3.38% Real WACC		4.61% Real WACC		8.82% Real WACC	
	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)
	$/kW.h	$/MW	$/kW.h	$/MW	$/kW.h	$/MW
A	B	C	D	E	F	G
Vista Mountain Case 1: 0.9 MW	$0.368	$2,330,074	$0.412	$2,658,409	$0.577	$3,901,681
Vista Mountain Case 2: 2.3 MW	$0.194	$1,094,589	$0.214	$1,248,829	$0.290	$1,832,876

The Vista Mountain Case 1 with 0.9 MW net development scale shows about two times higher LCOE and LCOC under each WACC scenarios compared to the higher scale capacity and energy Case 2 [with 2.3 MW]. This highlights that any small scale version of the project is likely not financially attractive.

Refer to Appendix D - Financial Tables for further details.

4.0 McARTHUR SPRINGS

4.1 SITE DESCRIPTION

McArthur Springs is located approximately 42 km East of North Klondike Highway southeast of Stewart Crossing, and approximately 75 km south of Mayo, as shown on Figure 10. The site is located within the Ddhaw Ghro Habitat Protection Area, and is designated for mineral exporation development by the Selkirk First Nation. With the remote location of the springs, current site access conditions are challenging, due to overall rugged terrain. As a result of this, a longer access road is necessary to access the geothermal plant site. It is therefore assumed that the optimum transmission line route will follow the access road from the plant to interconnection along the North Klondike Highway.

4.1.1 Regional Geology and Site Observations

Site visits were not included in the scope of this project, therefore the McArthur Springs site and geology observations are based on available reports (e.g. Schillereff, Johnston, and Dennett, February, 2009; Dennett and Klump, April, 2010; Menzies and Dennett, October, 2009; Carlson and Zondervan, September, 2009; Carlson and Zondervan, June, 2009), and satellite/aerial images of the surrounding landscape. The springs are associated with an intensely folded geological terrane, within the Selwyn Fold Belt. The McArthur Pluton, a major intrusive body, is also a significant feature in the McArthur springs area, and is oriented relatively parallel to the Tintina Trench (which is located 8 km south of the spring site). The springs exit at the southwest margin of the pluton, where it had intruded sedimentary and meta-sedimentary bedrock at the margin of the basin. These bedrock units include siltstones, mudstones and chert, with interbedded sandstones and schists. Based on the orientation of the creek where the springs are located, the spring site is assumed to be hosted within a subsidiary fault zone, trending at approximately 60° to the main regional fault trend.

The spring discharges at 18 individual vents, distributed over an area of approximately 150 m x150 m, and exiting from river valley fill overburden deposits. Variation in the preciptates from groundwater flows at the discharge areas, suggest that there have been changes in flows, or variation in discharge sites, over the life of this spring. Unique to this site is the relatively fesh

spring groundwater geochemistry, which suggests short residence times within the subsurface circulation system.

A relatively flat area will be selected near the spring site, suitable for construction of the powerhouse and condenser. Limited overburden stripping and rock excavation in the form of local chipping rather than blasting is anticipated to prepare the site for construction. Due to the extents of bedrock visible, it is expected that all major structures can be founded on slabs cast directly to rock with smaller components such as pipe supports or doweled directly to the rock surface.

While the project site lies within the zone of discontinuous permafrost in Canada, in general permafrost is most common within fine grained glaciolacustine soils that are poorly drained and where layers of peat and vegetation insulate the ground and prevent permaforst thaw. At this time, permafrost design issues are not included within the conceptual assessments.

4.1.2 Availability of Construction Material

Construction materials would need to be sourced to provide for access road construction, as well as for concrete production. From a review of satellite photography, existing rock outcrops and talus materials could be developed to produce all aggregate needs for the project. Importantly, the cut-fill balance of the road design would require optimization, as best possible, to mitigate the need for significant importation of construction materials, and enhance efficient and cost effective utilization of materials available within the project footprint and along the access road alignment. A Geotechnical investigation of the surrounding area could be required to optimize the road alignment, and also confirm sources of additional construction materials, if the available local sources are insufficient, or otherwise difficult to develop for construction use. Some photos of the McArthur site that show the typical valley rockfills and bedrock outcrops in the project area are contained within reference reports such as Schillereff, Johnston, and Dennett (February, 2009).

4.2 PLANT ARRANGEMENT

4.2.1 Organic Rankine Cycle (ORC) Power Plant

The McArthur Springs site was estimated to produce geothermal fluid at 160°C; which is significantly higher than Vista Mountain. The higher water temperature delivers more heat for the hydrocarbon fluid to absorb in the heat exchanger. The more heat absorbed by the working fluid, the higher pressure flowing through the turbine-generator unit which results in a higher plant capacity. The ORC components are similar to both cases at Vista Mountain, only the system size is larger. For further details on functionality of the ORC, refer to Section 3.2.1. Figures 11 and 12 demonstrate the organic rankine cycle schematic for the different PI values.

For both Case 3 and Case 4, it is proposed that the arrangement consist of two production wells and one injection well. All wells were assumed to be 2700 metres deep and they would be located approximately 1000 m apart. The wells will have ø13 ⅜" anchor casings down to approximately 400 m depth and a ø9 ⅝" production liner from 300 m down to approximately 1000 m. The production part of the wells will be drilled with a ø8 ½" drill bit and a ø7" slotted liner will be run in the production part down to the bottom of the well or 2700 m depth. Installed in the wells will be ø8" line-shaft pumps. A small building covering the well head and associated equipment would be equipped with either a roof hatch or a completely removable roof to allow for easy installation and maintenance of the pumps. Buried insulated pipe would connect the wells to the plant.

Figure 13 and Figure 14 show the proposed plant layout. The turbine, generator and control rooms will be housed in a powerhouse due to the local climate. The heat exchangers and condensing equipment are located outdoors adjacent to the powerhouse.

4.2.2 Transmission Line

The transmission line for Case 3 and 4 is 138kV which will follow the McArthur Springs access road until it dead ends onto the North Klondike Highway. Located north of the Pelly and MacMillan rivers, the proposed transmission line path lies entirely within Nacho Nyak Dun First

Nation and Selkirk First Nation traditional territory and the westernmost portion of the line is within the Selkirk First Nation settlement land.

With relatively little geological or site specific information, the exact transmission line corridor within the McArthur Springs region is undetermined at this time, along with the required length of transmission line. For cost estimating purposes, an approximated transmission line length of 42 km is assumed.

Similar to the Vista Mountain location; there has been no consideration to the overall grid capacity at the tie-in locations, and any constraints or limitations of the existing or future grid extensions have not be evaluated. Costs for upgrades that may be required have not been carried in the estimates in this report.

4.3 POWER AND ENERGY POTENTIAL

4.3.1 Estimates of Potential Energy

The efficiency of an ORC geothermal power plant is inversely proportional to the ambient temperature. In other words; the higher the ambient temperature, the lower the efficiency and more power is needed to condense the working fluid. This results in a lower plant capacity during the summer. In the winter months, the efficiency increases and less power is required to condense and a higher plant capacity is achieved. The following tables show the gross and net plant capacity ranges for both cases.

CASE #3

	T_{amb} [°C]	P_{gross} [MW]	P_{net} [MW]
	15	2,6	1,9
Design case:	**8**	**2,8**	**2,1**
	0	3,1	2,4

CASE #4

	T_{amb} [°C]	P_{gross} [MW]	P_{net} [MW]
	15	6,4	4,9
Design case:	**8**	**7,0**	**5,5**
	0	7,7	6,2

As mentioned earlier, a constant decrease of 2% per year has been assumed. The actual performance of the wells would depend on the local conditions. Monitoring of the well production rates and drawdown values would be required during the operation of the station.

4.3.2 Case 3 - Monthly Generation Profile

The energy production was estimated using monthly climate normals recorded from 1981 to 2010 at the Whitehorse A station which were provided by weather records of Government of Canada.

The assumptions used for this estimation of the average annual energy production are:

- The plant net capacity was linearly interpolated between 2.4 MW – 2.1 MW for monthly climate normals between 0°C - 8°C
- The plant net capacity was linearly interpolated between 2.1 MW – 1.9 MW for normals between 8°C and 15°C.
- The plant net capacity is 2.4 MW for any monthly climate normal under 0°C.
- Plant availability of approximately 95%.

The monthly generation profile for Case 3 is shown on Figure 15.

The maximum energy production would occur in between the months of December and March. Table 8 summarizes the monthly generation profile resulting with an initial yearly total of 18.62 GWh. As discussed, the capacity and yearly energy production of the plant decreases over time; therefore, after 30 years, it is expected that the annual energy production will be decreased to 10.37 GWh.

TABLE 8
CASE 3 SUMMARY OF INITIAL AVERAGE MONTHLY ENERGY

	MONTHLY AVERAGE ENERGY (MWh)
January	1,696
February	1,532
March	1,696
April	1,616

July	1,357
August	1,391
September	1,457
October	1,683
November	1,642
December	1,696
Yearly Total (MWh)	**18,620**

4.3.3 Case 4 - Monthly Generation Profile

The assumptions used for this estimation of the average annual energy production are:

- The net plant capacity was linearly interpolated between 6.2 MW – 5.5 MW for monthly climate normals between 0°C - 8°C
- The plant net capacity was linearly interpolated between 5.5 MW – 4.9 MW for normals between 8°C and 15°C
- The plant net capacity is 6.2 MW for any monthly climate normal under 0°C.
- Plant availability of approximately 95%, to account for inspection/repair time.

The monthly generation profile for Case 4 is shown on Figure 16.

The maximum average energy production would occur in between the December and March months. Table 9 summarizes the monthly generation profile resulting with a yearly total of 48.24 GWh. The capacity and yearly energy production of the plant decreases over time; therefore, after 30 years, it is expected that the annual energy production will be decreased to 26.85 GWh.

TABLE 9

December	4,382
Yearly Total (MWh)	**48,240**

4.4 COST ESTIMATES

Costing for both cases was completed for comparison. The total 2.1 MW net plant, Case 3, is estimated at approximately $114,000,000, as summarized in Table 10. The total 5.5 MW project cost, Case 4, is estimated at approximately $127,000,000, as summarized in Table 9. Detailed estimates of the project direct costs have been provided in Appendix C – Detailed Cost Estimates. This appendix also include a brief discussion of the basis for the cost estimate.

TABLE 10
McARTHUR SPRINGS SUMMARIZED COSTS

ITEM			CASE 3 2.1 MW COST (2015 $)	CASE 4 5.5 MW COST (2015 $)
Contractor Direct Costs			**$45,010,000**	**$50,170,000**
Site Work			$110,000	$130,000
Structures & Excavation			$1,660,000	$2,550,000
Power Plant			$4,400,000	$8,400,000
Wells & Water Supply System			$8,800,000	$9,050,000
Transmission Line & Interconnection			$11,120,000	$11,120,000
Access			$18,420,000	$18,420,000
Environmental & Mitigation Items			$500,000	$500,000
General Contractor Indirect Costs	35%	of Directs	**$15,750,000**	**$17,560,000**
Travel and Camp Costs	10%	of Directs	**$4,500,000**	**$5,020,000**
Subtotal			**$65,260,000**	**$72,750,000**
Contingency	30%	of Subtotal	**$19,580,000**	**$21,830,000**
Total Construction Cost			**$84,840,000**	**$94,580,000**
Contractor Markups			**$17,140,000**	**$19,110,000**
Profit	12%	of Const.	$10,181,000	$11,350,000
Head Office Overhead	7.0%	of Const.	$5,939,000	$6,621,000
Bonding & Insurance	1.2%	of Const.	$1,018,000	$1,135,000
Total Contractor Price			**$101,980,000**	**$113,690,000**
Owner Costs			**$12,040,000**	**$13,310,000**
Environmental Licencing/Consulting	3.0%	of Directs	$1,350,000	$1,505,000
Prefeasibility Study	0.5%	of Directs	$225,000	$251,000
Feasibility Study	1.5%	of Directs	$675,000	$753,000
Final Design	9.0%	of Directs	$4,051,000	$4,515,000
Site Assistance & Quality Assurance	6.0%	of Directs	$2,701,000	$3,010,000
Owner's Administration	2.0%	of Contract	$2,040,000	$2,274,000
Pre-Drilling Go/No Go Exploration			$1,000,000	$1,000,000
Total Project Cost			**$114,000,000**	**$127,000,000**

The total project costs shown are expected to be inclusive of all project costs. Given the limited amount of design work performed to date, a contingency of 30% has been included. Also, the allowances for contractor indirect costs, travel and accommodation, profit, overhead, etc. are based on KGS Group's recent experience on hydroelectric development projects in various remote locations in Canada (including the Mayo B Hydroelectric project).

4.5 CONSTRUCTION SCHEDULE & LIFE OF THE PROJECT

The preliminary construction schedule is shown on Figure 17. A pre-design phase including the test well drilling and confirmation of plant capacity has been considered in the context of the total project schedule. If the pre-design phase where to start immediately, site works would start 3rd quarter 2018. The earliest possible in service date would be 4th quarter 2019.

The potential life span for both Case 3 and 4 are estimated at 30 years.

4.6 OPERATION AND MAINTENANCE COSTS

At this early stage of design, it is difficult to estimate the operation and maintenance costs, but generally, an ORC geothermal plant of the sizes in question here can be operated by one person working approximately half-time. On top of this, scheduled and unscheduled maintenance needs to occur. The O&M cost includes all expenses that are related to the operation and maintenance of the power plant like overhead costs, supervision of equipment (turbine, generator, heat exchangers, buildings, pipes, wellhead etc.), maintenance (both work and material) and monitoring. Besides the labor cost the other costs include some consumable goods (lubricants, spare parts, etc.), taxes, and other expenses such as waste disposal.

To estimate yearly average maintenance costs, published data for ORC geothermal plants was used. Costs per kW of capacity from the report "*Assessment of Current Costs of Geothermal Power Generation in New Zealand (2007 Basis)", by Sinclair Knight Merz, 2009,* was used as a basis. The published data was for 20 MW plants, therefore, the values obtained were scaled up to account for the anticipated increase cost per kW for the significantly smaller Vista Mountain cases. The O&M costs were estimated at:

- Case 3 (0.9 MW plant): $800,000 per year.
- Case 4 (2.3 MW plant): $1,800,000 per year.

4.7 LEVELIZED COSTS

The Levelized Cost of Energy ("LCOE") and Levelized Cost of Capacity ("LCOC") are a useful means of comparing energy options based on financial attributes, providing the levelized cost of a unit of energy or capacity of a resource option at the point of interconnection with the Yukon power grid. The LCOE and LCOC estimates adopted for this assessment assume a full utilization of the energy and capacity of the reviewed option.

The following financial assumptions are used for LCOE and LCOC analysis ($2015) of the McArthur Springs geothermal resource options:

- The capital costs, including transmission/interconnection costs identified during the review and provided in this report:
    - McArthur Springs Case 3 at $113.0 Million.
    - McArthur Springs Case 4 at $126.0 Million.
- Annual fixed operating and maintenance costs identified during the review and provided in this report:
    - McArthur Springs Case 3 at $0.8 Million/Year.
    - McArthur Springs Case 4 at $1.8 Million/Year.
- Annual energy output [KWHr] and capacity [MW] outputs are based on evaluation of each option provided in this report, including the assumed 2% yearly degradation over the life.
- Expected life of all options assumed to be 30 years [assumed in-service by the start of 2020].
- Inflation rate of 2%.
- Weighted average cost of capital (WACC) as specified by YEC:
    - Rate of 5.45% (nominal) and 3.38% (real), assuming 2% inflation.
- The options are also reviewed using higher WACC (assumed to be used in the assessments of independent power producers [IPP] options):
    - Rate of 6.7% (nominal) and 4.61% (real).
    - Rate of 11% (nominal) and 8.82% (real).

Table 11 below provides a summary of the LCOE and LCOC for each scale of McArthur Springs development cases under each of the WACC scenarios.

TABLE 11

LCOE AND LCOC FOR McARTHUR SPRINGS CASES

Geothermal Cases	Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC)					
	3.38% Real WACC		4.61% Real WACC		8.82% Real WACC	
	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)
	$/kW.h	$/MW	$/kW.h	$/MW	$/kW.h	$/MW
A	B	C	D	E	F	G
McArthur Springs Case 3: 2.1 MW	$0.469	$3,220,803	$0.527	$3,674,652	$0.746	$5,393,197
McArthur Springs Case 4: 5.5 MW	$0.225	$1,388,937	$0.250	$1,584,655	$0.343	$2,325,759

The McArthur Springs Case 3 with 2.1 MW net development scale shows more than two times higher LCOE and LCOC under each of the WACC scenarios compared to the higher scale Case 4 capacity and energy. This highlights that any small scale version of the project is likely not financially attractive.

The detailed tables are provided in Appendix D – Financial Tables.

5.0 REVIEW OF RISKS

The process proposed for the geothermal generating plants is well established and it is not expected that there are significant risks with the availability of equipment or the technology.

The risks identified with the geothermal developments discussed in this report are related to the unknowns with the geothermal field. Namely, the temperature of the fluid, the production index of the wells, the depth of the wells required, the size of the geothermal field and the chemical properties of the geothermal fluid. Table 12 discusses the effects of these parameters.

TABLE 12
RISKS IDENTIFIED WITH THE GEOTHERMAL DEVELOPMENTS

PARAMETER	IMPACT
Temperature of fluid	Efficiency and feasibility of the power plant is directly related to temperature
Production Index	Higher the yield from the wells (L/s) results in more efficient utilization of wells (i.e. reduced drawdown and thus reduced associated pumping costs) and this makes the plant more feasible
Temperature gradient	Well depth is related to the temperature gradient and the well depth affects the cost of drilling
Size of geothermal field	The size of the power plant relative to the size of the geothermal field and can also affect life time of the plant.
Chemical properties	Dissolved solids and/or gases may require mitigation by higher plant operating pressures, and may effect a limitation on cooling of the fluid, or necessitate chemical treatment. This may increase parasitic load, reduce plant power efficiency, and/or increase operating/maintenance costs

As shown in the preliminary project schedule, one or two wells should be drilled prior to detailed design to confirm the available resource. Once the results from the exploration wells are known, a GO – NO GO decision would have to be made. The cases presented are expected to be the estimated upper and lower bounds of the potential geothermal well production capacities.

As mentioned in Table 12, the well depth affects the cost of drilling. Figure 18 shows how the drilling cost developes with the depth when drilling a vertical 2000 m deep well where the production section is drilled with a ø8 ½" drill bit. The cost does not include preparation for the drilling such as roads, drill pad, water supply, surface casingetc. From the graph, one can read that the marginal cost for depth is rather small and will be still smaller when the cost of preparation is included. The drilling risk will however increase with increased depth and the depth and strength of anchor and production castings limits the maximum depth of the well.

6.0 CONCLUSIONS AND RECOMMENDATIONS

6.1 CONCLUSIONS

Frorm the information to date within the reports and information provided by Yukon Energy, it is concluded that there is a modest geothermal resource available for development in the Yukon. The inferred temperatures at all of the sites reviewed are relatively low and would therefore require the use of a binary geothermal plant arrangement (organic rankine cycle).

Of the sites reviewed that are within the 25 km corridor on either side of existing or planned transmission infrastructure, the Vista Mountain site appears to be the most promising. It is located on crown lands, close to the load centre of Whitehorse, has a relatively high inferred temperature, and is very close to the North Klondike Highway and the Takhini substation

The most promising site reviewed was McArthur Springs. Although it does not lie within the 25 km corridor on either side of existing or planned transmission infrastructure, it has the highest inferred resource temperature. Unfortunately, the length of the access road and transmission lines required to develop this site increase the estimated project costs considerably.

Since no exploration wells have been drilled at any of the sites reviewed, including the Vista Mountain and McArthur Springs sites, there is considerable uncertainty regarding the actual reservoir temperature, fluid chemistry, and production index (PI) of the geothermal wells. This report presents optimistic and pessimistic cases for the PI at each site. The resulting plant capacities were determined using the geothermal fluid temperature that was inferred using from existing geothermometer calculations. Further surveys and geophysical investigation would be required to refine the estimates presented herein.

The expected plant capacities from the Vista Mountain site range from 0.9 MW net output to 2.3 MW net output. The expected plant capacities from the McArthur Springs site range from 2.1 MW net output to 5.5 MW net output. The actual plant capacity that can be developed will be dependant on the actual geothermal fluid temperature and the PI values encountered once the production test wells are drilled and assessed.

The LCOE and LCOC analyses in this report were performed assuming full utilization of the energy option throughout each year during the 30 year life assumed under each scale of development. The following compares the financial attribute analysis of the resource options reviewed:

- The McArthur Springs option is materially larger than Vista Mountain at each of the two scales examined for each option, i.e., the smallest McArthur Springs case (Case 3) is roughly the same scale as the largest Vista Mountain case (Case 2).
- Both of these geothermal resource options are not economically attractive if the larger scale development case is not confirmed for the option through further studies, i.e., levelized unit costs per kW.h (LCOE) or per MW (LCOC) are more than twice as high for the smallest scale case versus the largest scale case for each option. McArthur Springs case (Case 3) shows the highest LCOE and LCOC reflecting high capital cost [more than 2.5 times the capital cost compared to roughly the same scale for the Vista Mountain case].
- The real LCOE ($2015) for the largest scale cases examined for each option is in the range of 19-22 cents/kW.h, i.e., $0.194/kW.h for Vista Mountain Case 2 (2.3 MW) and $0.225/kW.h for McArthur Springs Case 4 (5.3 MW). However, the McArthur Springs Case 4 option requires the larger load demand for fossil energy displacement in order to be competitive financially with the Vista Mountain Case 2 option.

McArthur Springs requires a much longer transmission line (assumed at 138 kV) to connect to the Yukon electrical grid. There could be potential financial benefits not considered in this analysis if the new transmission could be utilized by other loads or resource options.

6.2 RECOMMENDATIONS

The cost of drillling exploration wells at either of these sites is substantial. This is especially true for the McArthur Springs site, given its distance from any established access road. Therefore, further studies should be perfomed to quantify and delineate the resource at each site. The first studies should focus on the surface geology and structural arrangements and geochemistry in each area. With this, the estimated power capacity value can be used as a go/no-go decision for further work. If then, it is decided to proceed further, geophysical surveys and other surface mapping, as well as shallow drilling of smaller diamater test wells to determine thermal gradients would be required.

Following the additional studies, should either of these sites be considered further for development, at least one exploration well should be drilled at that site prior to making a final GO/NO GO decision. Since an exploration well could be developed into a production well if the project proceeds, the cost of the exploration is implicitly included in the cost estimates provided herein.

Once more precise information is known for resource temperature, fluid chemistry and well production index, the ORC process could be refined, preliminary equipment selections could be completed and the cost estimates for the project refined.

7.0 STATEMENT OF LIMITATIONS AND CONDITIONS

7.1 THIRD PARTY USE OF REPORT

This report has been prepared for Yukon Energy Corporation to whom this report has been addressed and any use a third party makes of this report, or any reliance on or decisions made based on it, are the responsibility of such third parties. KGS Group accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions undertaken based on this report.

7.2 CAPITAL COST ESTIMATE STATEMENT OF LIMITATIONS

The cost estimates included with this report have been prepared by KGS Group using its professional judgment and exercising due care consistent with the level of detail required for the stage of the project for which the estimate has been developed. These estimates represent KGS Group's opinion of the probable costs and are based on factors over which KGS Group has no control. These factors include, without limitation, site conditions, availability of qualified labour and materials, present workload of the Bidders at the time of tendering and overall market conditions. KGS Group does not assume any responsibility to Yukon Energy Corporation, in contract, tort or otherwise in connection with such estimates and shall not be liable to Yukon Energy Corporation if such estimates prove to be inaccurate or incorrect.

NOTES:
1. Wetland, Watercourse and Waterbody layers shown were obtained from GeoYukon base data.
2. All units are metric and in metres unless otherwise specified. Transverse Mercator Projection, NAD 1983, Zone 8. Elevations are in metres above sea level (MSL).

APPENDIX B

SITE RANKING SUMMARY

APPENDIX B - SITE RANKING SUMMARY

Site Ranking	Spring Name Within 50 km corridor	St. Line Distance to T Line	Approx. Access Road Length, KM	Approx. T Line Length, KM	LOCATION			Site Geology (inferred)	Surface Temp.	Geothermometer Estimated Temp °C	Geochemistry	Spring Flow Rate	Comments	References
					LAT.	LONG	Description							
1	Vista MT Warm Springs	1	1	1			~20 km North of Whitehorse ~1 km west of Klondike Hwy.	-Granite pluton associtated with Whitehorse trough - Thick overburden cover. Assumed deep flow system and major fault system	14	110	$CaCo_3$ + SO_4		-Meteoric water conditions, short residence time	1
2	Takhini	1	1	1	60.867	135.367	~33 km North of Whitehorse ~ 6 km North of Yukon Hwy 1	- Fractured Basalt - Whitehorse trough-fault zones - Thin sedimentary cover	47	96	$CaSo_4$	340 L/min		1,2, 4
3	Stinky Lake Warm Springs	1	1	1			~10 km North of Whitehorse	- Fractured Basalt - Whitehorse trough-fault zones - Thin sedimentary cover	19	85	CaMg HCO_3 H25 odour		-Possible origin of thermal water in sedimentary carbonate rich rocks	1, 2, 14
4	Versluce	1	1	1	60.767	135.15	~16 km North of Whitehorse	- Fractured Basalt - Whitehorse trough-fault zones - Thin sedimentary cover	13	54	CaMg HCO_3	60 L/min	- West of Porter Creek - NE of Whitehorse landfill	1,2, 5
5	Jarvis River / Warm Springs	5	5	5	60.9	137.95	Shakwak Valley ~31 km north west of Haines Junction (5 km south of Yukon Hwy 1)	- Thick overburden deep geothermal vertical faults	≤16	100	$NaHCO_3$		- Most seismicly active area in Yukon - Artesian flow from O/B at 47 m, - Possible meteroic origin difficult to seal drill hole	2, 12
6	Partridge Creek	15	20	20	63.697	137.28	~115 km SE of Dawson	Tintina Trench-Zone of intense fracturing, faulting and shearing	25	95	Na-HCO_3-SO_4		-Terrain/access challenges -Thermal water has long residence time (>>10,000 years); limited young, shallow water.	13
7	McArthur Spring (>50 km corridor)	37	45	45	60.067	135.7	Selkirk First Nation Lands ~32 km West of Yukon Hwy #2 (NW of Pelly Crossing)	- Selwin Fold belt	54	120	$NaHCO_3$		- Springs SW of McArthur Pluton	2, 10
8	Mayo Well	1	1	1	63.6	135.883	~17 km North of Mayo		15		$NaHCO_3$			6
9	Atlin	20	1	22	59.4	133.583	~165 km SE of Whitehorse		29		$Ca(CO_3)_2$			7
10	Morin North	22	33	33	59.983	134.217	~100 Km S of Whitehorse		<29		$Ca(CO_3)_2$			8
	Morin Middle				59.967	134.217								9
	Morin South				59.967	134.217								11
11	Jones Lake	22	22	22			~115 km SE of Whitehorse		<29		$Ca(CO_3)_2$			10
Sites near 50 km Corridor														
1	McPherson	41	50	50	61.867	129.617	~200 km N of Watson Lake ~30 Km NW of Yukon Hwy		N/A					12
2	Volcano Mountain	44	50	50			~40 km NW of Pelly Crossing	Volcano deposits of the Selkirk Volcanics are the youngest (<10,000 yrs)	N/A				- No Surface springs detected - Subsurface drilling required	2

Notes:

1. See YEC Figure 1: Location Plan with Grid Overview and hand marked geothermal sites.
2. Geothermometoe calculated temperatures estimated using the silica based method are considered to be a more plausible lower temperature estimate, versus the higher temperature Na-K-Ca based method.

APPENDIX C

DETAILED COST ESTIMATES

BASIS OF COST ESTIMATES

KGS Group has completed and is currently involved in several Canadian utility development projects. These projects are located in similarly remote locations, such as northern Manitoba, northeastern Ontario, and in northern Saskatchewan. The building and site costs for this geothermal project our based on KGS Group's recent experience.

Mannvit has been involved with the design and construction of several geothermal projects; throughout the world. The well and power plant costs, including the turbine, generator, heat exchangers, condensers, controls and pipeline costs are based from their database of projects.

Well costs included are "normal" costs for deep well drilling. Some areas in the world are currently seeing a 20% to 30 % reduction in these costs due to the slowdown in oil exploration and development. Depending on the timing of any well drilling, these savings may or may not be realized.

Direct costs include the construction expenses of the proposed geothermal development, including all temporary works such as access roads required during construction as well as all component costs needed during development. These component costs, including the turbine, generator, wells, transmission lines and interconnection have been estimated based on calculated material quantities for the arrangements and unit prices.

At this conceptual level of study the various indirect costs have been estimated as percentages of the direct costs, including the General Contractor's indirect costs, travel and camp costs, contingencies, and contractor markups. Owner's costs have also been estimated as percentages of the project direct costs, and include environmental approval studies and consultations through the approval process with all stakeholders. Owner's costs also include additional feasibility assessment costs, final design, site assistance, quality assurance and interest during construction. The Mayo B contract, as well as other more recent hydro projects, were used to develop a criteria for estimating the indirect and owner costs for the potential geothermal development for this study.

APPENDIX D

FINANCIAL TABLES

Table 1: Summary Yukon Energy Corporation Geothermal Generation Options

Step 1 - Financial analysis

Geothermal Cases	Option Assumptions											Levelized Cost of Energy (LCOE) and Levelized Cost of Capacity (LCOC)					
	Capital Cost (2015$)			Annual Fixed O&M Costs (2015$)	Annual Variable O&M Costs (2015$)	Annual Average Capacity [net output] - First Year	Reliable Winter Capacity [net output] - First Year	Annual Average Capacity Factor	Annual Average Energy - First Year	Expected Life	Expected In-Service Date (January 1)	3.38% Real WACC		4.61% Real WACC		8.82% Real WACC	
	Plant Capital Cost	Transmission Capital Cost	Total Capital Cost									LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)	LCOE (2015$)	LCOC (2015$)
	$000	$000	$000	$000	$/MW.h	MW	MW	%	GW.h	Years	Year	$/kW.h	$/MW	$/kW.h	$/MW	$/kW.h	$/MW
A	B	C	D=B+C	E	F	G	H	I	J	K	L	M	N	O	P	Q	R
Vista Mountain Case 1: 0.9 MW	$35,400	$2,400	$37,800	$350	$0	1.0	1.1	95%	8.2	30	2019	$0.368	$2,330,074	$0.412	$2,658,409	$0.577	$3,901,681
Vista Mountain Case 2: 2.3 MW	$42,800	$2,400	$45,200	$800	$0	2.5	2.8	95%	20.9	30	2019	$0.194	$1,094,589	$0.214	$1,248,829	$0.290	$1,832,876
McArthur Springs Case 3: 2.1 MW	$86,100	$27,900	$114,000	$800	$0	2.2	2.4	95%	18.6	30	2020	$0.469	$3,220,803	$0.527	$3,674,652	$0.746	$5,393,197
McArthur Springs Case 4: 5.5 MW	$99,100	$27,900	$127,000	$1,800	$0	5.8	6.2	95%	48.2	30	2020	$0.225	$1,388,937	$0.250	$1,584,655	$0.343	$2,325,759

Notes:
1. Annual average capacity is based on average available capacity throughout the year - Table 1 shows capacity and energy in year 1 of operation.
2. For each project a 3%/year degradation of annual capacity assumed over the life of project [annual energy also reduced by 3%/year].

Step 2 - Ranking

The review of Geothermal options identified two separate projects, each with 2 different scales of development.

Technical Attributes

1. Each project provides reliable energy and capacity, but is not dispatchable [technically dispatchable, however, it is not economically feasible to dispatch].
2. Each project option degrades each year in capacity and energy.
3. The only differences are:
   - in scale: McArthur Springs option is materially larger than Vista Mountain at each of the two scales examined for each project; and
   - in distance to grid: McArthur Springs requires much longer transmission line to connect to the Yukon electrical grid.

Financial Attributes

1. Vista Mountain Case 2 with 2.3 MW option shows the lowest LCOE and LCOC. This option also has a lower capital cost compared to McArthur Project with a similar scale of development option.
2. McArthur Springs Case 4 with 5.5 MW option shows the second lowest LCOE and LCOC. However, this option requires larger load demand than other cases in order to develop on an economic basis.
3. Both of the smaller scale options, Vista Mountain Case 1 [0.9 MW] and McArthur Springs Case 3 [2.1 MW], show much higher LCOE and LCOC, highlighting that small scale versions of each project are not financially attractive. McArthur Springs Case 3 capital cost is 2.5 times higher compared to Vista Mountain Case 2 [even though Case 3 has a slightly smaller amount of capacity and energy output].

Summary

Considering isolated nature of the Yukon Electrical grid, the best option depends on following:
- Energy demand:
  - If the energy demand requires in the range of 2.5 to 3 MW of reliable winter capacity and about 20 GW.h/year energy in near term (or less), Vista Mountain case is best option
  - If the energy demand requires in the range of 6 MW of reliable winter capacity and about 50 GW.h/year energy in near term, McArthur Springs is a competitive option only if the larger scale development is confirmed.
  - Any materially smaller load requirement than assumed in Case 2 (for Vista Mountain) and Case 4 (for McArthur Springs) will result in much higher cost per unit of energy for either option.
- Potential benefit from new transmission as regards other loads or resource options might add benefit to the McArthur Springs larger scale option that is not considered in this analysis.

Table A-1: Financial Analysis (WACC at 5.45%): **Vista Mountain Case 1: 0.9 MW**

			Average MW	Winter MW

Abstract

The Yukon Energy Corporation (YEC) is entering a new planning cycle for future upgrades and improvements to the Yukon Territory's electricity supply. This report, prepared by Solvest Inc., is intended to assist in the future planning of the Yukon electricity grid by providing information on the viability of utility scale photovoltaic solar energy at several locations across the Yukon. Expected electricity generation capabilities are modelled, and a preliminary financial analysis presented. These numbers can be used to compare against other proposed energy projects in the areas of hydro, wind, geothermal and energy storage that are also currently being completed.

Four locations were initially investigated as potential sites for 1MW, 5MW or 10MW photovoltaic power plants. Of these sites, one at Haines Junction and one near Whitehorse were settled on as being the most appropriate. Both have large, flat, unshaded spaces, and are close to urban locations with high demand for electricity. The Haines Junction site is located close to both the airport and the dump, and is not likely to be ideal for many other uses. The Whitehorse site is already human impacted and clear of trees – an old quarry that is no longer in use.

The energy modeling revealed that the 1MW installations yielded 1050 – 1190 MWh annually for panels installed on fixed tilt racking. There was no significant influence on energy production due to location choice. For 1MW installations using single axis tracking, the annual energy yield jumped to 1290 – 1490 MWh. Moving from single axis tracking to dual axis tracking only improved the energy yield by about 6%, while increasing the cost and complexity of the installation significantly.

For 5MW installations, the annual energy yield for fixed tilt racking systems fell between 5230 and 5460 MWh. For single axis tracking systems, the yield was between 6000 and 6750 MWh depending on the choice of modules. For 10 MW fixed tilt racking systems, the annual energy yield was about 11,000 to 11,500 MWh.

Different inverter choices were also modeled, and the energy yield between the inverter options was similar. The major difference comes from the cost. Two different quotations for central inverters were obtained, which were significantly different. String inverters can be more expensive due to the increased number of inverters and wiring complexity, however the string inverter system costs here fell between the two central inverter costs.

The LCOE for the 1MW systems ranged from $0.17 to $0.20/kWh. The LCOE for the 5MW systems is quite attractive, ranging from $0.14 to $0.18 on average. For the 10MW system, additional battery storage is needing for smoothing in case of power fluctuations, since the 10MW system will have a greater penetration of the electricity grid. For the 10MW system along with battery storage, the LCOE is about $0.21/kWh. Due to the area requirements, it will be difficult to fit 10MW of photovoltaics at the Haines Junction site. There is ample room at the Whitehorse Quarry site, however, so if a PV plant of this size is desired, it should be located at Whitehorse.

1. Introduction

There are three main groupings to this report: 1) All the information that defines the project and informs the site selection; 2) The energy modeling for each site and system option; and 3) The financial analysis of each option.

The site selection is outlined in Section 2: Site Selection Process, and includes the selection criteria and irradiance data. More helpful background information that will be required to complete the energy and financial sections is found in the technology review in Section 3, and the asset service life, operations and maintenance (O&M) plan, and the project schedule in Sections 4 through 6.

Sections 7 through 9 go through the energy modelling for the systems at each of the proposed site under the various technical options. Section 7 explains the loss inputs that were included in the PVSyst simulation. The complete monthly energy profile data can be found in Appendix A. Additional data from the energy simulations can be found in Appendix B.

Sections 10 through 12 walk through the highlights of the financial assessment. Section 10 describes the method by which the Levelized Cost of Electricity (LCOE) is calculated. Full tables of all the LCOE results for all the systems modeled can be found in Appendix C.

Conclusions, recommendations and potential show-stoppers are shared in the final section of the report.

In addition to this report, all the Excel files from the financial analysis, data from the PVSyst simulations, simulation reports, kmz and CAD files showing footprints of the sites, and project schedule Gantt charts are accompanying this report in a shared Dropbox folder. A “hard-copy” of all this data as well as the report will be submitted to YEC on either a CD or flash drive via mail.

2. Site Selection Process

2.1 Selection Criteria

The following criteria were evaluated when selecting the two sites for the proposed utility scale PV power plants:

1. **Solar Irradiance Profiles**. The solar irradiance data for each community on the Yukon Energy transmission grid was evaluated to determine which communities have favorable solar generation profiles. As shown in the chart above the solar irradiance profiles for the communities in the Yukon varies 8% between the lowest community (Keno Hill) and the highest community (Dawson).
2. **Proximity to existing transmission infrastructure**. By selecting sites close to existing substations, grid connection costs for the proposed power plants are minimized allowing lower transmission and distribution costs for Yukon Energy and a lower levelized cost of energy for the PV power plant.
3. **Proximity to communities**. In order to minimize construction costs and provide continued access for on-going maintenance, both sites selected are located close to existing communities. Additionally, given that a significant percentage of the load capacity on the Yukon electrical grid is located in the Whitehorse to Haines Junction corridor both sites selected are located in this area to minimize the distance from generation to the end consumer.
4. **Topographic Profile**. Utility scale solar generation requires a large amount of land (6-10 acres per MW) with minimal elevation changes across the property. Topographic maps of both Whitehorse and Haines Junction were carefully analyzed to determine which areas had enough flat land within close proximity to identified substations.
5. **Land Ownership**. Using the Yukon Lands-viewer tool (http://mapservices.gov.yk.ca/Lands/Load.htm) the identified areas were analyzed to confirm if there are any existing land use restrictions for the proposed sites such as wildlife reserves or residential development hold backs. Additionally, each site was verified against a data base to confirm that no third parties currently own the proposed properties.
6. **Open Land**. In order to minimize site preparation costs, sites with open land or minimal tree cover were selected. Mulching costs were estimated at $3500 an acre, so both chosen sites have minimal tree cover to try and reduce this cost.

2.2 Chosen locations

The solar irradiation map of the Yukon was investigated, and from the initial review four main sites of interest were chosen: Haines Junction, Whitehorse Copper, Takhini, and Canyon. Topographical maps were consulted, as well as site visits to the proposed locations, and from the initial four sites, Whitehorse and Haines Junction best fit the criteria. Takhini, from the topography graphs, had a very uneven site, and a large hill or ridge on the west side that would block the evening sun. Upon inspection, the site was also seen to be very boulder-strewn and construction would have been significantly difficult. Canyon was awkwardly shaped, and there was some question of land ownership. Both the Whitehorse Copper and Haines Junction sites were physically suitable and in close proximity to communities where the energy would be needed, and so they became the sites of choice.

Location #1: Whitehorse Copper

Nearest Community: Whitehorse

GPS Coordinates: 60.643440, -135.058548

Available Space: 120 Acres

Distance to Substation: 2.8 KM

Connection Voltage: 34.5 KV

Soil type: Mine Tailings

Geotechnical Analysis Required: Yes

Site Description: The chosen site is the old tailings pile for the Whitehorse Copper Mine which was operated from 1972 to 1982 near Mount Sima Ski Hill. The tailings pile was chosen as it is an abandoned mine site that cannot be used for traditional development projects without further reclamation work. The pile consists of 120 acres of open land with minimal fluctuations in elevation across the pile, which will reduce development costs for constructing the solar farm by eliminating land clearing costs and reducing the amount of compaction and excavation work required to prepare the site for construction.

Additional benefits of the site include, established road access, close proximity to the mount sima substation (2.8 Km), and a geotechnical profile consisting of fine grain mill material making it easy to drive piles to support the solar array. Finally, by being located within Whitehorse city limits, this site ensures that the distance from generation to the consumer is minimized and reduces construction costs by being located close to the main source of materials and labour within the Yukon.

Figure 2.1: Proposed site of a PV power plant at Whitehorse Copper

Location #2: Haines Junction

Nearest Community: Haines Junction

GPS Coordinates: 60.784897, -137.505541

Available Space: 65 Acres

Distance to Substation: 3.4 KM

Connection Voltage: 25 KV

Soil type: Organics/Clay

Geotechnical Analysis Required: Yes

Site Description: The chosen site is located 1 km north of the Haines Junction dump in a 65 acre, semi-open area with minimal elevation changes across the site. This site was selected due to its close proximity to the highway (500 m) and substation (3.4 km) as well as the site consists of largely open land with thin tree cover reducing land clearing costs significantly.

Additionally, by being located within Haines Junction, this site ensures that construction costs will be reduced by having accommodations for construction crews in close proximity from site.

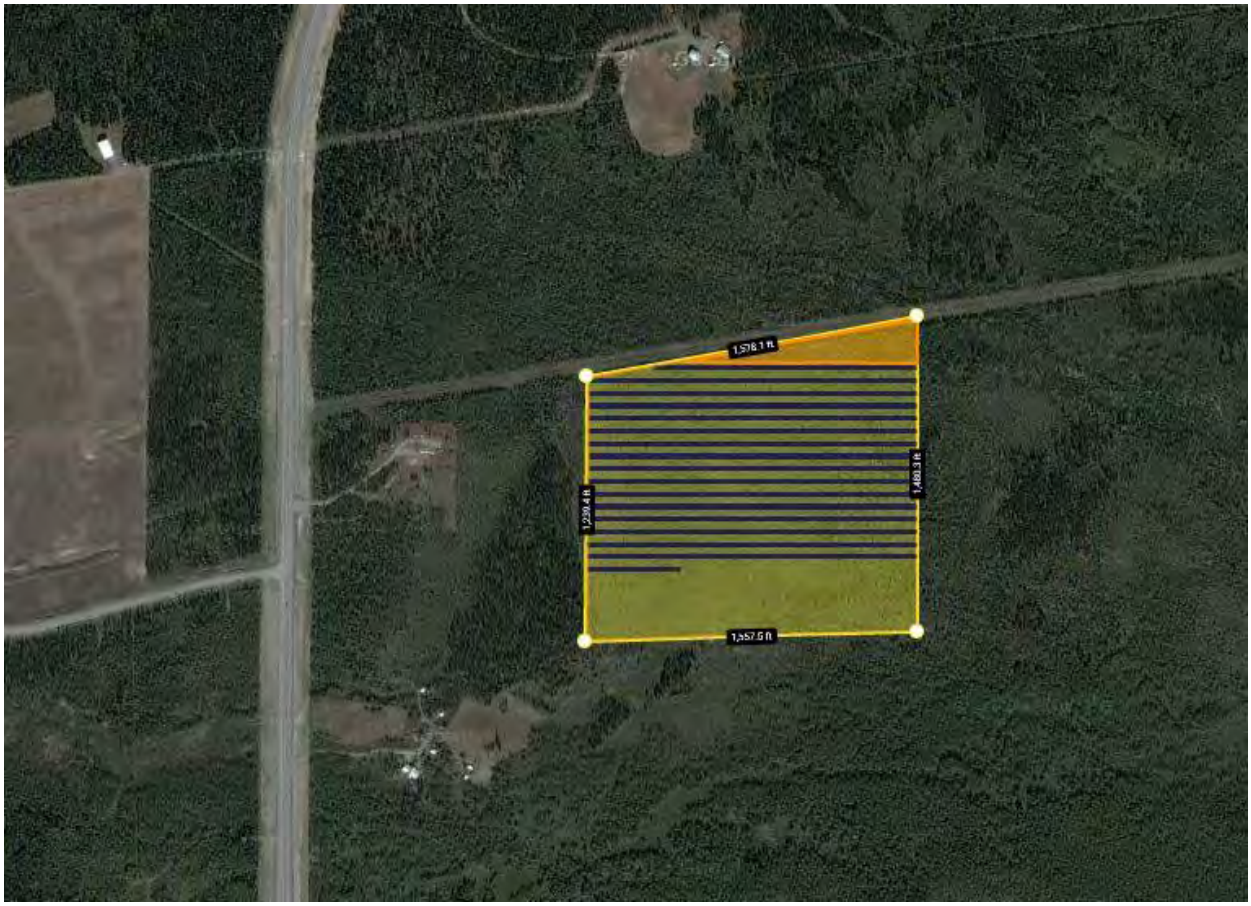

Figure 2.2: Proposed site of a PV power plant at Haines Junction

2.3 Irradiance Data

In order to determine the best locations in terms of solar resource in the Yukon, the solar irradiance data for the territory was analyzed. Table 2.1 shows the irradiance data for all major communities connected to the Yukon Energy transmission grid.

Table 2.1: Solar potential data for communities in the Yukon[1]

Municipality	Solar Potential (kWh/kW)
Whitehorse	985±158.0
Teslin	964±154.0
Tagish	981±157.0
Stewart Crossing	1011±162.0
Ross River	962±154.
Pelly Crossing	1016±163.0
Mayo	991±159.0
Marsh Lake	981±157.0
Keno Hill	961±154.0
Haines Junction	1038±166.0
Faro	966±155.0
Dawson	1043±167.0
Carmacks	1013±162.0
Carcross	978±157.0

Annual Irradiance figures shown were collected at a south facing tilt angle of latitude -15.

The data in Table 2.1 shows a variance of only 9% across all municipalities connected to the Yukon Energy Hydro Grid, and only 6 % variance from Whitehorse. Based on this information the two locations for further investigation will be Whitehorse and Haines Junction. This decision was made based on increased construction costs as one gets further from Whitehorse and will allow Yukon Energy to keep the proposed power plants close to existing electrical infrastructure and points of use.

Tables 2.2 and 2.3 show the solar irradiance data by month at various tilt angles for both Whitehorse and Haines Junction:

Table 2.2: Monthly irradiance data for Whitehorse (kWh/m^2/month)

2.3.1 Comparison of Yukon PV Potential Against Global Utility-Scale PV Installation Sites

To further illustrate that solar is a good choice of renewable energy on a utility-level scale for the Yukon, Table 2.4 lists the solar potential of the selected Yukon sites (kWh/kW) against a selection of comparable jurisdictions that have implemented grid scale solar around the world (e.g. Germany, Ontario, etc). While the Yukon is on the low side in terms of solar PV potential in Canada, it has higher potential than Berlin, Germany. Germany has a number of utility-scale PV installations, close to 100 MW in size, close to Berlin (the Brandenburg-Briest Solar Park is located less than 100 km from Berlin, and is 91 MW in size). The Yukon also has better solar potential than Japan, which has embraced solar in the

wake of the Fukushima nuclear disaster and now has a number of utility-scale PV plants located across the country (and notably in the Fukushima prefecture).

Table 2.4: Comparison of solar potential for various cities across Canada and around the World

Major Canadian cities and capitals	Yearly PV potential (kWh/kW)	Major cities worldwide	Yearly PV potential (kWh/kW)
Regina (Saskatchewan)	1361	Cairo, Egypt	1635
Calgary (Alberta)	1292	Capetown, South Africa	1538
Winnipeg (Manitoba)	1277	New Delhi, India	1523
Edmonton (Alberta)	1245	Los Angeles, U.S.A.	1485

3 Technology Review

In recent years, the price of solar panels and their related systems has dropped significantly. This has been the result of both economies of scale and design improvements. With the design improvements, there are now a wide variety of module technologies, inverter technologies, and racking systems. This section explores the types of modules, inverters, and racking systems that are currently on the market, looks at their performance under conditions in the north as well as their costs, and helps us to arrive at the options that will be best for YEC. There is also a section at the end that comments on the types of energy storage options available for grid applications and the option that we recommend accompanies larger solar utility projects in the Yukon.

3.1 Module Technologies

In this section we'll look at the major cell and module technologies that are on the market today, and then briefly touch a few that are in the pipeline so that in 5 or 10 years, so that if more solar projects are planned in the future, the viability of these new technologies can be looked at as well. An explanation of the following module and cell types is presented here:

- P-type vs N-type silicon for solar cells
- Multicrystalline solar cells
- Monocrystalline solar cells
- Bi-facial cells and panels
- Thin film cells and panels
- Emerging technologies

3.1.1 P-type vs N-type Silicon

While not as widely adopted as p-type silicon technologies, n-type solar cells have been around for a long time, and have held the record for the highest-efficiency commercial solar products for about as long. The two most well-know are Sunpower's IBC (interdigitated back contact) cell, and Sayno's HIT cell (now owned by Panasonic). A number of other companies are now getting on board. Yingli's PANDA cell, Sunpreme's heterojunction bi-facial cell, and Suniva all make use of n-type silicon wafers.

N-type silicon has a number of benefits over p-type silicon, the first of which is that there is no light-induced degradation (LID) with n-type silicon. P-type silicon is typically doped with boron during the crystal growth process. Both Czochralski-grown and cast-multi silicon ingots are exposed to air during the casting process, which results in the presence of oxygen in the melt. When the silicon wafers later undergo high temperature processing during cell manufacturing, this creates boron-oxygen complexes, defects in the silicon, which activate after the cell is used in the light for the first time, and results in up to 2% degradation in module performance after deployment in the field. As n-type silicon is doped with phosphorous during the casting process, rather than boron, there is no chance for the boron-oxygen defects to form, resulting in a high quality material.

Similarly, n-type materials tend to be more resilient against other types of impurity defects as well, the most cited of which being iron. The lifetime of free electrons and holes in an n-type silicon wafer is also 3 times longer than in a p-type wafer due to the capture cross-section of the defects being smaller. For all these reasons, in an n-type wafer, once an electron has been generated by sunlight, the chance of that electron becoming part of the usable current of the solar cell is much, much higher.

While not an inherent material property, higher efficiency solar cells such as n-type solar cells, tend to have better temperature coefficients than p-type cells. When working in cold climates, the voltage change as a function of temperature becomes a critical design component. As temperature drops, the cell voltage increases. At very low temperatures, as can often be had in the Yukon, this voltage drop can risk exceeding the maximum allowable voltage on the inverters. As a result, strings of modules are limited to what the cold-temperature open-circuit voltage can reach. P-type solar modules have temperature coefficients of -0.31 %/°C typically (see Heliene and Canadian Solar data sheets). Sunpower's n-type modules have temperature coefficients in the range of -0.29 %/°C to -0.298 %/°C and Sanyo's HIT cell does even better with a temperature coefficient of -0.239 %/°C. This may be a function of the low-temperature manufacturing process that the HIT cell utilizes. Similar designs, such as Sunpreme's heterojunction bifacial cells, achieve a similar temperature coefficient of -0.23 %/°C. The benefit of having a temperature coefficient closer to zero is that you don't have to over-size your inverters to take into account high voltages in low weather, and you also don't have large voltages drops and resulting power drops in hot weather.

Despite the obvious benefits of using n-type wafers, their use has not become wide-spread yet due to several factors: the higher cost of the material; and difficulties in some of the processing steps. The material cost for n-type silicon is partly due to economies of scale – there is less demand for it, and so it is produced in smaller amounts by fewer manufacturers. The crystallization of n-type silicon also tends to be less uniform than that of p-type silicon, meaning that the phosphorous doping concentration in the silicon changes as the ingot crystallizes. This results in a range of material resistivities being produced during the casting process, and the resulting wafers need to be sorted and binned later to create batches with similar material characteristics. The processing steps become more difficult in two main places: high temperature boron diffusions for forming the p-n junction are difficult, and a good method was not discovered until the late '90s, and the typical surface passivation that is used on p-type solar cells (silicon nitride) does not work on n-type solar cells, and actually makes their performance worse, so alternate passivation methods had to be developed.

In summary, the benefits of modules employing n-type wafers is the absence of light-induced degradation, higher efficiency, better voltage performance in both high and low temperatures, and lower balance-of-system costs due to both the higher efficiency and better voltages. The only draw-back is due to the higher module price, but depending on the project, this may be offset due to the benefit in the aforementioned areas.

3.1.2 Polycrystalline

Polycrystalline, or multicrystalline, solar cells are produced from chunks of purified silicon which are heated in a ceramic crucible to above the melting point of silicon and then cooled in a controlled

manner. This forms blocks of polycrystalline silicon which are then cut and sliced into in wafers to form solar cells. Recognizable by their square cell shape, polycrystalline solar modules are less efficient than monocrystalline modules due to breaks within the crystal structure of the cell. However due to lower manufacturing costs, polycrystalline solar modules account for over 75% of the solar modules manufactured annually as of 2015[2].

Benefits:

- Lower manufacturing costs. (10- 15 cents per watt cheaper than standard monocrystalline, 50% cheaper than high efficiency monocrystalline cells)

Drawbacks:

- Lower efficiency. (Polycrystalline cells range from 14.5% to 17% efficiency, Monocrystalline ranges from 16% to 22%)
- Less efficient in low light conditions[3].

3.1.3 Monocrystalline

Monocrystalline solar cells are made from single crystal silicon ingots formed using the Czochralski method. A single crystal of silicon is used as a seed and dipped into vat of liquid silicon. The seed is lifted and rotated at a controlled speed, growing a single crystal silicon ingot out of the bath as it rises. The tubular crystal is then sawn into wafers, and the edges cut straight, except for their corners. Recognizable by the diamond pattern formed by the gaps between the corners of cells, monocrystalline solar modules are high efficiency solar cells producing more energy per square meter than polycrystalline solar modules[2].

Benefits:

- Higher efficiency. (Polycrystalline cells range from 14.5% to 17% efficiency, Monocrystalline ranges from 16% to 22%)
- Lower temperature coefficient, leading to improved performance in hot climates compared to Polycrystalline. (Monocrystalline averages -0.31% per degree C, Polycrystalline averages -0.40% per degree C)
- Improved low light condition performance (sunrise and sunset, cloudy weather) over polycrystalline solar cells due to higher shunt resistance (i.e. fewer shorts or flaws in the p-n junction)[3].

Drawbacks:

[2] https://www.ihs.com/pdf/Top-Solar-Power-Industry-Trends-for-2015_213963110915583632.pdf
[3] http://www.ecn.nl/docs/library/report/2005/rx05034.pdf

- Higher cost to manufacture due to requirement for single crystal silicon ingots. (Standard monocrystalline cells are 10- 15 cents per watt more than Polycrystalline, high efficiency monocrystalline cells are twice the price per watt)

3.1.4 Bi-Facial

Bi-Facial Solar cells are manufactured to allow the cells to absorb light on both sides. Traditional solar cells join the silicon cell to a solid conductive backing made of aluminum or copper, bi-facial cells bond the silicon to a grid shaped backing allowing light to be absorbed on both sides. Recognizable by their transparent glass frames with visible cells on the back side.

Benefits:

- Very high efficiency. (19% to 28% with backside power production factored in)
- Improved winter performance due to reflected light of snow covered surfaces. (Up to 50% more power per square meter under certain albedo conditions)
- Improved low light performance, due to using an amorphous Si layer, which has higher light absorption, as well as using monocrystalline silicon[4].
- Can be installed at various angles and orientations with limited impact on power production.
- Aesthetically appealing (often used by architects for building integrated solar installations)

Drawbacks:

- Very expensive to manufacture. (30-60% more per watt to manufacturer than polycrystalline modules)
- Require customized racking that does not obstruct the cells on the backside of the module.

3.1.5 Thin Film

Thin Film solar cells are made from depositing very thin layers of photovoltaic materials "film" onto a conductive backing. Each layer of film absorbs a separate spectrum of light and combine to form a solar cell. This manufacturing process makes these solar cells extremely thin and flexible allowing them to be installed in a variety of applications including on curved roof surfaces or in calculators.

Benefits:

- Lower cost to manufacture. (10 to 20 cents per watt cheaper than polycrystalline modules)
- Best low light performance of all the technologies studied in this report[5].

Drawbacks:

- Much lower efficiency. (Thin film modules average 10% to 15% cell efficiency levels)
- Large space requirements for similar power yields to silicon solar technologies.
- High operating voltages prohibit micro inverter use.

[4] http://www.ecn.nl/docs/library/report/2005/rx05034.pdf
[5] http://profs.sci.univr.it/~romeo/Publications/Derk_17Munich-1.pdf

- Reverse bias, as is experienced when portions of a module become shaded, can damage the junction.

Due to the damage that can be done to the module when it becomes shaded, which is highly likely in the event of snowfall, thin film panels are not recommended for use in the Yukon.

3.1.6 Developing Module Technologies

The following technologies are in various stages of development and commercialization. These technologies are being developed to address a variety of deficiencies with photovoltaics including low electrical conversion factors (efficiency), high manufacturing costs, and power density.

- **Organic Semiconductor Solar Cells** were discovered and tested by a team of scientists at Cambridge University in October 2014 studying how plants convert light to energy through the process of photosynthesis[6]. The team observed that plants are able to absorb both spin-triplet light photons and spin-singlet light photons, while current solar technologies can only capture spin-singlet light photons resulting in much of the available solar energy going to waste. This observation led them to create a unique solar cell with an organic semi-conductor layer to capture the spin-triplet light photons and an inorganic semi-conductor layer to capture the spin-singlet light photons leading to a world record cell efficiency of over 75%. While this technology is still in its infancy, if it can be successfully commercialized it has huge potential for the photovoltaics industry as it would drastically increase the power density of PV technology.
- **Perovskite Solar Cells** are solar cells formed with organic/in-organic compounds to mimic the cell structure of Perovskite, which is conducive to photovoltaic conductivity. By mimicking this cell structure scientists have been able to create thin, transparent solar cells with efficiencies ranging from 3.8-9% and semitransparent solar cells with efficiencies as high as 21%[7]. The manufacturing process for perovskite solar cells is much more cost effective than traditional silicon or thin-film solar technologies and could lead to a huge decline in module production prices. Additionally, the advent of transparent solar cells paves the way for use of photovoltaics in glass building construction which represents a huge growth market for photovoltaics. However, perovskites are very unstable and can dissolve in water so finding a cost effective and means of sealing the solar cells is critical in order to allow for commercialization[4].
- **Graphene Solar Cells** consist of using thin layers of graphene to form the conductive layer within the solar cells rather than silver and copper. Graphene's carbon nanostructure makes it an excellent conductor while being extremely strong, virtually transparent and flexible[8]. These traits could allow for high efficiency, transparent, and flexible solar cells that could be used widely in applications such as building integrated photovoltaics, however currently researchers are struggling to successfully integrate graphene with existing silicon photovoltaic technologies[5].
- **Concentrated Photovoltaics (CPV)** involve using lenses to concentrate the sun onto a solar cell, allowing for exponential power production per square meter. This technology has been

[6] http://www.cam.ac.uk/research/news/hybrid-materials-could-smash-the-solar-efficiency-ceiling
[7] http://www.rsc.org/chemistryworld/2015/10/thin-film-perovskite-solar-cell-passes-efficiency-test-0
[8] http://www.graphene-info.com/graphene-solar-panels

developed and successfully commercialized with over 500 MW of installed capacity as of 2014[9]. While CPV does significantly increase power density it does have a number of draw backs that have limited its wide spread implementation including:

- **Cooling problems:** concentrating the sun on a single point leads to increased temperatures which can damage and destroy solar cells if not effectively managed.
- **Requires direct sunlight:** this severely limits the number of locations in which CPV can be implemented[10].
- **Manufacturing costs**: concentrating lenses are made of highly reflective glass which is very costly to manufacture. Additionally, cooling systems for high concertation CPV can be complex and expensive.

3.2 Inverter Technologies

Inverters are critical component to any photovoltaic system from residential installations to large utility scale power plants. Photovoltaic modules produce direct current (DC) which must be converted to alternating current (AC) in order to be used in homes and buildings or transmitted through the electrical grid. Inverters convert DC power to AC power by "switching" the DC current off rapidly inducing an AC current in a secondary conductor. The AC signal is then smoothed out using a sine wave filter to ensure its frequency matches the electrical grid[11]. There are three types of inverters used in photovoltaic applications:

- Central inverters
- String inverters
- Micro inverters

3.2.1 Central Inverters

Central inverters are designed for large scale PV installations and range in size from 100 kW to 3 MW rated capacity. When installing a central inverter, multiple strings of PV modules are combined in parallel in combiner boxes before connecting to the inverter, the high voltage DC power is then inverted to 3 phase AC power before being transmitted to the grid. Additionally, many central inverters come with prewired transformer and switch gear packages allowing high voltage grid connection right at the inverter. Accounting for over 40% of all inverter sales globally, central inverters are the industry standard for large scale PV installations with ever evolving technology[12]. In 2016, central inverter designs are expected to shift from 1000VDC architecture to 1500 VDC designs to allow for longer string sizing and reduced balance of system costs for large installations[13].

[10] http://www.greenrhinoenergy.com/solar/market/micro_market.php
[11] http://www.homepower.com/articles/solar-electricity/equipment-products/how-inverters-work

[12] https://www.ihs.com/pdf/Top-Solar-Power-Industry-Trends-for-2015_213963110915583632.pdf

[13] http://www.greentechmedia.com/articles/read/1500-Volt-Systems-Will-Account-for-4.6-GW-of-Global-Utility-Scale-Solar-In

Benefits:

1. Low manufacturing cost per rated DC watt. (8 to 20 cents USD per watt)
2. Prewired, "plug and play" designs allow for quick installation times.
3. Proven, "bankable" technology. With over 8 GW in annual installations and a 100 GW installed globally, central inverters have a well-established track record for reliable performance for utility scale PV power plants[9].
4. Integrated design. Most major central inverter suppliers offer fully integrated containerized inverter solutions which feature central inverters, a transformer, switch gear, and SCADA platform allowing for easy system design and seamless grid integration.
5. Minimizes electrical architecture complexity, reducing electrical installation labor costs.

Drawbacks:

1. No module level monitoring or string optimization. This means central inverters cannot be used in areas with partial or constant shading concerns as shading one module will impact entire strings. Additionally, module level failures cannot be detected remotely and can only be identified using thermal scans of the power plant adding the to the maintenance costs.
2. Required Annual Maintenance. Due to the size of the inverters central inverters produce a lot of heat and require complex cooling systems in order to ensure they continue to function optimally.
3. Concentrated points of failure. With input capacities typically ranging from 250 KW to 1.5 MW when a central inverter fails a large portion of a PV power plant is down until the inverter is brought online. This can be a concern for remote locations where technicians are not readily available.
4. Lifespan. Central inverters typically require significant upgrades after 12 to 15 years, which must be budgeted for in order to allow for PV power plants to fulfill their 30 year operational lifespans.
5. Temperature sensitive. Central inverters cannot operate in temperatures below -25 C and must be housed in heated containers if installed in locations with winter temperatures below -30.
6. Heavy. Central inverters typically weight 1500 to 3000 KG or more if packaged with transformers and switch gear. This limits where they can be installed and generally require being installed on concrete pads.

3.2.2 String Inverters

String inverters are designed for a wide variety of PV installations and range in size from 2 KW single phase units to 40 KW three phase units. Typically string inverters have built in maximum power point tracking (MPPT) allowing the inverter to optimize the performance of 1-3 strings of modules depending on the inverter size. Single phase string inverters typically have a maximum DC input voltage of 600V while three phase string inverters allow for 1000V and in some cases 1500V DC input voltages[14].

[14] http://www.greentechmedia.com/articles/read/1500-Volt-Systems-Will-Account-for-4.6-GW-of-Global-Utility-Scale-Solar-In

Benefits:

1. No maintenance. String inverters have self-contained cooling systems and are outdoor rated for operating temperatures as low as -40 C.
2. Small compact design allows for deployment on racking, sides of buildings or in containerized solutions, providing system designers flexibility.
3. Decentralized design. With rate capacities ranging from 2KW to 40 KW, if a string inverter fails on a large PV installation a small segment of the power plant is down during the repairs.
4. Allow for power optimizer use. Power optimizers provide module level DC voltage optimization and monitoring minimizing the effects of shading and allowing system operators to monitor the power production of each module.

Drawbacks:

1. Higher cost. String inverters are more expensive than central inverters per installed DC watt of PV capacity. (15 to 30 cents USD per watt)
2. Increased balance of system costs and electrical architecture complexity. Installing string inverters decentralizes the AC system architecture of a PV power plant leading to increased design and installation costs associated with additional AC wiring/infrastructure.
3. Lifespan. String inverters typically need replacing after 12 to 15 years of operating time depending on conditions. Replacement costs must be budgeted for in order for PV power plants to fulfill their 30 year operational lifespans.
4. Complex system integration. While increasingly common, string inverters are typically not designed for utility scale applications leading to potential problems when integrating them with grid connection SCADA platforms and secondary switchgear packages. It is recommended that installers using string inverters for utility scale applications purchase them from vertically integrated suppliers such as Schneider, ABB or SMA to ensure that there is available grid connection equipment that is compatible with the inverters.

3.2.3 Micro Inverters

Micro inverters are connected to each module and invert the DC power supply directly at the module, eliminating the need for DC wiring. While typically used for residential and small commercial applications, micro inverters can be used for utility scale power generation.

Benefits:

1. No high voltage DC wiring. This increases the safety of solar installations and minimizes line loss concerns.
2. Completely decentralized design. Micro inverter designs ensure that module and inverter failures do not have any impact on the rest of the system. Additionally, the “plug and play” nature of micro-inverters means that personnel with minimal training can safely perform repairs.
3. Life span. Micro inverters carry 25 year comprehensive warranties ensuring that they will last the entire service life off the PV power plant.

4. Module level MPPT. Micro Inverters provide module level DC voltage optimization minimizing the effects of shading as well as allow system operators to monitor the power production of each module.
5. Easy to install. Micro inverters are "plug and play" units allowing for low qualified personnel to install a larger percentage of the PV system architecture minimizing installation costs.

Drawbacks:

1. High cost. For utility scale PV installations micro inverters are typically 50% more than string inverters and twice the cost of central inverters per DC watt[15]. (30 to 50 cents per watt USD)
2. Increased balance of system costs and electrical architecture complexity. Micro inverters completely decentralize the electrical system architecture of a PV power plant leading to increased design and installation costs associated with adding combiner boxes, medium voltage transformers, and large amounts of high amperage AC wiring.
3. Complex system integration. Micro inverters were not designed for utility scale applications and are typically manufactured by companies that are not vertically integrated, making communicating with SCADA platforms and secondary switchgear packages more complex and expensive.

3.3 Racking Technologies

There are a number of options available for mounting solar panels depending on the situation and environment in which they're being used. The most common for utility scale applications are fixed tile racking, single axis tracking, and dual axis tracking. More recently, rail trackers are also beginning to be used.

3.3.1 Fixed Racking

Over 90% of all utility scale PV power generation (systems >500KW) is installed as ground mount installations and of those 70% of the installations are fixed racking[16]. Ranging from concrete ballasted designs, to pile drive foundations, fixed racking provides PV power plant designers reliability and flexibility at an extremely low cost.

Benefits:

1. Very low cost. With an average price of $0.20 per watt USD fully installed for system over 1 MW, fixed ground mount racking is the lowest cost racking solution on the market[13].
2. Flexible. Ground mount racking can easily be customized to handle a variety of terrain and geotechnical conditions with varied foundation options including, driven piles, helical screws, concrete ballast, or rock bolts. This allows system designers to customize their racking to handle almost any terrain type allowing for solar installations in a wide variety of locations.

[15] https://emp.lbl.gov/sites/all/files/lbnl-188238_1.pdf
[16] https://emp.lbl.gov/sites/all/files/lbnl-188238_1.pdf

3. Robust and reliable. Comprised of galvanized steel or anodized aluminum with no moving parts, fixed ground mount racking ensures system operators that there will be no maintenance concerns and that the racking will outlast the life span of the project.
4. Ease of installation. Fixed racking designs are quite simple and can easily be assembled quickly by low qualified personnel lowering installation costs. Additionally, low continuous spans of racking make wire management easy to manage limiting the amount of work required by more expensive electrical personnel.

Drawbacks:

1. Lower power production as modules are fixed in place.

3.3.2 Single Axis Trackers

Single Axis trackers follow the sun as it moves east to west throughout each day leading to increased power production. With movement on only one axis, single axis tracker designs are relatively simple and light weight allowing for deployment in a variety of locations with only small amounts of maintenance required.

Benefits:

1. Increased power production. Single axis trackers allow for increased power production of 20 to 30% annually depending on the installation location.
2. Simple designs. By moving on a single axis these trackers have simple designs that require minimal annual maintenance.
3. Light weight/lower wind resistance. Typical single axis trackers are made of lightweight materials allowing for them to be installed using a ballasted design or helical screws making installations less complex than dual axis trackers.

Drawbacks:

1. Higher cost than racking. With an average price of $0.30 per watt USD fully installed for system over 1 MW.
2. Less power production that dual axis trackers.
3. Greater land use requirements due to inter-row shading as the trackers follow the sun throughout the day.
4. Annual maintenance is often required.
5. Less flexible foundation design than fixed racking.

3.3.3 Dual Axis Trackers

Dual Axis trackers follow track the sun both east-west as well as vertically across the sky throughout the day. This allows for maximum power yields per module as the modules will always be directly pointing at the sun.

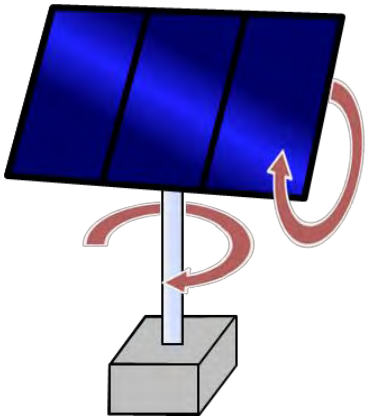

Photo Credit: Sedona Solar Technology

Benefits:

1. Maximum power generation per module producing up to 45% more power per module compared with fixed installations[17].

Drawbacks:

1. High Cost. With an average price of $0.70 per watt USD fully installed for system over 1 MW.
2. Single point of failure. Traditional dual axis trackers rotate around a complex single bearing that allows the tracker to move both directions and is required to support the weight of up to 40 solar modules. This design often leads to the bearing failure, causing the tracker to jam ad can lead to long down times and high maintenance costs.
3. High Wind Problems. Due to having 40 modules mounted side by side, traditional dual axis trackers are not designed to handle high winds and can experience structural failure in winds of 150 kph or more.
4. Large Foundation Requirements. The weight of traditional dual axis tracking systems requires large concrete foundations adding considerable costs to installing them.
5. Heavy Components. Due to the stresses being concentrated on a single point, dual axis trackers are constructed on heavily reinforced materials that weigh a considerable amount. This adds significant extra costs when transporting the trackers to remote locations.
6. Non Scalable. Each tracker is an isolated unit leading to limited cost savings when installing larger system.
7. Large land use requirements. Inter-tracker shading can be a significant problem if trackers are located too closely together leading to large land use requirements.

[17] https://emp.lbl.gov/sites/all/files/lbnl-188238_1.pdf

3.3.4 Rail Trackers

Rail trackers are a unique dual axis tracker that is designed to address many of shortfalls of dual axis trackers. While it is a new product on the market is has shown excellent potential to become a key player in the tracking market in the years to come.

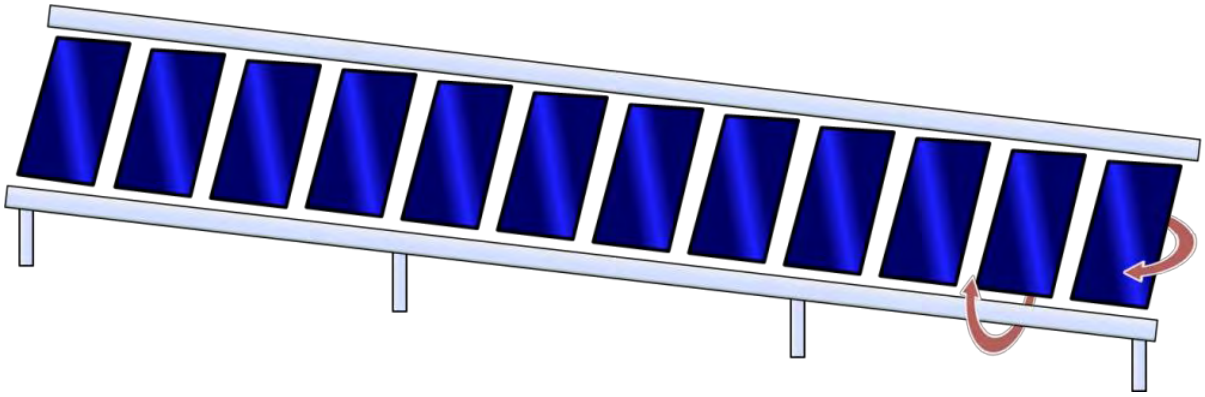

Photo Credit: Sedona Solar Technology

Benefits:

1. Maximizes power production per module by allowing for flexible frame sizes, allowing for designers to use large high wattage modules with minimal extra cost.
2. Low levelized cost of energy. Rail tracking prices are slightly lower than single axis trackers ($.25 USD per watt) while providing power production yields 5% lower than dual axis trackers.
3. Weight is spread out over the entire array significantly reducing the stress on the actuators.
4. Simple design. Rail trackers have just 2 moving parts that operate in a single axis, reducing complexity and making the system less prone to failure.
5. Does not require concrete foundations. This leads to significant savings in installation costs as well as decreased installation time.
6. Space between modules significantly decreases the wind resistance of the dual axis tracker enabling it to safely handle wind speeds of up to 240kph[18].
7. Scalable design allows for frames to share actuators, producing significant cost savings for utility scale projects.
8. Reduced land use requirements compared with standard dual axis trackers as trackers are long single rows with no inter-row shading concerns.

Drawbacks:

1. Limited track record. As this is a new technology there are a limited number of installations globally at this time providing a small data set from which to draw modeling and design conclusions. This is expected to change as more installations come online in 2016-2017 using rail trackers.

[18] http://sedonasolartechnology.com/technology/

2. Inter-module shading at higher latitude locations. Due to the frame design, when the sun is located at either true-east or true west, the modules will partially shade one another down the row limiting power production at those times. This has a small impact on annual power production compared with dual axis trackers in northern locations.

3.4 Energy Storage

For the Yukon, it's expected that battery storage for energy back-up will only be required for the 10MW installation scenario. It's been seen in Germany and other locations that the grid can handle solar PV penetration well above 10% before stability becomes an issue. It should be noted that the location of PV in relation to the loads should also be taken into account. Two locations are studied in this report – Whitehorse, and Haines Junction. As Whitehorse is the major centre of population and industry for the territory, and has a high demand for electricity, adding 5 to 10 MW of solar PV may only account for about 10 to 20% of the local energy use. For Whitehorse, storage may not be necessary. For Haines Junction, a 5 MW PV plant may make up a much larger chunk of the local electricity supply. For Haines Junction then, to ensure a stable grid locally, it may be desirable to include some energy storage. Figure 3.1 shows the type of storage options for grid scale applications that are good for various timescales. For maintaining grid stability, only 5 to 15 min of energy storage capacity is needed to bridge the gap until a back-up generation source, such as stored hydro, can be brought online, and so batteries would be a suitable option for the projects being looked at by YEC (if it's deemed they're needed – we would need a bit more data about the local energy demand to full answer that question).

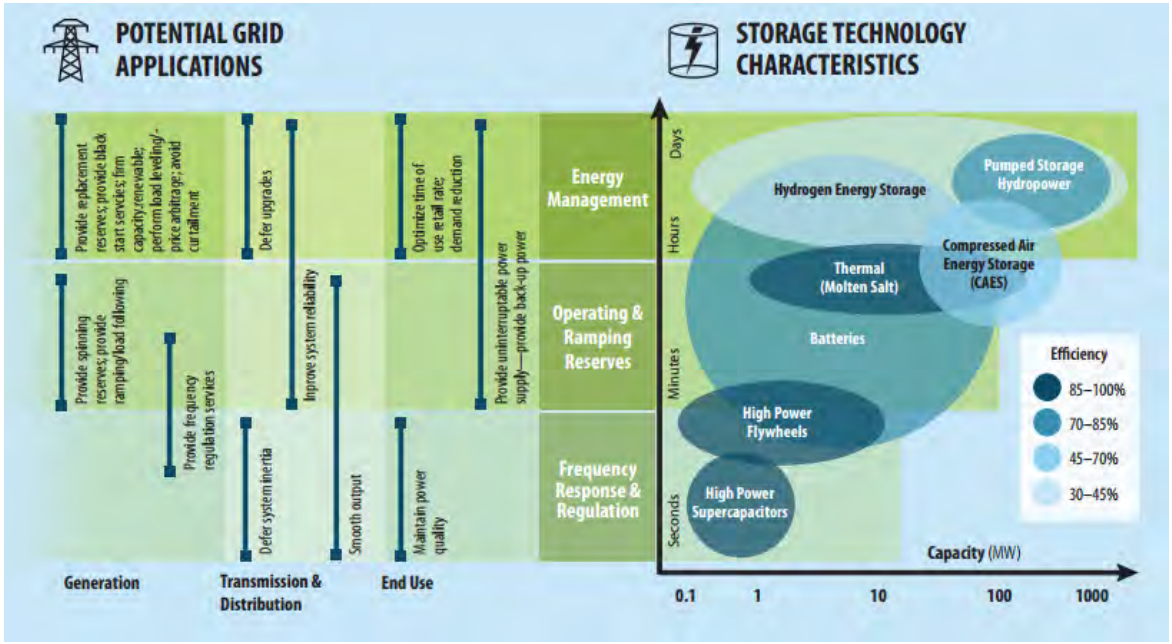

Figure 3.1: Energy storage options for grid applications[19]

[19] http://www.nrel.gov/docs/fy16osti/64764.pdf

For this reports, originally an 8 MW, 15 min battery storage option was included for the 10 MW power plant. This energy storage component was a Younicos system. The energy storage is no longer part of the financial analysis, but should you wish to include it, this was the system we were working with.

4 Asset Service Life

Typical asset service lifetimes are detailed in Table 4.1. As can be seen, the majority of the components of a PV system are expected to be good for at least 25 to 30 years. The only component that has a shorter lifetime that the system lifetime of 30 years is the inverters. As a result, a large investment in maintenance in Year 20 of the financial model reflects the expected replacing of the inverters at this point in the lifetime of the system.

Table 4.1: Asset service lifetimes

Component	Service Life	Warranty	Maintenance Costs (Annually)	Replacement Cost
Modules	30 + years	25 year power warranty 10 – 25 year product warranty	Cleaning = $1000 per MW	N/A
Inverters	20 years	10 years	$2000 per MW	$0.10 USD per W
Energy Storage Inverters	25 Years	10 years	$2000 per MW	
Battery	25 years	25 years	$65,000 per year	
SCADA/Plant Controller	25 years	5 years	$250 annual software update	
Racking	30 + years	5 years	None	N/A
Single Axis Trackers	25 + years	5 years basic + 5 year extended	$800 USD per MW	N/A
Medium Voltage Substations	30 years	2 years	None	N/A
DC Wiring	30 + Years	N/A	$2000 USD per MW	$0.90 CAD per M as needed
DC Combiner Boxes	30 + Years	2 Years	$3000 USD per MW	N/A
AC Wiring	30 + Years	N/A	None. Wire is buried in conduit/sheathed in armored cable.	
Chain Link Fence	30 + years	1 Year	None	N/A

5 Operations and Maintenance Plan

The operations and maintenance plan for the 1 MW and 5 MW power plants will be identical with the costs scaling proportionally. The O&M plan for a 10 MW facility will be more complex due to the overall size of the power plant and incorporation of batteries into the design.

5.1 Maintenance Training

Local workers would be trained in the following areas:

1. Module replacement.
2. DC Wiring/Combiner box repairs.
3. Tracker bearing/motor repairs.
4. String Inverter replacement.
5. Component communication system repairs.
6. General grounds keeping/fencing repairs.

5.2 Spare Parts List

As part of the construction costs a certain number of spare components will be purchased. These will include:

- Modules: 8 pallets – 200 modules
- Inverters: This only applies to string inverters, and 1 unit per MW would be kept on-hand.
- Tracker bearings: 25 bearing per MW or as manufacturer advises
- PV wire: 1 KM of positive and negative wire
- MC4 connectors: 100 connectors with a crimping kit
- Combiner boxes: 2 combiner boxes per MW

5.3 1 MW/5MW O&M Plan

Service	Frequency	Cost per MW	Description
Module Cleaning	Bi-Annually	$1000	Using a squeegee to clean modules and remove dust/animal droppings
DC Wiring Inspections	Annually	$1000	Inspect all above surface DC wiring for damage caused by animals or wires that have come loose from their clips.
Thermal Scans for the Modules	Annually	$2000	Using an infrared camera to can modules for faulty modules. Malfunctioning modules will have increased resistance leading to increased levels of heat.
Thermal Scans of Combiner Boxes	Annually	$1000	Using an infrared camera to scan combiner boxes. Boxes with loose connections will produce more heat due to higher resistance between connections.
Tracker Inspections	Annually	$1500	Inspecting motors and bearing ensuring they are operating as expected and not wearing unevenly.
Thermal Scans of Inverters	Annually	$1000	Scan the DC disconnects and combiner boxes connected to the inverter for loose connections.

HVAC Unit Inspection	Annually	$500	Inspecting the HVAC unit that heats the insulated containers housing the inverters and transformers.
General grounds Keeping	Spring/Fall	$2000	Trimming any weeds that are growing under the trackers/racking, repairing any damage to the fencing, and removing garbage.
24/7 System Monitoring	Always	$10,000	Third party monitoring usually provided by the inverter manufacture using a software platform that communicates with the telemetry of the inverters and trackers. This system is accessible by the monitoring company, the local utility and the plant owner.
Total Annual Cost:		$20,000/ $100,000	1 MW = $20,000 per year, 5 MW = $100,000 per year

5.4 10 MW O&M Plan

Service	**Frequency**	**Cost**	**Description**
Module Cleaning	Bi-Annually	$10,000	Using a squeegee to clean modules and remove dust/animal droppings
DC Wiring Inspections	Annually	$10,000	Inspect all above surface DC wiring for damage caused by animals or wires that have come loose from their clips.
Thermal Scans for the Modules	Annually	$20,000	Using an infrared camera to can modules for faulty modules. Malfunctioning modules will have increased resistance leading to increased levels of heat.
Thermal Scans of Combiner Boxes	Annually	$10,000	Using an infrared camera to scan combiner boxes. Boxes with loose connections will produce more heat due to higher resistance between connections.
Tracker Inspections	Annually	$15,000	Inspecting motors and bearing ensuring they are operating as expected and not wearing unevenly.
Thermal Scans of Inverters	Annually	$20,000	Scan the DC disconnects and combiner boxes connected to the inverter for loose connections.
HVAC Unit Inspection	Annually	$5,000	Inspecting the HVAC unit that heats the insulated containers housing the inverters and transformers.
General grounds Keeping	Spring/Fall	$20,000	Trimming any weeds that are growing under the trackers/racking, repairing any damage to the fencing, and removing garbage.
24/7 System Monitoring	Always	$130,000	Third party monitoring would be provided by the energy storage system supplier as the energy storage inverter system will have a built in SCADA controller that will integrate the PV and batteries into once control unit.
Total Annual Cost:		**$240,000**	

6 Project Schedules

The project schedules for the 1 MW, 5 MW and 10 MW plants are shown in this section. Copies of the Gantt charts can be found in the Excel files accompanying this report.

6.1 Whitehorse Schedule – 10 MW

Task	Require Time (Weeks)
Environmental Assessment	52
Geo-technical Assessment	4
Finalize System Layout	4
Structural Engineering Review	4
Finalize Electrical Schematics	4
Electrical Engineering Review	4
Materials Ordered	2
Finalize Construction Plan	4
Survey and Mark-out all racking, trenching and pad locations	2
Power Line construction from substation to site	4
Dig cable trenches and level pads	2
Chain link fence construction	2
Position Inverter Centers	1
Racking Construction	4
DC Electrical Work and Inverter Connections	2
Module Installation	4
AC wiring and MV Substation Connections	2
Grid Connection	1
SCADA Installation	1
System Testing	1

6.2 Haines Junction Schedule – 5 MW & 1MW

Task	Require Time (Weeks)
Environmental Assessment	52
Clear and Mulch Property	4
Geo-technical Assessment	4
Finalize System Layout	4
Structural Engineering Review	4
Finalize Electrical Schematics	4
Electrical Engineering Review	4
Finalize Construction Plan	4
Materials Ordered	2
Survey and Mark-out all racking, trenching and pad locations	2
Access Road Construction	6

Power Line construction from substation to site	4
Dig cable trenches and level pads	2
Chain link fence construction	2
Position Inverter Centers	1
Racking Construction	4
DC Electrical Work and Inverter Connections	2
Module Installation	4
AC wiring and MV Substation Connections	2
Grid Connection	1
SCADA Installation	1
System Testing	1
Power Plant Commissioned	1

7 Energy Modeling Methodology

There are a number of things that can affect the energy performance of a PV power plant. The efficiency of the panels chosen, the panel's response to temperature changes, the racking and tracking systems, the inverters, and the distance to the nearest substation all have an effect. To better understand how much energy can be generated at each site using different systems designs, simulations were run using PVSyst. The following system design components were evaluated in the simulations:

- Module type
- Inverter type
- Racking type
- Plant size

PVSyst is a powerful modeling program that's also capable of modeling a number of loss mechanisms in the plant. In this section we explain the rationale behind the modules, inverters, and racking systems that were modeled, as well as the various losses that were included in the simulations.

7.1 Systems Component Choices for the PVSyst Simulations

7.1.1 Module Selection

The following modules were analysed for their performance at Haines Junction using PVSyst:

- Heliene polycrystalline (320W)
- Canadian Solar monocrystalline (290W)
- Canadian Solar polycrystalline (320W)
- Sunpower n-type monocrystalline (445W)
- Panasonic Heterojunction with Intrinsic Thin layer (HIT) (330W), n-type
- Prism Solar bi-facial, n-type (343W)

Heliene – Based in Canada, so prices are more stable (priced in $CDN). Shipped from Ontario. Comparable to Canadian Solar modules, as they supply fairly standard p-type mono and p-type multi panels.

Canadian Solar – Headquartered in Canada, with manufacturing in both Canada and China. Again, more stable prices in Canadian dollars. They can ship from Canada or Asia, and costs on shipping by sea from Asia may actually be cheaper. Heliene and Canadian Solar mono- and multi-crystalline panels are both fairly standard panels with nothing special or surprising. Both manufacturers use p-type silicon, and hence are subject to 2% light-induced degradation (LID) once they go into use in the field.

Sunpower – US company, with manufacturing in Asia, mainly the Philippines. Prices are in USD, so subject to some fluctuation, shipping by boat from Asia should be a reasonable cost. These are n-type silicon solar cells, so not subject to the 2% LID experienced by the p-type cells. This is the only supplier studied that has a 25 year warranty on both the product and power production. The typical

warranty terms for all the other panels are a 10 year product warranty, with a 20 to 25 year guarantee on power production (80% production guaranteed after 25 years in service, typically).

Panasonic – Originally the HIT was developed by Sanyo, and then this portion of the company was purchase by Panasonic. Based in Japan, however there is a presence in Canada as well (Panasonic Eco Solution, in Mississauga, does a lot of work with smart grids, green energy, and energy storage). The n-type heterojunction cell offered by Panasonic has the best temperature stability, meaning that the voltage does not fluctuate with temperature nearly as much as the other panels studied.

Prism Solar – Bi-facial cells. US company, Prism Solar has manufacturing in Arizona and New York for the modules. Quotes in USD, so price fluctuations based on currency exchange rates to be expected. Bi-facial cells are able to take advantage of light reflecting onto the back of the cell, boosting the current and hence the power output of the panels by up to 2%.

7.1.2 Inverter Selection

The following inverters were analysed for their performance using PVSyst:

- Schneider Electric central inverter – Conext Core XC-540
- SMA string inverter – Sunny Tripower 60-US-10
- ABB central inverter – PVS800

Micro inverters were not modeled, as there is some question as to whether or not they will be able to hold up to the harsh weather conditions experienced in the Yukon.

Also, it should be noted that after running a few simulations with the Schneider inverter and comparing them to the ABB inverter results, the difference in energy yield was negligible. The energy models were run using just one type of central inverter (the Schneider ones) after that. When doing the financial analysis, the central inverter energy results are used for both the Schneider and ABB analyses – the only differences come from the price difference between the two system.

7.1.3 Racking Selection

The following racking systems were analysed for their performance using PVSyst:

- Fixed tilt racking – (manufacturer not important for the energy analysis)
- Single axis trackers – Deger TOPTracker 40NT and 8.5
- Dual axis trackers – Deger D60H

For the most part, the supplier of the racking systems is not important in terms of energy production. The critical criteria, particularly for the trackers, is whether or not they can achieve the optimal angles for the Yukon. Panels should be at an angle of 45° in the Yukon for maximum energy yield, however the Deger TOPTrackers are limited to 30° according to the data sheets (see accompanying documentation). Other suppliers, or even Deger, should be able to provide a solution that meets YEC's needs, however there may be an extra engineering cost associated with this type of design change.

7.2 Assumptions Used in the PVSyst Model

The following assumptions were included in the PVSyst simulation:

Albedo:

- Snow albedo (0.8) November thru February
- March is half-way at 0.6, April and October at 0.4
- The rest of the year – 0.2 for grass

Fixed Rack Tilt:

- Fixed tilt angle is 45° - optimal tilt angle for the locations chosen

Soiling:

- Soiling in the winter is 20% (mostly due to snow). As the tilt angle is fairly high, snow is not expected to accumulate too much

Temperature:

- Maximum voltage was calculated at -40°C. PVSyst will not allow a lower temperature to be input, but some voltage space to allow for temperatures to drop to -45°C is recommended.

Maintenance:

- Down-time for maintenance 3 times per year, randomly distributed, total time down is 7.3 days for the year

Shading:

- Spacing between racking/modules was chosen to maintain less than 5% near shading as much as possible.

Electrical:

- Wiring loss was limited to 1.5% - default, and what the electrical design should aim for to avoid too much voltage loss during transmission

7.3 A Note on Spacing Requirements and Shading

A short test was done to illustrate the effect that shading has on the power generation of a PV installation. Here, 1 MW of Heliene monocrystalline modules are arranged in an array with the following dimensions:

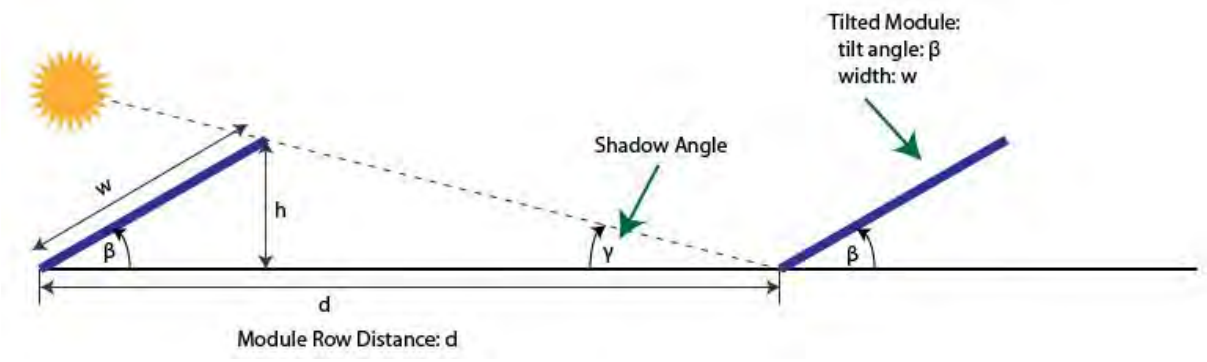

Figure 7.1: Row spacing, d, for an array using fixed tilt racking [http://www.greenrhinoenergy.com/].

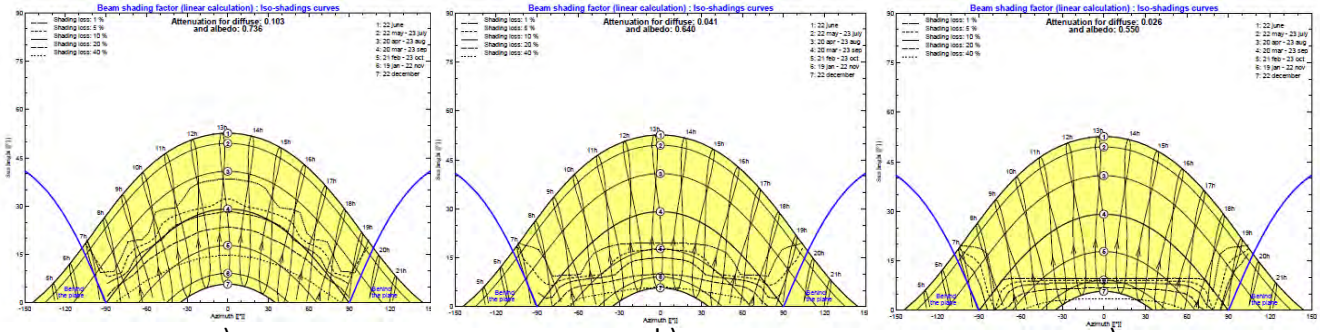
The row-to-row distance, *x*, was varied to show the effect of increased shading on power production. Spacings of 5m, 10m, and 15m were used here. The row-to-row distance to ensure no shading at noon on 21 December was calculated to be 17.4m, for comparison.

Shading profiles

The shading profiles over the course of the year for the three different row spacings, as calculated by PVSyst, are shown in Figure 7.2.



a) b) c)

Figure 7.2: Shading profile for a) 5m row separation; b) 10m row separation, and c) 15m row separation

As expected, the less shaded the panels produce more energy. However, the extent to which this is a benefit is a trade-off with the increased area required for the array. A larger area requirement means more area needs to be cleared of brush, and longer wire lengths are needed to connect up the array, as well as larger wire diameters. This can add to the over-all up front costs of the project, and looking into how the finances are affected by the increases in energy yield are important in making a decision on the best array design.

Table 7.1 shows some key parameters for the 3 different row spacing designs: near shading %, energy yield, installation area, and estimated LCOE. LCOE calculations were based on a 30 year project lifetime.

Table 7.1: Effect of row spacing on energy yield and LCOE

Row Spacing	Near Shading (%)	Annual Energy Yield (MWh)	Installation Area (acres)	LCOE ($/kWh)
5 m	12.0	918.6	3.1	0.2680
10 m	5.2	1013	6.2	0.2442
15 m	3.3	1040	9.3	0.2398

While the benefit from moving from a 5m spacing to a 10m spacing is clear, there begins to be diminishing returns beyond that point. For the purpose of the simulations throughout this report, the near shadings value was attempted to be kept below 5% to provide a balance between maximizing energy and reducing area requirements, while maintaining a decent LCOE

8 Haines Junction Energy Analysis

In this section we look at the various options for a power plant at Haines Junction, and recommend what, for this location, makes the most sense. The following options have been modeled: different panel technologies, racking systems, tracking systems, and inverter setups.

8.1 Racking and Tracking Simulation Results

8.1.1 Fixed Tilt Racking

Simulations with the various panel types were run in PVSyst using fixed racking tilted at 45°. The results can be seen in Table 8.1.

Table 8.1: Annual energy production of PV power plants at Haines Junction using fixed racking and central inverters vs. string inverters

	Central	String	Central
Haines Junction	**1 MW (MWh/yr)**	**1 MW (MWh/yr)**	**5 MW (MWh/yr)**
Heliene 72P-320W	1168	1168	5603
CDN Solar CS6K-290MS	1103		5385
CDN Solar CS6X-320P	1163		5475
Sunpower SPR-440NE-WHT-D	1125	1106	5389
Panasonic VBHN330SJ47	1110		5319
Prism Bi60-343BSTC	1143	1124	5560

The installed capacity varied slightly depending on the string arrangements. As expected, the more efficient the solar panel, the fewer panels will be needed in order to get to the desired installed capacity. At the 1 MW size, area is not a critical characteristic yet, however, so lower efficiency modules, well spaced out may come in with the best price per watt.

8.1.2 Single Axis and Dual Axis Tracking

The energy modeling results from PVSyst for a PV plant using single axis and dual axis tracking, as well as central vs. string inverters, are detailed in Table 8.2.

Table 8.2: Annual energy production of PV power plants at Haines Junction using single axis and dual axis tracking, and central inverters vs. string inverters

	Single Axis	Single Axis	Dual Axis	Single Axis
	Central	String	Central	Central
Haines Junction	1MW (MWh/yr)	1MW (MWh/yr)	1MW (MWh/yr)	5MW (MWh/yr)
Heliene 72P-320W	1437	1360	1439	5751
CDN Solar CS6K-290MS	1461		1433	6750
CDN Solar CS6X-320P	1389		1356	6425
Sunpower SPR-440NE-WHT-D	1352	1294	1425	6723
Panasonic VBHN330SJ47	1435		1383	6526
Prism Bi60-343BSTC	1480		1423	6695

The increase in energy generated when going from fixed tilt racking to single axis tracking is significant – a nearly 30% increase (see Table 8.3). However, when moving from single axis to dual axis, the energy yield effects are not as impressive – only 5.6% for the Sunpower cells, and a negative impact on the Canadian Solar poly cells, possibly due to the increased shading from the way in which the panels orient themselves. The percent increase in energy production production between each type of module and tracking system is detailed in Table 8.3.

Table 8.3: Relative increase in annual energy production with each type of tracking system, for each module type, for a 1MW plant

Haines Junction	Fixed	Single	Increase from Fixed	Dual	Increase from Single
Heliene 72P-320W	1119	1403	25.4%	1405	0.1%
CDN Solar CS6K-290MS	1056	1399	32.5%	1373	-1.9%
CDN Solar CS6X-320P	1113	1413	27.0%	1379	-2.4%
Sunpower SPR-440NE-WHT-D	1109	1334	20.3%	1405	5.3%
Panasonic VBHN330SJ47	1112	1438	29.3%	1386	-3.6%
Prism Bi60-343BSTC	1111	1438	29.4%	1383	-3.8%

The increase in energy production from fixed tilt racking to single axis tracking is significant; once the financial analysis is taken into account, this may be the ideal system for Haines. However, the relative increase in production from single axis to dual axis tracking is much less pronounced, while the increase in complexity of the system is quite significant.

As the impact of having dual axis tracking is not necessarily beneficial, dual axis tracking was not simulated for the larger systems. Table 8.4 shows the increase in energy production when going from

fixed tilt to single axis tracking for a 5 MW system at Haines Junction – about a 25% increase in annual energy yield.

Table 8.4: Increase in specific energy production for single axis trackers over fixed tilt for a 5MW system

Haines Junction - 5MW	Fixed	Single	Increase
Heliene 72P-320W	1029	1248	21.3%
CDN Solar CS6K-290MS	986	1238	25.6%
CDN Solar CS6X-320P	1002	1253	25.0%
Sunpower SPR-440NE-WHT-D	988	1240	25.5%
Panasonic VBHN330SJ47	1021	1272	24.6%
Prism Bi60-343BSTC	1036	1301	25.6%

8.2 Effect of inverters

Only a selection of the original eight panel types was modeled with string inverters, to show the trends and save on simulation time. A comparison of power production of central vs. string inverters can be seen in Table 8.5.

Table 8.5: Effect of string inverters on fixed and single-axis mounted 1MW arrays (specific energy production)

	Fixed			Single Axis		
	Central	String		Central	String	
Modules	Specific Production (kWh/kWp)	Specific Production (kWh/kWp)	% increase	Specific Production (kWh/kWp)	Specific Production (kWh/kWp)	% increase
Heliene 72P-320W	1110	1119	0.81%	1385	1402	1.23%
Sunpower SPR-440NE-WHT-D	1102	1084	-1.63%	1330	1296	-2.56%
Prism Bi60-343BSTC	1083	1090	0.65%	1405		-

In the case of the fixed tilt arrays, the string inverters can provide a modest energy benefit of 0.6% to 0.8%. For the single axis arrays, the string inverters can give a benefit up to 1.6%. A final assessment of whether the string inverters as worth it will come from the financial analysis.

8.3 Area Requirements

The types of panels used, and the type of racking or tracking, will determine the footprint required for the installation. Table 8.6 shows the area requirements for each module type studied, with each choice of racking.

Table 8.6: Area requirements for 1, 5 and 10 MW PV installations

	Area (acres) - Fixed Tilt			Area (acres) - Trackers		
Modules	1 MW	5 MW	10 MW	1 MW	5 MW	10 MW
Heliene Poly	13.6	45.7	91.4	39.5	74	148
CDN Solar Mono	9.9	49.9	99.8	35.6	66.7	133.4
CDN Solar Poly	10.9	53.6	107.2	38	71.2	142.4
Sunpower	8.5	40	80	28.4	53.4	106.8
Panasonic HIT	8.9	40.4	80.8	24.9	46.7	93.4
Prism Bi-facial	8.9	43.5	87	30	54	108

8.3.1 Haines Junction – 1 MW Array Footprints

Figures 8.1 and 8.2 illustrate the smallest and largest potential plant footprints for 1 MW arrays at Haines Junction.

Figure 8.1: 1 MW fixed tilt area requirements at Haines Junction. Left: Smallest (8.5 acres); Right: Largest (13.6 acres)

Figure 8.2: 1 MW single axis tracker area requirements at Haines Junction. Left: Smallest (25 acres); Right: Largest (40 acres)

8.3.2 Haines Junction – 5 MW Array Footprints

Figures 8.3 and 8.4 illustrate the smallest and largest potential plant footprints for 5 MW arrays at Haines Junction.

Figure 8.3: 5 MW fixed tilt area requirements at Haines Junction. Left: Smallest (40 acres); Right: Largest (53.6 acres)

Figure 8.4: 5 MW single axis tracker area requirements at Haines Junction. Smallest option only (40 acres). The installation options over 55 acres do not fit at this location.

From the footprints, it can be seen that as the array size increases at this location, space becomes much more of a premium. If a 5 MW installation is desired at Haines Junction, some of the less efficient panels may not be suitable. A 10 MW installation already cannot be accommodated at this location.

9 Whitehorse Quarry Energy Analysis

In this section we look at the various options for a power plant at the Copper Quarry site in Whitehorse, and recommend what, for this location, makes the most sense. The following options have been modeled: different panel technologies, racking systems, tracking systems, and inverter setups.

9.1 Racking and Tracking Simulation Results

9.1.1 Fixed Tilt Racking

Simulations with the various panel types were run in PVSyst using fixed racking tilted at 45°. The results can be seen in Table 9.1.

Table 9.1: Annual energy production of PV power plants at Haines Junction using fixed racking and central inverters

Whitehorse Quarry	Central 1 MW (MWh/yr)	Central 5 MW (MWh/yr)	Central 10 MW (MWh/yr)
Heliene 72P-320W	1123	5647	11471
CDN Solar CS6K-290MS	1059	5435	*11067**
CDN Solar CS6X-320P	1107	5555	*11311**
Sunpower SPR-440NE-WHT-D	1189	5456	11136
Panasonic VBHN330SJ47	1151	5391	*10977**
Prism Bi6-343BSTC	1152	5634	*11472**

** Values in italics were calculated based on trends, not run through the simulation program, due to the long duration these large simulations take.*

String inverters were not modeled at the Whitehorse location, as it's expected that the trends will be similar to those seen at the Haines Junction location (Section 8.1.1). It was seen in that section that there is not a large difference in the energy harvested using either inverter set-up. Cost and maintenance concerns will play a larger role in inverter choice than energy expectations.

Monthly energy expectations for each design choice can be found in Appendix B.

9.1.2 Single Axis and Dual Axis Tracking

As dual axis tracking was seen to not be effective in the Haines Junction simulations, it was left out of the analysis at Whitehorse. The energy modeling results from PVSyst for a PV plant using single tracking and central inverters are detailed in Table 9.2.

Table 9.2: Annual energy production of PV power plants at Whitehorse Quarry using single axis tracking, and central inverters

	Central	Central	Central
Whitehorse	**1 MW (MWh/yr)**	**5 MW (MWh/yr)**	**10 MW (MWh/yr)**
Heliene 72P-320W	1344	6041	*13960**
CDN Solar CS6K-290MS	1366	6786	*13468**
CDN Solar CS6X-320P	1290	6447	*13765**
Sunpower SPR-440NE-WHT-D	1330	6757	13558
Panasonic VBHN330SJ47	1326	6555	*13359**
Prism Bi6-343BSTC	1483	6934	*13961**

** Values in italics were calculated based on trends, not run through the simulation program, due to the long duration these large simulations take.*

The increase in energy generated when going from fixed tilt racking to single axis tracking is significant – on average over 25% (see Table 9.3).

Table 9.3: Relative increase in annual energy production with each type of tracking system, for each module type, for a 1 MW plant

Whitehorse - 1MW	Fixed	Single	Increase
Heliene 72P-320W	1075	1313	22.1%
CDN Solar CS6K-290MS	1056	1309	24.0%
CDN Solar CS6X-320P	1059	1312	23.9%
Sunpower SPR-440NE-WHT-D	1074	1312	22.2%
Panasonic VBHN330SJ47	1101	1329	20.7%
Prism Bi60-343BSTC	1119	1441	28.8%

The increase in energy production from fixed tilt racking to single axis tracking is significant; once the financial analysis is taken into account, this may be the ideal system. Table 9.4 shows the increase in energy production when going from fixed tilt to single axis tracking for a 5 MW system at Whitehorse – an average 22.6% increase in annual energy yield.

Table 9.4: Increase in specific energy production when moving from fixed tilt tacking to single axis trackers for a 5 MW installation at Whitehorse Quarry

Whitehorse - 5MW	Fixed	Single	Increase
Heliene 72P-320W	1081	1311	21.3%
CDN Solar CS6K-290MS	1041	1300	24.9%
CDN Solar CS6X-320P	1064	1312	23.3%
Sunpower SPR-440NE-WHT-D	1076	1333	23.9%
Panasonic VBHN330SJ47	1080	1314	21.7%
Prism Bi60-343BSTC	1117	1348	20.7%

Table 9.5 shows the increase in energy production when going from fixed tilt to single axis tracking for a 10 MW system at Whitehorse. Only one data point is shown, due to the size of the simulations – Sunpower, requiring the least number of modules due to their high efficiency – was able to be modeled in a reasonable time frame. It's expected that the other types of modules would also experience about a 20% increase in energy yield by moving to single axis tracking.

Table 9.5: Increase in specific energy production when moving from fixed tilt tacking to single axis trackers for a 10 MW installation at Whitehorse Quarry

Whitehorse – 10 MW	Fixed	Single	Increase
Sunpower SPR-440NE-WHT-D	11,136	13,558	21.7%*

**This value was used to extrapolate the energy production of all the module types.*

9.2 Area Requirements

The types of panels used, and the type of racking or tracking, will determine the footprint required for the installation. Table 8.6, re-shown from the Haines Junction analysis, contains the area requirements for each module type studied with each choice of racking.

Table 8.6: Area requirements for 1, 5 and 10 MW PV installations

	Area (acres) - Fixed Tilt			Area (acres) - Trackers		
Modules	1 MW	5 MW	10 MW	1 MW	5 MW	10 MW
Heliene Poly	13.6	45.7	91.4	39.5	74	148
CDN Solar Mono	9.9	49.9	99.8	35.6	66.7	133.4
CDN Solar Poly	10.9	53.6	107.2	38	71.2	142.4
Sunpower	8.5	40	80	28.4	53.4	106.8
Panasonic HIT	8.9	40.4	80.8	24.9	46.7	93.4
Prism Bi-facial	8.9	43.5	87	30	54	108

9.2.2 Whitehorse – 1 MW Array Footprints

Figures 9.1 and 9.2 illustrate the smallest and largest potential plant footprints for 1 MW arrays at the Whitehorse Quarry.

Figure 9.1: 1 MW fixed tilt area requirements at Whitehorse. Left: Smallest (8.5 acres); Right: Largest (13.6 acres)

Figure 9.2: 1 MW single axis tracker area requirements at Whitehorse. Left: Smallest (25 acres); Right: Largest (40 acres)

9.2.3 Whitehorse – 5 MW Array Footprints

Figures 9.3 and 9.4 illustrate the smallest and largest potential plant footprints for 5 MW arrays at the Whitehorse Quarry.

Figure 9.3: 5 MW fixed tilt area requirements at Whitehorse. Left: Smallest (40 acres); Right: Largest (53.6 acres)

Figure 9.4: 5 MW single axis tracker area requirements at Whitehorse. Left: Smallest (46 acres); Right: Largest (74 acres)

From the footprints, it can be seen that there is ample space at the quarry for 5 MW arrays using any of the module or racking types available.

9.2.4 Whitehorse – 10 MW Array Footprints

Figures 9.5 and 9.6 illustrate the smallest and largest potential plant footprints for 10 MW arrays at the Whitehorse Quarry.

Figure 9.5: 10 MW fixed tilt area requirements at Whitehorse. Left: Smallest (80 acres); Right: Largest (107 acres)

Figure 9.6: 10 MW single axis trackers area requirements at Whitehorse. Only the smallest array options (less than 110 acres – 93 acres shown) will fit.

For the 10 MW array, any module option will work with fixed racking. However, when moving to single axis tracking, more space is required to ensure the modules don't become too shaded, and **only the three highest efficiency modules – Sunpower, Panasonic, and Prism Solar – will meet the area restrictions.**

10 Financial Analysis Methodology

The financial analyses for each size and location of power plant were approached in the same manner. Before getting into the details of the analyses, a few notes on the engineering expenses are explained.

10.1 Engineering Fees Explanation

At first glance the estimated engineering costs for the construction of the proposed solar arrays might seem quite low. This is due to the fact that much of the engineering costs associated with constructing a solar array are represented in the costs of various materials for the project.

Structural/Civil Engineering:

When constructing a utility scale solar power plant, developers will typically work with integrated racking companies such a Schletter or Sunlink. These companies have in-house structural, civil and geotechnical engineering teams that will fully engineer and stamp the racking design before manufacturing the racking according the specifications.

This approach ensures that clients receive racking that is designed for the geotechnical and climatic conditions on location, giving solar project developers peace of mind that their racking will last the entire operating life of the power plant.

Geotechnical Engineering:

When designing solar farms with ground mount racking/trackers, a geotechnical analysis of the site must be performed in order to determine the racking substructure design and piling layout/depths. While the racking supplier will typically analyze the geotechnical samples collected they do not provide the onsite engineering teams to collect the samples for analysis. The added cost of collecting the samples is represented in each budget with the analysis of the samples incorporated into the racking costs.

Electrical Engineering:

Typically, utility scale solar power plants use Central Inverter or String Inverter electrical architecture with all DC/AC electrical equipment provided by an integrated electrical supplier such a Schneider, ABB, or SMA.

In the case of central inverters this typically means central inverters are housed in pre-wired skids or containers along with step-up transformers and switch gear. These containers or skids are fully engineered by the supplier to the plant specifications, allow for direct grid connection to the primary bushings of the transformer in each container. As with the racking this engineering work is performed/stamped by the suppliers in house engineering team with the cost included in the materials cost.

When constructing solar power plants with string inverters, developers typically look to the inverter supplier to provide pre-wire substations containing step-up transformers and switch gear allowing for multiple string inverters to connect to the grid at one central location. These substations are pre-engineered to work with the specific string inverter used on location by the inverter supplier's in-house engineering team with the engineering costs absorbed in the cost of the materials.

Environmental Engineering:

Typically, environmental engineering is not required for most utility scale solar projects unless constructed on previously contaminated sites or old landfills. However, it is advised that solar project developers pay for a basic third party baseline environmental assessment of any property being considered for a solar power plant to ensure that there are no pre-existing contaminants on location that could be disturbed as part of construction or lead to misplaced liability for the costs of cleaning the contamination at a later date. The cost of a baseline environmental assessment is represented in the budget for each proposed project in this report.

10.2 Capital Expenditures Examples

An example of the detailed capital expenditures is shown in Table 10.1. The breakdown for each individual technology choice can be found in the Excel spreadsheets accompanying this report. Table 10.1 shows a 1 MW installation at Haines Junction using central inverters.

Table 10.1: CapEx breakdown example – Heliene 72P modules using ABB central inverters and fixed tilt racking

	Price
Component	**$1,520,799.97**
Modules	**$844,168.77**
Heliene 72P	$844,168.77
Racking	**$354,631.20**
Schletter	$354,631.20
Inverter Centers (ABB Central Inverters)	**$225,000.00**
SCADA (included with inverters)	**$0.00**
Electrical Components	**$85,000.00**
Fencing	**$12,000.00**
Service	**$483,000.00**
Shipping	**$105,000.00**
Driving Piles	**$20,000.00**
Surveying	**$8,000.00**
Geo-Technical Assessment	**$15,000.00**
Environmental Quality Assessment	**$5,000.00**
Road Construction and Excavation	**$40,000.00**
Crane Services	**$4,000.00**
Tree/Brush Removal	**$60,000.00**
Fencing Installation	**$16,000.00**
System Design & Engineering	**$45,000.00**
Civil Engineering	**$25,000.00**
Electrical Engineering Review	**$35,000.00**
Electrical Installation	**$25,000.00**
Solar Installation	**$70,000.00**

Commissioning	**$10,000.00**
Project Management Costs	**$65,000.00**
OHS Management	**$5,000.00**
Project Management	**$50,000.00**
Logistics Management	**$10,000.00**
Other Costs	**$390,320.00**
Taxes	**$103,440.00**
Duty	
Permitting	**$80,000.00**
Land Purchase	
10% Contingency	**$206,880.00**
TOTAL:	**$2,459,119.97**

10.3 Operations and Maintenance Examples

Operations and maintenance costs were broken down in a similar manner. Full details can be found in the accompanying financial spreadsheets and two examples are shown in Tables 10.2 and 10.3 for reference. In addition to the annual maintenance costs, some increased expenses are included for once the product warranties on some of the components begin to expire. There is also a large inverter replacement cost at Year 20.

Table 10.2: Example of annual operations and maintenance costs for 1MW fixed tilt PV installation at Haines Junction

Repair	Year 1
Module cleaning	$1,000.00
Brushing and grounds upkeep	$2,000.00
Module hot spot monitoring	$2,000.00
DC wiring inspections	$1,000.00
Land use payments	$4,000.00
Inverter repairs after warranty expires	($2,000.00) Y6+
Inverter & combiner box inspections	$2,000.00
Possible inverter replacement - Y20	($147,945.00) Y20
HVAC maintenance	$500.00
24/7 monitoring	$10,000.00
Insurance	$7,000.00
Total Annual Costs:	**$29,500.00**

Table 10.3: Example of annual operations and maintenance costs for 10MW fixed tilt PV installation at Whitehorse Quarry

Maintenance/Repair	Year 1
HVAC maintenance	$5,000.00
Module cleaning	$10,000.00
Module hot spot monitoring	$20,000.00
DC wiring, combiner and inverter thermal inspections	$40,000.00
Energy storage maintenance	$20,000.00
Inverter repairs after warranty expires	($10,000.00) Y6+
Inverter consumables	$2,500.00
Possible inverter replacement	($1,125,000.00) Y20
Reserve Fund	$76,400.70
24/7 monitoring	$130,000.00
Total Annual Costs:	**$303,900.70**

10.4 Levelized Cost of Electricity (LCOE)

The Levelized Cost of Electricity (LCOE) was calculated for each generation option at Haines. These were calculated over 30 years, using the real Weighted Average Cost of Capital of 3.38% provided by YEC for YEC resource options. LCOE was calculated using the following equation:

$$LCOE = \frac{\sum_{t=1}^{n} \frac{I_t + M_t + F_t}{(1+r)^t}}{\sum_{t=1}^{n} \frac{E_t}{(1+r)^t}}$$

Where

- I = capital expenditures in year t
- M = operations and maintenance costs in year t
- F = fuel costs in year t
- E = energy generated in year t
- r = discount rate

For our purposes, the fuel costs of this project are zero.

11 Financial Analysis – Haines Junction

11.1 Capital Expenses at Haines Junction

The over-all capital expenses are summarized for the various Haines Junction projects. Here we will show average results to give a sense of the magnitude of the project expenses. Full details for each project can be found in the accompanying financial analysis spreadsheets.

Table 11.1: Average capital and operating expenses for PV power plant at Haines Junction using various racking options

	Capital Cost (2015$)			Annual Fixed O&M Costs (2015$)
	Plant Capital Cost	Transmission Capital Cost	Total Capital Cost	
	$000	$000	$000	$000
Fixed Tilt: 1 MW	$2,876,350	$0*	$2,876,350	$31,500
Fixed Tilt: 5 MW	$12,359,119	$460,000	$12,819,119	$142,600
Single Axis: 1 MW	$3,434,393	$0*	$3,434,393	$36,926
Single Axis: 5 MW	$12,994,800	$460,000	$13,454,800	$169,252

**For a 1 MW project at Haines, the existing power lines running nearby should be able to accommodate this amount of additional current generation*

This gives a sense of the expected over-all project costs. The value of each project in terms of levelized costs of electricity (LCOE) is better for comparing projects of different sizes, and are presented in the following sections.

11.2 Financial Trends Due to Module Cost

Full tables of LCOE data can be found in Appendix C. A subset of the data, as well as average results, is presented here for simplicity.

Table 11.2 shows the calculated LCOE results for a 1MW array using SMA inverters and fixed tilt racking at Haines Junction. In general, all the LCOE results for all simulations in all locations follow the general trend seen here. Heliene Poly, Prism, and Canadian Solar Mono fluctuate between providing the lowest LCOE, mostly due to differences in system sizing and the amount of racking required. Sunpower is always the most expensive option. At the 1MW level, there is ample area for the arrays using any technology, and a decision can be made entirely on price and the ease of maintenance.

Table 11.2: LCOE values for 1 MW fixed tilt PV installations at Haines Junction using SMA string inverters.

Photovoltaic Options	3.38% Real WACC	4.61% Real WACC	8.82% Real WACC
	LCOE (2015$)	LCOE (2015$)	LCOE (2015$)
	$/kW.h	$/kW.h	$/kW.h
Inverter Option 2: Heliene Poly	$0.166	$0.186	$0.262
Inverter Option 2: CDN Solar Mono	$0.198	$0.222	$0.315
Inverter Option 2: CDN Solar Poly	$0.200	$0.224	$0.318
Inverter Option 2: Sunpower	$0.238	$0.268	$0.384
Inverter Option 2: Panasonic HIT	$0.204	$0.229	$0.325
Inverter Option 2: Prism Bi-Facial	$0.184	$0.207	$0.292

11.3 Fixed Tilt Racking vs. Trackers

The average LCOE values for each type of installation was calculated for the Haines Junction location and can be seen in Table 11.3.

Table 11.3: Comparison of average LCOE values for different racking options at Haines Junction.

Photovoltaic Options	3.38% Real WACC	4.61% Real WACC	8.82% Real WACC
	LCOE (2015$)	LCOE (2015$)	LCOE (2015$)
	$/kW.h	$/kW.h	$/kW.h
Fixed Tilt: 1 MW	$0.189	$0.213	$0.302
Fixed Tilt: 5 MW	$0.173	$0.193	$0.272
Single Axis: 1 MW	$0.178	$0.200	$0.281
Single Axis: 5 MW	$0.165	$0.185	$0.261
Dual Axis: 1 MW	$0.192	$0.215	$0.304

Despite the fact that the capital and maintenance expenses are higher for single axis tracking projects, since the trackers allow for 22% to 25% more energy to be collected, the cost of the energy is much lower. As expected, dual axis tracking comes in as the most expensive option due to the limited energy benefit and increased cost and complexity.

11.4 Effect of Inverter Choice

The average LCOE values for each inverter option was calculated for the 5 MW, fixed tilt racking Haines Junction installation. The results can be seen in Figure 11.1. This graph is typical of what is seen in all the installations looked at in this report. Both Schneider and ABB have central inverter options, however one is the most expensive choice, and one is the least. The difference in energy collected between central and string inverters is only slight, not enough to have an impact one way or the other on the LCOE. As such, inverter choice should be made based on maintenance concerns and weather-resistance rather than on cost or energy.

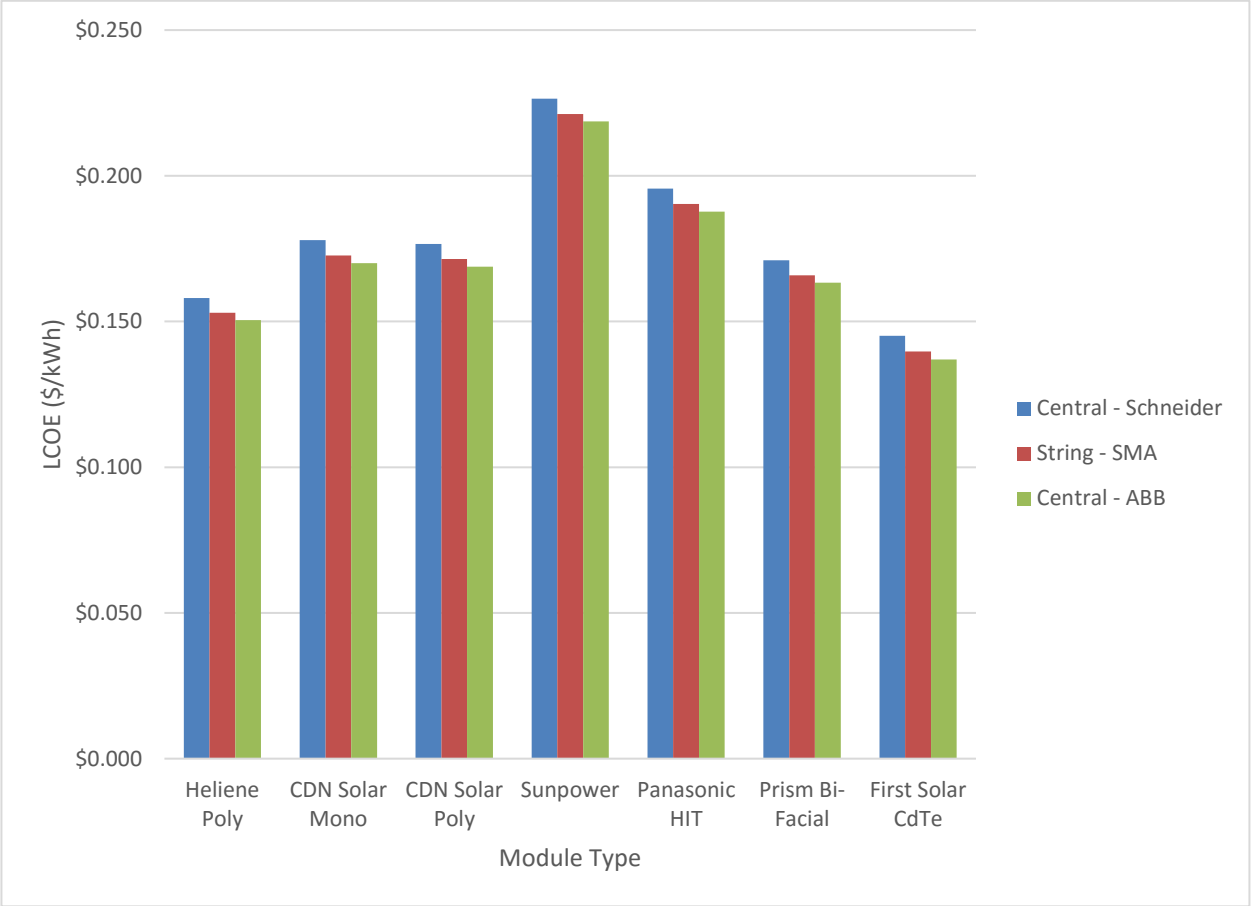


Figure 11.1: Comparison of average LCOE values for different inverter options at Haines Junction.

12 Financial Analysis – Whitehorse

12.1 Capital Expenses at Whitehorse

The over-all capital expenses are summarized for the various Whitehorse projects. Here we will show average results to give a sense of the magnitude of the project expenses. Full details for each project can be found in the accompanying financial analysis spreadsheets.

Table 12.1: Average capital and operating expenses for PV power plant at Whitehorse using various racking options

	Capital Cost (2015$)			Annual Fixed O&M Costs (2015$)
	Plant Capital Cost	Transmission Capital Cost	Total Capital Cost	
Fixed Tilt: 1 MW	$2,855,817	$460,000	$3,315,817	$31,500
Fixed Tilt: 5 MW	$12,225,363	$460,000	$12,685,363	$142,600
Fixed Tilt: 10 MW	$25,041,563	$460,000	$25,501,563	$307,384
Single Axis: 1 MW	$3,244,377	$460,000	$3,704,377	$36,926
Single Axis: 5 MW	$12,998,387	$460,000	$13,458,387	$167,346
Single Axis: 10 MW	$28,130,039	$460,000	$28,590,069	$352,346

This gives a sense of the expected over-all project costs. The value of each project in terms of levelized costs of electricity (LCOE) is better for comparing projects of different sizes, and are presented in the following sections.

12.2 Fixed Tilt Racking vs. Trackers

The average LCOE value for each type of installation was calculated for the Whitehorse location and can be seen in Table 12.2.

Table 12.2: Average LCOE comparison of the various installation types and sizes at Whitehorse

Photovoltaic Options	3.38% Real WACC	4.61% Real WACC	8.82% Real WACC
	LCOE (2015$)	LCOE (2015$)	LCOE (2015$)
	$/kW.h	$/kW.h	$/kW.h
Fixed Tilt: 1 MW	$0.200	$0.227	$0.333
Fixed Tilt: 5 MW	$0.157	$0.178	$0.259
Fixed Tilt: 10 MW	$0.172	$0.193	$0.272
Single Axis: 1 MW	$0.193	$0.219	$0.321
Single Axis: 5 MW	$0.140	$0.159	$0.233
Single Axis: 10 MW*	$0.163	$0.183	$0.258

***Sunpower, Prism Solar and Panasonic options only*

The same trends are seen here that were seen at Haines Junction – as you increase from 1 to 5 MW in size, the price drops due to economies of scale. There are also benefits in going from fixed racking to

single axis tracking. While the trackers are more expensive to install and maintain, the added energy benefit out-weights the costs and the LCOE drops.

12.3 Comparison Against Haines Junction

To better see how the two sites stack up against each other, we compare their LCOE values. Tables 12.3 and 12.4 compare the fixed tilt installation costs and single axis tracker installation costs at the two sites.

Table 12.3: LCOE comparison of fixed tilt installations at Haines Junction and Whitehorse

Photovoltaic Options	3.38% Real WACC	4.61% Real WACC	8.82% Real WACC
	LCOE (2015$)	LCOE (2015$)	LCOE (2015$)
	$/kW.h	$/kW.h	$/kW.h
Haines: 1 MW	$0.178	$0.201	$0.293
Haines: 5 MW	$0.159	$0.180	$0.262
Whitehorse: 1 MW	$0.200	$0.227	$0.333
Whitehorse: 5 MW	$0.157	$0.178	$0.259
Whitehorse: 10 MW	$0.172	$0.193	$0.272

Table 12.4: LCOE comparison of single axis tracker installations at Haines Junction and Whitehorse

Photovoltaic Options	3.38% Real WACC	4.61% Real WACC	8.82% Real WACC
	LCOE (2015$)	LCOE (2015$)	LCOE (2015$)
	$/kW.h	$/kW.h	$/kW.h
Haines: 1 MW	$0.178	$0.200	$0.281
Haines: 5 MW	$0.165	$0.185	$0.261
Whitehorse: 1 MW	$0.193	$0.219	$0.321
Whitehorse: 5 MW	$0.140	$0.159	$0.233
Whitehorse: 10 MW*	$0.163	$0.183	$0.258

**Sunpower, Prism and Panasonic options only*

Interestingly, a 1 MW installation is more cost effective at Haines Junction than it is at Whitehorse. This is because, even though the land needs to be cleared at Haines, the site can make use of nearby low voltage lines as a connection point. As the size of the installation increases to 5 MW, better transmission lines are required to be installed to handle the current, and the cost increases. At Whitehorse, a transmission line will need to be built regardless of the size of the install, and so that cost is included in the price for the 1 MW option as well as the others.

At the 5 MW level, with the increased land clearing requirements at Haines as well as the transmission line installation, Whitehorse becomes the best option for the PV plant.

Only the Whitehorse location can accommodate a 10 MW PV plant. And it should be noted again that with trackers, only the three highest efficiency panels – Sunpower, Panasonic, and Prism Solar – will be able to be used.

12.4 Module Comparison

Once more, we quickly look at how the module performance stacks up in terms of cost. Table 12.5 shows the detailed LCOE breakdown for a 5 MW single axis tracker installation at Whitehorse using Schneider central inverters. Jumping to 10 MW, there would likely be an LCOE increase of about $0.015/kWh for the 3.38% real WACC case.

Table 12.5: Comparison of LCOE for various module options in a 5 MW single axis tracker installation at Whitehorse making use of Schneider central inverters

Photovoltaic Options	**3.38% Real WACC**	**4.61% Real WACC**	**8.82% Real WACC**
	LCOE (2015$)	**LCOE (2015$)**	**LCOE (2015$)**
	$/kW.h	**$/kW.h**	**$/kW.h**
Heliene Poly	$0.153	$0.170	$0.238
CDN Solar Mono	$0.151	$0.169	$0.239
CDN Solar Poly	$0.152	$0.170	$0.239
Sunpower	$0.190	$0.214	$0.305
Panasonic HIT	$0.168	$0.189	$0.267
Prism Bi-Facial	$0.165	$0.185	$0.263

While Sunpower modules certainly are more expensive, the Prism Solar and Panasonic options are reasonable. Of these, Prism bi-facial modules are the least expensive, and the Panasonic modules have the best weather characteristics and come from a highly bankable company. Either are a good option.

13 Summary and Recommendations

Site and Panel Recommendations

Two excellent sites were found as potential locations for future photovoltaic power plants: Haines Junction, near the airport and dump, and the old Copper Quarry site in Whitehorse.

For 1 MW installations, Haines Junction is the most cost effective site, with either Heliene Poly or Prism Bi-Facial modules and single axis trackers being recommended.

For 5 MW installations and larger, the Whitehorse site becomes the most cost effective option. Lower prices for electricity and capacity are achieved at the 5 MW level. For fixed tilt installations at both sites, any module can be used. For single axis trackers at Haines Junction, only the three highest efficiency panels – Sunpower, Panasonic, and Prism – will fit in the available space. Heliene and Prism solar panels again have the lowest LCOE.

For 10 MW installations, only the Whitehorse site has adequate space available. For fixed tilt racking installations, any modules can be used. For single axis tracking, only the three most efficient panels (Sunpower, Panasonic, and Prism Solar) will fit.

Racking and Inverter Recommendations

In general, we recommend the use of single axis trackers due to the large increase in energy collected (22% to 25%), even through they cost more to install and maintain. The gains out-weigh the costs.

The difference between central inverters and string inverters was found to have no significant effect on the energy generation. The cost between the two options is also very comparable. String inverters are recommended as maintenance and replacement could be done by local workers as opposed to waiting for servicing of central inverters by the manufacturer, however this should be weighed against the weather-resistance of the inverter choice, and the price and service contracts that can be negotiated with the suppliers.

Financial Summary

The LCOE for the 1MW systems ranged from $0.16 to $0.20/kWh.

The LCOE for the 5MW systems is quite attractive, ranging from $0.14 to $0.18 on average.

For the 10MW system, additional battery storage is needing for smoothing in case of power fluctuations, since the 10MW system will have a greater penetration of the electricity grid. For the 10MW system along with battery storage, the LCOE is about $0.21/kWh. When the energy storage is taken out of the equation, the LCOE for a 10 MW solar plant becomes on average $0.16/kWh to $0.17/kWh.

Potential Show Stoppers

There are a several things to keep in mind when planning this project that could be potential show-stoppers:

1. YESAB assessment has an issue with the perceived environmental impact (mostly pertains to Haines Junction).
2. Archeological site is discovered during pre-construction (Only applies to Haines junction as the quarry is all old mine tailings that have been processed).
3. General Public does not want development at either location.
4. Mineral rights dispute (Whitehorse location only)
5. Rare/Endangered species discovered living on location (Haines Junction only).
6. Sudden collapse in the Canadian Dollar as all major components are provided by US based suppliers.
7. Aboriginal groups objecting/opposing the project.

Appendix A – Monthly Profile Data

Tables of monthly energy generation data for the PV array configurations looked at in this report.

1 MW Haines Junction Monthly Generation Data

January						
Module	**Racking**	**Inverter**	**Array Energy (kWh)**	**Energy to Grid (kWh)**	**Array Efficiency (%)**	**System Efficiency (%)**

This document entitled Final Report - Front End Engineering Design (FEED) Study, Yukon Bioenergy Demonstration Project in Haines Junction, Yukon was prepared by Stantec Consulting Ltd. for the account of Yukon Energy. The material in it reflects Stantec's best judgment in light of the information available to it at the time of preparation. Any use which a third party makes of this report, or any reliance on or decisions made based on it, are the responsibilities of such third parties. Stantec Consulting Ltd. accepts no responsibility for damages, if any, suffered by any third party as a result of decisions made or actions based on this report.

This version of the report is to support Yukon Energy's public release of the document. Due to the sensitive nature of the feedstock costing information and proprietary and confidential information provided by the equipment vendors, some information has been omitted. Omitted information was deemed to represent breaches of trust related to information transfer during the course of the study, and would impact the competitive advantage of the new company's operations, equipment vendors, and feedstock suppliers.

Executive Summary

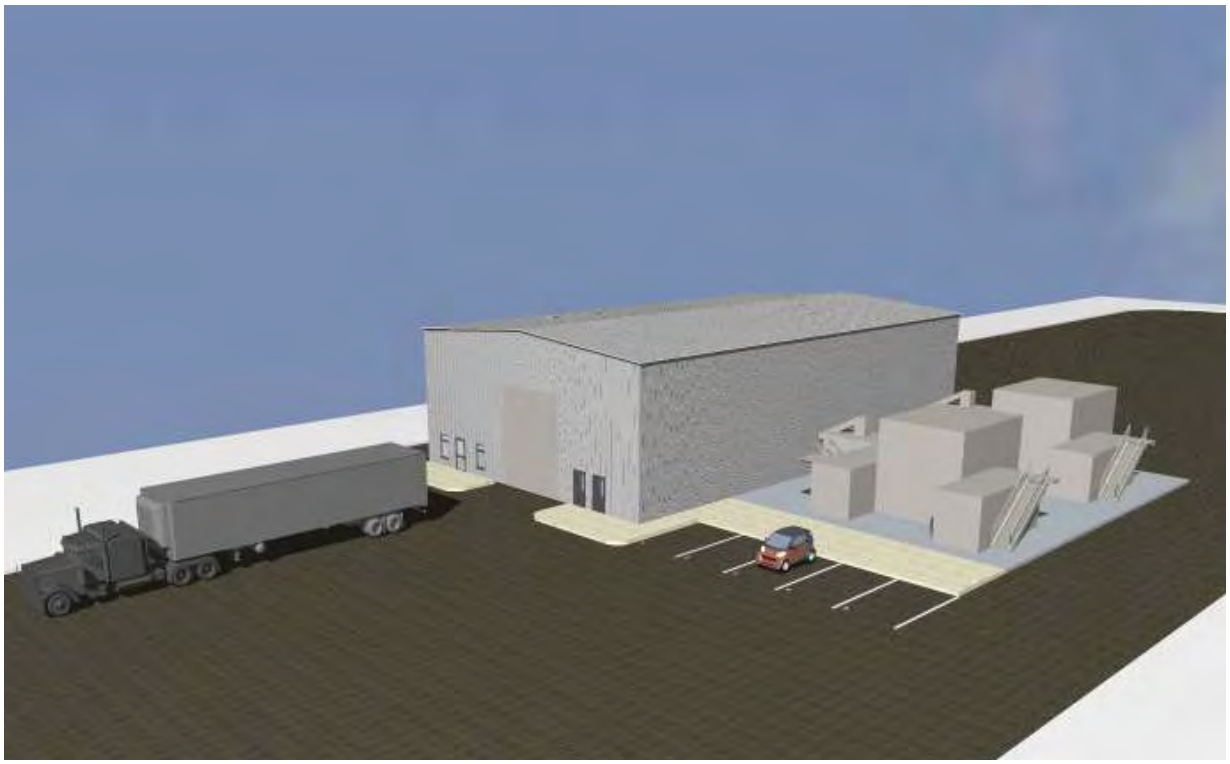
Stantec Consulting Ltd. (Stantec) has been contracted by a Steering Committee led by Yukon Energy Corporation (YEC) and the Champagne and Aishihik First Nations (CAFN) to complete a Front End Engineering Design (FEED) Study for the Yukon Bioenergy Demonstration Project in Haines Junction, Yukon. The focus of the study was to evaluate available biomass gasification technologies for application in the North in the range of 2 MW_e – 4 MW_e and determine its potential viability. The primary objectives were to complete a preliminary design of the facility, define its business case, draft baseline conditions and an impact assessment to form part of a submission to the Yukon Environmental and Socio-Economic Assessment Board (YESAB), and develop and support the engagement of CAFN members and members of the public.

The first steps in the study were to review the available gasification technologies and conduct site visits with members of the Steering Committee. The cursory technology review revealed that although available around the world, gasification technology using a reciprocating engine (as required for the project) is not developed to a high level of commercialization seen with conventional technologies. Any installation made for this project would be one of only a few in Canada, and one of only a handful in comparable cold climates. Furthermore, for most of the vendors contacted for quotations, this installation would represent one of only a few supplying their technology in conjunction with a reciprocating engine.

After narrowing the technology search by those applicable to the study's requirements, three vendors were approached to conduct site visits. Stantec and members of the Steering Committee visited Nexterra, Entropic, and Community Power Corporation (CPC) installations in Canada. Following the site visits, giving consideration to the technology review and waste heat usage, the facility's preliminary design would focus on a smaller generation capacity (0.5 MW_e to 2.0 MW_e) to better align with heating requirements of the village (for combined heat and power production) and to facilitate consideration of smaller gasification technology vendors.

Using the CPC units as a basis, Stantec prepared a preliminary design for a 500 kW_e gasification plant to be located near the centre of Haines Junction to facilitate heating local buildings. Given the smaller installation capacity, the focus of the design was to allow for future expansion for the facility once it is proven at the 500 kW_e scale as a demonstration project. Therefore, the preliminary design incorporated the ability to expand by an addition 500 kW_e, and increase in size to 2.0 MW_e to meet the study objectives. Opinions of probable capital cost and a rendering of the potential facility are presented below:

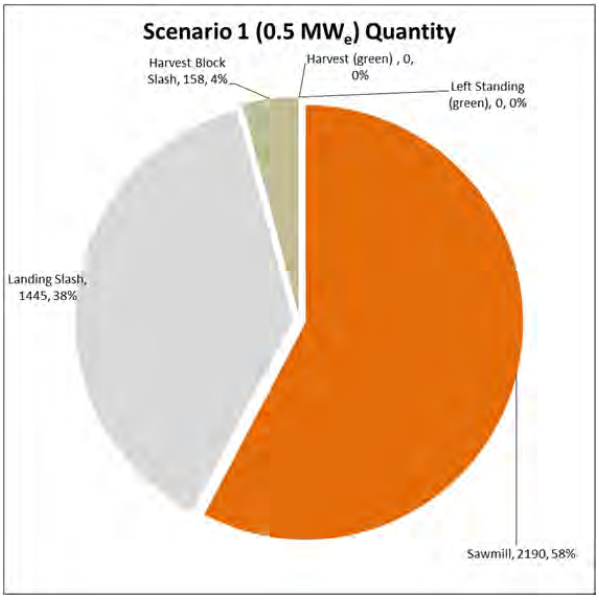
Option	Description	Opinion of Probable Capital Cost
1	500 kWe – Full Building Enclosure	$ 12.7 M
2	500 kWe – Architectural Building Enclosure	$ 13.5 M
3	500 kWe – Fuel Handling Enclosed	$ 11.4 M
4a	1,000 kWe – 500 kWe Expansion	(Exp = $ 9.8 M) $ 22.5 M
4b	2,000 kWe – 1,500 kWe Expansion	$ 45.0 M

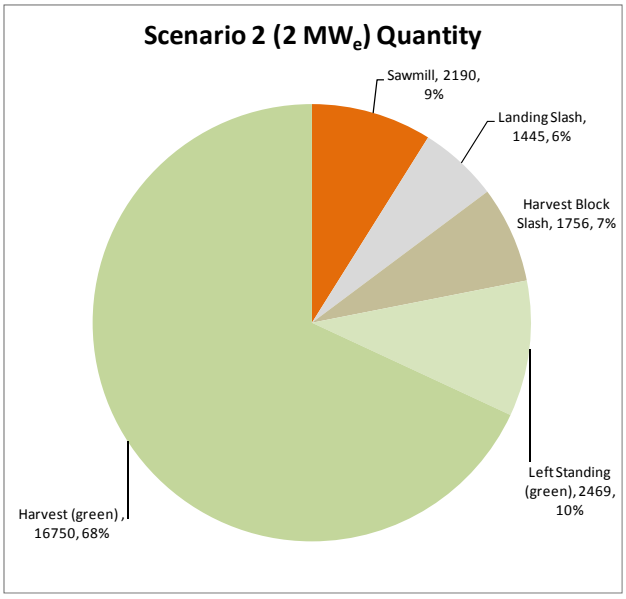


500 kW_e – Fuel Handling Enclosed – Artistic Concept

With any biomass installation, the two greatest ongoing costs are those to fuel the plant, and those for operation and maintenance (O&M). Stantec developed an opinion of operating costs, using the minimum number of operators requested for CPC's equipment, while AGFOR conducted a feedstock assessment to support determining the plant fuel costs as well as the development of the impact assessment. AGFOR's assessment determined that based on existing harvesting operations, a plant capacity of 500 kW_e could likely be supplied with minimal impact to existing operators/policies. This supply would be primarily sawmill residues and forest harvesting residues at the landing and in the harvest block; mostly dead trees from the spruce beetle infestation until that supply runs out. The larger plant capacities would require additional biomass supplied from new harvesting operations/policies and would extend into harvesting green trees sooner. Based on meeting with local regulators and harvesting operators, an opinion of probable supply costs below were determined, including sourcing breakdown.

Option	Description	Opinion of Probable Cost ($/GMT)
500 kWe	Roadside Chipping and Supplied Directly to Plant	Omitted
	Secondary Storage and Chipping	Omitted
2,000 kWe	Roadside Chipping and Supplied Directly to Plant	Omitted
	Secondary Storage and Chipping	Omitted





With a preliminary plant and feedstock supply concept established, a draft Environmental and Socio-economic Impact Assessment (IA) was prepared based on information currently available on the project and existing conditions in the area. The report includes an overview of the effects assessment and regulatory regimes associated with permitting the project, scoping of the assessment to include relevant Valued Components (VC), summaries of baseline conditions for each VC and expected effects and proposed mitigation. Determination of significance was based on residual effects after implementation of mitigation. Adaptive management and monitoring activities are also outlined where deemed applicable. The environmental and socio-economic impact assessment report draft is included in an appendix and is drafted to support a complete project submission to YESAB at a later date. The public and First Nation consultation activities are covered in the IA, with the draft engagement plan presented in a separate appendix.

The final aspect of the study was a review of the business model, funding opportunities and assessment of financial viability. Options for owning and operating different aspects of the plant are presented and weighed. The most suitable approach will be dependent on the technology and vendor selected, and the level of involvement in fuel supply the New Company (NEWCO) wishes to assume. A number of avenues for project funding are available, but will again depend on the technology and approach taken on the project; more risky, new technologies that do not have a commercial offering would likely qualify for additional funding, but more commercial technologies likely will not qualify. Continued funding through NRCan, which has funded this study in part, is a top candidate.

The financial analysis focused on ten (10) different plant options that varied with respect to generation capacity, building enclosure design, and vendor selection. To determine the potential viability of these options, financial cases were prepared for each installation taking into account the plant life span, capital and operation costs, and feedstock costing among other key

parameters. Without any initial capital subsidization, none of the options were viable. Project viability was achieved for a select number of options assuming the project partners could successful receive capital subsidies from one or more sources. Impacts of electricity pricing in conjunction with capital subsidy were also explored to assess viability. The highest returns came from switching technology vendors to Proton Power from CPC with the financial results shown in the table below due to their lower quoted price.

	Item	Option #9 – 500 kW_e Fuel Enclosed $50/GMT, $200/MWh, 67% Capital Subsidy
500 kW_e	Return on Investment (ROI)	15.1%
	Internal Rate of Return (IRR)	23.1%
2.0 MW_e	**Item**	**Option #10 – 2000 kW_e Fuel Enclosed $50/GMT, $200/MWh, 67% Capital Subsidy**
	Return on Investment (ROI)	10.0%
	Internal Rate of Return (IRR)	18.0%

1.0 Project Definition

At the project's onset, it was necessary to define the technology base that would be applicable to the project and the community that would house it. To this end an initial catalogue of technologies was prepared, reviewed and ranked, and ultimately used to determine the project's path forward. This section covers an overview of the findings of this effort as was presented in the project's Interim Report #1. The interim report is attached in Appendix A for further information and reference.

1.1 CATALOGUE OF TECHNOLOGIES

The production of electricity through the conversion of biomass can be accomplished using a variety of different processes and a multitude of feedstocks. The production of bioenergy not only employs a previously underutilized fuel source, but also mitigates the effects of energy production on the environment. When selecting the appropriate technology, it is important to keep in mind the available feedstocks, required amount of generated electricity, environmental standards, capital cost, and process efficiency (McKendry, 2001). Accordingly, with timber being the sole feedstock at the present time, and the target energy production range at the time of the interim report being 2 - 4 MW_e, three different types of biomass conversion options will be investigated: gasification, pyrolysis and an externally fired gas turbine.

1.1.1 Conversion Options

Each of the conversion options, along with their different reactor types and/or arrangements are described in detail in the report presented in Appendix A. Summary tables for the main advantages and disadvantages for the host of technologies are presented in Table 1.1 and 1.2. Of all the technologies, the updraft and downdraft gasifiers were the most applicable to the requirements of the project from the standpoint of complexity, power generation capacity, feedstock acceptance, and level of development.

Table 1.1 Properties of Gasification Reactor Types (McKendry, 2001)

Reactor Type	Advantages	Disadvantages
Fixed bed, updraft	Simple, inexpensive process Exit gas temperature about 250°C Operates satisfactorily under pressure High carbon conversion efficiency Low dust levels in gas High thermal efficiency	Large tar production Potential channeling Potential bridging Small feed size Potential clinkering
Fixed bed, down draft	Simple process Only traces of tar in product gas	Minimum feed size Limited ash content allowable Limits to scale up capacity Potential for bridging and clinkering
Fluidized bed, circulating	Flexible process Up to 850°C operating temperature	Corrosion and attrition problems Poor operational control using biomass
Fluidized Bed, bubbling	Flexible feed rate and composition High ash fuels acceptable Able to pressurize High CH_4 in product gas High volumetric capacity Easy temperature control	Operating temperature limited by ash clinkering High product gas temperature High tar and fines content in gas Possibility of high C content in fly ash

Table 1.2 Advantages and Disadvantages of Biomass Pyrolysis Systems (Vamvuka, 2011)

Reactor Type	Advantages	Disadvantages
Fluid type	Good solids mixing High heat transfer rates Good temperature control Ease of scaling	Heat transfer to bed must be proven at large scale Max particle sizes up to 6 mm If circulating, increased complexity of system, char attrition and reactor wear
Entrained flow	None	Low heat transfer rates Limited gas/solid mixing Small particle sizes required
Rotating cone	Good solids mixing No carrier gas required Ease of scaling Small investment cost	Heat transfer to bed must be proven at large scale Small particle sizes required
Vacuum reactor	No carrier gas required Lower temperature required Can process larger particles	Low heat transfer rates Solids residence time high Liquid yield rather low
Ablative reactor	Heat transfer gas not required Lower temperature required Can process larger particles Compact design and intensive system	Reaction rates limited by heat transfer to the reactor Char abrasion Scaling is costly

1.2 TECHNOLOGY REVIEW AND RANKING

Throughout the world one can find biomass gasification taking place from a scale suitable to heat a home, to that to capable of generating electricity to supply the grid. The focus of this study was to concentrate on a gasification technology capable of producing a syngas for cleanup that could then be introduced to a reciprocating engine in the initial capacity range of 2 – 4 MW_e. Although the technology could be innovative, it must be at or near commercialization to facilitate its installation in a northern community (i.e., not for research but practical/reliable use). Several technologies also require the use of steam, which is not available through co-locating near an existing facility, nor considered for self-generation. Two other biomass technologies were showcased for comparison (external fired gas turbine and pyrolysis-oil/ethanol/bio-oil).

To facilitate screening of the technologies, a ranking or scoring system was established to support the technology recommendation. The criterion used for the ranking system as well as the points awarded by criterion are outlined in Table 1.3. The ranking system does not include items affecting all the biomass systems, such as feedstock availability, socio-economic viability,

job creation, or permitting requirements as these are common to all the systems at this level of evaluation.

Table 1.3 Interim Report Screening Criterion

Level of Development	R&D / Pilot – 0 Pts.	Demonstration – 3 Pts.	Commercial – 5 Pts.
Capacity Range	Outside 2-4 MW_e – 0 Pts.	Within 2-4 MW_e* - 5 Pts.	
Use of Engine for Power	No – 0 Pts.	Yes – 5 Pts.	
Gasification Complexity**	Advanced – 0 Pts.	Standard – 3 Pts.	Direct Comb. – 5 Pts.
Installation Base	1 Installation – 0 Pts.	2 Installations – 3 Pts.	More than two – 5 Pts.
Steam Required	Yes – 0 Pts.	No – 5 Pts.	
Achievable Score	**Minimum – 0 Pts.**	**Maximum – 30 Pts. (100%)**	

* Includes modular units capable of entering range (i.e. if maximum size is 1 MW_e, two units could be installed to enter desired range). Units significantly larger than the range would be excluded due to uncertainties regarding scale-down.

** Complexity is based on system design. Advanced is representative of dual bed or pressurized gasifiers, BFBs, and CFBs; Standard represents draft gasifiers (low to medium Btu syngas) to clean-up and the engine; and Direct Combustion is for the externally fired gas turbine.

1.2.1 Catalog of Technologies

In the interim report, each technology was ranked according to the screening criterion presented in Table 1.3. A sample of the scorecard developed for each technology considered is presented on the following page in Table 1.4. Please refer to Appendix A for the scorecards prepared for the other technology vendors.

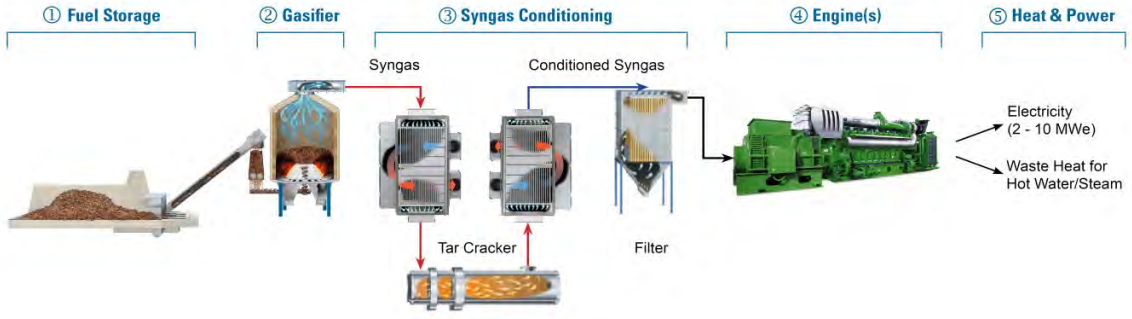
Table 1.4 Sample Technology Screening Scorecard

Developer / Company:	Nexterra Systems Corp.	**Location:**	Multiple – Oak Ridge, Vancouver, Victoria, North Carolina, New Westminster, UBC
Owner:	Various	**Status:**	Operational
Technology:	Dual Bed (BFB & CFB)	**Tech Status:**	Demonstration CHP
Capacity:	UBC: 2 MW_e, 3 MW_{th}	**Application:**	CHP w/ District Heating

Nexterra is the most recognizable Canadian gasification vendor. With installations of their gasifier throughout Canada and the USA, they have developed a solid platform for biomass gasification (low-medium calorific value syngas). Their most recent installation on the University of British Columbia campus is their first CHP using a reciprocating engine. The complexity of the system is Standard with an updraft gasifier and syngas clean-up. Nexterra's gasifier is a proven technology (for heating and steam turbine applications, but not in conjunction with an engine) and does not require steam.

Level of Development	Demonstration – 3 Pts.
Capacity Range	Within 2-4 MW_e - 5 Pts.
Use of Engine for Power	Yes – 5 Pts.
Gasification Complexity	Standard – 3 Pts.
Installation Base	1 Installations – 0 Pts.
Steam Required	No – 5 Pt.
Score	**21 Pts. (70%)**

Nexterra Advanced Biomass Heat and Power System



SIMPLIFIED ILLUSTRATION

① Fuel Storage - wood residue delivered to storage facility and conveyed to gasifier.
② Gasification Technology - gasification process converts wood residue into clean, renewable synthetic gas or "syngas."
③ Syngas Conditioning Technology - syngas is conditioned and upgraded to meet fuel specification for engine.
④ Engine(s) - high-efficiency internal combustion engine(s) operates on syngas instead of natural gas to generate electricity & heat.
⑤ Heat & Power - systems will generate heat & electricity at small-scale (2 - 10 MWe) economically with efficiencies of up to 65%.

1.3 TECHNOLOGY SELECTION

A summary of the technology scorecards determined in the interim report is presented in Table 1.5 on the following page. In reviewing each vendor's score, the top scores, greater than 20 pts., were ranked from one (1) to six (6). Given the criteria considered, the smaller, modular systems in the smaller capacity ranges took the top two rankings: (1) Community Power Corp., and (2) Biomass Engineering Ltd. The other downdraft unit, Pyroforce ranked third (3) followed by the alternative external fired gas turbine unit (4) Talbott's/Entropic. The final two rankings represent the larger updraft systems: (5) Nexterra, and (6) B&W Vølund. As a select number of vendors were used to represent each category, the groupings in the table highlight which has the best potential to be applicable to this project. This approach was selected with the understanding that bids from additional vendors would be considered later in the project.

1.3.1 Interim Report #1 Technology Recommendation

The technology summary in the previous subsection ranked three (3) technologies as front-runners based on their current installation base and applicability to general project requirements. In order to make a meaningful recommendation at the time the interim report was completed, it was also important to assess as many known considerations as possible. Additional consideration was given to feedstock supply (or lack of secure supply), the availability of trained operators, and plant efficiencies (or production of waste heat). These additional considerations lead to the recommendation to consider a smaller sized plant (or small capacity units) as they require less fuel (easier to secure feedstock), typically required a lower skillset operator (ex-electricians/mechanics compared to stationary engineers), and scored higher on the screening assessment. Part of this recommendation also served to match the plant capacity to the building heating load available in the village.

Table 1.5 Summary of Vendor Scorecards

Technology	Developer/ Owner	Level of Develop.	Capacity Range	Engine	Complexity	Installation Base	Steam Req.	Score	Rank	Elec. Eff.*	Enivron
'Large Scale" Gasification											
Bubbling Fluidized Bed (5,500 kW_e)	Andritz-Carbona (EU – Denmark)	5	0	5	0	0	0	10 (33%)			
2 – 4 MW_e Gasification											
Updraft Gasifier (2,000 kW_e)	Nexterra (CAN – BC)	3	5	5	3	0	5	21 (70%)	5	26%	
Updraft Gasifier (2,000 kW_e)	B&W Vølund (EU – Denmark)	5	5	5	0	5	0	20 (67%)	6		
Dual Bed (2,700 kW_e)	FICFB (Repotec) (EU – Austria)	3	5	5	0	3	0	16 (53%)			
Small Scale / Modular Gasification											
Downdraft Gasifier (100 kW_e)	Community Power Corp. (NA – USA)	5	5	5	3	5	5	28 (93%)	1	20%	California Certified
Downdraft Gasifier (300 kW_e)	Biomass Engineering (EU – UK)	5	5	5	3	3	5	26 (87%)	2		
2-Zone Downdraft (150 kW_e)	Pyroforce (EU – Swiss)	3	5	5	3	3	5	24 (80%)	3		

* Approximate based on published information

1.4 FACILITY VISIT OF SELECT TECHNOLOGIES

Based on the results of technology assessment it was desired to see a number of units in operation. Interim Report #2, available in Appendix B, covers the results of the vendor visits in detail. The next two sub-sections present the overall results of the Nexterra and CPC site visit.

1.4.1 Nexterra Visit

The site visit for Nexterra took place at 10:00 am on Monday, November 5, 2012 on the UBC campus. Phil Beaty, Vice President, Strategic Relationships, for Nexterra, and Brent Sauder, Director, Strategic Initiatives for UBC facilitated the visit. Initially the group met in a conference room on campus to discuss the university's experience during the project's development and execution. This was followed by a guided tour of the facility with the Nexterra representative and operating staff only. During the visit, the plant was operational.

1.4.1.1 Project Overview

This project was kick-started by John Grace of UBC based on his academic research into gasification and more specifically gas conditioning/clean-up. UBC and Nexterra wanted a demonstration-sized plant to prove the concept and facilitate R&D at the university. Based on the UBC concept, GE came in as a partner and supported the development.

UBC is unique in that it is its own municipality with its own substation. The challenge in BC is the low power rates brought on by their hydro resources. That said, UBC still had the desire to demonstrate a BC technology in BC. On the waste heat side, they are also in the process of converting their existing steam district heating system over to hot water.

For UBC the social license was the first step, with five (5) sites initially under consideration. Faculty members were quick to get onboard for the research ability, and the community soon adopted a "yes, in my backyard" mentality. In the end, the unit was located on the edge of the campus in order to reduce truck traffic for fuel deliveries. During full operation, UBC receives three (3) trucks a day, with enough storage for a three (3) day weekend.

On the permitting side, UBC requested the strictest emission regulations be met. To that end, UBC requested that the system be designed and will be tested to meet Metro Vancouver requirements, as well as those in the USA jurisdictions of San Joaquin Valley and the state of Massachusetts. The facility is further equipped with a local and external air shed monitoring system.

Building construction was initially completed using standard steel building formats. During the project's development UBC worked with FP Innovations and selected a new construction method – cross-linked timber or CLT. The current facility uses CLT for the roof and walls of the building.

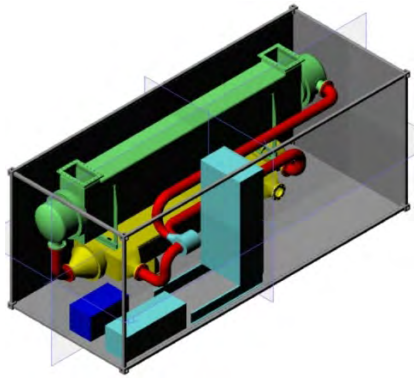
The Nexterra system does require trained operators to run the facility. Operators would require similar skills to that of boiler operators, and if a hot water system was installed, they would not require steam tickets. That said, a 4th to 3rd class ticket would be a starting point for skilled operator requirements. Although the system is automated, skilled operators are required to react quickly in an upset condition. As a minimum, the system requires two (2) full-time staff on-site 24 hours a day / 7 days a week. Currently the UBC plant operates in eight (8) hours shifts, requiring a minimum of eight (8) trained operators to support the plant.

1.4.1.2 Overall Impression

General impression of the group following the visit was that the installation was very large and more complex than expected. The size of the facility, number of operators, and perceived complexity of operation did not seem appropriate for a unit to be located in Haines Junction. The capital cost, maintenance requirements, parts availability, and service technician/operator skill set were also of concern. Mr. Beaty re-iterated that the UBC unit was the first of its kind for Nexterra and they are not actively marketing it. It will be more than a year before annual performance numbers are available, and only then would Nexterra begin to entertain installing their second unit. Further discussion revealed that Nexterra is not interested in a northern site for their second installation.

1.4.2 Entropic Visit

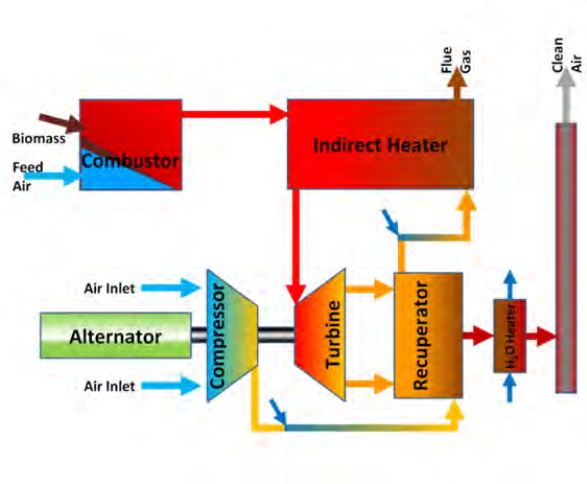
The site visit for Entropic took place at 9:00 am on Tuesday, November 6, 2012 on the University of Manitoba (U of M) campus. Dr. Eric Bibeau, NSERC/Manitoba Hydro Industrial Research Chair in Alternative Energy and co-founder of Entropic, facilitated the visit. Initially the group met in Dr. Bibeau's office on campus to discuss Entropic's technology and product development. This was followed by a guided tour of the installation with Dr. Bibeau. During the visit, the plant was not operational and it was unclear when it would achieve demonstration status.



1.4.2.1 Project Overview

Entropic is in the R&D stages of their technology. The concept is to design a biomass system with a small footprint that can compete on a conventional technology's price point of $4M/MW$_e$.

Using the price point as a basis Dr. Bibeau and this team are trying to apply a hybrid Brayton Cycle to achieve high efficiency power generation in a modular package of 250 kW_e.



The Entropic design builds upon that of the indirect fired Brayton Cycle. The principle difference is in the thermodynamics in that they inject water at critical points in the process to increase unit efficiency. Although only currently theoretical in models, the team at U of M are trying to get their unit up and running. Should they be successful, the hybrid design touts the benefits of maximized energy transfer through increase mass through the turbine, decreased turbine inlet temperature (therefore reduced stress on the unit), maximize equipment capacities, and overall increase in efficiency – to double that of a standard externally fired unit.

1.4.2.2 Overall Impression

General impression of the group following the visit was that this technology/vendor was not appropriate for future consideration. The technology is not near a viable status for consideration on this project, though appears promising.

1.4.3 CPC Visit

The site visit for Community Power Corporation (CPC) took place at 1:00 pm on Tuesday, November 6, 2012 at Pineland Forest Nursery in Hadashville, Manitoba. Carl Peterson, Field Engineer, facilitated the visit for CPC. This unit is located on, and integrated to Pineland's operations, but is owned by Manitoba Hydro. Jeremy Langner is the Project Manager for Manitoba Hydro (MH), but was unavailable at the time of the site visit. Mr. Langner did provide Stantec with some information on the project as a follow-up to the visit. The General Manager of Pineland, Trevor Stanley, was also unable to attend the site visit, but joined the group later in the evening to answer questions and discuss the project. The tour of the unit took place immediately upon arrival, with questions & answers carrying the group through until departure. During the visit the plant was operational.

1.4.3.1 Project Overview

The following overview was developed from follow-up information provided by Mr. Langner.

The CPC system is manufactured in a series of five (5) 20 ft. shipping containers. Shipping the unit in this containerized form allows the majority of the work to be performed at the manufacturer's facility. The Pineland system was installed in June and July 2012, and Manitoba Hydro/CPC/Pineland have been testing it ever since. The unit has been run to peak capacity and has been able to generate a maximum of approximately 120 kW_e of electricity gross, with about 20 kW_e of parasitic loss. Pineland is also recovering heat off of the engine's cooling jackets and exhausts, and sending this to a thermal loop to heat greenhouses. The heat supplements Pineland's existing 2 MW_{th} biomass boiler, located in an adjacent building.

The CPC system uses a stainless steel downdraft gasifier with air injection points throughout the fixed bed. A vibrating grate can dump material if required. The temperature profile is precisely controlled throughout the bed to insure good gas quality. This allows the filtration system to be very simple – filter bags with backup carbon safety filters. This filters out a very fine carbon dust from the gas. The gas is then sent to two (2) 8.1 L V8 spark-ignition engines, each connected to a 65 kW_e alternator. Another feature of the system is the biomass dryer that uses heat from the gas cooling heat exchanger to dry the feedstock. This allows MH/Pineland to accept up to 45% moisture content, and dry down to approximately 15% moisture.

With regards to fuel rates and flows, MH currently pays in the range of $55 to $65 per tonne as delivered for their biomass supply. The wood chips come from several sources within 2 hours or less of the project site. The fuel consumption is stated by CPC as 90 kg of dry biomass per hour, however, MH have not been running consistently enough to determine a more accurate figure. The CPC system can accept ¼" x ¼" through 2" x 2" chips.

As far as maintenance costs are concerned, MH does not have enough data to provide concrete figures. It will highly depend on the number of oil changes per month. CPC has specified an oil change every 10 days. MH are also budgeting the equivalent of 1 hour per day of daily checks, and two (2 to 3 man-days per month spent on gasifier maintenance. During this initial start-up phase, these numbers are expected to be higher.

Operating efficiency is also difficult to determine giving the limited operating hours. Assuming MH/Pineland are burning 90 kg/hr for 100 kW of output (net), and the biomass has a higher heating value of 20 MJ/kg (dry), MH would have a net electrical efficiency of approximately 20%. MH believes that the total efficiency will be at least double when they include the heat.

In a discussion with the Mr. Peterson, CPC typically provides four weeks of commissioning and start-up services. This includes two (2) weeks on-site to commission the unit and systems, one (1) week of full-time training for site personnel, and one (1) week of field supervision following the training. Beyond the four (4) weeks, Mr. Peterson indicated that CPC monitor the unit

remotely for any system warnings or errors. As for the level of skill required to operate the units, Mr. Peterson indicated that the majority of operators are ex-electricians or ex-mechanics. Ex-electricians are preferred give the system electronics and potential advantage when troubleshooting problems, but both have been successful at operating the units.

1.4.3.2 Overall Impression

General impression of the group following the visit was that this technology/vendor was the most appropriate of those visited for Haines Junction. Apart for the small capacity (100 kW_e) the plant's simplicity of operation, level of operator skill required, and proven heat recovery potential make it a strong candidate for installation in the Yukon.

2.0 Preliminary Design

The following subsections outline the preliminary engineering for the FEED study. The first subsection reviews information on the vendors contacted as part of the RFQ process. Vendor information packages are presented in Appendix C for the Steering Committee's review and reference. Not all information requested is available and follow-up requests and questions have been made to the vendors.

The final two subsections outline the facility siting exercise as well as aspects of the preliminary design and opinions of probable cost. The costing presented covers the preliminary options to utilize the CPC 500 kW_e (2 x 250 kW_e) units both inside a building (Option #1) and outside a building (Option #3). An option to have the building exterior completed with an architectural design is also provided (Option #2). As the intent would be to expand the demonstration project in the near future, a fourth option is presented to expand the initial 500 kW_e plant by an additional 500 kW_e in Option #4.

Each option is reviewed briefly in this report with additional information available in Appendix D (Option #1), Appendix E (Option #2), Appendix F (Option #3), and Appendix G (Option #4). Appendices contain the engineering drawings created to support the costing effort as well as the more detailed line item opinions of probable capital cost.

2.1 VENDOR RESPONSE TO RFQ

Each of the vendors contacted as part of the RFQ process are reviewed in the following subsections with their detailed packages contained in Appendix C. Information contained here and in the appendix represents vendor proprietary information and costing. This should not be considered for distribution outside the project team.

2.1.1 B&W Volund

Despite initially being a promising technology source, discussions with B&W Volund revealed otherwise. Upon conversing about the project details, particularly the feedstock characterization, it was determined that the moisture content present in the feedstock was too low for use in B&W Volund's technology. They therefore declined to provide a quotation/information package.

2.1.2 Nexterra

As mentioned previously during the site visit of their facility at UBC, while being an appropriate technology it is not being actively marketed. Nexterra wishes to operate the UBC unit for at least a year before pursuing a second installation. Even after a year, the general impression provided by Nexterra was that the next installation is not likely to be in the North.

2.1.2.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.1 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section.

Table 2.1 Nexterra Summary

nexterra		**Headquarters:**	Vancouver, British Columbia	
Developer / Company:	Nexterra	**Vendor Rep:**	None	
System Information	**Quoted Capacity:**	2.0 MW_e		
	Model Number:	Standard CHP System		
	System Configuration:	1-Stage Updraft Gasifier, 1x IC Engine		
	**denotes scaled values*	**As Quoted**	**500 kW_e**	**2.0 MW_e**
Fuel Requirements	**Moisture Content as Fired:**	20%		
	Feedstock Consumption (dry basis):	1,474 kg/hr 3,250 lb/hr	N/A	1,474 kg/hr 3,250 lb/hr
	Feedstock Size:	N/A		
Unit Performance	**Net Electric Generating Capacity:**	2.0 MW_e	N/A	2.0 MW_e
	Operating Parasitic Load:	N/A	N/A	N/A
	Availability:	91%		
	Recoverable Heat:	2.93 MW_{th}	N/A	2.93 MW_{th}

	Electrical Efficiency:	31%		
Commercial	**Delivery Lead Time:**	N/A		
	Published Equipment Price:	$18M - $20M	N/A	$18M - $20M

2.1.3 Community Power Corporation

In response to our RFP, Community Power Corporation responded with a budgetary proposal for the design, supply, transportation to site, and supervision of erection and startup, of a demonstration bioenergy system. The proposal outlined several risks that CPC was concerned with that may have a significant impact on the project. These included:

- Long-term bioenergy system reliability and availability (downtime) have not yet been confirmed in a remote, cold climate community.
- Impact of cold climate is not yet known on system performance.
- Operation and maintenance costs need to be verified.
- Sustainable biomass harvesting plan needs to be confirmed.
- Impact of biomass variability on system performance needs to be confirmed (biomass type, heating value, cleanliness, moisture content, etc.).
- Requirements for and impact of permitting and environmental performance requirements are not fully understood.
- Availability of local operators with appropriate maintenance skills.

Given the number and importance of these risk areas, CPC strongly recommends consideration of an initial, single BioMax 100 (kW_e) demonstration system that can address the risk areas at lower cost while still providing all of the insight needed to design and implement the larger follow on 500 kW_e to 2 MW_e deployment. Therefore, based on CPC's experience in bioenergy and renewable energy demonstration projects in remote communities throughout the world, they propose consideration of one, 100 kW_e BioMax bioenergy as described in their proposal.

2.1.3.1 Vendor Summary

To quickly highlight key aspects of the vendor's response, Table 2.2 has been prepared to summarize data provided. A comparison table of all vendors is available in the next sub-section.

2.1.3.2 Vendor Response

A copy of CPC's response to the RFQ is included in Appendix C for reference as received.

Table 2.2 Community Power Corporation Summary

Community Power Corporation *A Wholly Owned Subsidiary of Afognak Native Corporation*		**Headquarters:**	Littleton, Colorado
